- Exception: It always throws SQLFeatureNotSupportedException.

getBlob

```
Blob getBlob(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in blob type.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already

closed, then it throws SQLException.

```
Blob getBlob(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getBoolean

```
boolean getBoolean(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in boolean type. For more informati on about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GO LDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
boolean getBoolean(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getByte

```
byte getByte(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in byte type. For more information a bout whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
byte getByte(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getBytes

```
byte[] getBytes(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in byte[] type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
byte[] getBytes(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getCharacterStream

```
Reader getCharacterStream(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in reader type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Reader getCharacterStream(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getClob

```
Clob getClob(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in clob type.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Clob getClob(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getDate

```
Date getDate(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in date type. For more information a bout whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** . It uses local time zone and locale when creating a date object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Date getDate(int parameterIndex, Calendar cal) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in date type. For more information a bout whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** . It uses time zone and locale of cal when creating a date object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Date getDate(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Date getDate(String parameterName, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getDouble

```
double getDouble(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in double type. For more informatio n about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOL DILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
double getDouble(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getFloat

```
float getFloat(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in float type. For more information a bout whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
float getFloat(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getInt

```
int getInt(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in int type. For more information ab out whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
int getInt(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getLong

```
long getLong(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in long type. For more information a bout whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDIL OCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
long getLong(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getNCharacterStream

```
Reader getNCharacterStream(int parameterIndex) throws SQLException
```

- Operation: Currently, it does not support NCHAR-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Reader getNCharacterStream(String parameterName) throws SQLException
```

- Operation: Currently, it does not support NCHAR-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

getNClob

```
NClob getNClob(int parameterIndex) throws SQLException
```

- Operation: Currently, it does not support NClob-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

```
NClob getNClob(String parameterName) throws SQLException
```

- Operation: Currently, it does not support NClob-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

getNString

```
String getNString(int parameterIndex) throws SQLException
```

- Operation: Currently, it does not support NCHAR-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

```
String getNString(String parameterName) throws SQLException
```

- Operation: Currently, it does not support NCHAR-family type.
- Exception: It always throws SQLFeatureNotSupportedException.

getObject

```
Object getObject(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in Java object type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Object getObject(int parameterIndex, Map<String,Class<?>> map) throws SQLException
```

- Operation: It is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Object getObject(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Object getObject(String parameterName, Map<String,Class<?>> map) throws SQLException
```

- Operation: It is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

getRef

```
Ref getRef(int parameterIndex) throws SQLException
```

- Operation: It does not support ref type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
Ref getRef(String parameterName) throws SQLException
```

- Operation: It does not support ref type.
- Exception: It always returns SQLFeatureNotSupportedException.

getRowId

```
RowId getRowId(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in rowid type. For more information

about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
RowId getRowId(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getShort

```
short getShort(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in short type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
short getShort(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getSQLXML

```
SQLXML getSQLXML(int parameterIndex) throws SQLException
```

- Operation: It does not support SQLXML type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
SQLXML getSQLXML(String parameterName) throws SQLException
```

- Operation: It does not support SQLXML type.
- Exception: It always returns SQLFeatureNotSupportedException.

getString

```
String getString(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in string type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
String getString(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getTime

```
Time getTime(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in time type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . It uses local time zone when creating a time object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Time getTime(int parameterIndex, Calendar cal) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in time type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . It uses time zone of cal when creating a time object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Time getTime(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Time getTime(String parameterName, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getTimestamp

```
Timestamp getTimestamp(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in timestamp type. For more inform ation about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . It uses local time zone when creating a timestamp object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Timestamp getTimestamp(int parameterIndex, Calendar cal) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in timestamp type. For more inform ation about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . It uses time zone of cal when creating a timestamp object.
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
Timestamp getTimestamp(String parameterName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Timestamp getTimestamp(String parameterName, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getURL

```
URL getURL(int parameterIndex) throws SQLException
```

- Operation: It does not support URL type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
URL getURL(String parameterName) throws SQLException
```

- Operation: It does not support URL type.
- Exception: It always returns SQLFeatureNotSupportedException.

registerOutParameter

```
void registerOutParameter(int parameterIndex, int sqlType) throws SQLException
```

- Operation: It registers out parameters positioned in parameterIndex as sqlType. All out parameters sh ould be registered before executing the stored procedure. JDBC type of out parameter specified as sq lType determines Java type which is used in a get method to read parameter parameter value. For mo re information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter me thod for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLFeatureNotSupprtedException.

```
void registerOutParameter(int parameterIndex, int sqlType, int scale) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void registerOutParameter(int parameterIndex, int sqlType, String typeName) throws
SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void registerOutParameter(String parameterName, int sqlType) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void registerOutParameter(String parameterName, int sqlType, int scale) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void registerOutParameter(String parameterName, int sqlType, String typeName) throws
SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setAsciiStream

```
void setAsciiStream(String parameterName, InputStream x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setAsciiStream(String parameterName, InputStream x, int length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setAsciiStream(String parameterName, InputStream x, long length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setBigDecimal

```
void setBigDecimal(String parameterName, BigDecimal x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setBinaryStream

```
void setBinaryStream(String parameterName, InputStream x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setBinaryStream(String parameterName, InputStream x, int length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setBinaryStream(String parameterName, InputStream x, long length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setBlob

```
void setBlob(String parameterName, Blob x) throws SQLException
```

- Operation: It does not support blob type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
void setBlob(String parameterName, InputStream inputStream) throws SQLException
```

- Operation: It does not support blob type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
void setBlob(String parameterName, InputStream inputStream, long length) throws SQLException
```

- Operation: It does not support blob type.
- Exception: It always returns SQLFeatureNotSupportedException.

setBoolean

```
void setBoolean(String parameterName, boolean x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setByte

```
void setByte(String parameterName, byte x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setBytes

```
void setBytes(String parameterName, byte[] x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setCharacterStream

```
void setCharacterStream(String parameterName, Reader reader) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setCharacterStream(String parameterName, Reader reader, int length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setCharacterStream(String parameterName, Reader reader, long length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setClob

```
void setClob(String parameterName, Clob x) throws SQLException
```

- Operation: It does not support clob type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
void setClob(String parameterName, Reader reader) throws SQLException
```

- Operation: It does not support clob type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
void setClob(String parameterName, Reader reader, long length) throws SQLException
```

- Operation: It does not support clob type.
- Exception: It always returns SQLFeatureNotSupportedException.

setDate

```
void setDate(String parameterName, Date x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setDate(String parameterName, Date x, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setDouble

```
void setDouble(String parameterName, double x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setFloat

```
void setFloat(String parameterName, float x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setInt

```
void setInt(String parameterName, int x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setLong

```
void setLong(String parameterName, long x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setNCharacterStream

```
void setNCharacterStream(String parameterName, Reader value) throws SQLException
```

- Operation: It does not support NChar.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNCharacterStream(String parameterName, Reader value, long length) throws SQLException
```

- Operation: It does not support NChar.
- Exception: It always throws SQLFeatureNotSupportedException.

setNClob

```
void setNClob(String parameterName, NClob value) throws SQLException
```

- Operation: It does not support NClob.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNClob(String parameterName, Reader reader) throws SQLException
```

- Operation: It does not support NClob.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNClob(String parameterName, Reader reader, long length) throws SQLException
```

- Operation: It does not support NClob.
- Exception: It always throws SQLFeatureNotSupportedException.

setNString

```
void setNString(String parameterName, String value) throws SQLException
```

- Operation: It does not support NChar.
- Exception: It always throws SQLFeatureNotSupportedException.

setNull

```
void setNull(String parameterName, int sqlType) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNull(String parameterName, int sqlType, String typeName) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setObject

```
void setObject(String parameterName, Object x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setObject(String parameterName, Object x, int targetSqlType) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setObject(String parameterName, Object x, int targetSqlType, int scale) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setRowId

```
void setRowId(String parameterName, RowId x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setShort

```
void setShort(String parameterName, short x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setSQLXML

```
void setSQLXML(String parameterName, SQLXML xmlObject) throws SQLException
```

- Operation: It does not support SQLXML type.
- Exception: It always returns SQLFeatureNotSupportedException.

setString

```
void setString(String parameterName, String x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setTime

```
void setTime(String parameterName, Time x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setTime(String parameterName, Time x, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setTimestamp

```
void setTimestamp(String parameterName, Timestamp x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setTimestamp(String parameterName, Timestamp x, Calendar cal) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setURL

```
void setURL(String parameterName, URL val) throws SQLException
```

- Operation: It does not support URL type.
- Exception: It always throws SQLFeatureNotSupportedException.

wasNull

```
boolean wasNull()
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface)
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

unwrap

```
boolean isWrapperFor(Class<?> iface)
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

Clob

free

```
void free() throws SQLException
```

- Operation: It frees the sources owned by this object.
- Exception: It does not occur.

getAsciiStream

```
InputStream getAsciiStream() throws SQLException
```

- Operation: It returns the clob object value in InputStream type.
- Exception: If the clob is freed, it throws SQLException.

getCharacterStream

```
Reader getCharacterStream() throws SQLException
```

- Operation: It returns the clob object value in reader type.
- Exception: If the clob is freed, it throws SQLException.

```
Reader getCharacterStream(long pos, long length) throws SQLException
```

- Operation: It returns the clob object value in reader type as big as the length from the location define d as pos.
- Exception: When the blob is freed, if pos is smaller than 1 or if length is smaller than 1, or if pos + len is equal to or bigger than the length of clob object, then it throws SQLException.

getSubString

```
String getSubString(long pos, int length) throws SQLException
```

- Operation: It returns the string which includes the clob object value as big as the length from the len gth defined as pos.
- Exception: When the clob is freed, if pos is smaller than 1 or if length is smaller than 0, then it throws SQLException.

length

```
long length() throws SQLException
```

- Operation: It returns the data length of the clob object.
- Exception: If the clob object is freed, it throws SQLException.

position

```
long position(Clob searchstr, long start) throws SQLException
```

- Operation: It returns the location from which the clob object searchstr starts defined in the clob objec t value. searchstr search starts from the location of start. If searchstr is not found in the clob object th en -1 is returned.
- Exception: When the clob is freed, if start is smaller than 1, then it throws SQLException.

```
long position(String searchstr, long start) throws SQLException
```

- Operation: It returns the location from which the string object searchstr starts defined in the clob obj ect value. searchstr search starts from the location of start. If searchstr is not found in the clob object then -1 is returned.
- Exception: When the clob is freed, if start is smaller than 1, then it throws SQLException.

setAsciiStream

```
OutputStream setAsciiStream(long pos) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setCharacterStream

```
Writer setCharacterStream(long pos) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setString

```
int setString(long pos, String str) throws SQLException
```

- Operation: It records str from the given pos location in the clob object value, and returns the recorde d length. If the value exists in pos location, then it is overwritten. If it reaches to the end of the clob v alue while recording the string type, then the length of the clob value is extended so that it can inclu de the additional bytes.
- Exception: When the clob is freed, if pos is smaller than 1, then it throws SQLException.

```
int setString(long pos, String str, int offset, int len) throws SQLException
```

- Operation: It records the clob object value from pos location as long as the len length from offset loc ation of the given string object str, and returns the recorded length. If the value exists in pos location, then the value is overwritten. If it reaches to the end of the clob value while recording the string type, then the length of the clob value is extended so that it can include the additional bytes.
- Exception: When the clob is freed, if pos is smaller than 1 or if it is bigger than offset + len, then it thr ows SQLException.

truncate

```
void truncate(long len) throws SQLException
```

- Operation: It truncates the length of the clob object into the given len length.
- Exception: When the clob is freed, if len is smaller than 0 or if the clob size is smaller than len, then it throws SQLException.

CommonDataSource

getLoginTimeout

```
int getLoginTimeout() throws SQLException
```

- Operation: It returns the login timeout setting value. Login timeout is used as a timeout value when p erforming socket connection to the server. If the value is not set, 0 is returned. 0 means infinite stand by.
- Exception: It does not occur.

getLogWriter

```
PrintWriter getLogWriter() throws SQLException
```

- Operation: It returns the log writer which is set in the DataSource. If it is not set, null is returned. Log writer refers to PrintWriter to write various trace logs. For more information about logging, refer to **L ogging**.
- Exception: It does not occur.

setLoginTimeout

```
void setLoginTimeout(int seconds) throws SQLException
```

- Operation: It sets the login timeout value. Login timeout is used as a timeout value when performing socket connection to the server. 0 means infinite standby.
- Exception: It does not occur.

setLogWriter

```
void setLogWriter(PrintWriter out) throws SQLException
```

- Operation: It sets the log writer in DataSource. If the value is not set, the default value is null. Log wri ter refers to PrintWriter to write various trace logs. If the value is set, trace log, query log, and protoc ol log are written according to the options, and connection object which is created from DataSource and all objects which are created from connection object such as Statement, ResultSet, perform loggi ng. Trace log, query log, protocol log options can be specified in the connection url or property. For more information about logging, refer to **Logging**.
- Exception: It does not occur.

setDataSourceName

```
void setDataSourceName(String aDataSourceName)
```

- Operation: It sets the data source name. It is not the mandatory information required for the connecti on. It is the information charged separately to distinguish objects.
- Exception: It does not occur.

setServerName

```
void setServerName(String aServerName)
```

- Operation: It sets the server name, which is the connection URL. It is the mandatory information requi red for the connection.
- Exception: It does not occur.

setDatabaseName

```
void setDatabaseName(String aDBName)
```

- Operation: It sets the database name. It is the mandatory information required for the connection.
- Exception: It does not occur.

setNetworkProtocol

```
void setNetworkProtocol(String aProtocol)
```

- Operation: It is the network protocol information. It is not the mandatory information required for th e connection.
- Exception: It does not occur.

setUser

```
void setUser(String aUser)
```

- Operation: It sets the connection account name. It is the mandatory information required for the con nection.
- Exception: It does not occur.

setPassword

```
void setPassword(String aPassword)
```

- Operation: It sets the connection account password. It is the mandatory information required for the connection.
- Exception: It does not occur.

setPortNumber

```
void setPortNumber(int aPort)
```

- Operation: It sets the port number used when connecting to the server. It is the mandatory informati on required for the connection.
- Exception: It does not occur.

```
void setPortNumber(String aPort)
```

- Operation: It sets the port number used when connecting to the server. It is the mandatory informati on required for the connection.
- Exception: It does not occur.

setRoleName

```
void setRoleName(String aRoleName)
```

- Operation: It specifies the role of when connecting to server. It is not mandatory information required for the connection, but it is the connection related information. One of "", "ADMIN", "SYSDBA" is spe cified.
- Exception: It does not occur.

setDescription

```
void setDescription(String aDescription)
```

- Operation: It sets the description about the data source. It is not used for the connection.
- Exception: It does not occur.

setConnectionProperties

```
void setConnectionProperties(Properties aProps)
```

- Operation: It defines the properties which can be used in various connections.
- Exception: It does not occur.

setURL

```
void setURL(String aURL) throws SQLException
```

- Operation: It specifies the serverName, portNumber, and database Name in URL form. It has URL as same as the URL of when connecting via DriverManager.
- Exception: If it is the wrong format, it throws SQLException.

```
void setUrl(String aUrl) throws SQLException
```

It is as same as setURL (String aURL).

setLogTarget

```
void setLogTarget(String aTarget)
```

- Operation: If setLogWriter can not be called, the log writer is set by this method. Currently, it is supported only when aTarget is "console", other values are ignored. If it is set to "console", all loggings below the connection object which is generated from the DataSource are output to the console.
- Exception: It does not occur.

setTraceLog

```
void setTraceLog(String aMode)
```

- Operation: It sets the trace log. If aMode is *on*, the trace logging is on.
- Exception: It does not occur.

setQueryLog

```
void setQueryLog(String aMode)
```

- Operation: It sets the query log. If aMode is *on*, the query logging is on.

- Exception: It does not occur.

setProtocolLog

```
void setProtocolLog(String aMode)
```

- Operation: It sets the protocol log. If aMode is *on*, the protocol logging is on.
- Exception: It does not occur.

Connection

abort

```
void abort(Executor executor) throws SQLException
```

- Operation: It terminates the connection object. The connection of the connection object is physically closed and the status becomes closed. It returns the resource used by the connection object. Either al l threads accessing to the current connection is normally terminated or it throws SQLException.
- Exception: If the connection is closed or the executor is null, then it throws SQLException. If the secur ity manager exists and checkPermission method rejects the abort call, then it throws SecurityExceptio n.
- Since: 1.7

clearWarnings

```
void clearWarnings() throws SQLException
```

- Operation: It clears the warning object(s) owned by the current connection object.
- Exception: It does not occur.

close

```
void close() throws SQLException
```

- Operation: It breaks the connection with GOLDILOCKS not to use anymore the current connection an d closes all statement objects created from the object. If already closed, any operation is not perform ed.
- Exception: It may happen when an error occurs from the server or it does not respond.

commit

```
void commit() throws SQLException
```

- Operation: For non-auto commit mode, the commit is executed for the current connection.
- Exception: If it is already closed or is on the auto-commit mode, it throws SQLException.

createArrayOf

```
Array createArrayOf(String typeName, Object[] elements) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

createBlob

```
Blob createBlob() throws SQLException
```

- Operation: It creates the object which implemented the blob interface. The first returned object does not have a data. The data can be added to the blob object by using setBytes method of the blob inter face.
- Exception: If it is already closed, it throws SQLException.

createClob

```
Clob createClob() throws SQLException
```

- Operation: It creates the object which implemented the clob interface. The first returned object does not have a data. The data can be added to the clob object by using setString method of the clob inter face.
- Exception: If it is already closed, it throws SQLException.

createNClob

```
NClob createNClob() throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

createSQLXML

```
SQLXML createSQLXML() throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

createStatement

```
Statement createStatement() throws SQLException
```

- Operation: It creates statement object. The ResultSet type created by the statement is ResultSet.TYPE_FORWARD_ONLY, and concurrency is ResultSet.CONCUR_READ_ONLY, and holdability is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If it is already closed, it throws SQLException.

```
Statement createStatement(int resultSetType, int resultSetConcurrency) throws SQLException
```

- Operation: It creates statement object which creates ResultSet including the user defined resultset type and resultset concurrency. The holdability of ResultSet which are generated from the statement object is as same as the holdability of the connection type. The default holdability of connection is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If it is already closed, it throws SQLException.

```
Statement createStatement(int resultSetType, int resultSetConcurrency, int
resultSetHoldability) throws SQLException
```

- Operation: It creates a statement object which creates ResultSet including the user defined resultset type, resultset concurrency and holdability.
- Exception: If it is already closed, it throws SQLException.

createStruct

```
Struct createStruct(String typeName, Object[] attributes) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getAutoCommit

```
boolean getAutoCommit() throws SQLException
```

- Operation: It returns the current auto commit mode. If setAutoCommit() has not been called, it returns true.
- Exception: It does not occur.

getCatalog

```
String getCatalog() throws SQLException
```

- Operation: It gets the current catalog name of the database.
- Exception: If an error occurs from the server or it does not respond, then it throws SQLException.

getClientInfo

```
Properties getClientInfo() throws SQLException
```

- Operation: It returns client information set by the user. If setting information does not exist, It returns null.
- Exception: It does not occur.

```
String getClientInfo(String name) throws SQLException
```

- Operation: It returns specific client information set by the user. If the corresponding information does not exist, it returns null.
- Exception: It does not occur.

getHoldability

```
int getHoldability() throws SQLException
```

- Operation: It returns the default holdability value of statements created by this object. The default val ue is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: It does not occur.

getMetaData

```
DatabaseMetaData getMetaData() throws SQLException
```

- Operation: It gets a DatabaseMetaData object which can be queried for metadata information from t his object. It always returns the same object.
- Exception: If it is already closed, it throws SQLException.

getNetworkTimeout

```
int getNetworkTimeout() throws SQLException
```

- Operation: It returns the current network timeout (millisecond). 0 means that it is limitless.
- Exception: If it is already closed, it throws SQLException.
- Since: 1.7

getTransactionIsolation

```
int getTransactionIsolation() throws SQLException
```

- Operation: It gets the transaction isolation level which is set on the current session (connection). The default value which is set on the server is Connection.TRANSACTION_READ_COMMITTED.
- Exception: If an error occurs from the server, it throws SQLException.

getTypeMap

```
Map<String,Class<?>> getTypeMap() throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getWarnings

```
SQLWarning getWarnings() throws SQLException
```

- Operation: It returns a warning which the server responds to connection object until now. If a warnin g does not exist or clearWarnings() is already performed, it returns null.
- Exception: It does not occur.

isClosed

```
boolean isClosed() throws SQLException
```

- Operation: It queries whether close() is successfully called. If close() is successfully performed, it retur ns true. Otherwise, it returns false.
- Exception: It does not occur.

This method does not inform a user whether the connection to a physical server is broken. Even if the actual connection is broken it returns true when close () has never been called.

isReadOnly

```
boolean isReadOnly() throws SQLException
```

- Operation: If the session(connection) is read only mode, it returns true. Otherwise, it returns false. The default value is false. Communication with the server occurs.
- Exception: If an error occurs from the server or it does not respond, it throws SQLException.

isValid

```
boolean isValid(int timeout) throws SQLException
```

- Operation: If isClosed() returns true or the heart beat query is sent to the server and response is not successfully received, it returns false. Otherwise, it returns true.
- Exception: It does not occur.

nativeSQL

```
String nativeSQL(String sql) throws SQLException
```

- Operation: It returns the native SQL recognized by the server for the given user SQL statement. GOLDILOCKS always return the value as same as given by the user because the server recognizes the user's SQL statement literally.
- Exception: It does not occur.

prepareCall

```
CallableStatement prepareCall(String sql) throws SQLException
```

- Operation: It returns CallableStatement object for calling stored procedures. ResultSet type created from this CallableStatement is ResultSet.TYPE_FORWARD_ONLY, the concurrency is ResultSet.CONCUR_READ_ONLY, and the holdability is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If it is already closed or the SQL statement is wrong, then it throws SQLException.

```
CallableStatement prepareCall(String sql, int resultSetType, int resultSetConcurrency) throws SQLException
```

- Operation: It creates CallableStatement object which creates ResultSet with the resultset type and the resultset concurrency specified by the user. The holdability of ResultSet created from this CallableStatement is as same as that of the connection. The default holdability value of the connection is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If it is already closed or the SQL statement is wrong, then it throws SQLException.

```
CallableStatement prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability) throws SQLException
```

- Operation: It creates CallableStatement object which creates ResultSet with the resultset type, the resultset concurrency and the holdability specified by the user.
- Exception: If it is already closed or the SQL statement is wrong, then it throws SQLException.

prepareStatement

```
PreparedStatement prepareStatement(String sql) throws SQLException
```

- Operation: It sends the SQL statement to the server and prepares (parsing, validation, optimization), and it returns the PreparedStatement object which controls the prepared statement to the user. The type of ResultSet generated by the PreparedStatement is ResultSet.TYPE_FORWARD_ONLY, and concurrency is ResultSet. CONCUR_READ_ONLY, and holdability is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If it is already closed or the SQL statement is wrong, it throws SQLException.

```
PreparedStatement prepareStatement(String sql, int autoGeneratedKeys) throws SQLException
```

- Operation: If autoGeneratedKeys is Statement.NO_GENERATED_KEYS, it operates in the same way as prepareStatement(String sql) method. If autoGeneratedKeys is Statement.RETURN_GENERATED_KEYS and sql is INSERT statement, then it returns PreparedStatement object searching for the auto generated key to the user.
- Exception: If it is already closed, the SQL statement is wrong or autoGeneratedKeys value is neither Statement.NO_GENERATED_KEYS nor Statement.RETURN_GENERATED_KEYS, then it throws SQLException.

If the auto generated key does not exist in the table, then the ResultSet is closed.

```
PreparedStatement prepareStatement(String sql, int[] columnIndexes) throws SQLException
```

- Operation: If columnIndexes is null, it operates in the same way as the prepareStatement(String sql)

method. If sql is INSERT statement and columnIndexes is not null, then it returns PreparedStatement object searching for the designated auto generated key with the given index array to the user.
- Exception: If it is already closed or the SQL statement is wrong, it throws SQLException. If an invalid i ndex exists in columnIndexes, then it throws SQLException.

```
PreparedStatement prepareStatement(String sql, int resultSetType, int resultSetConcurrency)
throws SQLException
```

- Operation: It sends the SQL statement to the server and prepares (parsing, validation, optimization). I t returns the PreparedStatement object which controls the prepared statement to the user. It creates the PreparedStatement object generating ResultSet which includes the user defined result set type an d result set concurrency. The holdability of ResultSet which is generated by PreparedStatement is as s ame as the holdability of connection. The default holdability value of connection is ResultSet.HOLD_C URSORS_OVER_COMMIT.
- Exception: If it is already closed or the SQL statement is wrong, it throws SQLException.

```
PreparedStatement prepareStatement(String sql, int resultSetType, int resultSetConcurrency,
int resultSetHoldability) throws SQLException
```

- Operation: It sends the SQL statement to the server and prepares (parsing, validation, optimization). I t returns the PreparedStatement object which controls the prepared statement to the user. It creates the PreparedStatement object generating ResultSet which includes the user defined result set type an d result set concurrency and holdability.
- Exception: If it is already closed or the SQL statement is wrong, it throws SQLException.

```
PreparedStatement prepareStatement(String sql, String[] columnNames) throws SQLException
```

- Operation: If columnNames is null, it operates in the same way as prepareStatement(String sql) meth od. If sql is INSERT statement and columnNames is not null, then it returns PreparedStatement object searching for the designated auto generated key with the given column name to the user.
- Exception: If it is already closed or the SQL statement is wrong, it throws SQLException. If an invalid c olumn name exists in columnNames, then it throws SQLException.

releaseSavepoint

```
void releaseSavepoint(Savepoint savepoint) throws SQLException
```

- Operation: It removes the savepoint from the server. It also removes all savepoints after this savepoint.
- Exception: If it is already closed or the savepoint object was already released or it is not the GOLDILO CKS savepoint object, it throws SQLException.

rollback

```
void rollback() throws SQLException
```

- Operation: If it is non auto commit mode, it rolls back the current transaction.
- Exception: If it is already closed or it is the auto commit mode or an error is returned from the server, it throws SQLException.

```
void rollback(Savepoint savepoint) throws SQLException
```

- Operation: If it is non auto commit mode, it performs partial rollback to the savepoint for the current transaction.
- Exception: If it is already closed or it is the auto commit mode or an error is returned from the server or the savepoint is not valid, it throws SQLException.

setAutoCommit

```
void setAutoCommit(boolean autoCommit) throws SQLException
```

- Operation: It changes the auto commit mode for the current connection. If the performed transactio n exists and the non auto commit mode is changed to the auto commit, it performs commit.
- Exception: It is as same as the exception which may occur during the commit process.

setCatalog

```
void setCatalog(String catalog) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setClientInfo

```
void setClientInfo(Properties properties) throws SQLException
```

- Operation: It sets the user defined client information. Existing client information is eliminated. It does not affect the server.
- Exception: It does not occur.

```
void setClientInfo(String name, String value) throws SQLException
```

- Operation: It adds the user defined client information. Existing client information is retained.

- Exception: It does not occur.

setHoldability

```
void setHoldability(int holdability) throws SQLException
```

- Operation: It sets the ResultSet holdability which is generated by the statement generated from this o bject. If the method is not called, the default value is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: It does not occur.

setNetworkTimeout

```
void setNetworkTimeout(Executor executor, int milliseconds) throws SQLException
```

- Operation: It sets the maximum waiting time until the database responds to the request by the conne ction or the object created from the connection. If it remains without receiving the response, then it i s returned together with SQLException and the connection object is closed.
- Exception: If it is already closed, the executor is null, or the millisecond is smaller than 0, then it thro ws SQLException. If the security manager exists and checkPermission method rejects the setNetwork Timeout call, then it throws SecurityException.
- Since: 1.7

setReadOnly

```
void setReadOnly(boolean readOnly) throws SQLException
```

- Operation: It sets the read only property of the current session (connection). The default value is false.
- Exception: If it is already closed or an error is returned from the server, it throws SQLException.

setSavepoint

```
Savepoint setSavepoint() throws SQLException
```

- Operation: If it is the non auto commit mode, it sets the savepoint for the current transaction. The sa vepoint name is internally determined.
- Exception: If it is already closed or it is the auto commit mode or an error is returned from the server, it throws SQLException.

```
Savepoint setSavepoint(String name) throws SQLException
```

- Operation: If it is the non auto commit mode, it sets the savepoint whose name is specfied by the use

r for the current transaction.

- Exception: If it is already closed or it is the auto commit mode or an error is returned from the server, it throws SQLException.

setTransactionIsolation

```
void setTransactionIsolation(int level) throws SQLException
```

- Operation: It changes the transaction isolation for the current session (connection). The supported va lue is Connection.TRANSACTION_READ_COMMITED, Connection.TRANSACTION_READ_UNCOMMIT TED, and Connection.TRANSACTION_SERIALIZABLE. Connection.READ_UNCOMMITTED is set to Con nection.TRANSACTION_READ_COMMITED, and Connection.TRANSACTION_REPEATABLE_READ is s et to Connection.TRANSACTION_SERIALIZABLE.
- Exception: If it is already closed or the level has the wrong value, it throws SQLException.

setTypeMap

```
void setTypeMap(Map<String,Class<?>> map) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

isWrapperFor

```
void isWrapperFor(Class<?> iface) throws SQLException
```

- Operation: It queries whether this object is a class which implements the iface interface. If it is, it retu rns true. Otherwise, it returns false. It does not determine the presence of the wrapper but it only qu eries only whether the given argument class type is implemented because GOLDILOCKS connection o bject is not the wrapper of any other class.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface) throws SQLException
```

- Operation: It eventually returns itself, even when it is unwrapped because GOLDILOCKS connection is not the wrapper of any other class. It returns itself after casting it to the corresponding type. If iface is an argument of isWrapperFor() method and false is returned, the method throws an exception.
- Exception: If iface is not the type of this object (if this object returns the unimplemented type), it thro ws SQLException.

ConnectionPoolDataSource

getPooledConnection

```
PooledConnection getPooledConnection() throws SQLException
```

- Operation: It creates the PooledConnection object. Various connection information, such as user na me, password, connection URL should be set through the setter method in advance.
- Exception: If the connection fails, it throws SQLException.

```
PooledConnection getPooledConnection(String user, String password) throws SQLException
```

- Operation: It creates the PooledConnection object. Username and password shall comply with the ar gument. Other connection information should be set to the setter method in advance.
- Exception: If the connection fails, it throws SQLException.

DatabaseMetaData

allProceduresAreCallable

```
boolean allProceduresAreCallable() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

allTablesAreSelectable

```
boolean allTablesAreSelectable() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

autoCommitFailureClosesAllResultSets

```
boolean autoCommitFailureClosesAllResultSets() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

dataDefinitionCausesTransactionCommit

```
boolean dataDefinitionCausesTransactionCommit() throws SQLException
```

- Operation: It always returns false because it does not automatically commit DDL statements at run-time.
- Exception: It does not occur.

dataDefinitionIgnoredInTransactions

```
boolean dataDefinitionIgnoredInTransactions() throws SQLException
```

- Operation: It always returns false, because DDL statements are included in a transaction.
- Exception: It does not occur.

deletesAreDetected

```
boolean deletesAreDetected(int type) throws SQLException
```

- Operation: If type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

doesMaxRowSizeIncludeBlobs

```
boolean doesMaxRowSizeIncludeBlobs() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

getAttributes

```
ResultSet getAttributes(String catalog, String schemaPattern, String typeNamePattern, String attributeNamePattern) throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getBestRowIdentifier

```
ResultSet getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable) throws SQLException
```

- Operation: It returns a ResultSet including one row consisting with rowid information because the ro wid type is supported for all tables. If the table does not exist, it returns an empty ResultSet.
- Exception: If the table is null or an error is returned from the server, it throws SQLException.

getCatalogs

```
ResultSet getCatalogs() throws SQLException
```

- Operation: It returns a ResultSet which has the catalog name in a column.
- Exception: If an error is returned from the server, it throws SQLException.

getCatalogSeparator

```
String getCatalogSeparator() throws SQLException
```

- Operation: It returns a catalog separator character.
- Exception: If an error is returned from the server, it throws SQLException.

getCatalogTerm

```
String getCatalogTerm() throws SQLException
```

- Operation: It returns a catalog term character.
- Exception: If an error is returned from the server, it throws SQLException.

getClientInfoProperties

```
ResultSet getClientInfoProperties() throws SQLException
```

- Operation: It returns a ResultSet including client information.
- Exception: If an error is returned from the server, it throws SQLException.

getColumnPrivileges

```
ResultSet getColumnPrivileges(String catalog, String schema, String table, String
columnNamePattern) throws SQLException
```

- Operation: It returns a ResultSet including column privilege information of the column in the table. If the table or the column corresponding to the column name pattern does not exist, it returns an empt y ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getColumns

```
ResultSet getColumns(String catalog, String schemaPattern, String tableNamePattern, String
columnNamePattern) throws SQLException
```

- Operation: It returns a ResultSet including all column information of the table. If the table or the colu mn corresponding to the column name pattern does not exist, it returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getConnection

```
Connection getConnection() throws SQLException
```

- Operation: It returns the connection object which created the DatabaseMetaData object.
- Exception: It does not occur.

getCrossReference

```
ResultSet getCrossReference(String parentCatalog, String parentSchema, String parentTable,
String foreignCatalog, String foreignSchema, String foreignTable) throws SQLException
```

- Operation: It returns a ResultSet including information of the foreign keys which refers to the given p arent table in the given foreign key table. If reference relationship does not exist, it returns an empty ResultSet.
- Exception: If the foreign table or parent table is null or an error is returned from the server, it throws SQLException.

getDatabaseMajorVersion

```
int getDatabaseMajorVersion() throws SQLException
```

- Operation: It returns the major version of the product.
- Exception: If an error is returned from the server, it throws SQLException.

getDatabaseMinorVersion

```
int getDatabaseMinorVersion() throws SQLException
```

- Operation: It returns the minor version of the product.
- Exception: If an error is returned from the server, it throws SQLException.

getDatabaseProductName

```
String getDatabaseProductName() throws SQLException
```

- Operation: It returns the product name.
- Exception: If an error is returned from the server, it throws SQLException.

getDatabaseProductVersion

```
String getDatabaseProductVersion() throws SQLException
```

- Operation: It returns the product version.
- Exception: If an error is returned from the server, it throws SQLException.

getDefaultTransactionIsolation

```
int getDefaultTransactionIsolation() throws SQLException
```

- Operation: It returns the default transaction isolation. The default value which is set on the server is C onnection.TRANSACTION_READ_COMMITTED.
- Exception: If an error is returned from the server, it throws SQLException.

getDriverMajorVersion

```
int getDriverMajorVersion() throws SQLException
```

- Operation: It returns the major version of GOLDILOCKS JDBC driver.
- Exception: It does not occur.

getDriverMinorVersion

```
int getDriverMinorVersion() throws SQLException
```

- Operation: It returns the minor version of GOLDILOCKS JDBC driver.
- Exception: It does not occur.

getDriverName

```
String getDriverName() throws SQLException
```

- Operation: It returns "GOLDILOCKS JDBC Driver".
- Exception: It does not occur.

getDriverVersion

```
String getDriverVersion() throws SQLException
```

- Operation: It returns GOLDILOCKS JDBC driver version string. It includes the protocol version.
- Exception: It does not occur.

getExportedKeys

```
ResultSet getExportedKeys(String catalog, String schema, String table) throws SQLException
```

- Operation: It returns a ResultSet including foreign key information referring to the column in the give n table.
- Exception: If an error is returned from the server, it throws SQLException.

getExtraNameCharacters

```
String getExtraNameCharacters() throws SQLException
```

- Operation: It returns "-$".
- Exception: It does not occur.

getFunctionColumns

```
ResultSet getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern,
String columnNamePattern) throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getFunctions

```
ResultSet getFunctions(String catalog, String schemaPattern, String functionNamePattern)
throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getIdentifierQuoteString

```
String getIdentifierQuoteString() throws SQLException
```

- Operation: It returns an identifier quote character. The value that is set on the server is ".
- Exception: If an error is returned from the server, it throws SQLException.

getImportedKeys

```
ResultSet getImportedKeys(String catalog, String schema, String table) throws SQLException
```

- Operation: It returns a ResultSet including parent key information to which the foreign key column in the given table refers.
- Exception: If an error is returned from the server, it throws SQLException.

getIndexInfo

```
ResultSet getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate) throws SQLException
```

- Operation: It returns a ResultSet including index information of the given table. If unique is true, only unique index information is displayed. The approximate argument is ignored.
- Exception: If an error is returned from the server, it throws SQLException.

getJDBCMajorVersion

```
int getJDBCMajorVersion() throws SQLException
```

- Operation: It returns JDBC major version of GOLDILOCKS JDBC driver. It can vary depending on the ja r file in use.
- Exception: It does not occur.

getJDBCMinorVersion

```
int getJDBCMinorVersion() throws SQLException
```

- Operation: It returns JDBC minor version of GOLDILOCKS JDBC driver. It can vary depending on the ja r file in use.
- Exception: It does not occur.

getMaxBinaryLiteralLength

```
int getMaxBinaryLiteralLength() throws SQLException
```

- Operation: It gets the maximum binary length from the server. 0 refers that the maximum length is in finite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxCatalogNameLength

```
int getMaxCatalogNameLength() throws SQLException
```

- Operation: It gets the maximum length of the catalog name from the server. 0 refers that the maxim um length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxCharLiteralLength

```
int getMaxCharLiteralLength() throws SQLException
```

- Operation: It gets the maximum literal length from the server. 0 refers that the maximum length is inf inite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnNameLength

```
int getMaxColumnNameLength() throws SQLException
```

- Operation: It gets the maximum length of the column name from the server. 0 refers that the maxim um length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnsInGroupBy

```
int getMaxColumnsInGroupBy() throws SQLException
```

- Operation: It gets the maximum number of columns available to use in *group by* clause from the serv er. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnsInIndex

```
int getMaxColumnsInIndex() throws SQLException
```

- Operation: It gets the maximum number of columns available to use as the index from the server. 0 r efers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnsInOrderBy

```
int getMaxColumnsInOrderBy() throws SQLException
```

- Operation: It gets the maximum number of columns available to use in *order by* clause from the serve r. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnsInSelect

```
int getMaxColumnsInSelect() throws SQLException
```

- Operation: It gets the maximum number of columns available to use in select target clause from the s erver. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxColumnsInTable

```
int getMaxColumnsInTable() throws SQLException
```

- Operation: It gets the maximum number of columns available to use in the table from the server. 0 re fers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxConnections

```
int getMaxConnections() throws SQLException
```

- Operation: It gets the maximum number of connection to the server from the server. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxCursorNameLength

```
int getMaxCursorNameLength() throws SQLException
```

- Operation: It gets the maximum length of the cursor name from the server. 0 refers that the maximum length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxIndexLength

```
int getMaxIndexLength() throws SQLException
```

- Operation: It gets the maximum size for a single index key from the server.
- Exception: If an error is returned from the server, it throws SQLException.

The JDBC specification defines that the available maximum size of a single index is returned in bytes, but its value is meaningless, because index size does not have limit. It operates in this way for it to have the same meaning as ODBC.

getMaxProcedureNameLength

```
int getMaxProcedureNameLength() throws SQLException
```

- Operation: It gets the maximum length of the procedure name from the server. 0 refers that the maximum length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxRowSize

```
int getMaxRowSize() throws SQLException
```

- Operation: It gets the maximum number of rows in a table from the server. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxSchemaNameLength

```
int getMaxSchemaNameLength() throws SQLException
```

- Operation: It gets the maximum length of the schema name from the server. 0 refers that the maxim um length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxStatementLength

```
int getMaxStatementLength() throws SQLException
```

- Operation: It gets the maximum string length of an SQL statement from the server. 0 refers that the maximum length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxStatements

```
int getMaxStatements() throws SQLException
```

- Operation: It gets the maximum number of statements which can be open at once from the server. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxTableNameLength

```
int getMaxTableNameLength() throws SQLException
```

- Operation: It gets the maximum string length of the table name from the server. 0 refers that the ma ximum length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxTablesInSelect

```
int getMaxTablesInSelect() throws SQLException
```

- Operation: It gets the maximum number of tables which can be used in the select statement from th e server. 0 refers that the maximum number is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getMaxUserNameLength

```
int getMaxUserNameLength() throws SQLException
```

- Operation: It gets the maximum string length of the user name from the server. 0 refers that the max imum length is infinite.
- Exception: If an error is returned from the server, it throws SQLException.

getNumericFunctions

```
String getNumericFunctions() throws SQLException
```

- Operation: It gets a list of numeric-related functions corresponding to SQL standard from the server. Each function name is distinguished by comma (,).
- Exception: If an error is returned from the server, it throws SQLException.

getPrimaryKeys

```
ResultSet getPrimaryKeys(String catalog, String schema, String table) throws SQLException
```

- Operation: It returns a ResultSet including all primary keys in a given table.
- Exception: If an error is returned from the server, it throws SQLException.

getProcedureColumns

```
ResultSet getProcedureColumns(String catalog, String schemaPattern, String
procedureNamePattern, String columnNamePattern) throws SQLException
```

- Operation: It returns a ResultSet including column information corresponding to the given name patt ern for a given procedure.
- Exception: If an error is returned from the server, it throws SQLException.

getProcedures

```
ResultSet getProcedures(String catalog, String schemaPattern, String procedureNamePattern)
throws SQLException
```

- Operation: It returns a ResultSet including procedure information of a given name pattern.
- Exception: If an error is returned from the server, it throws SQLException.

getProcedureTerm

```
String getProcedureTerm() throws SQLException
```

- Operation: It gets the keyword which refers to the procedure from the server.
- Exception: If an error is returned from the server, it throws SQLException.

getResultSetHoldability

```
int getResultSetHoldability() throws SQLException
```

- Operation: It returns the default holdability property of ResultSet. It is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: It does not occur.

getRowIdLifetime

```
RowIdLifetime getRowIdLifetime() throws SQLException
```

- Operation: It always returns RowIdLifetime.ROWID_VALID_FOREVER.
- Exception: It does not occur.

getSchemas

```
ResultSet getSchemas() throws SQLException
```

- Operation: It returns a ResultSet including information about all schemas in the server.
- Exception: If an error is returned from the server, it throws SQLException.

```
ResultSet getSchemas(String catalog, String schemaPattern) throws SQLException
```

- Operation: It returns a ResultSet including information for all schemas which meet the pattern of a given schema name. The catalog is ignored.
- Exception: If an error is returned from the server, it throws SQLException.

getSchemaTerm

```
String getSchemaTerm() throws SQLException
```

- Operation: It gets the keyword which refers to the schema from the server.

- Exception: If an error is returned from the server, it throws SQLException.

getSearchStringEscape

```
String getSearchStringEscape() throws SQLException
```

- Operation: It returns the escape characters used in *like* clause as a string.
- Exception: If an error is returned from the server, it throws SQLException.

getSQLKeywords

```
String getSQLKeywords() throws SQLException
```

- Operation: It returns the keywords which can not be used in SQL statement, separated by comma (,).
- Exception: If an error is returned from the server, it throws SQLException.

getSQLStateType

```
int getSQLStateType() throws SQLException
```

- Operation: It always returns DatabaseMetaData.sqlStateSQL99.
- Exception: It does not occur.

getStringFunctions

```
String getStringFunctions() throws SQLException
```

- Operation: It gets a list of functions which handle the strings and corresponds to SQL standard. Each function name is distinguished by comma (,).
- Exception: If an error is returned from the server, it throws SQLException.

getSuperTables

```
ResultSet getSuperTables(String catalog, String schemaPattern, String tableNamePattern) throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getSuperTypes

```
ResultSet getSuperTypes(String catalog, String schemaPattern, String typeNamePattern) throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getSystemFunctions

```
String getSystemFunctions() throws SQLException
```

- Operation: It gets a list of system functions corresponding to SQL standard. Each function name is separated by the comma (,).
- Exception: If an error is returned from the server, it throws SQLException.

getTablePrivileges

```
ResultSet getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern) throws SQLException
```

- Operation: It returns a ResultSet including privilege information of all tables which satisfy the condition.
- Exception: If an error is returned from the server, it throws SQLException.

getTables

```
ResultSet getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types) throws SQLException
```

- Operation: It returns a ResultSet including information of all tables which satisfy the condition.
- Exception: If an error is returned from the server, it throws SQLException.

getTableTypes

```
ResultSet getTableTypes() throws SQLException
```

- Operation: It returns a ResultSet containing information of all table types.
- Exception: If an error is returned from the server, it throws SQLException.

getTimeDateFunctions

```
String getTimeDateFunctions() throws SQLException
```

- Operation: It gets functions which are related to time and date and corresponds to SQL standard. Eac h function name is separated by the comma(,).
- Exception: If an error is returned from the server, it throws SQLException.

getTypeInfo

```
ResultSet getTypeInfo() throws SQLException
```

- Operation: It returns a ResultSet including information of the data type.
- Exception: If an error is returned from the server, it throws SQLException.

getUDTs

```
ResultSet getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)
throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

getURL

```
String getURL() throws SQLException
```

- Operation: It returns the URL used to connect to the server.
- Exception: It does not occur.

getUserName

```
String getUserName() throws SQLException
```

- Operation: It returns the current user name which maintains a session.
- Exception: If an error is returned from the server, it throws SQLException.

> ⚠️ A user name may be different from the user name used to connect firstly because the user can be changed during a session.

getVersionColumns

```
ResultSet getVersionColumns(String catalog, String schema, String table) throws SQLException
```

- Operation: It returns an empty ResultSet.
- Exception: If an error is returned from the server, it throws SQLException.

insertsAreDetected

```
boolean insertsAreDetected(int type) throws SQLException
```

- Operation: It always returns false regardless of the type.
- Exception: It does not occur.

isCatalogAtStart

```
boolean isCatalogAtStart() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

isReadOnly

```
boolean isReadOnly() throws SQLException
```

- Operation: It gets the information whether the current connection is the read only mode from the ser ver.
- Exception: If an error is returned from the server, it throws SQLException.

locatorsUpdateCopy

```
boolean locatorsUpdateCopy() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

nullPlusNonNullIsNull

```
boolean nullPlusNonNullIsNull() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

nullsAreSortedAtEnd

```
boolean nullsAreSortedAtEnd() throws SQLException
```

- Operation: It always returns false. It does not separately sort null.
- Exception: It does not occur.

nullsAreSortedAtStart

```
boolean nullsAreSortedAtStart() throws SQLException
```

- Operation: It always returns false. It does not separately sort null.
- Exception: It does not occur.

nullsAreSortedHigh

```
boolean nullsAreSortedHigh() throws SQLException
```

- Operation: It always returns true. Null is positioned at last by default.
- Exception: It does not occur.

nullsAreSortedLow

```
boolean nullsAreSortedLow() throws SQLException
```

- Operation: It always returns false. Null is positioned at last by default.
- Exception: It does not occur.

othersDeletesAreVisible

```
boolean othersDeletesAreVisible(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

othersInsertsAreVisible

```
boolean othersInsertsAreVisible(int type) throws SQLException
```

- Operation: It always returns false regardless of the type.
- Exception: It does not occur.

othersUpdatesAreVisible

```
boolean othersUpdatesAreVisible(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

ownDeletesAreVisible

```
boolean ownDeletesAreVisible(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

ownInsertsAreVisible

```
boolean ownInsertsAreVisible(int type) throws SQLException
```

- Operation: It always returns false regardless of the type.
- Exception: It does not occur.

ownUpdatesAreVisible

```
boolean ownUpdatesAreVisible(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

storesLowerCaseIdentifiers

```
boolean storesLowerCaseIdentifiers() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

storesLowerCaseQuotedIdentifiers

```
boolean storesLowerCaseQuotedIdentifiers() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

storesMixedCaseIdentifiers

```
boolean storesMixedCaseIdentifiers() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

storesMixedCaseQuotedIdentifiers

```
boolean storesMixedCaseQuotedIdentifiers() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

storesUpperCaseIdentifiers

```
boolean storesUpperCaseIdentifiers() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

storesUpperCaseQuotedIdentifiers

```
boolean storesUpperCaseQuotedIdentifiers() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsAlterTableWithAddColumn

```
boolean supportsAlterTableWithAddColumn() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsAlterTableWithDropColumn

```
boolean supportsAlterTableWithDropColumn() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsANSI92EntryLevelSQL

```
boolean supportsANSI92EntryLevelSQL() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsANSI92FullSQL

```
boolean supportsANSI92FullSQL() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsANSI92IntermediateSQL

```
boolean supportsANSI92IntermediateSQL() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsBatchUpdates

```
boolean supportsBatchUpdates() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsCatalogsInDataManipulation

```
boolean supportsCatalogsInDataManipulation() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsCatalogsInIndexDefinitions

```
boolean supportsCatalogsInIndexDefinitions() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsCatalogsInPrivilegeDefinitions

```
boolean supportsCatalogsInPrivilegeDefinitions() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsCatalogsInProcedureCalls

```
boolean supportsCatalogsInProcedureCalls() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsCatalogsInTableDefinitions

```
boolean supportsCatalogsInTableDefinitions() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsColumnAliasing

```
boolean supportsColumnAliasing() throws SQLException
```

- Operation: It gets information whether to support the column aliasing from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsConvert

```
boolean supportsConvert() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsConvert

```
boolean supportsConvert(int fromType, int toType) throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsCoreSQLGrammar

```
boolean supportsCoreSQLGrammar() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsCorrelatedSubqueries

boolean supportsCorrelatedSubqueries() throws SQLException

- Operation: It always returns true.
- Exception: It does not occur.

supportsDataDefinitionAndDataManipulationTransactions

```
boolean supportsDataDefinitionAndDataManipulationTransactions() throws SQLException
```

- Operation: It always returns true. It can perform DML and DDL with a single transaction.
- Exception: It does not occur.

supportsDataManipulationTransactionsOnly

```
boolean supportsDataManipulationTransactionsOnly() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsDifferentTableCorrelationNames

```
boolean supportsDifferentTableCorrelationNames() throws SQLException
```

- Operation: It gets information whether the table correlation name should be different from the table name from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsExpressionsInOrderBy

```
boolean supportsExpressionsInOrderBy() throws SQLException
```

- Operation: It gets information whether the calculation can be used in *order by* clause from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsExtendedSQLGrammar

```
boolean supportsExtendedSQLGrammar() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsFullOuterJoins

```
boolean supportsFullOuterJoins() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsGetGeneratedKeys

```
boolean supportsGetGeneratedKeys() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsGroupBy

```
boolean supportsGroupBy() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsGroupByBeyondSelect

```
boolean supportsGroupByBeyondSelect() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsGroupByUnrelated

```
boolean supportsGroupByUnrelated() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsIntegrityEnhancementFacility

```
boolean supportsIntegrityEnhancementFacility() throws SQLException
```

- Operation: It gets information whether to support SQL integrity enhancing feature from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsLikeEscapeClause

```
boolean supportsLikeEscapeClause() throws SQLException
```

- Operation: It gets information whether to support escape clause in like statement from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsLimitedOuterJoins

```
boolean supportsLimitedOuterJoins() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsMinimumSQLGrammar

```
boolean supportsMinimumSQLGrammar() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsMixedCaseIdentifiers

```
boolean supportsMixedCaseIdentifiers() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsMixedCaseQuotedIdentifiers

```
boolean supportsMixedCaseQuotedIdentifiers() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsMultipleOpenResults

```
boolean supportsMultipleOpenResults() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsMultipleResultSets

```
boolean supportsMultipleResultSets() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsMultipleTransactions

```
boolean supportsMultipleTransactions() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsNamedParameters

```
boolean supportsNamedParameters() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsNonNullableColumns

```
boolean supportsNonNullableColumns() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOpenCursorsAcrossCommit

```
boolean supportsOpenCursorsAcrossCommit() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOpenCursorsAcrossRollback

```
boolean supportsOpenCursorsAcrossRollback() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOpenStatementsAcrossCommit

```
boolean supportsOpenStatementsAcrossCommit() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOpenStatementsAcrossRollback

```
boolean supportsOpenStatementsAcrossRollback() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOrderByUnrelated

```
boolean supportsOrderByUnrelated() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsOuterJoins

```
boolean supportsOuterJoins() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsPositionedDelete

```
boolean supportsPositionedDelete() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsPositionedUpdate

```
boolean supportsPositionedUpdate() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsResultSetConcurrency

```
boolean supportsResultSetConcurrency(int type, int concurrency) throws SQLException
```

- Operation: It returns true for all ResultSet types and all concurrency. It returns false for the invalid arg uments.
- Exception: It does not occur.

supportsResultSetHoldability

```
boolean supportsResultSetHoldability(int holdability) throws SQLException
```

- Operation: If the holdability is ResultSet.CLOSE_CURSORS_AT_COMMIT or ResultSet.HOLD_CURSOR S_OVER_COMMIT, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

supportsResultSetType

```
boolean supportsResultSetType(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_FORWARD_ONLY, ResultSet.TYPE_SCROLL_INSENSITIVE or R esultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

supportsSavepoints

```
boolean supportsSavepoints() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSchemasInDataManipulation

```
boolean supportsSchemasInDataManipulation() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSchemasInIndexDefinitions

```
boolean supportsSchemasInIndexDefinitions() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSchemasInPrivilegeDefinitions

```
boolean supportsSchemasInPrivilegeDefinitions() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSchemasInProcedureCalls

```
boolean supportsSchemasInProcedureCalls() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSchemasInTableDefinitions

```
boolean supportsSchemasInTableDefinitions() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSelectForUpdate

```
boolean supportsSelectForUpdate() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsStatementPooling

```
boolean supportsStatementPooling() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsStoredFunctionsUsingCallSyntax

```
boolean supportsStoredFunctionsUsingCallSyntax() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

supportsStoredProcedures

```
boolean supportsStoredProcedures() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSubqueriesInComparisons

```
boolean supportsSubqueriesInComparisons() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSubqueriesInExists

```
boolean supportsSubqueriesInExists() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSubqueriesInIns

```
boolean supportsSubqueriesInIns() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsSubqueriesInQuantifieds

```
boolean supportsSubqueriesInQuantifieds() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsTableCorrelationNames

```
boolean supportsTableCorrelationNames() throws SQLException
```

- Operation: It gets information whether to support the table correlation name from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsTransactionIsolationLevel

```
boolean supportsTransactionIsolationLevel(int level) throws SQLException
```

- Operation: It gets information whether to support the transaction isolation level from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsTransactions

```
boolean supportsTransactions() throws SQLException
```

- Operation: It always returns true.
- Exception: It does not occur.

supportsUnion

```
boolean supportsUnion() throws SQLException
```

- Operation: It gets information whether to support the union operation from the server.
- Exception: If an error is returned from the server, it throws SQLException.

supportsUnionAll

```
boolean supportsUnionAll() throws SQLException
```

- Operation: It gets information whether to support the union all operation from the server.
- Exception: If an error is returned from the server, it throws SQLException.

updatesAreDetected

```
boolean updatesAreDetected(int type) throws SQLException
```

- Operation: If the type is ResultSet.TYPE_SCROLL_SENSITIVE, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

usesLocalFilePerTable

```
boolean usesLocalFilePerTable() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

usesLocalFiles

```
boolean usesLocalFiles() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

DataSource

getConnection

```
Connection getConnection() throws SQLException
```

- Operation: It opens and returns a new connection object. The information required for connection sh ould be set through a separate non-standard method in advance.
- Exception: If the connection to the server fails, it throws SQLException.

```
Connection getConnection(String username, String password) throws SQLException
```

- Operation: It opens and returns a new connection object with the username and password. Other inf ormation required for the connection should be set through a separate non-standard method in adva nce.
- Exception: If the connection to the server fails, it throws SQLException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface) throws SQLException
```

- Operation: This class is not implemented as the wrapper of any other class. If the object is an instance of iface, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface) throws SQLException
```

- Operation: It returns *this* because this class is not implemented as the wrapper of any other class.
- Exception: If the object is not an instance of iface, it throws SQLException.

Driver

acceptsURL

```
boolean acceptsURL(String url) throws SQLException
```

- Operation: If the url is not null and it starts with "jdbc:goldilocks:", it returns true. Otherwise, it return s false.
- Exception: It does not occur.

connect

```
Connection connect(String url, Properties info) throws SQLException
```

- Operation: It creates and returns a new connection object. The url should include the server address, DB name and port.
- Exception: If the url is invalid or the connection from the server fails, it throws SQLException.

getMajorVersion

```
int getMajorVersion() throws SQLException
```

- Operation: It returns the major version of GOLDILOCKS JDBC driver.
- Exception: It does not occur.

getMinorVersion

```
int getMinorVersion() throws SQLException
```

- Operation: It returns the minor version of GOLDILOCKS JDBC driver.
- Exception: It does not occur.

getPropertyInfo

```
DriverPropertyInfo[] getPropertyInfo(String url, Properties info) throws SQLException
```

- Operation: It gets the list of available property when GOLDILOCKS JDBC driver is connected.
- Exception: It does not occur.

jdbcCompliant

```
boolean jdbcCompliant() throws SQLException
```

- Operation: It always returns false.
- Exception: It does not occur.

NClob

This class is not implemented.

free

```
void free() throws SQLException
```

getAsciiStream

```
InputStream getAsciiStream() throws SQLException
```

getCharacterStream

```
Reader getCharacterStream() throws SQLException
```

```
Reader getCharacterStream(long pos, long length) throws SQLException
```

getSubString

```
String getSubString(long pos, int length) throws SQLException
```

length

```
long length() throws SQLException
```

position

```
long position(Clob searchstr, long start) throws SQLException
```

```
long position(String searchstr, long start) throws SQLException
```

setAsciiStream

```
OutputStream setAsciiStream(long pos) throws SQLException
```

setCharacterStream

```
Writer setCharacterStream(long pos) throws SQLException
```

setString

```
int setString(long pos, String str) throws SQLException
```

```
int setString(long pos, String str, int offset, int len) throws SQLException
```

truncate

```
void truncate(long len) throws SQLException
```

ParameterMetaData

ParameterMetaData object is returned by PreparedStatement.getParameterMetaData(). The parameterMetaData of the GOLDILOCKS JDBC does not use the actual DB information but it is based on the basic type varchar for other information (such as type, etc.) except for in/out. It is because in/out is the only information got from the server on the parameter after prepared. For example, if it is prepared with the query statement which is "Select * from t1 where a =?", the parameter type used in the condition clause is not determined. The server generally assumes it a varchar type.

getParameterClassName

```
String getParameterClassName(int param) throws SQLException
```

- Operation: It returns java.lang.String. The parameter type is regarded as varchar.
- Exception: If the param value exceeds the range of the number of parameters, it throws SQLException.

getParameterCount

```
int getParameterCount() throws SQLException
```

- Operation: It returns the number of parameters. It is also the number of ? used in the query statement.
- Exception: It does not occur.

getParameterMode

```
int getParameterMode(int param) throws SQLException
```

- Operation: It returns the in/out mode of the param-th parameter. It returns one of ParameterMetaData.parameterModeIn, ParameterMetaData.parameterModeInOut, ParameterMetaData.parameterModeOut, or ParameterMetaData.parameterModeUnknown. The case of returning parameterModeUnknown value does not exist until now.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

getParameterType

```
int getParameterType(int param) throws SQLException
```

- Operation: It returns Types.VARCHAR for all parameters.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

getParameterTypeName

```
String getParameterTypeName(int param) throws SQLException
```

- Operation: It returns "VARCHAR" for all parameters.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

getPrecision

```
int getPrecision(int param) throws SQLException
```

- Operation: It returns 4000 for all parameters. The parameter is regarded as varchar(4000) by default.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

getScale

```
int getScale(int param) throws SQLException
```

- Operation: It returns 0 for all parameters. The parameter is regarded as varchar(4000) by default.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

isNullable

```
int isNullable(int param) throws SQLException
```

- Operation: It always returns ParameterMetaData.parameterNullableUnknown.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

isSigned

```
boolean isSigned(int param) throws SQLException
```

- Operation: It always returns false.
- Exception: If the param value exceeds range of the number of parameters, it throws SQLException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface) throws SQLException
```

- Operation: It enquires if it the object is an instance of iface. If so, it returns true. Otherwise, it returns false.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface) throws SQLException
```

- Operation: If the object is an instance of iface, it casts this object to iface type and returns it.
- Exception: If the object is not an instance of iface, it throws SQLException.

PooledConnection

addConnectionEventListener

```
void addConnectionEventListener(ConnectionEventListener listener) throws SQLException
```

- Operation: It registers the ConnectionEventListener object. After then, if close() of the connection obj ect (logical connection) which is returned from PooledConnection is called or the actual connection is broken, ConnectionEvent is generated to the registered listeners.
- Exception: It does not occur.

addStatementEventListener

```
void addStatementEventListener(StatementEventListener listener) throws SQLException
```

- Operation: It does not perform any operation. GOLDILOCKS JDBC driver does not implement the met hod. Statement pooling feature is performed by the external middleware.
- Exception: It does not occur.

close

```
void close() throws SQLException
```

- Operation: It calls close() of the physical connection that the object has.
- Exception: It may occur in close() of physical connection.

getConnection

```
Connection getConnection() throws SQLException
```

- Operation: It returns logical connection owned by the object.
- Exception: It does not occur.

removeConnectionEventListener

```
void removeConnectionEventListener(ConnectionEventListener listener) throws SQLException
```

- Operation: It removes the registered ConnectionEventListener. After then, ConnectionEvent is not tra nsferred to this listener.

- Exception: It does not occur.

removeStatementEventListener

```
void removeStatementEventListener(StatementEventListener listener) throws SQLException
```

- Operation: It does not perform any operation.
- Exception: It does not occur.

PreparedStatement

addBatch

```
void addBatch() throws SQLException
```

- Operation: It registers the currently bound data as batch job. If any of this batch job is registered, an error occurs when performing execute (), executeUpdate (), executeQuery () execution. If any one is not bound for the parameter, an error occurs. After addBatch if another addBatch is performed again at the state without binding with the method of setXXX () type, it registers the batch job as the previously bound value.
- Exception: If a parameter which has never been bound exists, it throws an exception.

clearParameters

```
void clearParameters() throws SQLException
```

- Operation: It removes all of currently bound data and information. But if at least one batch job is registered, operation is not performed.
- Exception: It does not occur.

execute

```
boolean execute() throws SQLException
```

- Operation: It executes the prepared statement based on the bound data to the current parameter. If the executed statement is the select statement, it returns true and gets a ResultSet from the object. Otherwise, it returns false.
- Exception: If the batch job is registered, the bound parameters are insufficient or an error occurs on the server when executing, it throws an exception.

executeQuery

```
ResultSet executeQuery() throws SQLException
```

- Operation: It executes the prepared statement based on the bound data to the current parameter and fetches, then creates and returns a ResultSet object.
- Exception: If the batch job is registered or the bound parameters are insufficient or an error occurs on the server when executing, it throws an exception.

executeUpdate

```
int executeUpdate() throws SQLException
```

- Operation: It executes the prepared statement based on the bound data to the current parameter. It r eturns the number of updated records. If updated record with DDL statements does not exist, it retur ns 0.
- Exception: If the batch job is registered or the statement is not a select statement or the bound para meters are insufficient or an error occurs on the server when executing, it throws an exception.

getMetaData

```
ResultSetMetaData getMetaData() throws SQLException
```

- Operation: It gets ResultSetMetaData object. If the prepared statement is not the select statement (It is the statement which does not return ResultSet), it returns an empty ResultSetMetaData. The meth od can be called before executing.
- Exception: If an error occurs on the server, it throws an exception.

getParameterMetaData

```
ParameterMetaData getParameterMetaData() throws SQLException
```

- Operation: It gets the ParameterMetaData object. It can be called before executing. However, all par ameters are assumed to be varchar(4000) because information about the exact parameter type is not known to the server.
- Exception: If an error occurs on the server, it throws an exception.

setArray

```
void setArray(int parameterIndex, Array x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setAsciiStream

```
void setAsciiStream(int parameterIndex, InputStream x) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARCHAR type. It does n

ot execute the encoding operation because the input data is a binary form. It does not consider the c haracter set and assumes it as ascii data.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

⚠️ The cost of conversion to VARCHAR occurs in the server because it is bound to LONG VARCHA R. If the length can be known, it is recommended to use void setAsciiStream(int parameterIndex, InputStream x, int length).

```
void setAsciiStream(int parameterIndex, InputStream x, int length) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARCHAR type. It does n ot execute the encoding operation because the input data is a binary form. It does not consider the c haracter set and and assumes it as ascii data. If English data is inserted or the server client character s et environment is identical, this method is faster than setCharacterStream or setString when inserting the data as varchar.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setAsciiStream(int parameterIndex, InputStream x, long length) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARCHAR type. It does n ot execute the encoding operation because the input data is a binary form. It does not consider the c haracter set and assumes it as ascii data. If English data is inserted or the server client character set en vironment is identical, this method is faster than setCharacterStream or setString when inserting the data as varchar.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setBigDecimal

```
void setBigDecimal(int parameterIndex, BigDecimal x) throws SQLException
```

- Operation: It binds the BigDecimal object to the parameter index as NUMBER type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setBinaryStream

```
void setBinaryStream(int parameterIndex, InputStream x) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARBINARY type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setBinaryStream(int parameterIndex, InputStream x, int length) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARBINARY type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setBinaryStream(int parameterIndex, InputStream x, long length) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARBINARY type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setBlob

```
void setBlob(int parameterIndex, Blob x) throws SQLException
```

- Operation: It binds the blob object to the parameter index as LONG VARBINARY type.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

```
void setBlob(int parameterIndex, InputStream inputStream) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARBINARY type.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

```
void setBlob(int parameterIndex, InputStream inputStream, long length) throws SQLException
```

- Operation: It binds the InputStream object to the parameter index as LONG VARBINARY type. The nu mber of characters included in InputStream is as many as the length.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

setBoolean

```
void setBoolean(int parameterIndex, boolean x) throws SQLException
```

- Operation: It binds the data x to the parameter index as BOOLEAN type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setByte

```
void setByte(int parameterIndex, byte x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_SMALLINT type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setBytes

```
void setBytes(int parameterIndex, byte[] x) throws SQLException
```

- Operation: It binds the data x to the parameter index as VARBINARY or LONG VARBINARY type. If th e length of x is equal to or smaller than 4000, it is bound as VARBINARY, and if it is bigger than 4000, it is bound as LONG VARBINARY type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setCharacterStream

```
void setCharacterStream(int parameterIndex, Reader reader) throws SQLException
```

- Operation: It binds the reader object to the parameter index as LONG VARCHAR type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setCharacterStream(int parameterIndex, Reader reader, int length) throws SQLException
```

- Operation: It binds the reader object to the parameter index as LONG VARCHAR type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setCharacterStream(int parameterIndex, Reader reader, long length) throws SQLException
```

- Operation: It binds the reader object to the parameter index as LONG VARCHAR type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setClob

```
void setClob(int parameterIndex, Clob x) throws SQLException
```

- Operation: It binds the clob object to the parameter index as LONG VARCHAR type.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

```
void setClob(int parameterIndex, Reader reader) throws SQLException
```

- Operation: It binds the reader object to the parameter index as LONG VARCHAR type.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

```
void setClob(int parameterIndex, Reader reader, long length) throws SQLException
```

- Operation: It binds the reader object to the parameter index as LONG VARCHAR type. The number of characters included in reader is as many as the length.
- Exception: If parameterIndex is smaller than 0 or it is bigger than the number of parameters, it throw s SQLException.

setDate

```
void setDate(int parameterIndex, Date x) throws SQLException
```

- Operation: It binds the data x to the parameter index as DATE type. It is equivalent to calling setDate (parameterIndex, x, Calendar.getInstance()). The local timezone is applied.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setDate(int parameterIndex, Date x, Calendar cal) throws SQLException
```

- Operation: It binds the data x to the parameter index as DATE type. Date x is regarded as timezone of cal.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setDouble

```
void setDouble(int parameterIndex, double x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_DOUBLE type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setFixedCHAR

```
void setFixedCHAR(int parameterIndex, String x) throws SQLException
```

- Operation: It binds the data x to the parameter index as CHAR type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setFloat

```
void setFloat(int parameterIndex, float x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_REAL type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setInt

```
void setInt(int parameterIndex, int x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_INTEGER type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setLong

```
void setLong(int parameterIndex, long x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_BIGINT type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setNCharacterStream

```
void setNCharacterStream(int parameterIndex, Reader value) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNCharacterStream(int parameterIndex, Reader value, long length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setNClob

```
void setNClob(int parameterIndex, NClob value) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNClob(int parameterIndex, Reader reader) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
void setNClob(int parameterIndex, Reader reader, long length) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setNString

```
void setNString(int parameterIndex, String value) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setNull

```
void setNull(int parameterIndex, int sqlType) throws SQLException
```

- Operation: It binds null to the parameter index as GOLDILOCKS type corresponding to sqlType. For more information about GOLDILOCKS type mapped to sqlType, refer to **SQL types → GOLDILOCKS types**.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setNull(int parameterIndex, int sqlType, String typeName) throws SQLException
```

- Operation: It binds null to the parameter index as GOLDILOCKS type corresponding to sqlType type. For more information about GOLDILOCKS type mapped to sqlType, refer to **SQL types → GOLDILOCKS types**. The third argument, typeName, is ignored because REF or the user type is not supported.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setObject

```
void setObject(int parameterIndex, Object x) throws SQLException
```

- Operation: It binds the data x to the parameter index as the mapped GOLDILOCKS type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

Table 32-2 Java objects → GOLDILOCKS types

Java class	GOLDILOCKS type
null	VARCHAR
Boolean	BOOLEAN
Byte	NATIVE_SMALLINT
Short	NATIVE_SMALLINT
Integer	NATIVE_INTEGER
Long	NATIVE_BIGINT
Float	NATIVE_REAL
Double	NATIVE_DOUBLE
BigInteger	NATIVE_BIGINT
BigDecimal	NUMBER
String	VARCHAR or LONG VARCHAR
byte[]	VARBINARY or LONG VARBINARY
Date	DATE
Time	TIME
Timestamp	TIMESTAMP
Blob	N/A
Clob	N/A
InputStream	LONG VARBINARY
Reader	LONG VARCHAR
GoldilocksInterval	Corresponding INTERVAL type
RowId	ROWID
Others	N/A

```
void setObject(int parameterIndex, Object x, int targetSqlType) throws SQLException
```

- Operation: It binds the data x to the parameter index as GOLDILOCKS type corresponding to targetSqlType. For more information about GOLDILOCKS type mapped to targetSqlType, refer to **SQL types → GOLDILOCKS types**.
- Exception: It occurs if parameterIndex is smaller than 0 or it is greater than the number of parameters.

```
void setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength) throws SQLException
```

- Operation: It binds the data x to the parameter index as GOLDILOCKS type corresponding to targetSqlType. For more information about GOLDILOCKS type mapped to targetSqlType, refer to **SQL types → GOLDILOCKS types**. If x is InputStream or Reader then scaleOrLength indicates the data length. For other types this value is ignored.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setRef

```
void setRef(int parameterIndex, Ref x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setRowId

```
void setRowId(int parameterIndex, RowId x) throws SQLException
```

- Operation: It binds the data x to the parameter index as ROWID type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setShort

```
void setShort(int parameterIndex, short x) throws SQLException
```

- Operation: It binds the data x to the parameter index as NATIVE_SMALLINT type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setSQLXML

```
void setSQLXML(int parameterIndex, SQLXML xmlObject) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setString

```
void setString(int parameterIndex, String x) throws SQLException
```

- Operation: It binds the data x to the parameter index as VARCHAR or LONG VARCHAR type. If the le ngth of x is equal to or smaller than 4000, it is bound as VARCHAR, and if it is bigger than 4000, it is bound as LONG VARCHAR type.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setTime

```
void setTime(int parameterIndex, Time x) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIME type. It is equivalent to calling setTime (parameterIndex, x, Calendar.getInstance()). The local timezone is applied.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setTime(int parameterIndex, Time x, Calendar cal) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIME type. Time x is regarded as timezone of cal.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setTimestamp

```
void setTimestamp(int parameterIndex, Timestamp x) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIME type. It is equivalent to calling setTimes tamp(parameterIndex, x, Calendar.getInstance()). The local timezone is applied.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

```
void setTimestamp(int parameterIndex, Timestamp x, Calendar cal) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIMESTAMP type. Timestamp x is regarded a s timezone of cal.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

setUnicodeStream

```
void setUnicodeStream(int parameterIndex, InputStream x, int length) throws SQLException
```

- Operation: It is not implemented. (It is a deprecated method.)
- Exception: It always throws SQLFeatureNotSupportedException.

setURL

```
void setURL(int parameterIndex, URL x) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface) throws SQLException
```

- Operation: It queries whether this object is the class implementing the iface interface. If so, it returns true. Otherwise, it returns false. It does not determine the presence of the wrapper and it queries onl y whether the given argument class type is implemented because GOLDILOCKS PreparedStatement o bject is not the wrapper of any other class.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface) throws SQLException
```

- Operation: It eventually returns itself even when it is unwrapped because GOLDILOCKS PreparedStat ement is not the wrapper of any other class. It returns after casting to that type. If iface is an argume nt of isWrapperFor() method and false is returned, the method throws an exception.
- Exception: If iface is not this object type (The type which is not implemented by this object is given), i t throws SQLException.

executeBatchAtomic

```
boolean executeBatchAtomic() throws SQLException
```

- Operation: It is identical to executeBatch(), but it is atomically executed. The batch job is either entirel y succeeded or failed. It is performed faster than executeBatch(). If the executed statement is the sele ct statement, it returns true, otherwise, it returns false.
- Exception: If batch job is not registered or an error occurs on the server, it throws SQLException.

It is GOLDILOCKS JDBC-specific feature, and PreparedStatement object can be used after it is ca sted as GoldilocksPreparedStatement.
e.g. ((GoldilocksPreparedStatement)pstmt).executeBatchAtomic();

setTimeTimeZone

```
void setTimeTimeZone(int parameterIndex, Time x, Calendar cal) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIME WITH TIME ZONE type. Time x is regard ed as timezone of cal. Timezone information for DB column refers to timezone of cal.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

It is GOLDILOCKS JDBC-specific feature, and PreparedStatement object can be used after it is ca sted as GoldilocksPreparedStatement.
e.g. ((GoldilocksPreparedStatement)pstmt).setTimeTimeZone(1, aTime, aCalendar);

setTimestampTimeZone

```
void setTimestampTimeZone(int parameterIndex, Timestamp x, Calendar cal) throws SQLException
```

- Operation: It binds the data x to the parameter index as TIMESTAMP WITH TIME ZONE type. Timesta mp x is regarded as timezone of cal. Timezone information for DB column refers to timezone of cal.
- Exception: It occurs if parameterIndex is smaller than 0 or it is bigger than the number of parameters.

It is GOLDILOCKS JDBC-specific feature, and PreparedStatement object can be used after it is ca sted as GoldilocksPreparedStatement.
e.g. ((GoldilocksPreparedStatement)pstmt).setTimestampTimeZone(1, aTimestamp, aCalendar);

Ref

The class is not implemented.

getBaseTypeName

```
String getBaseTypeName() throws SQLException
```

getObject

```
Object getObject() throws SQLException
```

```
Object getObject(Map<String,Class<?>> map) throws SQLException
```

setObject

```
void setObject(Object value) throws SQLException
```

ResultSet

absolute

```
boolean absolute(int row) throws SQLException
```

- Operation: The fetched row cursor position is at the row-th. The first row is 1. 0 points to the previou s first row. If it is a negative number, it points to the last row. -1 points to the last row, and -2 points to the second row from the last row. If the cursor can be positioned within the fetched row cache, o nly the position information is changed within the cache. If it is not within the cache, it is fetched fro m the server again. If the row exceeds the range, the cursor is positioned before first or after last, and it returns false. Otherwise, the cursor is positioned at the corresponding row and it returns true.
- Exception: If ResultSet is closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or an error occurs from the server when fetching, it throws an exception.

If it is not in the cache, it should be fetched again. If the row is behind the current position, the number of rows(n) from row position are fetched from the server in favor of next(). If the row is prior to the current position, the number of n rows from the position(row-n+1) are fetched fro m the server in favor of previous().

afterLast

```
void afterLast() throws SQLException
```

- Operation: The row cursor is positioned at *after last*. If the row cache is the last row set (It is a part of the entire result set), only the cursor position is changed. Otherwise, it fetches the last row set (The t otal number of rows-n + 1 to n rows, n is the number of rows fetched from the server), then position s the cursor at *after last*.
- Exception: If ResultSet is closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or an error occurs from the server when fetching, it throws an exception.

beforeFirst

```
void beforeFirst() throws SQLException
```

- Operation: The row cursor is positioned at *before first*. If the row cache is the first row set (It is a part of the entire result set), only the cursor position is changed. Otherwise, it fetches the first row set (1 t o n rows, n is the number of rows fetched from the server), then positions the cursor at *before first*.
- Exception: If ResultSet is closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or an error occurs from the server when fetching, it throws an exception.

cancelRowUpdates

```
void cancelRowUpdates() throws SQLException
```

- Operation: Cursor update feature has not been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

clearWarnings

```
void clearWarnings() throws SQLException
```

- Operation: It clears all SQLWarning objects which is owned by ResultSet object.
- Exception: It does not occur.

close

```
void close() throws SQLException
```

- Operation: If the cursor is open on the server, it closes the cursor (If the cursor is already closed on the server, this operation is not performed. Namely, the protocol is not transferred.), and the current state of the ResultSet object is changed to be closed. If it is already closed, then any operation is not performed.
- Exception: If an error occurs on the server, it throws SQLException.

deleteRow

```
void deleteRow() throws SQLException
```

- Operation: Cursor update feature is not implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

findColumn

```
int findColumn(String columnLabel) throws SQLException
```

- Operation: It returns the index of the column name. The index of the first column is 1.

- Exception: If it is already closed or the column name is not found, it throws SQLException.

first

```
boolean first() throws SQLException
```

- Operation: It positions the row cursor at the first (the first row). If the row cache is the first row set (It is a part of the entire result set), only the cursor position is changed. Otherwise, it fetches the first row set (1 to n rows, n is the number of rows fetched from the server), then positions the cursor at the first. If the row exists, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or an error occurs from the server when fetching, it throws an exception.

getArray

```
Array getArray(int columnIndex) throws SQLException
```

- Operation: Array type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Array getArray(String columnLabel) throws SQLException
```

- Operation: Array type is not supported. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: It always throws SQLFeatureNotSupportedException.

getAsciiStream

```
InputStream getAsciiStream(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as InputStream type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to InputStream, it throws SQLException.

```
InputStream getAsciiStream(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as InputStream type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type

can not be converted to InputStream, it throws SQLException.

getBigDecimal

```
BigDecimal getBigDecimal(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as BigDecimal type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to BigDecimal, it throws SQLException.

```
BigDecimal getBigDecimal(int columnIndex, int scale) throws SQLException
```

- Operation: This is a deprecated method. It operates in the same way as getBigDecimal(int columnIndex). The scale is ignored.
- Exception: For more information, refer to **getBigDecimal**(int columnIndex).

```
BigDecimal getBigDecimal(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as BigDecimal type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to BigDecimal, it throws SQLException.

```
BigDecimal getBigDecimal(String columnLabel, int scale) throws SQLException
```

- Operation: This is a deprecated method. It operates in the same way as getBigDecimal(String columnLabel). The scale is ignored.
- Exception: For more information, refer to **getBigDecimal**(String columnLabel).

getBinaryStream

```
InputStream getBinaryStream(int columnIndex) throws SQLException
```

- Operation: It is as same as **getAsciiStream**(int columnIndex).
- Exception: For more information, refer to **getAsciiStream**(int columnIndex).

```
InputStream getBinaryStream(String columnLabel) throws SQLException
```

- Operation: It is as same as **getAsciiStream**(String columnLabel).

- Exception: For more information, refer to **getAsciiStream**(String columnLabel).

getBlob

```
Blob getBlob(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as blob type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to blob, it throws SQLException.

```
Blob getBlob(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as blob type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to blob, it throws SQLException.

getBoolean

```
boolean getBoolean(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as Boolean type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to Boolean, it throws SQLException.

```
boolean getBoolean(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as Boolean type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to Boolean, it throws SQLException.

getByte

```
byte getByte(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as byte type. For more information about GOLDIL

OCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .

- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to byte, it throws SQLException.

```
byte getByte(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as byte type. For more information a bout GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCK S type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to byte, it throws SQLException.

getBytes

```
byte[] getBytes(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as byte[] type. For more information about GOLDI LOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range, it throws SQLExceptio n.

If getBytes is performed for all GOLDILOCKS data types, it gets the binary form stored in DB.

```
byte[] getBytes(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as byte[] type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOC KS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist, it throws S QLException.

If getBytes is performed for all GOLDILOCKS data types, it gets the binary form stored in DB.

getCharacterStream

```
Reader getCharacterStream(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as reader type. For more information about GOLD ILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be

converted to reader, it throws SQLException.

```
Reader getCharacterStream(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as reader type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to reader, it throws SQLException.

getClob

```
Clob getClob(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as clob type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to clob, it throws SQLException.

```
Clob getClob(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as clob type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to clob, it throws SQLException.

getConcurrency

```
int getConcurrency() throws SQLException
```

- Operation: It returns concurrency of the current ResultSet object. It supports only ResultSet.CONCUR_READ_ONLY currently.
- Exception: It does not occur.

getCursorName

```
String getCursorName() throws SQLException
```

- Operation: It gets the cursor name of the server pointed by the ResultSet. The communication with the server occurs.
- Exception: If ResultSet is already closed or an error occurs on the server, it throws SQLException.

getDate

```
Date getDate(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as date type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the date object, local timezone is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to date, it throws SQLException.

```
Date getDate(int columnIndex, Calendar cal) throws SQLException
```

- Operation: It gets the columnIndex-th column data as date type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the date object, local timezone of cal is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to date, it throws SQLException.

```
Date getDate(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as date type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the date object, the local timezone is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to date, it throws SQLException.

```
Date getDate(String columnLabel, Calendar cal) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as date type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the date object, the local timezone of cal is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to date, it throws SQLException.

getDouble

```
double getDouble(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as double type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to double, it throws SQLException.

```
double getDouble(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as double type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to double, it throws SQLException.

getFetchDirection

```
int getFetchDirection() throws SQLException
```

- Operation: It always returns ResultSet.FETCH_FORWARD. The backward fetch is not supported.
- Exception: If ResultSet is already closed, it throws SQLException.

getFetchSize

```
int getFetchSize() throws SQLException
```

- Operation: It gets the number of rows fetched from the server at once. If it is 0, it calculates the maximum number of rows included in a communication packet per transmission. The default value is 0.
- Exception: If ResultSet is already closed, it throws SQLException.

getFloat

```
float getFloat(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as float type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to float, it throws SQLException.

```
float getFloat(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as float type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to float, it throws SQLException.

getHoldability

```
int getHoldability() throws SQLException
```

- Operation: It returns the holdability of the current ResultSet. It is the value determined when the ResultSet object is created, and it can not be changed in the meantime. The default value is ResultSet.HOLD_CURSOR_OVER_COMMIT.
- Exception: If ResultSet is already closed, it throws SQLException.

getInt

```
int getInt(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as int type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to int, it throws SQLException.

```
int getInt(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as int type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to int, it throws SQLException.

getLong

```
long getLong(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as long type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to long, it throws SQLException.

```
long getLong(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as long type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to long, it throws SQLException.

getMetaData

```
ResultSetMetaData getMetaData() throws SQLException
```

- Operation: It creates and returns the ResultSetMetaData object getting detailed information on the c olumn.
- Exception: If ResultSet is already closed or an error occurs while detailed information on the column i s fetched from the server, it throws SQLException.

getNCharacterStream

```
Reader getNCharacterStream(int columnIndex) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Reader getNCharacterStream(String columnLabel) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

getNClob

```
NClob getNClob(int columnIndex) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

```
NClob getNClob(String columnLabel) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

getNString

```
String getNString(int columnIndex) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

```
String getNString(String columnLabel) throws SQLException
```

- Operation: NCHAR family types are not supported currently.
- Exception: It always throws SQLFeatureNotSupportedException.

getObject

```
Object getObject(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as the most appropriate Java object type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range, it throws SQLException.

```
Object getObject(int columnIndex, Map<String,Class<?>> map) throws SQLException
```

- Operation: It is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Object getObject(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as the most appropriate Java object type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist, it throws SQLException.

```
Object getObject(String columnLabel, Map<String,Class<?>> map) throws SQLException
```

- Operation: It is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

getRef

```
Ref getRef(int columnIndex) throws SQLException
```

- Operation: REF type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
Ref getRef(String columnLabel) throws SQLException
```

- Operation: REF type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

getRow

```
int getRow() throws SQLException
```

- Operation: It returns the cursor position of the current ResultSet object. The first row is 1. If it is *befor e first*, it returns 0.
- Exception: If ResultSet is already closed, it throws SQLException.

getRowId

```
RowId getRowId(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as RowId type. For more information about GOLD ILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to RowId, it throws SQLException.

```
RowId getRowId(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as RowId type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOC KS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to RowId, it throws SQLException.

getShort

```
short getShort(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as short type. For more information about GOLDI LOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to short, it throws SQLException.

```
short getShort(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as short type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to short, it throws SQLException.

getSQLXML

```
SQLXML getSQLXML(int columnIndex) throws SQLException
```

- Operation: SQLXML type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
SQLXML getSQLXML(String columnLabel) throws SQLException
```

- Operation: SQLXML type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

getStatement

```
Statement getStatement() throws SQLException
```

- Operation: It returns the statement object which created the ResultSet object.
- Exception: If ResultSet is already closed, it throws SQLException.

getString

```
String getString(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as string type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . If getString() is performed for BINARY, VARBINARY, LONG VARBINARY, the string of hex code is returned.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range, it throws SQLException.

```
String getString(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as string. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . If getString() is performed for BINARY, VARBINARY, LONG VARBINARY, it returns the string of hex code.

- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist, it throws SQLException.

getTime

```
Time getTime(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as time type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the time object, local timezone is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to time, it throws SQLException.

```
Time getTime(int columnIndex, Calendar cal) throws SQLException
```

- Operation: It gets the columnIndex-th column data as time type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the time object, local timezone of cal is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to time, it throws SQLException.

```
Time getTime(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as time type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the time object, the local timezone is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to time, it throws SQLException.

```
Time getTime(String columnLabel, Calendar cal) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as time type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the time object, the local timezone is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to time, it throws SQLException.

getTimestamp

```
Timestamp getTimestamp(int columnIndex) throws SQLException
```

- Operation: It gets the columnIndex-th column data as timestamp type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type -**

1 . When creating the timestamp object, local timezone is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to timestamp, it throws SQLException.

```
Timestamp getTimestamp(int columnIndex, Calendar cal) throws SQLException
```

- Operation: It gets the columnIndex-th column data as timestamp type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the timestamp object, local timezone of cal is used.
- Exception: If ResultSet is already closed or the columnIndex exceeds the range or the type can not be converted to timestamp, it throws SQLException.

```
Timestamp getTimestamp(String columnLabel) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as timestamp type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the timestamp object, the local timezone is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to timestamp, it throws SQLException.

```
Timestamp getTimestamp(String columnLabel, Calendar cal) throws SQLException
```

- Operation: It gets the column data whose name is columnLabel as timestamp type. For more information about GOLDILOCKS type-specific support, refer to **Whether supporting getter method for GOLDILOCKS type - 1** . When creating the timestamp object, the local timezone of cal is used.
- Exception: If ResultSet is already closed or the corresponding columnLabel does not exist or the type can not be converted to timestamp, it throws SQLException.

getType

```
int getType() throws SQLException
```

- Operation: It returns the current ResultSet type. It returns one of ResultSet.TYPE_FORWARD_ONLY, ResultSet.TYPE_SCROLL_INSENSITIVE, ResultSet.TYPE_SCROLL_SENSITIVE.
- Exception: If ResultSet is already closed, it throws SQLException.

getUnicodeStream

```
InputStream getUnicodeStream(int columnIndex) throws SQLException
```

- Operation: It is a deprecated method. It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

```
InputStream getUnicodeStream(String columnLabel) throws SQLException
```

- Operation: It is a deprecated method. It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

getURL

```
URL getURL(int columnIndex) throws SQLException
```

- Operation: URL type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

```
URL getURL(String columnLabel) throws SQLException
```

- Operation: URL type is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

getWarnings

```
SQLWarning getWarnings() throws SQLException
```

- Operation: It returns a list of SQLWarning accumulated on the object so far. If it gets a warning from the server, it creates SQLWarning. If clearWarning is not performed, it continues to be accumulated. I f a warning does not occur, null is returned.
- Exception: It does not occur.

insertRow

```
void insertRow() throws SQLException
```

- Operation: Cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSe t.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws S QLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

isAfterLast

```
boolean isAfterLast() throws SQLException
```

- Operation: It queries whether the current cursor position is at *after last*. If so, it returns true. Otherwis

e, it returns false.
- Exception: If ResultSet is already closed, it throws SQLException.

isBeforeFirst

```
boolean isBeforeFirst() throws SQLException
```

- Operation: It queries whether the current cursor position is at *before first*. If so, it returns true. Other wise, it returns false.
- Exception: If ResultSet is already closed, it throws SQLException.

isClosed

```
boolean isClosed() throws SQLException
```

- Operation: It queries whether the current ResultSet is closed. If closed, it returns true. Otherwise, it re turns false. Even if the user does not call the close, ResultSet can be closed by closing the cursor of th e server. It is when, for example, the statement which created the ResultSet is closed, or the transacti on is committed when the holdability is ResultSet.CLOSE_CURSOR_AT_COMMIT mode, or an error o ccurs from the server during fetching.
- Exception: It does not occur.

isFirst

```
boolean isFirst() throws SQLException
```

- Operation: It queries whether the current cursor position is at first (the first row). If so, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed, it throws SQLException.

isLast

```
boolean isLast() throws SQLException
```

- Operation: It queries whether the current cursor position is at last (the last row). If so, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed, it throws SQLException.

last

```
boolean last() throws SQLException
```

- Operation: The row cursor is positioned at last (the last row). If the row cache is the last row set (It is a part of the entire result set), only the cursor position is changed. Otherwise, the row cursor is positioned at last after the last row set is fetched (row from last-n+1 to the last row, n is the number of rows fetched from the server). If the row exists, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or an error occurs from the server when fetching, it throws an exception.

moveToCurrentRow

```
void moveToCurrentRow() throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

moveToInsertRow

```
void moveToInsertRow() throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

next

```
boolean next() throws SQLException
```

- Operation: The row cursor is positioned at the next to the current row. If the current row is the last row of the row cache, the next row cache is fetched from the server. If the row exists, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or an error occurs from the server when fetching, it throws an exception.

previous

```
boolean previous() throws SQLException
```

- Operation: The row cursor is positioned at the row before the current position. If the current row is t he first row of the row cache, the previous row cache(n rows from x-n to x-1, x is the current row ind ex) is fetched from the server. If the row exists, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or a n error occurs from the server during fetching, it throws an exception.

refreshRow

```
void refreshRow() throws SQLException
```

- Operation: If ResultSet type is ResultSet.SCROLL_SENSITIVE, the current row cache is fetched from th e server. If any row is changed (by the same transaction or other transactions), it is reflected. If Result Set type is ResultSet.Scroll_INSENSITIVE, any operation is not performed.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or a n error occurs from the server during fetching, it throws an exception.

relative

```
boolean relative(int rows) throws SQLException
```

- Operation: It moves the row cursor from the current cursor position to the position apart as many as t he number of rows. If it can be moved within the current row cache, only the cursor position is chang ed. Otherwise, the cursor is moved after the row cache is fetched from the server. If the position to b e moved is backward from the current position (next direction), the row cache is fetched from rows t o rows+n-1 (in favor of next). If the position to be moved is forward from the current position(previo us direction), the row cache is fetched from rows-n+1 to rows (in favor of previous).
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY or a n error occurs from the server when fetching, it throws an exception.

rowDeleted

```
boolean rowDeleted() throws SQLException
```

- Operation: It queries whether the row of the current cursor position is deleted (by the same transacti on or other transactions). If deleted, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY, it t hrows an exception.

rowInserted

```
boolean rowInserted() throws SQLException
```

- Operation: It queries whether the row of the current cursor position is inserted (by the same transacti on or other transactions). If inserted, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY, it t hrows an exception.

rowUpdated

```
boolean rowUpdated() throws SQLException
```

- Operation: It queries whether the row of the current cursor position is updated (by the same transacti on or other transactions). If updated, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the ResultSet type is ResultSet.TYPE_FORWARD_ONLY, it t hrows an exception.

setFetchDirection

```
void setFetchDirection(int direction) throws SQLException
```

- Operation: The backward fetch is not supported by the server. Therefore, only ResultSet.FETCH_FOR WARD is available. SQLWarning occurs if other values are inserted.
- Exception: If ResultSet is already closed or the argument does not have the defined value, it throws a n exception.

setFetchSize

```
void setFetchSize(int rows) throws SQLException
```

- Operation: It specifies the number of rows fetched from the server at once. 0 refers that the server de termines it. If it is 0, it refers to the number of rows of which a communication packet can include at once for the forward only cursor. It is specified as 100 for the scrollable cursor.
- Exception: If ResultSet is already closed, it throws an exception.

updateArray

```
void updateArray(int columnIndex, Array x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateArray(String columnLabel, Array x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateAsciiStream

```
void updateAsciiStream(int columnIndex, InputStream x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateAsciiStream(int columnIndex, InputStream x, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateAsciiStream(int columnIndex, InputStream x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateAsciiStream(String columnLabel, InputStream x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateAsciiStream(String columnLabel, InputStream x, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateAsciiStream(String columnLabel, InputStream x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateBigDecimal

```
void updateBigDecimal(int columnIndex, BigDecimal x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBigDecimal(String columnLabel, BigDecimal x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateBinaryStream

```
void updateBinaryStream(int columnIndex, InputStream x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBinaryStream(int columnIndex, InputStream x, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu

ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBinaryStream(int columnIndex, InputStream x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBinaryStream(String columnLabel, InputStream x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBinaryStream(String columnLabel, InputStream x, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBinaryStream(String columnLabel, InputStream x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateBlob

```
void updateBlob(int columnIndex, Blob x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBlob(int columnIndex, InputStream inputStream) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBlob(int columnIndex, InputStream inputStream, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBlob(String columnLabel, Blob x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBlob(String columnLabel, InputStream inputStream) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBlob(String columnLabel, InputStream inputStream, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateBoolean

```
void updateBoolean(int columnIndex, boolean x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBoolean(String columnLabel, boolean x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateByte

```
void updateByte(int columnIndex, byte x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateByte(String columnLabel, byte x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateBytes

```
void updateBytes(int columnIndex, byte[] x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateBytes(String columnLabel, byte[] x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateCharacterStream

```
void updateCharacterStream(int columnIndex, Reader x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateCharacterStream(int columnIndex, Reader x, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateCharacterStream(int columnIndex, Reader x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateCharacterStream(String columnLabel, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateCharacterStream(String columnLabel, Reader reader, int length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateCharacterStream(String columnLabel, Reader reader, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateClob

```
void updateClob(int columnIndex, Clob x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateClob(int columnIndex, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateClob(int columnIndex, Reader reader, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateClob(String columnLabel, Clob x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateClob(String columnLabel, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateClob(String columnLabel, Reader reader, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateDate

```
void updateDate(int columnIndex, Date x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateDate(String columnLabel, Date x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateDouble

```
void updateDouble(int columnIndex, double x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateDouble(String columnLabel, double x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateFloat

```
void updateFloat(int columnIndex, float x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateFloat(String columnLabel, float x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateInt

```
void updateInt(int columnIndex, int x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateInt(String columnLabel, int x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateLong

```
void updateLong(int columnIndex, long x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateLong(String columnLabel, long x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateNCharacterStream

```
void updateNCharacterStream(int columnIndex, Reader x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNCharacterStream(int columnIndex, Reader x, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNCharacterStream(String columnLabel, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNCharacterStream(String columnLabel, Reader reader, long length) throws
SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateNClob

```
void updateNClob(int columnIndex, NClob nClob) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNClob(int columnIndex, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu

ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNClob(int columnIndex, Reader reader, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNClob(String columnLabel, NClob nClob) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNClob(String columnLabel, Reader reader) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNClob(String columnLabel, Reader reader, long length) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateNString

```
void updateNString(int columnIndex, String nString) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is Resu ltSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it thro ws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNString(String columnLabel, String nString) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateNull

```
void updateNull(int columnIndex) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateNull(String columnLabel) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateObject

```
void updateObject(int columnIndex, Object x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateObject(int columnIndex, Object x, int scaleOrLength) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateObject(String columnLabel, Object x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.

- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateObject(String columnLabel, Object x, int scaleOrLength) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateRef

```
void updateRef(int columnIndex, Ref x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateRef(String columnLabel, Ref x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateRow

```
void updateRow() throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateRowId

```
void updateRowId(int columnIndex, RowId x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateRowId(String columnLabel, RowId x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateShort

```
void updateShort(int columnIndex, short x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateShort(String columnLabel, short x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateSQLXML

```
void updateSQLXML(int columnIndex, SQLXML xmlObject) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateSQLXML(String columnLabel, SQLXML xmlObject) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateString

```
void updateString(int columnIndex, String x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateString(String columnLabel, String x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateTime

```
void updateTime(int columnIndex, Time x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateTime(String columnLabel, Time x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

updateTimestamp

```
void updateTimestamp(int columnIndex, Timestamp x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

```
void updateTimestamp(String columnLabel, Timestamp x) throws SQLException
```

- Operation: The cursor update feature has not yet been implemented. If ResultSet concurrency is ResultSet.CONCUR_READ_ONLY, it throws SQLException. If it is ResultSet.CONCUR_UPDATABLE, it throws SQLFeatureNotSupportedException.
- Exception: If it is already closed, it throws SQLException. Otherwise, refer to the operation.

wasNull

```
boolean wasNull() throws SQLException
```

- Operation: It queries whether the column value which was read last is NULL. If it is NULL, it returns true. Otherwise, it returns false.
- Exception: If ResultSet is already closed or the column value never has been read, it throws SQLException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface)
```

- Operation: It queries whether this object is the class which implemented the iface interface. If it so, it returns true. Otherwise, it returns false. It does not determine the presence of the wrapper and it queries only whether the given argument class type is implemented because GOLDILOCKS ResultSet object is not the wrapper of any other class.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface)
```

- Operation: It eventually returns itself even when it is unwrapped because GOLDILOCKS ResultSet is not the wrapper of any other class. It returns after casting to that type. If iface is an argument of isWrapperFor() method and false is returned, then the method throws an exception.
- Exception: If iface is not this object type (when this object type is not implemented.), it throws SQLException.

ResultSetMetaData

getCatalogName

```
String getCatalogName(int column) throws SQLException
```

- Operation: It returns the catalog name of the column.
- Exception: If the column value is wrong, it throws SQLException.

getColumnClassName

```
String getColumnClassName(int column) throws SQLException
```

- Operation: It returns the name of Java class which is the most appropriate to the column type. It is specified such as java.math.BigDecimal, and it refers to getName() method in Java. For binary type, it refer to byte[].class.getName(), so it can be specified such as '[B'.
- Exception: If the column value is wrong, it throws SQLException.

getColumnCount

```
int getColumnCount() throws SQLException
```

- Operation: It returns the number of columns that the ResultSet has.
- Exception: It does not occur.

getColumnDisplaySize

```
int getColumnDisplaySize(int column) throws SQLException
```

- Operation: It returns the maximum width when the column value is displayed.
- Exception: If the column value is wrong, it throws SQLException.

getColumnLabel

```
String getColumnLabel(int column) throws SQLException
```

- Operation: It gets the label of the column. For example, the label is "C1 + 1" and the name is "" for the query statement such as "select C1 + 1 from t1".
- Exception: If the column value is wrong, it throws SQLException.

getColumnName

```
String getColumnName(int column) throws SQLException
```

- Operation: It returns the alias name of the column. The original column name, not the alias name is defined to be returned in JDBC specification. However, it is recommended to use the alias name because some view names are meaningless or complicated. For example, both the name and label are "C2" for the query statement such as "select C1 as C2 from t1". For more information about the case of when name and label are different, refer to **getColumnLabel**.
- Exception: If the column value is wrong, it throws SQLException.

getColumnType

```
int getColumnType(int column) throws SQLException
```

- Operation: It returns the type of the column. The return value is defined in types. Types.OTHERS is returned for GOLDILOCKS interval family types. The constant values of the corresponding types are returned for the other types.
- Exception: If the column value is wrong, it throws SQLException.

getColumnTypeName

```
String getColumnTypeName(int column) throws SQLException
```

- Operation: It returns GOLDILOCKS column type name of the column.
- Exception: If the column value is wrong, it throws SQLException.

getPrecision

```
int getPrecision(int column) throws SQLException
```

- Operation: It returns the precision of the column. It returns 0 for the type without any precision.
- Exception: If the column value is wrong, it throws SQLException.

getScale

```
int getScale(int column) throws SQLException
```

- Operation: It returns the scale of the column. It returns 0 for the type without any scale.
- Exception: If the column value is wrong, it throws SQLException.

getSchemaName

```
String getSchemaName(int column) throws SQLException
```

- Operation: It returns the schema name of the column.
- Exception: If the column value is wrong, it throws SQLException.

getTableName

```
String getTableName(int column) throws SQLException
```

- Operation: It returns the table name of the column.
- Exception: If the column value is wrong, it throws SQLException.

isAutoIncrement

```
boolean isAutoIncrement(int column) throws SQLException
```

- Operation: It returns whether it is the column which is automatically given the unique value. If so, it r eturns true. Otherwise, it returns false.
- Exception: If the column value is wrong, it throws SQLException.

isCaseSensitive

```
boolean isCaseSensitive(int column) throws SQLException
```

- Operation: It returns whether the column is case sensitive. If it is case sensitive, it returns true. Other wise, it returns false.
- Exception: If the column value is wrong, it throws SQLException.

isCurrency

```
boolean isCurrency(int column) throws SQLException
```

- Operation: It always returns false because the currency of the column can not be determined by the s erver.
- Exception: If the column value is wrong, it throws SQLException.

isDefinitelyWritable

```
boolean isDefinitelyWritable(int column) throws SQLException
```

- Operation: It returns whether the column is updatable. GOLDILOCKS does not support the definitely writable. It always returns the value as same as isUpdatable().
- Exception: If the column value is wrong, it throws SQLException.

isNullable

```
int isNullable(int column) throws SQLException
```

- Operation: It returns whether the column has nullable. It returns either columnNullable or columnNo Nulls.
- Exception: If the column value is wrong, it throws SQLException.

isReadOnly

```
boolean isReadOnly(int column) throws SQLException
```

- Operation: It returns whether the column is read only. It always returns the opposite value of isUpdat able().
- Exception: If the column value is wrong, it throws SQLException.

isSearchable

```
boolean isSearchable(int column) throws SQLException
```

- Operation: It returns whether the column can be used in the conditional clause. It always returns true because all target columns in GOLDILOCKS can be used in the conditional clause.
- Exception: If the column value is wrong, it throws SQLException.

isSigned

```
boolean isSigned(int column) throws SQLException
```

- Operation: It returns whether the column has a sign. If it has a sign, it returns true. Otherwise, it retur ns false.
- Exception: If the column value is wrong, it throws SQLException.

isWritable

```
boolean isWritable(int column) throws SQLException
```

- Operation: It returns whether the column is updatable.
- Exception: If the column value is wrong, it throws SQLException.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface)
```

- Operation: It queries whether the object is a class implementing the iface interface. If so, it returns tr ue. Otherwise, it returns false. It does not determine the presence of the wrapper and it queries only whether the given argument class type is implemented because GOLDILOCKS ResultSetMetaData obj ect is not the wrapper of any other class.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface)
```

- Operation: It eventually returns itself, even when it is unwrapped because GOLDILOCKS ResultSetMet aData is not the wrapper of any other class. It returns after casting to that type. If iface is an argumen t of isWrapperFor() method and false is returned, the method throws an exception.
- Exception: If iface is not the type of the object (if this object returns the unimplemented type), it thro ws SQLException.

RowId

equals

```
boolean equals(Object obj) throws SQLException
```

- Operation: If RowId of this object is as same as RowId of obj, it returns true. Otherwise, it returns fals e.
- Exception: It does not occur.

getBytes

```
byte[] getBytes() throws SQLException
```

- Operation: It returns the byte array value of RowId.
- Exception: It does not occur.

hashCode

```
int hashCode() throws SQLException
```

- Operation: It returns the hash code value.
- Exception: It does not occur.

toString

```
String toString() throws SQLException
```

- Operation: It returns a base-64 string of RowId value.
- Exception: It does not occur.

RowSet

The class is not implemented

addRowSetListener

```
void addRowSetListener(RowSetListener listener) throws SQLException
```

clearParameters

```
void clearParameters() throws SQLException
```

execute

```
void execute() throws SQLException
```

getCommand

```
String getCommand() throws SQLException
```

getDataSourceName

```
String getDataSourceName() throws SQLException
```

getEscapeProcessing

```
boolean getEscapeProcessing() throws SQLException
```

getMaxFieldSize

```
int getMaxFieldSize() throws SQLException
```

getMaxRows

```
int getMaxRows() throws SQLException
```

getPassword

```
String getPassword() throws SQLException
```

getQueryTimeout

```
int getQueryTimeout() throws SQLException
```

getTransactionIsolation

```
int getTransactionIsolation() throws SQLException
```

getTypeMap

```
Map<String,Class<?>> getTypeMap() throws SQLException
```

getUrl

```
String getUrl() throws SQLException
```

getUsername

```
String getUsername() throws SQLException
```

isReadOnly

```
boolean isReadOnly() throws SQLException
```

removeRowSetListener

```
void removeRowSetListener(RowSetListener listener) throws SQLException
```

setArray

```
void setArray(int i, Array x) throws SQLException
```

setAsciiStream

```
void setAsciiStream(int parameterIndex, InputStream x) throws SQLException
```

```
void setAsciiStream(int parameterIndex, InputStream x, int length) throws SQLException
```

```
void setAsciiStream(String parameterName, InputStream x) throws SQLException
```

```
void setAsciiStream(String parameterName, InputStream x, int length) throws SQLException
```

setBigDecimal

```
void setBigDecimal(int parameterIndex, BigDecimal x) throws SQLException
```

```
void setBigDecimal(String parameterName, BigDecimal x) throws SQLException
```

setBinaryStream

```
void setBinaryStream(int parameterIndex, InputStream x) throws SQLException
```

```
void setBinaryStream(int parameterIndex, InputStream x, int length) throws SQLException
```

```
void setBinaryStream(String parameterName, InputStream x) throws SQLException
```

```
void setBinaryStream(String parameterName, InputStream x, int length) throws SQLException
```

setBlob

```
void setBlob(int i, Blob x) throws SQLException
```

```
void setBlob(int parameterIndex, InputStream inputStream) throws SQLException
```

```
void setBlob(int parameterIndex, InputStream inputStream, long length) throws SQLException
```

```
void setBlob(String parameterName, Blob x) throws SQLException
```

```
void setBlob(String parameterName, InputStream inputStream) throws SQLException
```

```
void setBlob(String parameterName, InputStream inputStream, long length) throws SQLException
```

setBoolean

```
void setBoolean(int parameterIndex, boolean x) throws SQLException
```

```
void setBoolean(String parameterName, boolean x) throws SQLException
```

setByte

```
void setByte(int parameterIndex, byte x) throws SQLException
```

```
void setByte(String parameterName, byte x) throws SQLException
```

setBytes

```
void setBytes(int parameterIndex, byte[] x) throws SQLException
```

```
void setBytes(String parameterName, byte[] x) throws SQLException
```

setCharacterStream

```
void setCharacterStream(int parameterIndex, Reader reader) throws SQLException
```

```
void setCharacterStream(int parameterIndex, Reader reader, int length) throws SQLException
```

```
void setCharacterStream(String parameterName, Reader reader) throws SQLException
```

```
void setCharacterStream(String parameterName, Reader reader, int length) throws SQLException
```

setClob

```
void setClob(int i, Clob x) throws SQLException
```

```
void setClob(int parameterIndex, Reader reader) throws SQLException
```

```
void setClob(int parameterIndex, Reader reader, long length) throws SQLException
```

```
void setClob(String parameterName, Clob x) throws SQLException
```

```
void setClob(String parameterName, Reader reader) throws SQLException
```

```
void setClob(String parameterName, Reader reader, long length) throws SQLException
```

setCommand

```
void setCommand(String cmd) throws SQLException
```

setConcurrency

```
void setConcurrency(int concurrency) throws SQLException
```

setDataSourceName

```
void setDataSourceName(String name) throws SQLException
```

setDate

```
void setDate(int parameterIndex, Date x) throws SQLException
```

```
void setDate(int parameterIndex, Date x, Calendar cal) throws SQLException
```

```
void setDate(String parameterName, Date x) throws SQLException
```

```
void setDate(String parameterName, Date x, Calendar cal) throws SQLException
```

setDouble

```
void setDouble(int parameterIndex, double x) throws SQLException
```

```
void setDouble(String parameterName, double x) throws SQLException
```

setEscapeProcessing

```
void setEscapeProcessing(boolean enable) throws SQLException
```

setFloat

```
void setFloat(int parameterIndex, float x) throws SQLException
```

```
void setFloat(String parameterName, float x) throws SQLException
```

setInt

```
void setInt(int parameterIndex, int x) throws SQLException
```

```
void setInt(String parameterName, int x) throws SQLException
```

setLong

```
void setLong(int parameterIndex, long x) throws SQLException
```

```
void setLong(String parameterName, long x) throws SQLException
```

setMaxFieldSize

```
void setMaxFieldSize(int max) throws SQLException
```

setMaxRows

```
void setMaxRows(int max) throws SQLException
```

setNCharacterStream

```
void setNCharacterStream(int parameterIndex, Reader value) throws SQLException
```

```
void setNCharacterStream(int parameterIndex, Reader value, long length) throws SQLException
```

```
void setNCharacterStream(String parameterName, Reader value) throws SQLException
```

```
void setNCharacterStream(String parameterName, Reader value, long length) throws SQLException
```

setNClob

```
void setNClob(int parameterIndex, NClob value) throws SQLException
```

```
void setNClob(int parameterIndex, Reader reader) throws SQLException
```

```
void setNClob(int parameterIndex, Reader reader, long length) throws SQLException
```

```
void setNClob(String parameterName, NClob value) throws SQLException
```

```
void setNClob(String parameterName, Reader reader) throws SQLException
```

```
void setNClob(String parameterName, Reader reader, long length) throws SQLException
```

setNString

```
void setNString(int parameterIndex, String value) throws SQLException
```

```
void setNString(String parameterName, String value) throws SQLException
```

setNull

```
void setNull(int parameterIndex, int sqlType) throws SQLException
```

```
void setNull(int paramIndex, int sqlType, String typeName) throws SQLException
```

```
void setNull(String parameterName, int sqlType) throws SQLException
```

```
void setNull(String parameterName, int sqlType, String typeName) throws SQLException
```

setObject

```
void setObject(int parameterIndex, Object x) throws SQLException
```

```
void setObject(int parameterIndex, Object x, int targetSqlType) throws SQLException
```

```
void setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength) throws
SQLException
```

```
void setObject(String parameterName, Object x) throws SQLException
```

```
void setObject(String parameterName, Object x, int targetSqlType) throws SQLException
```

```
void setObject(String parameterName, Object x, int targetSqlType, int scale) throws
SQLException
```

setPassword

```
void setPassword(String password) throws SQLException
```

setQueryTimeout

```
void setQueryTimeout(int seconds) throws SQLException
```

setReadOnly

```
void setReadOnly(boolean value) throws SQLException
```

setRef

```
void setRef(int i, Ref x) throws SQLException
```

setRowId

```
void setRowId(int parameterIndex, RowId x) throws SQLException
```

```
void setRowId(String parameterName, RowId x) throws SQLException
```

setShort

```
void setShort(int parameterIndex, short x) throws SQLException
```

```
void setShort(String parameterName, short x) throws SQLException
```

setSQLXML

```
void setSQLXML(int parameterIndex, SQLXML xmlObject) throws SQLException
```

```
void setSQLXML(String parameterName, SQLXML xmlObject) throws SQLException
```

setString

```
void setString(int parameterIndex, String x) throws SQLException
```

```
void setString(String parameterName, String x) throws SQLException
```

setTime

```
void setTime(int parameterIndex, Time x) throws SQLException
```

```
void setTime(int parameterIndex, Time x, Calendar cal) throws SQLException
```

```
void setTime(String parameterName, Time x) throws SQLException
```

```
void setTime(String parameterName, Time x, Calendar cal) throws SQLException
```

setTimestamp

```
void setTimestamp(int parameterIndex, Timestamp x) throws SQLException
```

```
void setTimestamp(int parameterIndex, Timestamp x, Calendar cal) throws SQLException
```

```
void setTimestamp(String parameterName, Timestamp x) throws SQLException
```

```
void setTimestamp(String parameterName, Timestamp x, Calendar cal) throws SQLException
```

setTransactionIsolation

```
void setTransactionIsolation(int level) throws SQLException
```

setType

```
void setType(int type) throws SQLException
```

setTypeMap

```
void setTypeMap(Map<String,Class<?>> map) throws SQLException
```

setURL

```
void setURL(int parameterIndex, URL x) throws SQLException
```

setUrl

```
void setUrl(String url) throws SQLException
```

setUsername

```
void setUsername(String name) throws SQLException
```

RowSetMetaData

The class is not implemented

setAutoIncrement

```
void setAutoIncrement(int columnIndex, boolean property) throws SQLException
```

setCaseSensitive

```
void setCaseSensitive(int columnIndex, boolean property) throws SQLException
```

setCatalogName

```
void setCatalogName(int columnIndex, String catalogName) throws SQLException
```

setColumnCount

```
void setColumnCount(int columnCount) throws SQLException
```

setColumnDisplaySize

```
void setColumnDisplaySize(int columnIndex, int size) throws SQLException
```

setColumnLabel

```
void setColumnLabel(int columnIndex, String label) throws SQLException
```

setColumnName

```
void setColumnName(int columnIndex, String columnName) throws SQLException
```

setColumnType

```
void setColumnType(int columnIndex, int SQLType) throws SQLException
```

setColumnTypeName

```
void setColumnTypeName(int columnIndex, String typeName) throws SQLException
```

setCurrency

```
void setCurrency(int columnIndex, boolean property) throws SQLException
```

setNullable

```
void setNullable(int columnIndex, int property) throws SQLException
```

setPrecision

```
void setPrecision(int columnIndex, int precision) throws SQLException
```

setScale

```
void setScale(int columnIndex, int scale) throws SQLException
```

setSchemaName

```
void setSchemaName(int columnIndex, String schemaName) throws SQLException
```

setSearchable

```
void setSearchable(int columnIndex, boolean property) throws SQLException
```

setSigned

```
void setSigned(int columnIndex, boolean property) throws SQLException
```

setTableName

```
void setTableName(int columnIndex, String tableName) throws SQLException
```

Savepoint

getSavepointId

```
int getSavepointId() throws SQLException
```

- Operation: It returns the id value which is automatically assigned.
- Exception: It throws SQLException because it does not have an ID if the savepoint object is created by giving its name.

getSavepointName

```
String getSavepointName() throws SQLException
```

- Operation: It returns the name specified at the time of when a savepoint object is created.
- Exception: If the savepoint created with an automatic id value, it throws SQLException.

SQLData

The class is not implemented.

getSQLTypeName

```
String getSQLTypeName() throws SQLException
```

readSQL

```
void readSQL(SQLInput stream, String typeName) throws SQLException
```

writeSQL

```
void writeSQL(SQLOutput stream) throws SQLException
```

SQLXML

The class is not implemented.

free

```
void free() throws SQLException
```

getBinaryStream

```
InputStream getBinaryStream() throws SQLException
```

getCharacterStream

```
Reader getCharacterStream() throws SQLException
```

getSource

```
<T extends Source> T getSource(Class<T> sourceClass) throws SQLException
```

getString

```
String getString() throws SQLException
```

setBinaryStream

```
OutputStream setBinaryStream() throws SQLException
```

setCharacterStream

```
Writer setCharacterStream() throws SQLException
```

setResult

```
<T extends Result> T setResult(Class<T> resultClass) throws SQLException
```

setString

```
void setString(String value) throws SQLException
```

Statement

addBatch

```
void addBatch(String sql) throws SQLException
```

- Operation: The SQL statement is added to the batch job.
- Exception: It does not occur.

cancel

```
void cancel() throws SQLException
```

- Operation: It is not supported.
- Exception: It always throws SQLFeatureNotSupportedException.

clearBatch

```
void clearBatch() throws SQLException
```

- Operation: It clears all registered batch jobs. If registered batch job does not exist, any operation is no t performed.
- Exception: It does not occur.

clearWarnings

```
void clearWarnings() throws SQLException
```

- Operation: It clears all SQLWarning objects which is owned by the statement object.
- Exception: It does not occur.

close

```
void close() throws SQLException
```

- Operation: The current statement object is closed, and it is released if the statement related informati on assigned to the server exists. If the ResultSet created by the object exists, it is closed. The object is removed from the connection object which created the statement object.
- Exception: If an error occurs when statement information is released from the server, it throws an exc

eption.

execute

```
boolean execute(String sql) throws SQLException
```

- Operation: It executes the SQL statement. If the executed SQL statement has the ResultSet, it returns true. Otherwise, it returns false.
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting from the server, it throws an exception.

```
boolean execute(String sql, int autoGeneratedKeys) throws SQLException
```

- Operation: It executes the SQL statement. If autoGeneratedKeys is Statement.RETURN_GENERATED_ KEYS and sql is INSERT statement, then it can get ResultSet searching for the auto generated key. Ot herwise, it it as same as execute(String sql).
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting from the server, it throws an exception.

```
boolean execute(String sql, int[] columnIndexes) throws SQLException
```

- Operation: It executes the SQL statement. If columnIndexes is not null and sql is INSERT statement, th en it can get ResultSet searching for the designated auto generated key with the given index. Otherw ise, it it as same as execute(String sql).
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting from the server, it throws an exception.

```
boolean execute(String sql, String[] columnNames) throws SQLException
```

- Operation: It executes the SQL statement. If columnNames is not null and sql is INSERT statement, th en it can get ResultSet searching for the designated auto generated key with the given column name. Otherwise, it it as same as execute(String sql).
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting from the server, it throws an exception.

executeBatch

```
int[] executeBatch() throws SQLException
```

- Operation: It executes the registered batch job in turn. The communication with the server occurs per each batch job. It returns the array of the number of rows in which the update reflected after executi ng each batch job.
- Exception: If the statement is already closed or any batch job is not registered or an error occurs whe

n executing from the server, it throws an exception.

It does not have definite advantage over the normal execute() because the batch jobs are not tr ansmitted and executed at once. Use a batch execution of the PreparedStatement for fast proce ssing.

executeQuery

```
ResultSet executeQuery(String sql) throws SQLException
```

- Operation: It executes the given SQL statement and gets part of results and creates the ResultSet.
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting on the server or the SQL statement is not the select statement, it throws an exception.

Its operation is a bit different from execute(). The communicate with the server occurs twice if g etResultSet() is performed for the same SQL statement after performing execute(). The executio n command is performed when performing execute(), and the fetch related command is perfor med when performing getResultSet(). On the other hand, executeQuery() assumes that the SQL statement is the select statement, and it executes all with a single communication until fetch.

executeUpdate

```
int executeUpdate(String sql) throws SQLException
```

- Operation: It executes the SQL statement. It returns the number of rows updated by the execution.
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting on the server or the SQL statement is the select statement, it throws an exception.

```
int executeUpdate(String sql, int autoGeneratedKeys) throws SQLException
```

- Operation: It executes the SQL statement. It returns the number of rows updated by the execution. If autoGeneratedKeys is Statement.RETURN_GENERATED_KEYS and sql is INSERT statement, then it ca n get ResultSet searching for the auto generated key. Otherwise, it it as same as executeUpdate(Strin g sql).
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting on the server or the SQL statement is the select statement, it throws an exception.

```
int executeUpdate(String sql, int[] columnIndexes) throws SQLException
```

- Operation: It executes the SQL statement. It returns the number of rows updated by the execution. If columnIndexes is not null and sql is INSERT statement, then it can get ResultSet searching for the desi gnated auto generated key with the given index. Otherwise, it it as same as executeUpdate(String sql) .
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting on the server or the SQL statement is the select statement, it throws an exception.

```
int executeUpdate(String sql, String[] columnNames) throws SQLException
```

- Operation: It executes the SQL statement. It returns the number of rows updated by the execution. If columnNames is not null and sql is INSERT statement, then it can get ResultSet searching for the desi gnated auto generated key with the given column name. Otherwise, it it as same as executeUpdate(S tring sql).
- Exception: If the statement is already closed or the batch job is registered or an error occurs when ex ecuting from the server or the SQL statement is the select statement, it throws an exception.

getConnection

```
Connection getConnection() throws SQLException
```

- Operation: It returns the connection object which created the object. If statement object is created w ith logical connection via the PooledConnection, the user gets the logical connection, not the physica l connection via the method.
- Exception: If the statement is already closed, it throws an exception.

getExplainPlan

```
String getExplainPlan() throws SQLException
```

- Operation: It is non-standard method, and it is the unique method of GoldilocksStatement. It gets th e generated plan text. It should set for generating the plan text via setExplainPlanOption to use the method. For more information about the detailed usage, refer to **Viewing Plan Text**.
- Exception: If the statement is already closed or an error occurs on the server, it throws an exception.

getExplainPlanOption

```
int getExplainPlanOption() throws SQLException
```

- Operation: It is non-standard method, and it is the unique method of GoldilocksStatement. It gets th e option for the generating the plan text which is currently set. The return value is one of the followin gs and the default value is GoldilocksStatement.EXPLAIN_PLAN_OPTION_OFF.
  - GoldilocksStatement.EXPLAIN_PLAN_OPTION_OFF

    - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ON
    - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ON_VERBOSE
    - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ONLY
- Exception: It does not occur.

getFetchDirection

```
int getFetchDirection() throws SQLException
```

- Operation: It always returns ResultSet.FETCH_FORWARD.
- Exception: If the statement is already closed, it throws an exception.

getFetchSize

```
int getFetchSize() throws SQLException
```

- Operation: It returns the default fetch size of ResultSet which is got from the statement object. The default value is 0, and 0 refers that the server determines the number of fetched rows. For more information, refer to **getFetchSize** of ResultSet.
- Exception: If the statement is already closed, it throws an exception.

getGeneratedKeys

```
ResultSet getGeneratedKeys() throws SQLException
```

- Operation: It returns ResultSet which can search the auto generated key of the result executed by this statement object. If the statement object has not created the key, then it returns the closed ResultSet object.
- Exception: If the statement is already closed or an error occurs on the server, it throws an exception.

getMaxFieldSize

```
int getMaxFieldSize() throws SQLException
```

- Operation: It returns the max field size. The value limits the maximum length of the column. If the column value is bigger than this length when fetching, the rest of the data is truncated. The default value is 0, and 0 refers that the maximum length is infinite.
- Exception: If the statement is already closed, it throws an exception.

getMaxRows

```
int getMaxRows() throws SQLException
```

- Operation: It returns the max rows. The max rows refer to the maximum number of rows of ResultSe t which is got from the statement. The rows more than the maximum number of rows are ignored. T he default value is 0, and 0 means infinity.
- Exception: If the statement is already closed, it throws an exception.

getMoreResults

```
boolean getMoreResults() throws SQLException
```

- Operation: It moves to the next result of the statement. The current ResultSet is closed.
- Exception: If the statement is already closed, it throws an exception.

```
boolean getMoreResults(int current) throws SQLException
```

- Operation: It moves to the next result of the statement. The current ResultSet is processed according to current value. It supports Statement.CLOSE_CURRENT_RESULT and Statement.CLOSE_ALL_RESUL TS only.
- Exception: If the statement is already closed, it throws an exception.

getQueryTimeout

```
int getQueryTimeout() throws SQLException
```

- Operation: It gets the value of the query timeout. The value is the timeout value which the sever appli es at execution. The execution is canceled and the user gets the error related to timeout if the executi on time exceeds the time. The unit is seconds and it applies the default value of the session if the use r does not specifically set it. The default value of the session is 0 if it is not set with the property, and i t refers to the infinite wait.
- Exception: If the statement is already closed, it throws an exception.

getResultSet

```
ResultSet getResultSet() throws SQLException
```

- Operation: It performs the fetch for the currently execution, and it gets part of fetched results, and cr eates and returns the ResultSet. JDBC specification defines to call this method once per the execution, but it is implemented to return the same object for several calls of the method.

- Exception: If the statement is already closed, it throws an exception. If an error occurs on the server when fetching, it throws an exception.

getResultSetConcurrency

```
int getResultSetConcurrency() throws SQLException
```

- Operation: It returns the ResultSet concurrency. The value determines the concurrency of ResultSet g enerated from the object. The default value is ResultSet.CONCUR_READ_ONLY. The updatable curso r is not yet supported.
- Exception: If the statement is already closed, it throws an exception.

getResultSetHoldability

```
int getResultSetHoldability() throws SQLException
```

- Operation: It returns the ResultSet holdability. The value determines the holdability of ResultSet gener ated from the object. The default value is ResultSet.HOLD_CURSORS_OVER_COMMIT.
- Exception: If the statement is already closed, it throws an exception.

getResultSetType

```
int getResultSetType() throws SQLException
```

- Operation: It returns the ResultSet type. The value determines the type of ResultSet generated from t he object. The default value is ResultSet.TYPE_FORWARD_ONLY.
- Exception: If the statement is already closed, it throws an exception.

getUpdateCount

```
int getUpdateCount() throws SQLException
```

- Operation: It returns the number of rows in which the update for the last execution is reflected. If the last executed SQL statement is not UPDATE statement nor is INSERT statement, it returns -1.
- Exception: It does not occur.

getUpdateRowCount

```
long getUpdateRowCount() throws SQLException
```

- Operation: It is as same as getUpdateCount, but the returned type is long. It is non-standard method, and the type casting to GoldilocksStatement should be performed to use it.
- Exception: It does not occur.

getWarnings

```
SQLWarning getWarnings() throws SQLException
```

- Operation: It returns SQLWarning accumulated on the object. If it does not exist, it returns null.
- Exception: It does not occur.

isClosed

```
boolean isClosed() throws SQLException
```

- Operation: It returns whether the statement is closed. If it is closed, it returns true. Otherwise, it retur ns false. It can be closed not only by the explicit call of close() but also by the server or the connection object.
- Exception: It does not occur.

isPoolable

```
boolean isPoolable() throws SQLException
```

- Operation: It returns whether the statement pooling is allowed for this object.
- Exception: It does not occur.

setCursorName

```
void setCursorName(String name) throws SQLException
```

- Operation: It sets a name for the cursor created by the currently executed statement.
- Exception: If an error occurs on the server when setting the cursor name, it throws an exception.

setEscapeProcessing

```
void setEscapeProcessing(boolean enable) throws SQLException
```

- Operation: JDBC can not ban the feature because the escape processing of the SQL statement is perf ormed in the server parser. Any operation is not performed.
- Exception: If the statement is already closed, it throws an exception.

setExplainPlanOption

```
void setExplainPlanOption(int option) throws SQLException
```

- Operation: It is non standard method, but it is the GoldilocksStatement unique method. It specifies th e plan text generation options. The option should be set to one of the followings, and each meaning is as follows.
  - GoldilocksStatement.EXPLAIN_PLAN_OPTION_OFF: The plan text is not generated.
  - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ON: The plan text is generated when executing.
  - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ON_VERBOSE: Detailed plan text is generated wh en executing.
  - GoldilocksStatement.EXPLAIN_PLAN_OPTION_ONLY: The plan text is generated when executing, but the actual execution is not performed.
- Exception: When setting a value other than four values above, it throws an exception.

setFetchDirection

```
void setFetchDirection(int direction) throws SQLException
```

- Operation: It sets the fetch direction. If the direction is not ResultSet.FETCH_FORWARD, it throws an exception because GOLDILOCKS supports only the forward fetch.
- Exception: If the statement is already closed or the direction is not FETCH_FORWARD, it throws an ex ception.

setFetchSize

```
void setFetchSize(int rows) throws SQLException
```

- Operation: It sets the default fetch size of ResultSet which is got from the statement object. The defa ult value is 0, and 0 refers that the server determines the number of fetched rows. For more informati on, refer to **setFetchSize** of ResultSet.
- Exception: If the statement is already closed, it throws an exception.

setMaxFieldSize

```
void setMaxFieldSize(int max) throws SQLException
```

- Operation: It sets the max field size. The value limits the maximum length of the column. If the colum n value is bigger than this length when fetching, the rest of the data is truncated. The default value is 0, 0 refers that the maximum length is infinity. It is valid for CHAR, VARCHAR, LONG VARCHAR, BIN ARY, VARBINARY, LONG VARBINARY types.
- Exception: If the statement is already closed, it throws an exception.

setMaxRows

```
void setMaxRows(int max) throws SQLException
```

- Operation: It sets the max rows. The max rows refers to the maximum number of rows of ResultSet which is got from the statement. The rows more than the maximum number of rows are ignored. Th e default is 0, and 0 means infinity.
- Exception: If the statement is already closed, it throws an exception.

setPoolable

```
void setPoolable(boolean poolable) throws SQLException
```

- Operation: It sets whether to pool the statement.
- Exception: It does not occur.

setQueryTimeout

```
void setQueryTimeout(int seconds) throws SQLException
```

- Operation: It sets the value of query timeout. The value is the timeout value which the sever applies a t the execution, and the execution is canceled and the user gets the error related to timeout if the ex ecution time exceeds the time. The unit is seconds and it applies the default value of the session if th e user idoes not specifically set it. The default value of the session is 0 if it is not set with the property, and 0 refers to the infinite wait.
- Exception: If the statement is already closed, it throws an exception.

isWrapperFor

```
boolean isWrapperFor(Class<?> iface) throws SQLException
```

- Operation: It queries whether the object is a class which implements the iface interface. If so, it retur ns true. Otherwise, it returns false. It does not determine the presence of the wrapper but it only que ries only whether the given argument class type is implemented because GOLDILOCKS statement obj ect is not the wrapper of any other class.
- Exception: It does not occur.

unwrap

```
<T> T unwrap(Class<T> iface) throws SQLException
```

- Operation: It eventually returns itself, even when it is unwrapped because GOLDILOCKS statement is not the wrapper of any other class. It returns after casting to that type. If iface is an argument of isWr apperFor() method and false is returned, the method throws an exception.
- Exception: If iface is not the type of the object (when this object returns the unimplemented type), it throws SQLException.

Struct

The class is not implemented.

getAttributes

```
Object[] getAttributes() throws SQLException
```

getAttributes

```
Object[] getAttributes(Map<String,Class<?>> map) throws SQLException
```

getSQLTypeName

```
String getSQLTypeName() throws SQLException
```

XAConnection

getXAResource

```
XAResource getXAResource() throws SQLException
```

- Operation: It returns XAResource object which can perform XA command. When the method is called for several times, the same result is continuously returned.
- Exception: It does not occur.

XADataSource

getXAConnection

```
XAConnection getXAConnection() throws SQLException
```

- Operation: It creates XAConnection object and returns it. The information required for the connectio n should be set as the separate non-standard methods in advance.
- Exception: When connection to the server is failed, it throws SQLException.

```
XAConnection getXAConnection(String user, String password) throws SQLException
```

- Operation: It opens and returns a new XAConnection object with the username and password. Other information required for the connection should be set as the separate non-standard methods in adva nce.
- Exception: When connection to the server is failed, it throws SQLException.

XAResource

commit

```
void commit(Xid xid, boolean onePhase) throws XAException
```

- Operation: It performs the XA commit command for the global transaction xid. If onePhase is set to t rue, one phase commit is performed.
- Exception: If the execution result error occurs, it throws XAException.

end

```
void end(Xid xid, int flags) throws XAException
```

- Operation: It performs the XA end command for the global transaction xid. The flags may be one of T MSUCCESS, TMFAIL, or TMSUSPEND.
- Exception: If the execution result error occurs, it throws XAException.

forget

```
void forget(Xid xid) throws XAException
```

- Operation: It performs the XA forget command for the global transaction xid.
- Exception: If the execution result error occurs, it throws XAException.

getTransactionTimeout

```
int getTransactionTimeout() throws XAException
```

- Operation: GOLDILOCKS does not support the transaction timeout. It always return 0.
- Exception: It does not occur.

isSameRM

```
boolean isSameRM(XAResource xares) throws XAException
```

- Operation: It has the unique rmid when XAResource object is created. Whether it is the same XAReso urce object is determined with this rmid.
- Exception: It does not occur.

prepare

```
int prepare(Xid xid) throws XAException
```

- Operation: It performs the XA prepare command for the global transaction xid.
- Exception: If the execution result error occurs, it throws XAException.

recover

```
Xid[] recover(int flag) throws XAException
```

- Operation: It performs XA recover command with the given flag, and the array of the prepared trans action branches is returned. The flag may be one of TMSTARTRSCAN, TMENDRSCAN, TMNOFLAGS.
- Exception: If the execution result error occurs, it throws XAException.

rollback

```
void rollback(Xid xid) throws XAException
```

- Operation: It performs the XA rollback command for the global transaction xid.
- Exception: If the execution result error occurs, it throws XAException.

setTransactionTimeout

```
boolean setTransactionTimeout(int seconds) throws XAException
```

- Operation: GOLDILOCKS does not support the transaction timeout. Any operation is not performed.
- Exception: It does not occur.

start

```
void start(Xid xid, int flags) throws XAException
```

- Operation: It starts the global transaction with the given flag. The flag may be one of TMNOFLAGS, T MJOIN, TMRESUME.
- Exception: If the execution result error occurs, it throws XAException.

GoldilocksInterval

To give value to a column of GOLDILOCKS by using a GoldilocksInterval object, refer to **Using Other Data Types**.

createIntervalYear

```
public static GoldilocksInterval createIntervalYear(int yearPrecision, boolean sign, int year)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given year value. The yearPrecision refers to th e number of digits which the year can have. The value of year should be equal to or bigger than 0. If t he time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given year value exceeds yearPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalYear(int yearPrecision, String year) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given year value. The yearPrecision refers to th e number of digits which the year can have. The value of year should be an integer equal to or bigger than 0.
- Exception: If the given year value exceeds yearPrecision, an error occurs.

createIntervalMonth

```
public static GoldilocksInterval createIntervalMonth(int monthPrecision, boolean sign, int
month) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given month value. The monthPrecision refers to the number of digits which the month can have. The value of month should be an integer equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given month value exceeds monthPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalMonth(int monthPrecision, String month) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given month value. The monthPrecision refers to the number of digits which the month can have. The value of month should be an integer equal to or bigger than 0.
- Exception: If the given month value exceeds monthPrecision, an error occurs.

createIntervalYearToMonth

```
public static GoldilocksInterval createIntervalYearToMonth(int yearPrecision, boolean sign,
int year, int month) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given year, month value. The yearPrecision refers to the number of digits which the year can have. The value of year, month should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given year value exceeds yearPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalYearToMonth(int yearPrecision, String
yearToMonth) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given yearToMonth value. The yearPrecision refers to the number of digits which the year can have. yearToMonth should satisfy "yy-mm" pattern.
- Exception: If the given year value exceeds yearPrecision, an error occurs.

createIntervalDay

```
public static GoldilocksInterval createIntervalDay(int dayPrecision, boolean sign, int day)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day value. The dayPrecision refers to the number of digits which the day can have. The value of day should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given day value exceeds dayPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalDay(int dayPrecision, String day) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given day value. The dayPrecision refers to the number of digits which the day can have. The value of day should be an integer equal to or bigger than 0.
- Exception: If the given day value exceeds dayPrecision, an error occurs.

createIntervalHour

```
public static GoldilocksInterval createIntervalHour(int hourPrecision, boolean sign, int hour)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given hour value. The hourPrecision refers to the number of digits which the hour can have. The value of hour should be equal to or bigger than 0.

If the time is a positive number, sign is true. If it is a negative number, sign is false.

- Exception: If the given hour value exceeds hourPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalHour(int hourPrecision, String hour) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given hour value. The hourPrecision refers to t he number of digits which the hour can have. The value of hour should be an integer equal to or big ger than 0.
- Exception: If the given hour value exceeds hourPrecision, an error occurs.

createIntervalMinute

```
public static GoldilocksInterval createIntervalMinute(int minutePrecision, boolean sign, int
minute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given minute value. The minutePrecision refer s to the number of digits which the minute can have. The value of minute should be equal to or bigg er than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given minute value exceeds minutePrecision, an error occurs.

```
public static GoldilocksInterval createIntervalMinute(int minutePrecision, String minute)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given minute value. The minutePrecision refer s to the number of digits which the minute can have. The value of minute should be an integer equal to or bigger than 0.
- Exception: If the given minute value exceeds minutePrecision, an error occurs.

createIntervalSecond

```
public static GoldilocksInterval createIntervalSecond(int secondPrecision, int
fractionalPrecision, boolean sign, int second, int microsecond) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given second value. The secondPrecision refer s to the number of digits of second, and the fractionalPrecision refers to the number of digits of micr osecond. The value of second and microsecond should be equal to or bigger than 0. If the time is a p ositive number, sign is true. If it is a negative number, sign is false.
- Exception: If the given second value exceeds secondPrecision or the given microSecond value exceed s fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalSecond(int secondPrecision, int
fractionalPrecision, boolean sign, int day, int hour, int minute, int second, int microsecond)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute, second, microsecond value. The secondPrecision refers to the number of digits of second when day, hour, minute, second i s converted to second. The fractionalPrecision refers to the number of digits of microsecond. The valu e of day, hour, minute, second, microsecond should be equal to or bigger than 0. If the time is a posi tive number, sign is true. If it is a negative number, sign is false.
- Exception: If the converted second value exceeds the secondPrecision or the microSecond value exce eds the fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalSecond(int secondPrecision, int
fractionalPrecision, String second) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given second string. The secondPrecision refer s to the number of digits of second. The fractionalPrecision refers to the number of digits of microsec ond. The second string should be one of "dd hh:mm:ss.ffffff" or "dd hh:mm:ss", "dd hh:mm", "dd hh" , "hh:mm", "ss.ffffff", "ss" patterns.
- Exception: If the converted second value exceeds the secondPrecision or the microSecond value exce eds the fractionalPrecision, an error occurs. If the string does not conform to the prescribed format, a n error occurs.

createIntervalDayToHour

```
public static GoldilocksInterval createIntervalDayToHour(int dayPrecision, boolean sign, int
day, int hour) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour value. The dayPrecision refers to the number of digits of day. The value of day, hour should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the day value exceeds dayPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalDayToHour(int dayPrecision, String dayToHour)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given dayToHour string. The dayPrecision refe rs to the number of digits of day. dayToHour should satisfy "dd hh" format. Or, if its format is "dd hh: mm:ss", all should be 0 except for dd, hh.
- Exception: If the day value exceeds dayPrecision or the given string does not satisfy the format, an err or occurs.

createIntervalDayToMinute

```
public static GoldilocksInterval createIntervalDayToMinute(int dayPrecision, boolean sign, int day, int hour, int minute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute value. The dayPrecision refers to the number of digits of day. The value of day, hour, minute should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the day value exceeds dayPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalDayToMinute(int dayPrecision, String dayToMinute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given dayToMinute string. The dayPrecision refers to the number of digits of day. dayToMinute should satisfy "dd hh:mm" format. Or, if its format is "dd hh:mm:ss", all should be 0 except for dd, hh, mm.
- Exception: If the day value exceeds dayPrecision or the given string does not satisfy the format, an error occurs.

createIntervalDayToSecond

```
public static GoldilocksInterval createIntervalDayToSecond(int dayPrecision, int fractionalPrecision, boolean sign, int day, int hour, int minute, int second, int microsecond) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute, second, microsecond value. The dayPrecision refers to the number of digits of day. The fractionalPrecision refers to the number of digits of microsecond. The value of day, hour, minute, second, microsecond should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the day value exceeds dayPrecision or the microsecond value exceeds the fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalDayToSecond(int dayPrecision, String dayToSecond) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given dayToSecond string. The dayPrecision refers to the number of digits of day. The fractionalPrecision refers to the number of digits of microsecond. dayToSecond should satisfy one of "dd hh:mm:ss.ffffff", "dd hh:mm:ss", "hh:mm:ss", "hh:mm" formats.
- Exception: If the day value or the converted day value exceeds dayPrecision or the microsecond value exceeds the fractionalPrecision or the given string does not satisfy the format, an error occurs.

createIntervalHourToMinute

```
public static GoldilocksInterval createIntervalHourToMinute(int hourPrecision, boolean sign,
int hour, int minute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given hour, minute value. The hourPrecision r efers to the number of digits of hour. The value of hour, minute should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the hour value exceeds hourPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalHourToMinute(int hourPrecision, boolean sign,
int day, int hour, int minute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute value. The hourPrecisi on refers to the number of digits of hour. The value of day, hour, minute should be equal to or bigge r than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the hour value or the converted hour value exceeds hourPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalHourToMinute(int hourPrecision, String
hourToMinute) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given hourToMinute string. The hourPrecision refers to the number of digits of hour. hourToMinute must satisfy "hh:mm" format. The value of ss or ffffff should be 0 for other formats.
- Exception: If the hour value or the converted hour value exceeds hourPrecision, an error occurs. If the given string does not satisfy the format, an error occurs.

createIntervalHourToSecond

```
public static GoldilocksInterval createIntervalHourToSecond(int hourPrecision, int
fractionalPrecision, boolean sign, int hour, int minute, int second, int microsecond) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given hour, minute, second, microsecond valu e. The hourPrecision refers to the number of digits of hour. The fractionalPrecision refers to the num ber of digits of microsecond. The value of hour, minute, second, microsecond should be equal to or b igger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the hour value exceeds hourPrecision or the microsecond value exceeds the fractionalPr ecision, an error occurs.

```
public static GoldilocksInterval createIntervalHourToSecond(int hourPrecision, int
fractionalPrecision, boolean sign, int day, int hour, int minute, int second, int microsecond)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute, second, microsecond value. The hourPrecision refers to the number of digits of hour. The fractionalPrecision refers to the number of digits of microsecond. The value of day, hour, minute, second, microsecond should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the hour value or the converted hour value exceeds hourPrecision or the microsecond value exceeds the fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalHourToSecond(int hourPrecision, int
fractionalPrecision, String hourToSecond) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given hourToSecond string. The hourPrecision refers to the number of digits of hour. The fractionalPrecision refers to the number of digits of microsecond. hourToSecond should satisfy "hh:mm:ss.ffffff", "hh:mm:ss", or "hh:mm" format. If dd is included, the value of converted hour should not exceed hourPrecision.
- Exception: If the hour value or the converted hour value exceeds hourPrecision or the microsecond value exceeds the fractionalPrecision, or the given string does not satisfy the format, an error occurs.

createIntervalMinuteToSecond

```
public static GoldilocksInterval createIntervalMinuteToSecond(int minutePrecision, int
fractionalPrecision, boolean sign, int minute, int second, int microsecond) throws
SQLException
```

- Operation: It creates GoldilocksInterval object with the given minute, second, microsecond value. The minutePrecision refers to the number of digits of minute. The fractionalPrecision refers to the number of digits of microsecond. The value of minute, second, microsecond should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the minute value exceeds the minutePrecision or the microsecond value exceeds the fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalMinuteToSecond(int minutePrecision, int
fractionalPrecision, boolean sign, int day, int hour, int minute, int second, int microsecond)
throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given day, hour, minute, second, microsecond value. The minutePrecision refers to the number of digits of minute. The fractionalPrecision refers to the number of digits of microsecond. The value of day, hour, minute, second, microsecond should be equal to or bigger than 0. If the time is a positive number, sign is true. If it is a negative number, sign is false.
- Exception: If the minute value or the converted minute value exceeds minutePrecision or the microsecond value exceeds the fractionalPrecision, an error occurs.

```
public static GoldilocksInterval createIntervalMinuteToSecond(int minutePrecision, int
fractionalPrecision, String minuteToSecond) throws SQLException
```

- Operation: It creates GoldilocksInterval object with the given minuteToSecond string. The minutePrecision refers to the number of digits of minute. The fractionalPrecision refers to the number of digits of microsecond. minuteToSecond should satisfy "mm:ss.ffffff" or "mm:ss" format. If dd or hh is included, the value of the converted minute should not exceed minutePrecision.
- Exception: If the minute value or the converted minute value exceeds the minutePrecision or the microsecond value exceeds the fractionalPrecision or the given string does not satisfy the format, an error occurs.

getSign

```
public int getSign()
```

- Operation: If the time is a positive number, 1 is returned. If the time is a negative number, -1 is returned.
- Exception: It does not occur.

getYear

```
public int getYear()
```

- Operation: It returns the year value. Whether the interval object is a negative number is not returned through getYear().
- Exception: It does not occur.

getMonth

```
public int getMonth()
```

- Operation: It returns the month value. Whether the interval object is a negative number is not returned through getMonth().
- Exception: It does not occur.

getAccumulatedMonth

```
public int getAccumulatedMonth()
```

- Operation: It converts the value of year and month to the value of month, and returns the result.

- Exception: It does not occur.

getDay

```
public int getDay()
```

- Operation: It returns the day value. Whether the interval object is a negative number is not returned t hrough getDay().
- Exception: It does not occur.

getHour

```
public int getHour()
```

- Operation: It returns the hour value. Whether the interval object is a negative number is not returned through getHour().
- Exception: It does not occur.

getAccumulatedHour

```
public int getAccumulatedHour()
```

- Operation: It converts the value of day and hour to the value of hour, and returns the result.
- Exception: It does not occur.

getMinute

```
public int getMinute()
```

- Operation: It returns the minute value. Whether the interval object is a negative number is not return ed through getMinute().
- Exception: It does not occur.

getAccumulatedMinute

```
public int getAccumulatedMinute()
```

- Operation: It converts the value of day, hour and minute to the value of minute, and returns the resul t.
- Exception: It does not occur.

getSecond

```
public int getSecond()
```

- Operation: It returns the second value. Whether the interval object is a negative number is not return ed through getSecond().
- Exception: It does not occur.

getAccumulatedSecond

```
public int getAccumulatedSecond()
```

- Operation: It converts the value of day, hour, minute and second to the value of second, and returns the result.
- Exception: It does not occur.

getMicroSecond

```
public int getMicroSecond()
```

- Operation: It returns the microsecond value. Whether the interval object is a negative number is not r eturned through getMicroSecond().
- Exception: It does not occur.

getAccumulatedMicroSecond

```
public long getAccumulatedMicroSecond()
```

- Operation: It converts the value of day, hour, minute, second and microsecond to the value of micros econd, and returns the result.
- Exception: It does not occur.

getTypeName

```
public String getTypeName()
```

- Operation: The type name is returned.
- Exception: It does not occur.

getSqlType

```
public int getSqlType()
```

- Operation: The type of this object is returned as the type constant defined in GoldilocksTypes.
- Exception: It does not occur.

toString

```
public String toString()
```

- Operation: The interval value which is indicated by this object is returned as a string value.
- Exception: It does not occur.

GOLDILOCKS Type

Constant Definition

```
public static final int INTERVAL_YEAR;
public static final int INTERVAL_MONTH;
public static final int INTERVAL_DAY;
public static final int INTERVAL_HOUR;
public static final int INTERVAL_MINUTE;
public static final int INTERVAL_SECOND;
public static final int INTERVAL_YEAR_TO_MONTH;
public static final int INTERVAL_DAY_TO_HOUR;
public static final int INTERVAL_DAY_TO_MINUTE;
public static final int INTERVAL_DAY_TO_SECOND;
public static final int INTERVAL_HOUR_TO_MINUTE;
public static final int INTERVAL_HOUR_TO_SECOND;
public static final int INTERVAL_MINUTE_TO_SECOND;
public static final int TIME_WITH_TIME_ZONE;
public static final int TIMESTAMP_WITH_TIME_ZONE;
public static final int REF_CURSOR;
```

These constants are used as like the constants of java.sql.Types. In other words, they are used when speci fying the types in setObject of PreparedStatement or the types in getObject of ResultSet. These types are separately provided by GoldilocksTypes because they are not defined in the JDBC standard.

Type Conversion

The following tables describe how to convert types.

Table 32-3 SQL types → GOLDILOCKS types

SQL type	GOLDILOCKS type
GoldilocksTypes.INTERVAL_DAY	INTERVAL DAY
GoldilocksTypes.INTERVAL_DAY_TO_HOUR	INTERVAL DAY TO HOUR
GoldilocksTypes.INTERVAL_DAY_TO_MINUTE	INTERVAL DAY TO MINUTE
GoldilocksTypes.INTERVAL_DAY_TO_SECOND	INTERVAL DAY TO SECOND
GoldilocksTypes.INTERVAL_HOUR	INTERVAL HOUR
GoldilocksTypes.INTERVAL_HOUR_TO_MINUTE	INTERVAL HOUR TO MINUTE
GoldilocksTypes.INTERVAL_HOUR_TO_SECOND	INTERVAL HOUR TO SECOND

SQL type	GOLDILOCKS type
GoldilocksTypes.INTERVAL_MINUTE	INTERVAL MINUTE
GoldilocksTypes.INTERVAL_MINUTE_TO_SECOND	INTERVAL MINUTE TO SECOND
GoldilocksTypes.INTERVAL_MONTH	INTERVAL MONTH
GoldilocksTypes.INTERVAL_SECOND	INTERVAL SECOND
GoldilocksTypes.INTERVAL_YEAR	INTERVAL YEAR
GoldilocksTypes.INTERVAL_YEAR_TO_MONTH	INTERVAL YEAR TO MONTH
GoldilocksTypes.REF_CURSOR	REF CURSOR
GoldilocksTypes.TIME_WITH_TIME_ZONE	TIME WITH TIME ZONE
GoldilocksTypes.TIMESTAMP_WITH_TIME_ZONE	TIMESTAMP WITH TIME ZONE
Types.ARRAY	N/A
Types.BIGINT	NATIVE_BIGINT
Types.BINARY	BINARY(2000)
Types.BIT	BOOLEAN
Types.BLOB	LONG VARBINARY
Types.BOOLEAN	BOOLEAN
Types.CHAR	CHAR(2000)
Types.CLOB	LONG VARCHAR
Types.DATALINK	N/A
Types.DATE	DATE
Types.DECIMAL	DECIMAL
Types.DISTINCT	N/A
Types.DOUBLE	NATIVE_DOUBLE
Types.FLOAT	FLOAT
Types.INTEGER	NATIVE_INTEGER
Types.JAVA_OBJECT	N/A
Types.LONGNVARCHAR	N/A
Types.LONGVARBINARY	LONG VARBINARY
Types.LONGVARCHAR	LONG VARCHAR
Types.NCHAR	N/A
Types.NCLOB	N/A
Types.NUMERIC	NUMBER
Types.NVARCHAR	N/A
Types.OTHER	N/A
Types.REAL	NATIVE_REAL
Types.REF	N/A
Types.REF_CURSOR	REF CURSOR
Types.ROWID	ROWID
Types.SMALLINT	NATIVE_SMALLINT
Types.SQLXML	N/A
Types.STRUCT	N/A

SQL type	GOLDILOCKS type
Types.TIME	TIME
Types.TIME_WITH_TIMEZONE	TIME WITH TIME ZONE
Types.TIMESTAMP	TIMESTAMP
Types.TIMESTAMP_WITH_TIMEZONE	TIMESTAMP WITH TIME ZONE
Types.TINYINT	NATIVE_SMALLINT
Types.VARBINARY	VARBINARY(4000)
Types.VARCHAR	VARCHAR(4000)

Table 32-4 Whether supporting getter method for GOLDILOCKS type - 1

	NATIVE_SMALLINT	NATIVE_INTEGER	NATIVE_BIGINT	NATIVE_REAL	NATIVE_DOUBLE
getByte	O	O	O	O	O
getShort	O	O	O	O	O
getInt	O	O	O	O	O
getLong	O	O	O	O	O
getFloat	O	O	O	O	O
getDouble	O	O	O	O	O
getBigDecimal	O	O	O	O	O
getBoolean	Avaliable only for 0,1	Avaliable only for 0,1	Avaliable only for 0,1	Avaliable only for 0,1	Avaliable only for 0,1
getString	O	O	O	O	O
getBytes	raw data	raw data	raw data	raw data	raw data
getDate	X	X	X	X	X

33.

Embedded SQL

33.1 Precompiler

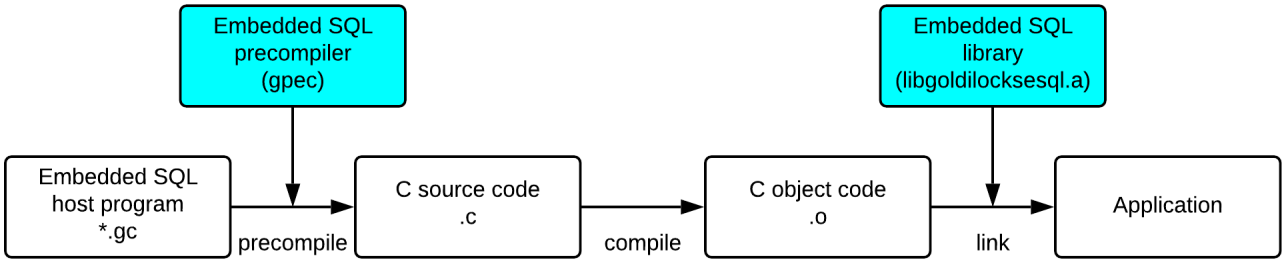
Overview

GOLDILOCKS precompiler is a programming development tool which enables a user to use embedded SQL in the high-level programming language. Currently, GOLDILOCKS supports the precompiler only for the language such as C/ C++, and it is called as gpec.

Developing Embedded SQL Applications

As described in **Figure 1 Developing the embedded SQL applications**, the user creates a C source program including embedded SQL, and converts it via gpec precompiler. Then, the pure C code is created of which the embedded SQL on the source code is converted to the contents calling the library of GOLDILOCKS. This C code uses C compiler of the system to perform compile as object code and link it with libgoldilocksesql.a which is an embedded SQL library provided by GOLDILOCKS, then completes the final application.

Figure 1 Developing the embedded SQL applications



Configuring Embedded SQL Application Development Tool

Embedded SQL application of GOLDILOCKS consists of the following elements.

Directory or File	Description
\bin\gpec	GOLDILOCKS precompiler embedded SQL for C
\include\goldilocksesql.h	It is an embedded SQL library header file. Precompiler automatically inserts it, so the user does not have to do any extra work.
\include\sqlca.h	It is the SQLCA data structure related header file.
\lib\libgoldilocksesql.a, \lib\libgoldilocksesqls.so	It is the embedded SQL run-time library.
\lib\libgoldilocks.a, \lib\libgoldilockss.so	It is the GOLDILOCKS DA/ CS mixed mode library.
\lib\libgoldilocksa.a, \lib\libgoldilocksas.so	It is the GOLDILOCKS DA mode library.

Directory or File	Description
\lib\libgoldilocksc.a, \lib\libgoldilockscs.so	It is the GOLDILOCKS CS mode library.
\sample\EmbeddedSQL	It is a sample program.

Building Application

This chapter describes the process to build an embedded SQL source program of GOLDILOCKS and make the application.

Precompile

Description

The user precompiles the C/ C ++ source code which was written by using embedded SQL, and generates the pure C/ C ++ source code. The core of this process is converting the user-created embedded SQL to t he library call provided by GOLDILOCKS, and the C/ C++ source code is not modified except for embedde d SQL.

Usage

The name of GOLDILOCKS precompiler is gpec, and it is located in $GOLDILOCKS_HOME/bin/.
gpec is used as follows.

```
$ gpec [OPTION]... <input file>
```

<input file> is input to gpec, and gpec generates the C/ C++ source code after precompile process. The e xtension of <input file> is *.gc, and it can be omitted. If <input file> does not have *.gc extension, the file name with the extension should be required.
For more information about options given to gpec, refer to **Precompiler Options**.

Example

```
$ gpec sample1

FileName: sample1
Pre-compile sample1.gc -> sample1.c
```

Compile

C/ C++ source code is generated after precompile process. The source code generates the object code by using the C/ C++ compiler provided in the platform. For more information about this process refer to the C/ C++ compiler manual which is provided by the user platform.

Link

The application is generated by linking the object codes generated through the process above, and GOLD ILOCKS supports libgoldilocksesql.a for an embedded SQL. The library includes the GOLDILOCKS APIs whi ch is converted from the embedded SQL by the precompiler, so it is prerequisite when making the embed ded SQL application.

Additionally, the required library varies upon the various operation modes of GOLDILOCKS, and the requi red library is selected and linked according to the operation mode of the current application as follows.

Operation mode	Static library	Shared object
DA dedicated	libgoldilocksa.a	libgoldilocksas.so
CS dedicated	libgoldilocksc.a	libgoldilockscs.so
DA/ CS mixed	libgoldilocks.a	libgoldilockss.so

Other link processes are as same as the process of generating the common C/ C++ application so refer to the linker manual provided by the user platform.

Example

make is used a lot to easily perform the precompile, compile, link process above. The following is an exa mple of Makefile to create the sample program. Refer to the following example to make the Makefile wh ich is suitable for the user environment.

```
GPEC = gpec
GPECFLAGS =
#GPECFLAGS = --unsafe-null --no-prompt
CC = gcc
CFLAGS = -g -Wall
INC = -I$(GOLDILOCKS_HOME)/include
LFLAGS = -L$(GOLDILOCKS_HOME)/lib
LIB = -lgoldilocksesql -lgoldilocksc -lpthread -lm -lrt

BINS = overview sample1 sample2 sample3 sample4 sample5 dyn1 dyn2 number date_time thread1
fetch_struct_array
```

```
ifneq ($(MAKECMDGOALS), clean)
ifneq ($(MAKECMDGOALS), all)
TARGET = $(MAKECMDGOALS)
OBJECT = $(TARGET).o
C_SRC  = $(TARGET).c
endif
endif
```

- Implicit rules

```
.SUFFIXES: .gc .c .o
.gc.c:
    $(GPEC) $(GPECFLAGS) $^          ❶ Precompile
.c.o:
    $(CC) $(CFLAGS) -c $(INC) $^     ❷ Compile
```

- Build rules

```
NoTarget :
    @echo "Syntax : make {all | sample_name | clean}"
    @echo "sample_name is one of '$(BINS)'"

all :
    for target in $(BINS); do \
        $(MAKE) $$target;     \
    done

$(OBJECT) : $(C_SRC)
$(TARGET) : $(OBJECT)
    $(CC) -o $@ $^ $(LFLAGS) $(LIB)    ❸ Link

clean :
    rm -rf $(BINS) *.o *.c *~ core
```

Sample

GOLDILOCKS provides a simple embedded SQL sample code to help to create an embedded SQL applicati on. The sample code is in $GOLDILOCKS_HOME/sample/EmbeddedSQL directory, and sample.sql which i s in the same directory should be executed first to execute the samples.

```
$ cd $GOLDILOCKS/sample/EmbeddedSQL
$ gsql test test -i sample.sql
$ make
Syntax : make {all ¦ sample_name ¦ clean}
sample_name is one of 'overview sample1 sample2 sample3 sample4 sample5 dyn1 dyn2 number
date_time thread1 fetch_struct_array'
```

If *make all* is executed, all samples are built. Execute make <sample_name> to build a particular sample al one. For <Sample_name>, refer to the message above. If sample2 is built and executed, and the result is as follows.

```
$ make sample2
gpec  sample2.gc
FileName: sample2.gc
Pre-compile sample2.gc -> sample2.c
gcc -g -Wall -c -I/home/mycomman/work/product/Gliese/home/include sample2.c
gcc -o sample2 sample2.o -L/home/mycomman/work/product/Gliese/home/lib -lgoldilocksesql
-lpthread -lm -lrt -lgoldilocksa
$ ./sample2
Connect goldilocks ...

Precompiler Options

This chapter describes the options of gpec.

--no-prompt, -n

Description

It does not output the version information.

Example

```
$ gpec --no-prompt sample2
FileName: sample2
Pre-compile sample2.gc -> sample2.c
$
```

--version, -v

Description

It outputs only the version information, then exits.

Example

```
$ gpec --version
$
```

--help, -h

Description

It outputs the help message. It performs the same operation even when an option or <input file> does no t exist in gpec.

Example

```
$ gpec --help
gpec is the GOLDILOCKS embedded SQL precompiler for C programs.
```

```
Usage:
  gpec [OPTION]... <input file>

Options:
  --no-prompt    No Print version information
  --version      Print version information and exit
  --help         Print help message
  --output       Describe output filename
  --unsafe-null  Allow a NULL fetch without indicator variable
  --include-path Describe header file path
  --no-lineinfo  Exclude line information
  --char_map     Mapping of character arrays ( CHARZ ¦ STRING )
  --cumulative   SQLERRD[2] records cumulative sum of rows processed for FETCH CURSOR.
  --autocommit   Set autocommit TRUE to all connection.
$
```

--output, -o

Description

It specifies the name of precompile result file. If this option is not given, the file name as same as <input file> is created with the extension of .c.

Example

- When an output is not used.

```
$ gpec sample2.gc
FileName: sample2.gc
Pre-compile sample2.gc -> sample2.c
$ ls
sample2.c  sample2.gc
```

- When an output is used.

```
$ gpec --output outfile.cpp sample2.gc
FileName: sample2.gc
Pre-compile sample2.gc -> outfile.cpp
$ ls
outfile.cpp  sample2.gc
```

--unsafe-null

Description

Even if it does not use the host indicator variable, It succeeds when NULL fetch occurs. It means that the operation is successful, but it does not mean that the NULL value can be fetched.

Example

```
$ gpec --unsafe-null sample2
FileName: sample2
Option : --unsafe-null
Pre-compile sample2.gc -> sample2.c
$
```

--include-path, -I

Description

It describes the path of the header file to refer when performing the precompile. Other header files are fo und by using EXEC SQL INCLUDE statement when performing the precompile. First, it searches in the dire ctory where the current file is located. If it can not find any file, then it searches in the directories where t he option is described in turn.

Example

The following is an example of when the header file is in include directory.

- When an error occurs.

```
$ gpec sample.gc
FileName: sample.gc
Pre-compile sample.gc -> sample.c
ERR-42000(41000): syntax error
Error at line 12, in file sample.gc
ERR-42000(41004): "decl.h": file not exist
ERR-42000(41000): syntax error
rsEmpRecord gRecord[] = {
^
Error at line 15, in file sample.gc
```

- When -I option is used.

```
$ gpec -Iinclude sample.gc
FileName: sample.gc
Pre-compile sample.gc -> sample.c
$
```

--no-lineinfo

Description

When gc file is converted to c file by default, GPEC adds #liine information to enable debugging with gc f ile. However, if this option is used, It does not add the line information through #line preprocessor when creating c file.

Example

```
$ gpec --no-lineinfo sample2
FileName: sample2
Pre-compile sample2.gc -> sample2.c
$
```

--char_map, -c

Description

It sets to which type the char type data declared in a DECLARE SECTION is mapped. The default value is 'STRING', and it is null-terminated data type. 'CHARZ' is space padded and null-terminated data type.

Example

```
$ gpec --char_map=STRING overview
FileName: overview
Pre-compile overview.gc -> overview.c
$ gpec --char_map=CHARZ overview
FileName: overview
Pre-compile overview.gc -> overview.c
```

--define, -D

Description

It is a define name used in gpec and it is set to 1.

Example

```
$ gpec --define=AAA preprocess
FileName: preprocess
Pre-compile preprocess.gc -> preprocess.c
$ gpec -D BBB preprocess
FileName: preprocess
Pre-compile preprocess.gc -> preprocess.c
ERR-42000(41028): 'BBB' macro is already defined at line 45, in file preprocess.gc
```

--cumulative

Description

It processes sqlerrd[2] in FETCH CURSOR statement as the accumulated total.

Example

```
$ gpec --cumulative sample.gc
FileName: sample Option : --cumulative
Pre-compile sample.gc -> sample.c
$
```

--autocommit

Description

It sets *auto commit* of all connections to TRUE.

Example

```
$ gpec --autocommit sample.gc
FileName: sample Option : --autocommit
Pre-compile sample.gc -> sample.c
$
```

33.2 Embedded SQL

Preprocessing

Overview

It performs the preprocessing before precompiling in gpec.

gpec supports the preprocess statements such as #if, #ifdef, #if defined, #ifndef #else, #elif, #endif, #define, #undef.

It can use a predefine by using a --define option of gpec. It is defined as 1 when it is predefined with a gpec option.
e.g. gpec --define=_DEV_ Test.gc is as same as #define _DEV_ (1) in Test.gc file.

Applicable Range

The host variable of SQL precompiler feature for gpec is applied only within a declare section and the feature is used in the EXEC SQL statement. (The host variable outside of the declare section can not be used in the host EXEC SQL statement.)
gpec preprocessor are applied all over the source.
Only the header file declared with EXEC SQL INCLUDE is applied to an include file.

```
#define _DEV1_
EXEC SQL BEGIN DECLARE SECTION;
#define _DEV2_
char username[10];
char password[10];
#ifdef _DEV1_
VARCHAR conn_str[20];  ❶
#elif defined _DEV2_
VARCHAR conn_str[30];  ❷
#endif
EXEC SQL END DECLARE SECTION;
```

❶ _DEV1_ is defined irrespective of the position of DECLARE SECTION, so it is processed as a host variable in gpec.
❷ _DEV1_ is defined, so its location becomes false, so is processed as a white space in gpec.

When creating c file from the file above using gpec, conn_str[20] is converted and #ifdef, #elif, #endif pr eprocessor statements and conn_str[30] are converted into white spaces as follows.

```
/* EXEC SQL BEGIN DECLARE SECTION; */
#define _DEV2_
char username[10];
char password[10];
/* VARCHAR conn_str[20]; */
struct { int len; char arr[20]; } conn_str; ❶

                              ❷

/* EXEC SQL END DECLARE SECTION; */
```

❶ _DEV1_ is defined irrespective of the position of DECLARE SECTION, so it is processed as a h ost variable in gpec.
❷ _DEV1_ is defined, so its location becomes false, so is processed as a white space in gpec.

Types

#if

- Syntax

```
#if constant
```

or

```
#if defined identifier
```

or

```
#if !defined identifier
```

- Example

```
#if 0
int sVar1;
#endif
#if 3-2   ❶ An operation is available.
int sVar2;
```

```
#endif
#if defined _DEV_
int sVar3;
#endif
#if !defined (_DEV_)
int sVar4;
#endif
```

#ifdef, #ifndef

- Syntax

```
#ifdef identifier
```

or

```
#ifndef identifier
```

- Example

```
#ifdef _DEV_
int sVar1;
#endif
#ifndef _DEV_
int sVar2;
#else
int sVar3;
#endif
```

#else, #elif, #endif

- Syntax

```
#else
```

or

```
#endif
```

or

```
#elif constant
```

or

```
#elif defined identifier
```

- Example

```
#if 1
int sVar1;
#else
int sVar2;
#endif
#if 0
int sVar3;
#elif 1
int sVar4;
#else
int sVar5;
#endif
#ifdef _DEV1_
int sVar6;
#elif defined _DEV2_
int sVar7;
#elif !defined _DEV3_
int sVar8;
#endif
```

#define, #undef

- Syntax

```
#define identifier
```

or

```
#define identifier constant
```

or

```
#undef identifier
```

- Example

```
#define _DEV1_
EXEC SQL BEGIN DECLARE SECTION;
#define _DEV2_
char username[10];
char password[10];
#ifdef _DEV1_
VARCHAR conn_str[20]; ❶
#elif defined _DEV2_
VARCHAR conn_str[30]; ❷
#endif
#undef _DEV2_
#ifdef _DEV2_
VARCHAR sDept[10];  ❸
#endif
EXEC SQL END DECLARE SECTION;
```

❶ _DEV1_ is defined, so it is processed as a host variable in gpec.
❷ #ifdef _DEV1_is true, so _DEV2_is processed as a white space in gpec.
❷ _DEV2_ is undefed, so it is processed as a white space in gpec.

An annotation can be used in #define. However, if #define are written along multiple lines, the n the annotation can not be correctly processed.

```
#define _DEF1_  1 \ ❶
    + 1
#define _DEF2_   1 \ /* this ❷
is comment */ + 1
#define _DEF3_  1  /* this is comment */ + 1  ❸
```

❶ _DEF1_ is processed as 1 + 1.
❷ _DEF2_is processed as 1.
❸ _DEF3_is processed as 1 + 1.

Constraints

Even though it is defined within a declare section, it is not extended to an EXEC SQL statement.

```
EXEC SQL BEGIN DECLARE SECTION;
#define C_EMP_NO   14
char username[10];
EXEC SQL END DECLARE SECTION;
EXEC SQL
    SELECT USERNAME INTO :username
    FROM EMP
    WHERE EMPNO = C_EMP_NO; ❶ A wrong MACRO is used.
```

Expansion

MACRO can be used in the middle of c statement or in the middle of EXEC SQL statement.

```
#define _DEV_
EXEC SQL BEGIN DECLARE SECTION;
char
#ifdef _DEV_
sTrue[10];
#else
sFalse[10];
#endif
EXEC SQL END DECLARE SECTION;
EXEC SQL SELECT
#ifdef _DEV_
         "true" INTO :sTrue
#else
         "false" INTO :sFalse
#endif
         FROM DUAL;
```

gpec can execute the preprocessor to create the following c code. The following is an example in which t he converting from SQL statement to c code is omitted.

```
#define _DEV_
EXEC SQL BEGIN DECLARE SECTION;
char

sTrue[10];
```

```
EXEC SQL END DECLARE SECTION;
EXEC SQL SELECT

         "true" INTO :sTrue

         FROM DUAL;
```

Connection

Connecting to Database

A process of connecting to the database server is required to perform the operation by connecting to the database in the embedded SQL program.
The syntax for connecting to the database is expressed in GOLDILOCKS as follows.

```
EXEC SQL [ AT <db_name> ] CONNECT <user_name> IDENTIFIED BY <password> [ AT <db_name> ] [
USING <conn_string> ]
<db_name> := dbname ¦ :hostvar
<user_name> := username ¦ :hostvar
<password> := password ¦ :hostvar
<conn_string> := connection_string ¦ :hostvar
```

An example of the most basic way to connect to database is as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
char username[10];
char password[10];
EXEC SQL END DECLARE SECTION;
strcpy( username, "test" );
strcpy( password, "test" );
...
EXEC SQL CONNECT :username IDENTIFIED BY :password;
```

GOLDILOCKS supports both D/A mode and C/S mode. The D/A mode is operated by attaching directly to the shared memory, and C/S mode is operated by connecting to the database by using TCP communicati

on. When operated in D/A mode, it is not necessary to include a separate server information as described above because the direct access from the same host of the database is performed. When operated in C/S mode, Data Source Name (DSN) should be specified to access. For more information about DSN, refer to **Data Source Configuration**.

connection_string information should be given to use DSN. USING clause is used to use connection_strin g information. An example of the connection statement whose DSN is "GOLDILOCKS", and using USING clause is as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
char username[10];
char password[10];
char conn_str[20];
EXEC SQL END DECLARE SECTION;
strcpy( username, "test" );
strcpy( password, "test" );
strcpy( conn_str, "DSN=GOLDILOCKS" );
...
EXEC SQL CONNECT :username IDENTIFIED BY :password USING :conn_str;
```

When developing an application, sometimes it is required to uniquely identify the respective connection. I t is the case of which each connection is performed in the multi-thread program in D/A mode. Or it is the case of which several connections are performed in C/S mode. The name is given to each connection by u sing AT clause.

AT clause may be positioned in front of CONNECT statement or USING clause. The example of AT clause i n CONNECT statement is as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
char username[10];
char password[10];
char conn_str[20];
char conn_name[10];
EXEC SQL END DECLARE SECTION;
strcpy( username, "test" );
strcpy( password, "test" );
strcpy( conn_str, "DSN=GOLDILOCKS" );
strcpy( conn_name, "DBCONN1" );
...
EXEC SQL CONNECT :username IDENTIFIED BY :password AT :conn_name USING :conn_str;
```

Disconnecting Database

It disconnects the connection to the database in the application. Like as the CONNECT statement, the dis connection is performed for the default connection or it is performed by giving a connection name. The s yntax for disconnecting all connections performed in the application is also provided.

Single Disconnection

There are two ways of disconnecting a single connection, which are explicit and implicit method.
The explicit method uses DISCONNECT statement as follows.

```
EXEC SQL [ AT <db_name> ] DISCONNECT;
```

The transaction is terminated via commit or rollback. The implicit disconnection is performed by adding R ELEASE option after the transaction termination statement.

```
EXEC SQL [ AT <db_name> ] { COMMIT/ROLLBACK } [ WORK ] RELEASE;
```

All Disconnection

All connections of the current application are disconnected all together as follows.

```
EXEC SQL DISCONNECT ALL;
```

Transaction

Database application consists of transaction units. Therefore, an embedded SQL program should be able to manipulate the transaction. This chapter describes how to manipulate the transaction.

Start and End of Transaction

A transaction starts in the SQL which is performed first after it is connected. The transaction is maintained until the end command explicitly occurs. There are two end commands, which are COMMIT and ROLLBA CK.

COMMIT

The transaction commit command causes the following actions.

- All data changes after the current transaction started are permanently reflected in the database.
- The reflected changes are visibly applied to all transactions which started after the changes or to the s ensitive cursor.

- All savepoints which are created in the current transaction are deleted.
- All locks which are obtained in the current transaction are released.
- All cursors which are opened in the current transaction are closed. (The holdable cursor is excluded.)
- The transaction is terminated.

The commit command is used as follows.

```
EXEC SQL COMMIT [ WORK ];
```

ROLLBACK

The rollback command types are as follows.

- Transaction full rollback
- Transaction partial rollback
- Statement-level rollback

The transaction rollback command causes the following actions.

- All data changes after the current transaction started are undone and it returns to the state of before the transaction starts.
- All savepoints which are created in the current transaction are deleted.
- All locks which are obtained in the current transaction are released.
- All cursors which are opened in the current transaction are closed. (The holdable cursor is excluded.)
- The transaction is terminated.

The rollback command is used as follows.

```
EXEC SQL ROLLBACK [ WORK ];
```

Transaction partial rollback uses the savepoint. The application developer explicitly specifies the savepoint, and the transaction partial rollback is implemented by undoing all operations up to the savepoint. The tra nsaction partial rollback command causes the following actions.

- All changes after the rollback savepoint are undone.
- All savepoints created after the rollback savepoint are deleted.
- All locks obtained after the rollback savepoint are released.

Transaction partial rollback command is used as follows.

```
EXEC SQL ROLLBACK TO SAVEPOINT <savepoint_name>;
```

Statement-level rollback undoes only the statement which is currently executed. For example, as if rows a re inserted to a table and the unique violation occurs so the current statement can not be performed, the

n only the currently executed statement should be undone so that the next operation may continue.

In this case, there is not a command to be explicitly specified by the user because GOLDILOCKS internally undoes the statement.

Auto Commit

If the embedded SQL of GOLDILOCKS generally performs the connection, transaction is operated in non auto-commit mode.

However, it may be required to adjust the auto-commit mode for the convenience of application develop ment or for the logical environment of the application. The embedded SQL precompiler of GOLDILOCKS may turn on or off the auto-commit mode with the following syntax.

```
EXEC SQL [ AT <db_name> ] ATUTOCOMMIT { ON ¦ OFF };
```

RELEASE Option

The currently used connection may be turned off by using the RELEASE option when ending the transacti on (commit/ rollback).
The option is allowed to be applied only for the transaction full commit rollback. It can not be used for th e transaction partially rollback (ROLLBACK TO SAVEPOINT).

Host Variables and Datatypes

The embedded SQL application aims at manipulating the data and querying to obtain the desired results by interworking with the database server.

A method for the application data to be transferred to the database server, or vise versa, is required for t his operation. The method to perform this role is defined as a host variable.

The application can use the host variables in the same way as C variables because the host variable is decl ared as a variable of C language. A host variable is treated as a part of the SQL statement and is responsi ble for the input/output of value between the database server and applications.

Declaring Host Variable

Host variable should be declared in the embedded SQL directive as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
```

- Declaring a host variable

```
EXEC SQL END DECLARE SECTION;
```

The section above is called as a declare section, and host variables can be declared within the declare sect ion in the same way as C variables. The following is an example of declaring a part of host variables.

```
EXEC SQL BEGIN DECLARE SECTION;
    int     empno;
    char    ename[20];
    double  salary;
EXEC SQL END DECLARE SECTION;
```

Declaring Function Argument

When using the function argument as a host variable, it is required to provide the information about the function argument. This information should be declared within the next embedded SQL directive.

```
EXEC SQL BEGIN ARGUMENT SECTION;
```

- Declaring a host variable

```
EXEC SQL END ARGUMENT SECTION;
```

The section above is called as an argument section, and the host variable should be declared as same as t he function argument's name and its type within the argument section.

```
void func( int empno, char ename[20], double salary )
{
EXEC SQL BEGIN ARGUMENT SECTION;
     int     empno;
     char    ename[20];
     double  salary;
EXEC SQL END ARGUMENT SECTION;
...
```

A pseudo type can not be used literally as a function argument, but it can be used by using the declare se ction and typedef keyword.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef VARCHAR domainName[20];
EXEC SQL END DECLARE SECTION;
```

```
void func( int * no, domainName * name )
{
    EXEC SQL BEGIN ARGUMENT SECTION;
    int        no[20];
    domainName name[20];
    EXEC SQL END ARGUMENT SECTION;
    EXEC SQL INSERT INTO EMP VALUES ( :no, :name );
}
```

If the host variable is declared as a pointer type, then the array length is unknown. Even when t he function argument is a pointer type, then the array length of the host variable should be spe cified in the argument section.

C Data Type for Host Variable

There are two types of C data used as the host variables, and which are a native type provided by the C la nguage and a data type additionally provided by GOLDILOCKS. The following table describes the data typ es provided by the embedded SQL of GOLDILOCKS.

C Native Datatype

C native datatype is the default data type provided by the C language, and its range and size are entirely dependent on the application development platform.

Table 33-1 C native datatype

C datatype	Description
char	It is a single character.
char[n]	It is a string with maximum length n.
short	It is a small integer (2 bytes).
int	It is an integer (4 bytes).
long	It is a large integer (4/8 bytes).
long long	It is a very large integer (8 bytes).
float	It is a single precision floating-point number.
double	It is a double precision floating-point number.

- char

char type represents a single character.

- char[n]

char[n] represents a string with maximum length n.
The following is an example.

```
EXEC SQL BEGIN DECLARE SECTION;
char strName[20];
EXEC SQL BEGIN DECLARE SECTION;
```

If it is declared as above, strName represents to the string data with the maximum length 20.
If strName is used as an output of ESQL, then it is space padded.

The maximum length of a char[] can not exceed 2001.

- short

It represents 2 bytes integer datatype.

- int

It represents 4 bytes integer datatype.

- long

Long type means a large integer, but the range of the actual value is determined in accordance with the platform. Long is 8 bytes integer in 64 bits Unix/Linux platform, but it is 4 bytes integer in 32 bits Unix/Linux platform.

- long long

It means very large integer, and it represents the 8 bytes integer.

- float

It is the float type of C language, and it represents the 4 bytes single-precision floating-point number.

- double

It is the double type of C language, and it represents the double-precision floating-point number.

Pseudo Datatype

Pseudo type supports the various forms of GOLDILOCKS type, and it is the type provided by GOLDILOCKS embedded SQL precompiler for the convenience of development. Most of its contents are implemented by using the structure of C.

Table 33-2 GOLDILOCKS embedded SQL pseudo type

Pseudo type	Description
VARCHAR[n]	It is a variable-length string with the maximum length n.
LONG VARCHAR	It is a variable-length string with the maximum length 100M (104857600).
BINARY[n]	It is a binary data with the maximum length n.
VARBINARY[n]	It is a variable-length binary data with the maximum length n.
LONG VARBINARY	It is a variable-length binary data with the maximum length 100M (104857600).
NUMBER	It is an integer whose number of significant digits is 38.
NUMBER(p)	It is an integer whose number of significant digits is p.
NUMBER(p, s)	It is a real number whose number of significant digits is p and whose scale is s.
BOOLEAN	It is a boolean type.
DATE	It is a date type data.
TIME	It is a time type data.
TIME WITH TIMEZONE	It is a time type data with timezone.
TIMESTAMP	It is a datetime type data.
TIMESTAMP WITH TIMEZONE	It is a time type data with timezone.
INTERVAL YEAR	It is an interval data type.
INTERVAL MONTH	
INTERVAL DAY	
INTERVAL HOUR	
INTERVAL MINUTE	
INTERVAL SECOND	
INTERVAL YEAR TO MONTH	
INTERVAL DAY TO HOUR	
INTERVAL DAY TO MINUTE	
INTERVAL DAY TO SECOND	
INTERVAL HOUR TO MINUTE	
INTERVAL HOUR TO SECOND	
INTERVAL MINUTE TO SECOND	

VARCHAR

VARCHAR type is the datatype in which the variable length string can be stored, and it consists of the foll owing structure.

```
struct {
    int  len;
    char arr[n];
}
```

n refers to the maximum length of VARCHAR type.

```
EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR varstr[100];
EXEC SQL END DECLARE SECTION;
```

For example, if it is declared as above, it is converted via precompile process as follows.

```
struct VARCHAR_varstr {
    int  len;
    char arr[100];
} varstr;
```

The application can use VARCHAR type as follows.

```
strcpy( varstr.arr, "abcde" );
varstr.len = strlen( varstr.arr );

EXEC SQL INSERT INTO TEST_T1 VALUES ( :varstr );
```

The length of VARCHAR can not exceed 4000.

LONG VARCHAR

LONG VARCHAR type is the datatype in which a long variable-length strings can be stored, and it consists of the following structure.

```
typedef struct SQL_LONG_VARIABLE_LENGTH_STRUCT
{
    SQLBIGINT   len;
    SQLCHAR   * arr;
} SQL_LONG_VARIABLE_LENGTH_STRUCT;
```

LONG VARCHAR type can be declared as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
    LONGVARCHAR long_text[1048576];
EXEC SQL END DECLARE SECTION;
```

LONG VARCHAR is different from VARCHAR. LONG VARCHAR can have the length up to 100M (104857 600), so it does not pre-allocate the space for the string when declaring. After declaring LONG VARCHAR, the memory space should be allocated in long_text.arr before actual use, and the application should relea se the allocated memory space. An example of using LONG VARCHAR is as follows.

```
long_text.arr = malloc( 1048576 );

gets( long_text.arr );
long_text.len = strlen( long_text.arr );

EXEC SQL INSERT INTO TEST_T1 VALUES ( :long_text );
...
free( long_text.arr );
```

LONG VARCHAR type can be declared by specifying the current length up to 100M (104857600).

BINARY

BINARY type is the datatype to literally handle the non-formal raw data, and it consists of the following structure. The example of declaring BINARY type is as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR binary[100];
EXEC SQL END DECLARE SECTION;
```

If it is declared as above, it is converted via precompile process as follows.

```
char binary[100];
```

Its form is as same as the character string storage form. char[n] is defined to store the string of database, but BINARY type is for storing the binary data. Therefore, the applications can use BINARY type in the same way as dealing with the character string data.

The maximum length of BINARY can not exceed 2000.

VARBINARY

VARBINARY type is the datatype in which the variable length binary data can be stored, and it consists of the following structure.

```
struct {
    int  len;
    char arr[n];
}
```

n refers to the maximum length of VARCHAR type.

```
EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR varbin[100];
EXEC SQL END DECLARE SECTION;
```

For example, if it is declared as above, it is converted via precompile process as follows.

```
struct VARBINARY_varbin {
    int  len;
    char arr[100];
} varbin;
```

The forms of VARBINARY type and VARCHAR type are same. VARCHAR is for storing the string data, but VARBINARY is for storing the binary data. VARCHAR and VARBINARY are same in all other aspects except for the aspect above. Therefore, the application can use both VARCHAR and VARBINARY types as follows.

```
memcpy( varbin.arr, binary_data, 50 );
varbin.len = 50;

EXEC SQL INSERT INTO TEST_T1 VALUES ( :varbin );
```

The length of VARBINARY can not exceed 4000.

LONG VARBINARY

LONG VARBINARY type is the datatype in which the long variable length binary data can be stored, and it consists of the following structure.

```
typedef struct SQL_LONG_VARIABLE_LENGTH_STRUCT
{
    SQLBIGINT   len;
    SQLCHAR   * arr;
} SQL_LONG_VARIABLE_LENGTH_STRUCT;
```

LONG VARBINARY type can be declared as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
    LONGVARBINARY long_bin[1048576];
EXEC SQL END DECLARE SECTION;
```

The difference between LONG VARBINARY and VARBINARY is that the space is not pre-allocated to store binary data when declaring LONG VARBINARY type.(It is as same as the difference between LONG VARCHAR and VARCHAR). After declaring LONG VARBINARY, the memory space should be allocated in long_bin.arr before actual use, and the application should release the allocated memory space after use. An example of using LONG VARBINARY is as follows.

```
long_bin.arr = malloc( 1048576 );

memcpy( long_bin.arr, long_binary_data, 1048576);
long_bin.len = 1048576;

EXEC SQL INSERT INTO TEST_T1 VALUES ( :long_bin );
...
free( long_bin.arr );
```

LONG VARBINARY type can be declared by specifying the current length up to 100M(104857600).

NUMBER

NUMBER type is the datatype which provides an SQL_NUMERIC_STRUCT defined in ODBC to make it to be used in the application.

```
#define SQL_MAX_NUMERIC_LEN 16
typedef struct tagSQL_NUMERIC_STRUCT
{
    SQLCHAR precision;
    SQLSCHAR scale;
    SQLCHAR sign; /* 1=pos 0=neg */
    SQLCHAR val[SQL_MAX_NUMERIC_LEN];
} SQL_NUMERIC_STRUCT;
```

NUMBER type is configured to express the real number type data with precision and scale. When declaring NUMBER type, precision and scale can also be declared. Scale and precision can be omitted as follows in some cases.

Table 33-3 Scale and precision of number types

Declaring NUMBER type	Description
NUMBER	It is as same as NUMBER(38, 0).
NUMBER(p)	It is as same as NUMBER(p, 0)
NUMBER(p, s)	It is a real number type data with precision p, scale s.

```
EXEC SQL BEGIN DECLARE SECTION;
    NUMBER        number_default;
    NUMBER(20)    number_20;
    NUMBER(30,10) number_30_10;
EXEC SQL END DECLARE SECTION;
```

For example, if the variable is declared as above, number_default variable is as same as the declaration of NUMBER(38, 0), and number_20 variable is as same as the declaration of NUMBER(20, 0). NUMBER type uses SQL_NUMERIC_STRUCT which is a ODBC type. The following is a sample of using NUMBER type.

```
/*
 * number.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
EXEC SQL INCLUDE SQLCA;
#define  SUCCESS  0
#define  FAILURE  -1
#define  PRINT_SQL_ERROR(aMsg)                                    \
    {                                                             \
        printf("\n");                                             \
        printf(aMsg);                                             \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
               sqlca.sqlcode,                                     \
               SQLSTATE,                                          \
               sqlca.sqlerrm.sqlerrmc );                          \
    }

int Connect(char *aHostInfo, char *aUserID, char *sPassword);
int CreateTable();
int DropTable();

unsigned long long ConvertMantisaToDecimal(SQLCHAR *aNumStrValue)
{
    unsigned long long sResult = 0;
    unsigned long long sLast=1;
    unsigned int sCurrent;
    unsigned int sLSD = 0;
    unsigned int sMSD = 0;
```

```
    int          i    = 1;
    for(i = 0; i < SQL_MAX_NUMERIC_LEN; i ++)
    {
        sCurrent = (unsigned char) aNumStrValue[i];
        sLSD = sCurrent % 16; //Obtain LSD
        sMSD = sCurrent / 16; //Obtain MSD
        sResult += sLast * sLSD;
        sLast = sLast * 16;
        sResult += sLast * sMSD;
        sLast = sLast * 16;
    }
    return sResult;
}

void PrintNumber(SQL_NUMERIC_STRUCT *aNumber)
{
    unsigned long long  sDigit;
    unsigned long long  sFraction;
    unsigned long long  sMantisa;
    unsigned long long  sFactor;
    int     i;
    sMantisa = ConvertMantisaToDecimal( aNumber->val );
    sFactor = 1;
    for( i = 0; i < aNumber->scale; i ++ )
    {
        sFactor *= 10;
    }
    sDigit = sMantisa / sFactor;
    sFraction = sMantisa % sFactor;
    if( sFraction != 0 )
    {
        printf("%llu.%-3llu", sDigit, sFraction);
    }
    else
    {
        printf("%llu", sDigit);
    }
}

int main(int     argc,

            (void)DropTable();
        default:
            break;
    }
    EXEC SQL ROLLBACK WORK RELEASE;
    return 0;
}
```

```
int CreateTable()
{
    EXEC SQL DROP TABLE IF EXISTS TEST_T1;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
```

- Create table

```
EXEC SQL CREATE TABLE TEST_T1 ( C1  INTEGER,
                                C2  NUMERIC(38,4),
                                C3  VARCHAR(20) );
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    EXEC SQL COMMIT WORK;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    return SUCCESS;
  fail_exit:
    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    EXEC SQL ROLLBACK WORK;
    return FAILURE;
}
```

- Drop table

```
int DropTable()
{
    EXEC SQL DROP TABLE TEST_T1;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    EXEC SQL COMMIT WORK;
    if(sqlca.sqlcode != 0)
    {
```

```
        goto fail_exit;
    }
    return SUCCESS;
  fail_exit:
    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    EXEC SQL ROLLBACK WORK;
    return FAILURE;
}

int Connect(char *aHostInfo, char *aUserID, char *sPassword)
{
    EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR  sUid[80];
    VARCHAR  sPwd[20];
    VARCHAR  sConnStr[1024];
    EXEC SQL END DECLARE SECTION;
```

- Log on GOLDILOCKS

```
strcpy((char *)sUid.arr, aUserID);
    sUid.len = (short)strlen((char *)sUid.arr);
    strcpy((char *)sPwd.arr, sPassword);
    sPwd.len = (short)strlen((char *)sPwd.arr);
    strcpy((char *)sConnStr.arr, aHostInfo);
    sConnStr.len = (short)strlen((char *)sConnStr.arr);
```

- DB connection

```
EXEC SQL CONNECT :sUid IDENTIFIED BY :sPwd USING :sConnStr;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    return SUCCESS;
  fail_exit:
    PRINT_SQL_ERROR("[ERROR] Connection Failure!");
    return FAILURE;
}
```

BOOLEAN

BOOLEAN type has the value of TRUE or FALSE. Actually, the variable is used as the variable of C languag e, so if the variable is 1, it refers to TRUE. If the variable is 0, it refers to FALSE.
The following is an example of using a simple BOOLEAN type variable.

```
EXEC SQL BEGIN DECLARE SECTION;
    BOOLEAN boolean;
EXEC SQL END DECLARE SECTION;

EXEC SQL SELECT IsEnable INTO :boolean FROM STATUS WHERE ID = 100;

if( boolean != 0 )
{
    print( "Enable Status : TRUE\n" );
}
else
{
    print( "Enable Status : FALSE\n" );
}
```

DATE

Date type can deal with dates and times. Date type has SQL_TIMESTAMP_STRUCT structure of ODBC.

```
typedef struct tagTIMESTAMP_STRUCT
{
        SQLSMALLINT    year;
        SQLUSMALLINT   month;
        SQLUSMALLINT   day;
        SQLUSMALLINT   hour;
        SQLUSMALLINT   minute;
        SQLUSMALLINT   second;
        SQLUINTEGER    fraction;
} TIMESTAMP_STRUCT;
typedef TIMESTAMP_STRUCT SQL_TIMESTAMP_STRUCT;
```

If the variable of DATE type is declared, the precompiler converts it to the structure above, and the meani ng of each field as same as SQL_TIMESTAMP_STRUCT of ODBC.

TIME

TIME type is the datatype which deals with time, and it has SQL_TIME_STRUCT structure of ODBC.

```
typedef struct tagTIME_STRUCT
{
        SQLUSMALLINT   hour;
        SQLUSMALLINT   minute;
        SQLUSMALLINT   second;
} TIME_STRUCT;
typedef TIME_STRUCT SQL_TIME_STRUCT;
```

If the variable of TIME type is declared, the precompiler converts it to the structure above, and the meaning of each field is as same as SQL_TIME_STRUCT of ODBC.

TIME WITH TIMEZONE

TIME WITH TIMEZONE type is the datatype which deals with the time with timezone, and it has the structure as follows.

```
typedef struct tagTIME_WITH_TIMEZONE_STRUCT
{
   SQLUSMALLINT hour;
   SQLUSMALLINT minute;
   SQLUSMALLINT second;
   SQLUINTEGER  fraction;
   SQLSMALLINT  timezone_hour;
   SQLSMALLINT  timezone_minute;
} TIME_WITH_TIMEZONE_STRUCT;
typedef TIME_WITH_TIMEZONE_STRUCT SQL_TIME_WITH_TIMEZONE_STRUCT;
```

If the variable of TIME WITH TIMEZONE type is declared, precompiler converts it to the structure above, and the meaning of each field is as follows.

Table 33-4 Fields of TIME WITH TIMEZONE

Field name	Description
hour	hour
minute	minute
second	second
fraction	the seconds below the decimal point
timezone_hour	hour of timezone
timezone_minute	minute of timezone

TIMESTAMP

TIMESTAMP type is the datatype which deals with date ~ time, and it has SQL_TIMESTAMP_STRUCT stru cture of ODBC.

```
typedef struct tagTIMESTAMP_STRUCT
{
        SQLSMALLINT    year;
        SQLUSMALLINT   month;
        SQLUSMALLINT   day;
        SQLUSMALLINT   hour;
        SQLUSMALLINT   minute;
        SQLUSMALLINT   second;
        SQLUINTEGER    fraction;
} TIMESTAMP_STRUCT;
typedef TIMESTAMP_STRUCT SQL_TIMESTAMP_STRUCT;
```

If the variable of TIMESTAMP type is declared, precompiler converts it to the structure above, and the me aning of each field as same as SQL_TIMESTAMP_STRUCT structure of ODBC.

TIMESTAMP WITH TIMEZONE

TIMESTAMP WITH TIMEZONE type is the datatype which deals with timestamp with timezone, and it has the following structure.

```
typedef struct tagTIMESTAMP_WITH_TIMEZONE_STRUCT
{
   SQLSMALLINT  year;
   SQLUSMALLINT month;
   SQLUSMALLINT day;
   SQLUSMALLINT hour;
   SQLUSMALLINT minute;
   SQLUSMALLINT second;
   SQLUINTEGER  fraction;
   SQLSMALLINT  timezone_hour;
   SQLSMALLINT  timezone_minute;
} TIMESTAMP_WITH_TIMEZONE_STRUCT;
typedef TIMESTAMP_WITH_TIMEZONE_STRUCT SQL_TIMESTAMP_WITH_TIMEZONE_STRUCT;
```

If the variable of TIMESTAMP WITH TIMEZONE type is declared, precompiler converts it to the structure a bove, and the meaning of each field is as follows.

Table 33-5 Fields of TIMESTAMP WITH TIMEZONE

Field name	Description
year	year
month	month
day	day
hour	hour
minute	minute
second	second
fraction	the seconds below the decimal point
timezone_hour	hour of timezone
timezone_minute	minute of timezone

The following is an example of dealing with DATE, TIME, TIMESTAMP, TIME WITH TIMEZONE, TIMESTAMP WITH TIMEZONE types.

```
/*
 * date_time.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1

  fail_exit:
    PRINT_SQL_ERROR("[ERROR] Connection Failure!");

    return FAILURE;
}
```

INTERVAL Types

INTERAVAL types are the datatypes which represent the time interval between two times. They are divide d into year ~ month family type and day ~ second family type. They are subdivided by specific types of ea ch family.
The following table describes the detailed classification of INTERVAL type.

Table 33-6 Classification of INTERVAL type

Family	Detailed type	Description
YEAR TO MONTH	INTERVAL YEAR	It is an interval in terms of years.
	INTERVAL MONTH	It is an interval in terms of months.
	INTERVAL YEAR TO MONTH	It is an interval in terms of years to months.
DAY TO SECOND	INTERVAL DAY	It is an interval in terms of days.
	INTERVAL HOUR	It is an interval in terms of hours.
	INTERVAL MINUTE	It is an interval in terms of minutes.
	INTERVAL SECOND	It is an interval in terms of seconds.
	INTERVAL DAY TO HOUR	It is an interval in terms of days to hours.
	INTERVAL DAY TO MINUTE	It is an interval in terms of days to minutes.
	INTERVAL DAY TO SECOND	It is an interval in terms of days to seconds.
	INTERVAL HOUR TO MINUTE	It is an interval in terms of hours to minutes.
	INTERVAL HOUR TO SECOND	It is an interval in terms of hours to seconds.
	INTERVAL MINUTE TO SECOND	It is an interval in terms of minutes to seconds.

INTERVAL type has the structure of SQL_INTERVAL_STRUCT of ODBC as follows.

```
typedef enum
{
    SQL_IS_YEAR      = 1,
    SQL_IS_MONTH     = 2,
    SQL_IS_DAY      = 3,
    SQL_IS_HOUR      = 4,
    SQL_IS_MINUTE     = 5,
    SQL_IS_SECOND     = 6,
    SQL_IS_YEAR_TO_MONTH   = 7,
    SQL_IS_DAY_TO_HOUR    = 8,
    SQL_IS_DAY_TO_MINUTE   = 9,
    SQL_IS_DAY_TO_SECOND   = 10,
    SQL_IS_HOUR_TO_MINUTE   = 11,
    SQL_IS_HOUR_TO_SECOND   = 12,
    SQL_IS_MINUTE_TO_SECOND   = 13
} SQLINTERVAL;
```

```
typedef struct tagSQL_YEAR_MONTH
{
    SQLUINTEGER  year;
    SQLUINTEGER  month;
} SQL_YEAR_MONTH_STRUCT;
typedef struct tagSQL_DAY_SECOND
{
    SQLUINTEGER  day;
    SQLUINTEGER  hour;
    SQLUINTEGER  minute;
    SQLUINTEGER  second;
    SQLUINTEGER  fraction;
} SQL_DAY_SECOND_STRUCT;
typedef struct tagSQL_INTERVAL_STRUCT
{
    SQLINTERVAL  interval_type;
    SQLSMALLINT  interval_sign;
    union {
        SQL_YEAR_MONTH_STRUCT  year_month;
        SQL_DAY_SECOND_STRUCT  day_second;
   } intval;
} SQL_INTERVAL_STRUCT;
```

All INTERVAL types listed above have the same structure. For each INTERVAL type, a valid field is separatel y distinguished within the structure. INTERVAL type is distinguished by interval_type field within the struct ure, and a real INTERVAL value is represented to intval union in the structure. The field which is used in in tval union is different by each type, and the following table describes the valid field depending on the typ e.

Table 33-7 The valid field depending on INTERVAL type

Type	?.interval_type	?.intval valid field
INTERVAL YEAR	SQL_IS_YEAR	*.year_month.year
INTERVAL MONTH	SQL_IS_MONTH	*.year_month.month
INTERVAL YEAR TO MONTH	SQL_IS_YEAR_TO_MONTH	*.year_month.year *.year_month.month
INTERVAL DAY	SQL_IS_DAY	*.day_second.day
INTERVAL HOUR	SQL_IS_HOUR	*.day_second.hour
INTERVAL MINUTE	SQL_IS_MINUTE	*.day_second.minute
INTERVAL SECOND	SQL_IS_SECOND	*.day_second.second *.day_second.fraction
INTERVAL DAY TO HOUR	SQL_IS_DAY_TO_HOUR	*.day_second.day

Type	?.interval_type	?.intval valid field
		*.day_second.hour
INTERVAL DAY TO MINUTE	SQL_IS_DAY_TO_MINUTE	*.day_second.day *.day_second.hour *.day_second.minute
INTERVAL DAY TO SECOND	SQL_IS_DAY_TO_SECOND	*.day_second.day *.day_second.hour *.day_second.minute *.day_second.second *.day_second.fraction
INTERVAL HOUR TO MINUTE	SQL_IS_HOUR_TO_MINUTE	*.day_second.hour *.day_second.minute
INTERVAL HOUR TO SECOND	SQL_IS_HOUR_TO_SECOND	*.day_second.hour *.day_second.minute *.day_second.second *.day_second.fraction
INTERVAL MINUTE TO SECOND	SQL_IS_MINUTE_TO_SECOND	*.day_second.minute *.day_second.second *.day_second.fraction

Fraction refers to the seconds below the decimal point. (The fraction field is valid only for INTERVAL type which includes SECOND.)

Special Type

The special data type provides the additional functionality and convenience for development of applicatio n rather than handling the data on its own. The following table describes the special types.

Table 33-8 Special types

Type	Description
SQL_CONTEXT	It manages run-time context within the multi-connection structure.
Struct	It constitutes a set of column as a structure, and it is used when dealing with ro w.
Typedef	The previously defined type is redefined as another name.

SQL_CONTEXT

SQL_CONTEXT is a special data type for managing the run-time context. Run-time context is used for the purpose of managing the connection and the individual data related to the connection on the run-time w hile the application is running.

SQL_CONTEXT variable is declared as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
SQL_CONTEXT my_context;
EXEC SQL BEGIN DECLARE SECTION;
```

ALLOCATE clause is used after declaring SQL_CONTEXT variable as follows.

```
EXEC SQL CONTEXT ALLOCATE :my_context;
```

USE clause is used for SQL_CONTEXT variable.

```
EXEC SQL CONTEXT USE :my_context;
```

USE clause specifies the context to be used, and the following describes how to go back to the default co ntext not the context declared by the application.

```
EXEC SQL CONTEXT USE DEFAULT;
```

The disused SQL_CONTEXT variable is released as follows.

```
EXEC SQL CONTEXT FREE :my_context;
```

The following is an example of using SQL_CONTEXT.

```
/*
 * thread1.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <pthread.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1

#define  PRINT_SQL_ERROR(aMsg)                                          \
    {                                                                   \
        printf("\n");                                                   \
        printf(aMsg);                                                   \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
```

```
                sqlca.sqlcode,                                          \
                SQLSTATE,                                               \
                sqlca.sqlerrm.sqlerrmc );                               \
    }

int Connect(sql_context aCtx, char *aHostInfo, char *aUserID, char *sPassword);
int CreateEmpTempTable();
int DropEmpTempTable();
void *clientThread(void *args);

typedef struct thread_param
{
    int    mNo;
    char  *mJobName;
} thread_param;

#define  THREAD_COUNT    2
char gJobName[THREAD_COUNT][20]= {
    "RND",
    "SUPPORT"
};

int main(int argc, char **argv)
{
    EXEC SQL BEGIN DECLARE SECTION;
    int          sEmpNo;

    }

    pthread_exit(0);
    return NULL;
}
```

SQL_CURSOR

The cursor variable is available for the query in the embedded SQL program. The cursor variable is a handle for the cursor which should be defined and opened by using PL/SQL in GOLDILOCKS server.

Declare the cursor variable in the embedded SQL by using SQL_CURSOR type. The following is an example of declaring the cursor variable.

```
EXEC SQL BEGIN DECLARE SECTION;
sql_cursor   emp_cursor;
SQL_CURSOR   sal_cursor;
sql_cursor * cur_ptr;
EXEC SQL END DECLARE SECTION;
cur_ptr = &emp_cursor;
```

The cursor variable is available by declaring with sql_cursor or SQL_CURSOR. The cursor variable follows the C range rules like as other host variables. It is transferable as the function parameter. It can also define

the cursor variable or the function which returns the pointer for the cursor variable. The following is an example of using the cursor variable as the function parameter and return.

```
SQL_CURSOR * alloc_cursor( sql_cursor * emp_cursor )
{
EXEC SQL BEGIN DECLARE SECTION;
    sql_cursor * ret_cursor;
EXEC SQL END DECLARE SECTION;
    ret_cursor = emp_cursor;
....
    return ret_cursor;
}
```

The cursor variable should be allocated before using it. Use **ALLOCATE** command after declaring the cursor variable to perform this operation. The following is an example of allocating ret_cursor which was used in alloc_cursor function in the example above.

```
EXEC SQL ALLOCATE :ret_cursor;
```

If the cursor variable is allocated, then the memory is allocated during the run-time, so it should be freed by using **FREE** command. The memory which was created when allocating the cursor variable is freed when CLOSE command is explicitly used or the connection is closed.

```
EXEC SQL FREE :ret_cursor;
```

The cursor variable should be opened in GOLDILOCKS database server. The embedded SQL command OPEN can not be used to opes the cursor variable. The cursor variable can be opened by calling the storing procedure or the function of PL/SQL opening the cursor, or by defining the anonymous block opening the cursor.

The following is an example of opening the cursor variable by calling the storing procedure of PL/SQL.

```
CREATE OR REPLACE PROCEDURE empProc( curs IN OUT SYS_REFCURSOR,
                                     dept IN INTEGER )
AS
BEGIN
   OPEN curs FOR SELECT ename FROM emp
                         WHERE deptno = dept ORDER BY ename;
END;
/
```

Define empProc storing procedure and call empProc storing procedure in the embedded SQL to open and FETCH the cursor variable as the example above.

The following is an example.

```
EXEC SQL BEGIN DECLARE SECTION;
SQL_CURSOR empCursor;
int  dept;
char ename[128];
EXEC SQL END DECLARE SECTION;
EXEC SQL ALLOCATE :empCursor;
EXEC SQL CALL empProc( :empCursor,  :dept );
while( 1 )
{
    EXEC SQL FETCH :empCursor INTO :ename;
    if( sqlca.sqlcode == 100 ) break;
    printf( "%s\n", ename );
}
```

The following is an example of defining the storing procedure and opening the cursor variable in the emb edded SQL.

```
EXEC SQL BEGIN DECLARE SECTION;
SQL_CURSOR empCursor;
int  dept;
char ename[128];
EXEC SQL END DECLARE SECTION;
EXEC SQL ALLOCATE :empCursor;
EXEC SQL EXECUTE
    BEGIN
        OPEN :empCursor FOR SELECT ename FROM emp
                                    WHERE dept_no = :dept ORDER BY ename;
    END;
END-EXEC;
while( 1 )
{
    EXEC SQL FETCH :empCursor INTO :ename;
    if( sqlca.sqlcode == 100 ) break;
    printf( "%s\n", ename );
}
```

The following is an example of closing the cursor variable through CLOSE command.

```
EXEC SQL CLOSE :empCursor;
```

When closing the cursor variable, the cursor is closed but it does not return the memory. The memory for the cursor variable can be returned through FREE command.

Allocating the cursor variable internally allocates the client's statement, so it is related to the co ntext. Therefore, open the cursor after allocating the cursor variable, then FETCH, CLOSE and F REE are operable within the same context only. For example, if the cursor variable is allocated in the default context and used in another named context then an error occurs.

Host Structure

The C structure can be used as a host variable in an embedded SQL of GOLDILOCKS. A typical scalar varia ble represents a single column, but using the structure enables to simply express multiple column sets.

Host structure can only be used only in INTO clause of SELECT INTO or FETCH INTO statement and in VAL UES clause of INSERT statement, but it can not be used in WHERE clause or UPDATE SET clause, because it has the same effect as when listing its member variables in sequence.

The structure is defined in the declare section to use the host structure, and it can be used as a host varia ble after declaring the structure variable. The structure is defined in the same way as defining the C struct, and it can also be used after defining the type via typedef.

The following is an example of using the host structure.

```
/*
 * sample4.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1
#define  PRINT_SQL_ERROR(aMsg)                                    \
    {                                                             \
        printf("\n");                                             \
        printf(aMsg);                                             \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",  \
               sqlca.sqlcode,                                     \
```

```
                SQLSTATE,                                               \
                sqlca.sqlerrm.sqlerrmc );                               \
    }
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;
EXEC SQL END DECLARE SECTION;

int Connect(char *aHostInfo, char *aUserID, char *sPassword);

int main(int argc, char **argv)
{
    EXEC SQL BEGIN DECLARE SECTION;
    rsRecord     sRecord;
    EXEC SQL END DECLARE SECTION;
    int  sRecordCount = 0;

    printf("Connect GOLDILOCKS ...\n");
    if(Connect("DSN=GOLDILOCKS", "test", "test") != SUCCESS)
    {
        goto fail_exit;
    }
```

        FROM   EMP
        ORDER BY EMPNO;

    EXEC SQL OPEN EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
```

```
    }

    printf(" EMPNO    ENAME                JOB      SALARY\n");
    printf("====== ==================== ========== ========\n");
    while( 1 )
    {
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sRecord;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
            goto fail_exit;
        }

        sRecordCount ++;

        printf("%6d %20s %10s %8ld\n",
               sRecord.mEmpNo, sRecord.mEName.arr, sRecord.mJob, sRecord.mSalary);
    }

    printf("====== ==================== ========== ========\n");
    printf("Record Count = %d\n", sRecordCount);
    printf("====== ==================== ========== ========\n");

    EXEC SQL CLOSE EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }

    EXEC SQL COMMIT WORK RELEASE;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
```

```
    }

    printf("\n\nSUCCESS\n");
    printf("############################\n");

    return 0;

  fail_exit:

    printf("\n\nFAILURE\n");
    printf("############################\n\n");

    EXEC SQL ROLLBACK WORK RELEASE;

    return 0;
}

int Connect(char *aHostInfo, char *aUserID, char *sPassword)
{
    EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR  sUid[80];
    VARCHAR  sPwd[20];
    VARCHAR  sConnStr[1024];
    EXEC SQL END DECLARE SECTION;
```

- Log on GOLDILOCKS

```
strcpy((char *)sUid.arr, aUserID);
    sUid.len = (short)strlen((char *)sUid.arr);
    strcpy((char *)sPwd.arr, sPassword);
    sPwd.len = (short)strlen((char *)sPwd.arr);
    strcpy((char *)sConnStr.arr, aHostInfo);
    sConnStr.len = (short)strlen((char *)sConnStr.arr);
```

- DB connection

```
EXEC SQL CONNECT :sUid IDENTIFIED BY :sPwd USING :sConnStr;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
```

```
    return SUCCESS;

  fail_exit:
    PRINT_SQL_ERROR("[ERROR] Connection Failure!");

    return FAILURE;
}
```

When a user declares a structure for using the host variable, the restriction is as follows. The nested structure is not allowed. If another structure exists within the structure declaration as shown below, it can not be used as the host variable.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    struct person {
        int          mEmpNo;
        varchar      mEName[20 + 1];
    } person;
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;
EXEC SQL END DECLARE SECTION;
```

Indicator Variable

Scalar Indicator

Host variables can be used together with the indicator variables combined with it. An indicator variable determines whether the current value of the host variable is NULL. The indicator variable is declared in the same way as the host variable, and it is declared only as an integer type of C (short, int, long, long long). Indicator is used as follows.

```
:hostvar INDICATOR :hostind
:hostvar :hostind (INDICATOR keyword can be omitted.)
```

The value of indicator variable means the followings.

Table 33-9 Value of input indicator

Value	Meaning
-1	NULL

Value	Meaning
>= 0	It inputs a host variable value.

Table 33-10 Value of output indicator

Value	Meaning
-1	NULL
0	All values are stored in a host variable.
> 0	It is the length of DB data when all values are not stored in a host variable due to an insufficient buffer size of host variable.

The following is an example of using the indicator.

```
/*
 * sample5.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1
#define  PRINT_SQL_ERROR(aMsg)                                          \
    {                                                                   \
        printf("\n");                                                   \
        printf(aMsg);                                                   \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",       \
               sqlca.sqlcode,                                           \
               SQLSTATE,                                                \
               sqlca.sqlerrm.sqlerrmc );                                \
    }

    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    EXEC SQL ROLLBACK WORK;

    return FAILURE;
}
```

Structure Indicator

If a host variable is a scalar variable, an Indicator variable is declared and combined with the host variable, then it is used. If the host variable is the structure, each variable configuring the structure can not be use d with an indicator variable. In this case, the indicator should also be the structure.

When declaring an indicator structure, it should comply with the followings.

- The number of indicator members should be as same as the number of host variable structure memb ers to be combined.
- All members of the indicator structure should have the integer data type.

For example, if the following structure is declared, the member of indicator structure should be four beca use the number of the variables of the structure is four.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;
EXEC SQL END DECLARE SECTION;
```

Therefore, it should be declared as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecordInd
{
    int          mEmpNoInd;
    int          mENameInd;
    int          mJobInd;
    int          mSalaryInd;
} rsRecordInd;
EXEC SQL END DECLARE SECTION;
```

Each indicator structure member sequentially corresponds one-to-one to the host variable structure mem ber which is combined to the indicator structure. When declaring as above, the combination relationship is as follows.

```
:rsRecordVar INDICATOR :rsRecordIndVar
```

Host variable	Indicator to be combined
rsRecordVar.mEmpNo	rsRecordIndVar.mEmpNoInd
rsRecordVar.mEName	rsRecordIndVar.mENameInd
rsRecordVar.mJob	rsRecordIndVar.mJobInd
rsRecordVar.mSalary	rsRecordIndVar.mSalaryInd

Embedded SQL

Host Variable

The host variable is used as the data input/output medium between the application and GOLDILOCKS. The input host variable transfers the data from the application to GOLDILOCKS, and the output host variable transfers the data from GOLDILOCKS to the application. The declarations of two variables are same and their roles are determined in the SQL statement in use.

The host variable which is located in INTO clause of SELECT or FETCH statement is the output host variable received the data from GOLDILOCKS. Other than that is the input host variable. The input host variable should be set before executing the SQL statement.

Host Indicator

The host variable literally uses the variable of C language, so a particular way to display NULL does not exist. The indicator variable can be used for that, and a single indicator is combined with a single host variable.

An indicator variable means the followings.

Table 33-11 Value of input indicator

Value	Meaning
-1	NULL
>= 0	It inputs a host variable value.

Table 33-12 Value of output indicator

Value	Meaning
-1	NULL
0	All values are stored in a host variable.
> 0	It is the length of DB data when all values are not stored in a host variable due to an insufficient buffer size of host variable.

Insert NULL

NULL is inserted in a column as follows.

```
EXEC SQL INSERT INTO EMP ( EMPNO, DEPTNO ) VALUES ( :empno, NULL );
```

However, if hard coding above is used to create the application, the flexibility becomes very poor. The following is an example of using the indicator variable.

```
deptno_ind = -1;
EXEC SQL INSERT INTO EMP ( EMPNO, DEPTNO ) VALUES ( :empno, :deptno :deptno_ind );
```

If the value of deptno_ind which is the indicator variable is -1, it is recognized as NULL regardless of the v alue of deptno which is the host variable.

Fetch NULL

When GOLDILOCKS receives the data, the indicator variable can be used to determine whether to be NUL L. The following is an example.

```
EXEC SQL DECLARE CUR_1 CURSOR FOR
    SELECT  EMPNO, DEPTNO
    FROM    EMP
    WHERE   EMPNO = :emp_number;
EXEC SQL OPEN CUR_1;

while( 1 )
{
    EXEC SQL FETCH CUR_1 INTO :empno, :deptno :deptno_ind;
    if( sqlca.sqlcode == SQL_NO_DATA )
    {
        break;
    }

    if( deptno_ind == -1 )
    {
        printf( "empno : %d, deptno : (null)\n", empno );
    }
    else
    {
        printf( "empno : %d, deptno : %d\n", empno, deptno );
    }
}

EXEC SQL CLOSE CUR_1;
```

If deptno_ind is -1 after performing FETCH, it determines that deptno is NULL.

Basic SQL Statement

All SQL statements provided in GOLDILOCKS is available in an embedded SQL. For more information abo ut SQL statements, refer to **Part III. SQL Manual**. When using an SQL statement in an embedded SQL, the SQL statement is specified after EXEC SQL keyword. This chapter describes Data Definition Language (DD L) or Data Manipulation Language (DML), and the next chapter describes the statements repeatedly retri

eving data as like a query.

SQLCA is checked to determine whether the SQL statement is successfully executed. For more informatio n, refer to **Handling Run-time Errors**.

DDL Statement

DDL statement is an SQL statement which creates, drops or alters GOLDILOCKS objects such as table, vie w, index. When executing a DDL statement in an embedded SQL application, the SQL statement is specifi ed after EXEC SQL keyword.

```
EXEC SQL DROP TABLE IF EXISTS EMP;
EXEC SQL
    CREATE TABLE EMP (
        EMPNO NUMBER(4) CONSTRAINT PK_EMP PRIMARY KEY,
        ENAME VARCHAR2(10),
        JOB VARCHAR2(9),
        SAL NUMBER(7,2),
        DEPTNO NUMBER(2) );
```

The host variable can not be used in DDL statement. Therefore, the following usage is wrong.

```
strcpy( table_name, "T1" );
EXEC SQL CREATE TABLE :table_name ( C1 INTEGER );
```

If DDL statement is to be used variably as above because the DDL statement is not defined while creating the application, the dynamic SQL statement can be used as follows.

```
strcpy( table_name, "T1" );
sprintf( sql_stmt, "CREATE TABLE %s ( C1 INTEGER )", table_name );
EXEC SQL EXECUTE IMMEDIATE :sql_stmt;
```

For more information, refer to **Embedded Dynamic SQL**.

Select Into Statement

The query is used to retrieve the data from GOLDILOCKS. Generally, the number of retrieved rows are not known, so the cursor object is declared and the process of open, fetch, close may be performed to use th e query statement. For more information, refer to **Cursor**.

However, the number of retrieved rows are known in a special case. For example, when the primary key i s known and the record with the same primary key is retrieved, then it can be predicted that the result eit her does not exist or has up to one record. The select into statement is used when the number of the res ult records is less than one as follows.

```
EXEC SQL
    SELECT ename, job, sal
    INTO :emp_name, :job_title, :salary
    FROM emp
    WHERE empno = :emp_number;
```

Several records can be retrieved by using select into statement when using host array. For more information about host array, refer to **Host Array**.

Insert Statement

The insert statement is used to insert rows into a table. The column value can be determined by using the host variable, and NULL can be inserted by using an indicator.

The following is an example of the insert statement.

```
EXEC SQL
    INSERT INTO EMP ( empno, ename, job, sal )
    VALUES ( :emp_number, :emp_name, :job_name :job_ind, :saraly );
EXEC SQL
    INSERT INTO DEPT ( deptno, dname, loc )
    VALUES ( 1, :dept_name, NULL );
```

When using host structure, data can be inserted in structure units instead of individually using h ost variable.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;

rsRecord  sInsertRec;
EXEC SQL END DECLARE SECTION;

sInsertRec.mEmpNo = 3000;
strcpy( sInsertRec.mEName.arr, "John" );
```

```
sInsertRec.mEName.len = strlen( sInsertRec.mEName.arr );
strcpy( sInsertRec.mJob , "RND" );
sInsertRec.mSalary = 3500;

EXEC SQL INSERT INTO EMP ( empno, ename, job, sal ) VALUES ( :sInsertRec );
```

Multiple rows can be inserted by using host array at once. For more information, refer to **Host Array**.

Update Statement

The update statement is used to update the column values of the specific rows in a table. The column value can be determined by using the host variable, and NULL can be inserted by using an indicator.
The following is an example of the update statement.

```
EXEC SQL
    UPDATE emp
    SET sal = :salary, deptno = :dept_number :deptno_ind
    WHERE empno = :emp_number;
```

Multiple rows can be updated by using host array at once. For more information, refer to **Host Array**.

Delete Statement

The delete statement removes the specific rows from a table.
The following is an example of the delete statement.

```
EXEC SQL
    DELETE FROM emp
    WHERE empno = :emp_number;
```

Multiple rows can be deleted by using host array at once. For more information, refer to **Host Array**.

PSM Statement

PSM statement creates a procedure or a function within a server and uses it.
For more information about PSM, refer to **PSM manual**.

Generally, it starts with EXEC SQL EXECUTE and ends with END-EXEC;. However, when creating a procedure or a function, EXEC SQL is used instead of EXEC SQL EXECUTE.

The following is an example of a statement creating and calling a procedure.

```
EXEC SQL
    CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 INTEGER )
      IS
        V1 INTEGER;
      BEGIN
        SELECT COUNT(*)
          INTO V1
          FROM T1
          WHERE T1.I1 >= A1 AND T1.I1 <= A2;
        DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
      END;
END-EXEC;
EXEC SQL CALL PROC1( 2, 4 );
```

The following is an example of a statement creating and calling a function.

```
EXEC SQL BEGIN DECLARE SECTION;
    int         sV1 = 0;
EXEC SQL END DECLARE SECTION;
EXEC SQL
    CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
      RETURN INTEGER
      IS
        V1 INTEGER;
      BEGIN
        SELECT COUNT(*)
          INTO V1
          FROM T1
          WHERE T1.I1 >= A1 AND T1.I1 <= A2;
        RETURN V1;
      END;
END-EXEC;
EXEC SQL CALL FUNC1( 2, 4 ) INTO :sV1;
```

The following is an example of an anonymous block statement.

```
EXEC SQL EXECUTE
    DECLARE
      V1 INTEGER := 0;
      FUNCTION FUNC1( A1 INTEGER )
        RETURN INTEGER
        IS
        BEGIN
          RETURN A1 * 10;
        END;
    BEGIN
      V1 := FUNC1( 10 );
      DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    END;
END-EXEC;
```

```
EXEC SQL EXECUTE
    DECLARE
      PROCEDURE PROC1( A1 INTEGER )
      IS
      BEGIN
        DBMS_OUTPUT.PUT_LINE( 'A1 = ' || A1 );
      END;
    BEGIN
      PROC1( 100 );
    END;
END-EXEC;
```

Cursor

The application executes the query to retrieve data from GOLDILOCKS. Generally, the cursor is used beca use the number of rows retrieved are not known when executing the query. The cursor is an identifier wh ich specifies the position of the current row in the query result set. The cursor can be manipulated via the following operations.

Declare Cursor

It declares a cursor. The cursor name and its query should be specified. The declared cursor name is used for different cursor manipulation commands later.

The following is an example of the cursor declaration.

```
EXEC SQL
    DECLARE RECORD_CUR1 CURSOR FOR
    SELECT   empno, ename, dept
    FROM     SEMP
    ORDER BY empno;
```

The cursor name is an identifier recognized and used by the precompiler, and it has nothing to do with th e variable of C program. The scope of the cursor is a file. Therefore, even when the cursor with the same name is defined in another file, it is considered as a separate cursor. In other words, all statements which perform the operations such as declare/ open/ fetch/ close of the cursor should exist on a single source fil e.

Open Cursor

It opens a cursor.

```
EXEC SQL OPEN <cursor_name>;
Example)
EXEC SQL OPEN EMP_CURSOR;
```

If the cursor is opened, it is prepared to fetch the result set which the query of the declared cursor is exec uted. However, it does not actually fetch the result. **Fetch Cursor** should be performed to actually fetch th e data.
The host variable which is used when executing the query does not affect the result set until the current c ursor is closed.

```
EXEC SQL DECLARE EMP_CURSOR CURSOR FOR
        SELECT    empno, ename, dept
        FROM      EMP
        WHERE     empno < :sNo
        ORDER BY  empno;

    sNo = 100;
    EXEC SQL OPEN EMP_CURSOR;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    while( 1 )
    {
        sNo = 10;
```

```
        EXEC SQL FETCH EMP_CURSOR INTO :emp_number, :emp_name, :dept_name;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            goto fail_exit;
        }
        ...
    }
```

In the example above, even if the cursor is opened with sNo = 100 and sNo is changed during the proces sing, it does not affect the result set until the cursor is closed.

Fetch Cursor

It fetches the row at the cursor position.

```
EXEC SQL FETCH <cursor_name> INTO <host_variable_list>;
Example)
EXEC SQL FETCH EMP_CURSOR INTO :emp_number, :emp_name, :dept_name;
```

The cursor should be declared first for FETCH operation, and it should be open. If FETCH is performed for the first time, the cursor moves to the first row of the result set and specifies it as a current row. Then, it f etches the current row into the host variable of INTO clause and returns. After then, if FETCH is repeatedl y performed, the cursor updates the current row to the next row, and then it repeatedly fetches the curre nt row into the host variable of INTO clause and returns. If the result does not exist even after performing FETCH, SQL_NO_DATA code is returned in sqlca.sqlcode, and the application checks this code to determi ne whether this operation is terminated.

Close Cursor

It closes a cursor.

```
EXEC SQL CLOSE <cursor_name>;
Example)
EXEC SQL CLOSE EMP_CURSOR;
```

The cursor should already be open to close it. The FETCH can not be performed in this cursor after closing the cursor. If the cursor is opened to use it again after it is close, then it becomes a new cursor. Therefore, the result set of the new cursor may be different from the result set of the previously closed cursor.

Reusing Cursor

The cursor name which was already declared is repeatedly reusable. This paragraph describes the sequence to reuse the same cursor name.

Sequence of Cursor Statement

- DECLARE CURSOR
  It can be performed after performing cursor CLOSE, COMMIT and ROLLBACK statements.
- OPEN
  It can be performed when the cursor is completely fetched or after performing CLOSE statement.
- FETCH
  It can be performed after performing cursor OPEN statement.
- CLOSE
  It can be performed after performing cursor OPEN statement or FETCH statement.

Cursor Statement and Host Variable

Cursor statement can be located in any place within a file. However, the usage of the cursor statement varies depending on whether the input host variable used in DECLARE statement is a global variable or a local variable.

- If the input host variable used in DECLARE statement is a local variable, then OPEN statement should be located in the function where DECLARE statement is located.
- If the input host variable used in DECLARE statement is a global variable, then OPEN statement can be located in the function which is different from where DECLARE statement is located.
- If the input host variable does not exist in DECLARE statement, then OPEN statement can be located in the function which is different from where DECLARE statement is located.

The reason is that the pointer of the host variable used in cursor declare statement is implicitly stored, and the pointer is used in cursor open statement, so if two statements are located in different functions and used host variables are local variables, then open statement refers to the invalid pointer. Therefore, it is recommended to locate both declare statement and open statement within the same function.

Example of Using Cursor

The following is an example of using DDL, DML and cursor.

```
/*
 * overview.gc
 *
 * Connect / Disconnect
 * DDL(Create/Drop table)
```

```
 * Basic DML(Insert, Delete, Update)
 * Standing Cursor
 */
EXEC SQL INCLUDE SQLCA;

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

#define  SUCCESS  0
#define  FAILURE  -1
#define  PRINT_SQL_ERROR(aMsg)                                          \
    {                                                                   \
        printf("\n");                                                   \
        printf(aMsg);                                                   \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
               sqlca.sqlcode,                                           \
               SQLSTATE,                                                \
               sqlca.sqlerrm.sqlerrmc );                                \
    }

EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsEmpRecord
{
    int      mEmpNo;
    char     mEName[20];
    char     mDept[10];
} rsEmpRecord;

rsEmpRecord gRecord[10] = {
    { 1, "Park", "RND" },
    { 2, "Kim", "CEO" },
    { 3, "Choi", "SALES" },
    { 4, "Lee", "CTO" },
    { 5, "Lyu", "RND" },
    { 6, "Ohn", "SUPPORT" },
    { 7, "Cheon", "RND" },
    { 8, "Sohn", "SALES" },
    { 9, "Smith", "WAIT" },
    { 10, "mycomman", "WAIT" }
};
```

```

    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");

    return FAILURE;
}
```

Cursor Property

The previous chapter described only the most basic cursor. However, the cursor may have various properti es, and it can perform various functions depending on the properties. An embedded SQL of GOLDILOCKS provides the cursor properties provided in ISO/IEC-9075-2 SQL Foundation and ODBC.
For more information about the cursor definition syntax and the property, refer to **DECLARE cursor_name** .

Scrollable Cursor

SCROLL is the cursor property of ISO type, and it determines whether the cursor is scrollable. The scrollabl e cursor can receive the position option in the FETCH statement, and the row at the position according to this option is fetched. If scrolling is impossible, it can FETCH only the row in the result set sequentially.

When declaring the scroll cursor, SCROLL option is used. The following is an example of the declaration.

```
EXEC SQL DECLARE cur_scroll SCROLL CURSOR FOR SELECT c1, c2 FROM t1;
```

With NO SCROLL option, the cursor which is unable to scroll is declared. When the scroll option is not given, the default value is NO SCROLL.
For the scrollable cursor, it is possible to specify the position information when fetching. This position information is called as fetch orientation, and it is as follows.

Table 33-13 Fetch orientation

Fetch orientation	Description
NEXT	It fetches the next row of the current position.
PRIOR	It fetches the previous row of the current position.
FIRST	It fetches the first row in the result set.
LAST	It fetches the last row in the result set.
CURRENT	It fetches the row of the current position.
ABSOLUTE <position>	• It fetches the row corresponding to *position* in the result set. • If the position value is a negative number, it fetches the row of the previous position from AFTER THE LAST ROW.
RELATIVE <position>	It fetches the row which is away as much as *position* from the current position.

If fetch orientation is ABSOLUTE or RELATIVE, the value of <position> is additionally required. The value of <position> may be an integer literal or the host variable of the integer type. The following is an example of fetch orientation.

```
EXEC SQL FETCH NEXT;
EXEC SQL FETCH PRIOR;
EXEC SQL FETCH FIRST;
EXEC SQL FETCH LAST;
EXEC SQL FETCH CURRENT;
EXEC SQL FETCH ABSOLUTE 100;
EXEC SQL FETCH RELATIVE :position;
```

Sensitive Cursor

Sensitivity is the cursor property of ISO type, and it determines whether the changes can be displayed if the result set is changed during the cursor operation. Sensitivity has the following three options.

Table 33-14 Sensitivity

Option	Description
SENSITIVE	The information which is deleted or updated in another transaction can be viewed
INSENSITIVE	The information which is deleted or updated after the cursor is opened can not be viewed.
ASENSITIVE	SENSITIVE/ INSENSITIVE is selected according to information of query.

If sensitive option is not specified, the default value is INSENSITIVE, and the cursor with the sensitive optio

n is declared as follows.

```
EXEC SQL DECLARE <cur_name> SENSITIVE CURSOR FOR SELECT c1, c2 FROM t1;
EXEC SQL DECLARE <cur_name> INSENSITIVE CURSOR FOR SELECT c1, c2 FROM t1;
EXEC SQL DECLARE <cur_name> ASENSITIVE CURSOR FOR SELECT c1, c2 FROM t1;
```

Holdable Cursor

Holdability is the cursor property of ISO type, and it determines whether the cursor is still held even after t he transaction which opened the current cursor is committed. Holdability has the following two options.

Table 33-15 Holdability

Option	Description
WITH HOLD	• The cursor is held even after the end of the transaction. • It can not be used with FOR UPDATE clause. • It can not be used with INSERT INTO ... RETURNING statement. • It can not be used with UPDATE ... RETURNING statement. • It can not be used with DELETE FROM ... RETURNING statement. • It can not be used in the query including the global temporary table whose table commit action is ON COMMIT DELETE ROWS.
WITHOUT HOLD	The cursor is closed when COMMIT/ ROLLBACK the transaction.
Rollback and cursor	• It closes a cursor which is included in a transaction when rolling back the transac tion. • It closes a cursor which is created after the savepoint when rolling back the trans action to the savepoint.

If holdable option is not specified, the default value is determined according to <cursor updatability>.

- If FOR READ ONLY or <cursor updatability> is not specified, it is WITH HOLD.
- If it is used with FOR UPDATE statement, it is WITHOUT HOLD.

The cursor using holdable option is declared as follows.

```
EXEC SQL DECLARE <cur_name> CURSOR WITH HOLD FOR SELECT c1, c2 FROM t1;
EXEC SQL DECLARE <cur_name> CURSOR WITHOUT HOLD FOR SELECT c1, c2 FROM t1 FOR UPDATE;
```

Static Cursor

Static cursor is the cursor property of ODBC type, and it is as same as INSENSITIVE SCROLL cursor of ISO t ype.

```
EXEC SQL DECLARE cur_static STATIC CURSOR FOR SELECT c1, c2 FROM t1;
```

For more information about how to fetch the static cursor, refer to **Scrollable Cursor**.

Keyset Driven Cursor

Keyset driven cursor is the cursor property of ODBC type, it is as same as SENSITIVE SCROLL cursor of ISO type.

```
EXEC SQL DECLARE cur_static KEYSET CURSOR FOR SELECT c1, c2 FROM t1;
```

Keyset driven cursor also has the scroll feature, so for more information about how to fetch, refer to **Scrol lable Cursor**.

Positioned DML

Positioned DML refers that delete or update statement can be executed for the finally fetched row using CURRENT OF <cursor_name> clause. The cursor should be open and point to the row by performing the F etch at least once to execute the positioned DML.

The following is an example of executing the positioned DML.

```
EXEC SQL DECLARE emp_cursor CURSOR FOR
     SELECT ename, sal FROM emp WHERE job = 'SALES'
     FOR UPDATE;
...
EXEC SQL OPEN emp_cursor;
EXEC SQL WHENEVER NOT FOUND GOTO ...
while( 1 )
{
    EXEC SQL FETCH emp_cursor INTO :emp_name, :salary;
    ...
    EXEC SQL UPDATE emp SET sal = :new_salary
         WHERE CURRENT OF emp_cursor;
}
```

Options

This chapter describes the applicable options when an embedded SQL source code is precompiled.

Precompiled Header File

When developing the embedded SQL program, it is efficient that the information referenced in common by multiple source codes is stored in the separated header file and the header file is included in the sourc

e code. C language supports this feature by using #include statement. However, when the header file is i ncluded by using #include of C language the target file is not precompliled but it is interpreted by the co mpiler of C language, so the declare section within the file is not converted by the precompliler.

EXEC SQL INCLUDE statement is used to convert and insert this header file into the source code by the pr ecompiler when creating the header file. The syntax is as follows.

```
EXEC SQL INCLUDE <filename>;
```

The statement above precompiles the given file and inserts it into the source code.

Specifying Header File Path

Generally, it preferentially searches for the directory in which the current source code is stored when sear ching for the header file. However, header files are often separately stored in many cases or they exist in other paths for many reasons.

In this case, the directory searching for the header file is given separately as an option, and the syntax is a s follows.

```
EXEC SQL OPTION( INCLUDE = <directory path> );
```

Several options can be listed and the directories are searched in the order given by the options when sear ching for the header file via EXEC SQL INCLUDE.

This option can be given via command-line option of precompiler. For more information, refer t o **--include-path, -I** of **Precompiler Options**.

Host Array

So far, only the scalar variables having only a single value as the host variable were described. This chapte r describes how to use the array with the host variable.
When using the host array, the program source code becomes simple, and the performance is improved, but It should be used carefully because there are restrictions.

Declaring Host Array

Declaration of the host array is as same as the declaration of the scalar variable. A variable is required onl y to be declared as an array itself. The following is an example of declaring the host array with its size 10.

```
EXEC SQL BEGIN DECLARE SECTION;
    int    empno[10];
    char   ename[10][20];
    double salary[10];
EXEC SQL END DECLARE SECTION;
```

The host array declaration has the following limitations.

- More than two-dimensional array is not allowed.
- Exceptionally, the string family (char, varchar) and binary family (binary, varbinary) can be used as the two-dimensional array because their array consists of an array subscript representing the array size an d data size.
- An array of pointer is not allowed.

Using Host Array

Accessing Host Array

How to use the host array in the SQL statement is as same as to use the scalar host variable.
The following is a simple example of the host array.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

The example above has the same feature as the following code.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
```

```
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
for( i = 0; i < 20; i ++ )
{
    EXEC SQL INSERT INTO emp (empno, ename, deptno)
        VALUES (:emp_number[i], :emp_name[i], :dept_number[i]);
}
```

When using several host variable arrays, the operation is performed for the array with the smallest array size among the host arrays. In the example above, 20 rows are inserted because the size of every host variable is 20. However, 10 rows are inserted as a result in the example below, if the array size of dept_number is specified as 10.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[10];
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

Using Host Indicator Array

If the host variable is an array, the indicator variable to be combined to it should also be an array. Also, the indicator variable and the host variable should have the same array size. The following is an example of adding the indicator variable to the example above.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
int    emp_number_ind[20];
```

```
char   emp_name[20][10];
int    emp_name_ind[20];
int    dept_number[20];
int      dept_number_ind[20];
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number
- Setting each indicator value of emp_number_ind, emp_name_ind, dept_number_ind

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number :emp_number_ind,
            :emp_name :emp_name_ind,
            :dept_number :dept_number_ind);
```

Restrictions

- When using several host variables, it is not allowed to use a mixture of scalar variables and array varia bles.
- The host array can not be used in WHERE clause of the select statement.
- The host array can not be used in CURRENT OF clause of the update, delete statements.

Array in INTO Clause

In GOLDILOCKS, rows are fetched by using SELECT INTO statement or cursor. An embedded SQL uses INT O clause in common for both two methods. Multiple rows are fetched by using the host array in INTO cla use.

Array in SELECT INTO

If the number of rows to be fetched is explicitly known, it is implemented by using the host array in **Select Into Statement**. Only the case of when row does not exist or a single row is fetched is described in **Select I nto Statement**. However, multiple rows can be fetched by using the host array in it.

The usage is as same as using scalar variables, but the Select Into statement with the array can be created just by declaring the host variable with the array.

```
EXEC SQL BEGIN DECLARE SECTION;
char   emp_name[50][20];
int    emp_number[50];
```

```
float  salary[50];
EXEC SQL END DECLARE SECTION;

EXEC SQL SELECT ENAME, EMPNO, SAL
    INTO :emp_name, :emp_number, :salary
    FROM EMP
    WHERE SAL > 1000;
```

In the example above, SELECT INTO statement is used to fetch 50 rows by declaring the host variable wit h an array. This statement fetches only the first 50 rows which meet the query criteria because it is an ind ependent execution unit.

Even if more than 50 rows meet the query criteria, it can not fetch the rear rows starting from t he 51th row by using the SELECT INTO statement. Cursor should be used when continuously fet ching rows.

Array When Using Cursor

If the number of rows in the result set is unknown for the current query, the cursor should be used. For m ore information about how to use the cursor, refer to **Cursor**. After declaring the cursor, multiple rows ca n be fetched at once by using the host variable of INTO clause as an array in FETCH statement.

```
EXEC SQL BEGIN DECLARE SECTION;
    int   emp_number[50];
    char  emp_name[50][20];
    char  dept_name[50][20];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE EMP_CURSOR CURSOR FOR
        SELECT    empno, ename, dept
        FROM      EMP
        WHERE     empno < :sNo
        ORDER BY  empno;

    sNo = 100;
    EXEC SQL OPEN EMP_CURSOR;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
```

```
    while( 1 )
    {
        EXEC SQL FETCH EMP_CURSOR INTO :emp_number, :emp_name, :dept_name;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            goto fail_exit;
        }
        ...
    }
```

50 rows can be fetched at once by using the host array in FETCH statement.

sqlca.sqlerrd[2]

The rows are fetched as many as the declared array size when using an array, but sometimes it can not fe tch as many as the declared array size because there is not a row any more. For example, if the array size i s declared as 50 and the number of rows in the result set are 30, then only 30 rows can be fetched. To so lve this problem, an embedded SQL of GOLDILOCKS provides information about the number of rows pro cessed by the current statement in sqlca.sqlerrd[2].
The number of rows processed in INSERT, UPDATE, DELETE, SELECT INTO, FETCH statements are returne d in sqlca.sqlerrd[2].

```
EXEC SQL BEGIN DECLARE SECTION;
    int   emp_number[50];
    char  emp_name[50][20];
    char  dept_name[50][20];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE EMP_CURSOR CURSOR FOR
        SELECT    empno, ename, dept
        FROM      EMP
        WHERE     empno < :sNo
        ORDER BY  empno;

    sNo = 100;
    EXEC SQL OPEN EMP_CURSOR;
    if(sqlca.sqlcode != 0)
    {
```

```
        goto fail_exit;
    }

    while( 1 )
    {
        EXEC SQL FETCH EMP_CURSOR INTO :emp_number, :emp_name, :dept_name;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            goto fail_exit;
        }

        for( i = 0; i < sqlca.sqlerrd[2]; i ++ )
        {
            printf( "%d %s %s\n", emp_number[i], emp_name[i], dept_name[i] );
        }
        ...
    }
```

For more information about sqlca, refer to **Handling Run-time Errors**.

Array in Insert Statement

If the host variable is declared as an array in INSERT statement, the array insert is implemented.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

The example above has the same feature as the following code.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
for( i = 0; i < 20; i ++ )
{
    EXEC SQL INSERT INTO emp (empno, ename, deptno)
        VALUES (:emp_number[i], :emp_name[i], :dept_number[i]);
}
```

- When using the array insert, all host variables should be array variables or all of them should be scalar variables.
- The number of inserted rows can be checked by using sqlca.sqlerrd[2].

Atomic Insert

Atomic insert is a special form of the array insert, and it has the following two characteristics.

- If any of the rows to be inserted is failed, the entire insert operation fails.
- The performance is outstanding because the command is transferred only once from the application t o GOLDILOCKS.

ATOMIC keyword is used for the atomic insert as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
```

```
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL ATOMIC INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

Array in Update Statement

The following is an example of using the array in update statement.

```
EXEC SQL BEGIN DECLARE SECTION;
char  job_title [10][20];
float commission[10];
EXEC SQL END DECLARE SECTION;

...

EXEC SQL UPDATE emp SET comm = :commission
    WHERE job = :job_title;
```

The example above has the same feature as the following code.

```
EXEC SQL BEGIN DECLARE SECTION;
char  job_title [10][20];
float commission[10];
EXEC SQL END DECLARE SECTION;

...
for( i = 0; i < 10; i ++ )
{
    EXEC SQL UPDATE emp SET comm = :commission[i]
        WHERE job = :job_title[i];
}
```

- When using the array update, all host variables should be array variables or all of them shou ld be scalar variables.

- The number of updated rows can be checked by using sqlca.sqlerrd[2].
- Array can not be used in CURRENT OF clause of UPDATE statement.

Array in Delete Statement

Array can be used in DELETE statement as follows.

```
EXEC SQL BEGIN DECLARE SECTION;
char job_title[10][20];
EXEC SQL BEGIN DECLARE SECTION;
...
EXEC SQL DELETE FROM emp
    WHERE job = :job_title;
```

The example above has the same feature as the following code.

```
EXEC SQL BEGIN DECLARE SECTION;
char job_title[10][20];
EXEC SQL BEGIN DECLARE SECTION;
...
for( i = 0; i < 10; i ++ )
{
    EXEC SQL DELETE FROM emp
        WHERE job = :job_title[i];
}
```

- When using the array delete, all host variables should be array variables or all of them shoul d be scalar variables.
- The number of deleted rows can be checked by using sqlca.sqlerrd[2].
- Array can not be used in CURRENT OF clause of DELETE statement.

Using FOR Clause

FOR clause is used to specify the array size when executing the SQL statement. FOR clause can be used in the following statements.

- SELECT INTO
- FETCH
- INSERT
- UPDATE

- DELETE

For clause can be used as follows.

```
EXEC SQL FOR :host_variable <sql_stmt>
EXEC SQL FOR <integer_constant> <sql_stmt>
```

The following is an example of using the for clause.

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
int      record_cnt;
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
record_cnt = 10;
EXEC SQL FOR :record_cnt INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

In the example above, the actual number of inserted rows are 10 because the size of the host array is give n as 20 but it is specified to perform as much as record_cnt by using the FOR clause.

FOR clause can not be used with CURRENT OF clause in UPDATE/ DELETE statements.

Structure Array

Using the general scalar variables as an array has the advantage of processing multiple rows at once, but i t has a limit that a variable can represent only a single column.
For more information about how to process multiple columns with a single host variable, refer to **Host Str ucture**. Multiple rows with multiple columns can be processed at once by declaring a host variable as a str ucture and using the structure as the array.

A structure array can be used in the following cases.

- Output host variable array: SELECT INTO, FETCH INTO statements
- Input host variable array: VALUES item of INSERT statement

Restrictions

A structure array can not be used in the following cases.

- It can not be used in WHERE clause or FROM clause.
- It can not be used in SET clause of UPDATE statement.

Declaring Structure Array

A structure is declared in an way of a common C language structure declaration. A structural variable can be directly declared, or it can be declared as a host variable after declaring type via typedef.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;
rsRecord     sRecord[10];

struct {
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20 + 1];
    long         mSalary;
} sResultRecord[10];
EXEC SQL END DECLARE SECTION;
```

When declaring the structure for using the host variable, the nested structure can not be used. If another structure is inside the structure declaration as follows, it can not be used as a host variable.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsRecord
{
    struct person {
        int          mEmpNo;
        varchar      mEName[20 + 1];
    } person;
```

```
    char         mJob[20 + 1];
    long         mSalary;
} rsRecord;
EXEC SQL END DECLARE SECTION;
```

Indicators of Structure Array

As described in **Structure Indicator**, if a host variable is the structure, the Indicator variable should also be the structure. For the same reason, if the host variable is the structure array, the indicator variable should also be the corresponding structure array.

The declaration of the Indicator structure array should comply with the followings.

- It should have the number of members as many as the host variable structure to be combined by the i ndicator.
- All members of the Indicator structure should have a integer data type.
- The size of the indicator structure array should be as same as that of the host variable structure array. If size of the Indicator structure array is smaller, the number of array executions should be limited by using FOR clause when executing SQL statement.

Mixed Use of Structure and Scalar Variable

When the host structure is transferred to GOLDILOCKS, its structure members are sequentially listed. The following is an example of mixed use of the host structure and the scalar variable.

```
EXEC SQL BEGIN DECLARE SECTION;
    typedef struct rsEmp
    {
        int          mEmpNo;
        varchar      mEName[20 + 1];
    } rsEmp;
    rsEmp     sEmp[5];
    char      sJob[5][20 + 1];
    long      sSalary[5];
EXEC SQL END DECLARE SECTION;

EXEC SQL
    DECLARE EMP_CUR CURSOR FOR
    SELECT empno, ename, job, sal
    FROM   EMP
    ORDER BY EMPNO;
EXEC SQL OPEN EMP_CUR;
```

```
EXEC SQL
    FETCH EMP_CUR
    INTO  :sEmp, :sJob, :sSalary;
```

The structure rsEmp and the scalar variables sJob, sSalary are used together in FETCH statement. This stat ement is internally interpreted as four variables sEmp.mEmpNo, sEmp.mEName, sJob and sSalary. The ho st structure and the host scalar variable can be used together in this way.

The following is an example of mixed use of the host structure array, structure array indicator, structure a nd scalar variable.

```
/*
 * fetch_struct_array.gc
 *  : structure array fetch
 *  : structure indicators
 *  : mix structure, scalar variable
 *  : sqlca.sqlerrd[2]
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1

#define  PRINT_SQL_ERROR(aMsg)                                  \
    {                                                           \
        printf("\n");                                           \
        printf(aMsg);                                           \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
               sqlca.sqlcode,                                   \
               SQLSTATE,                                        \
               sqlca.sqlerrm.sqlerrmc );                        \
    }
EXEC SQL BEGIN DECLARE SECTION;
typedef struct rsEmp
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
```

```
} rsEmp;
EXEC SQL END DECLARE SECTION;

int Connect(char *aHostInfo, char *aUserID, char *sPassword);

int main(int argc, char **argv)
{
    EXEC SQL BEGIN DECLARE SECTION;
    rsEmp     sEmp[5];
    char      sJob[5][20 + 1];
    long      sSalary[5];
    EXEC SQL END DECLARE SECTION;
    int  sRecordCount = 0;
    int  i;

    printf("Connect GOLDILOCKS ...\n");
    if(Connect("DSN=GOLDILOCKS", "test", "test") != SUCCESS)
    {
        goto fail_exit;
    }
```

- Retrieve employee

```
EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP
        ORDER BY EMPNO;

    EXEC SQL OPEN EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }

    printf(" EMPNO    ENAME                JOB       SALARY\n");
    printf("====== ==================== ========== ========\n");

    while( 1 )
    {
```

```
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sEmp, :sJob, :sSalary;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
            goto fail_exit;
        }

        sRecordCount += sqlca.sqlerrd[2];

        for( i = 0; i < sqlca.sqlerrd[2]; i ++ )
        {
            printf("%6d %20s %10s %8ld\n",
                   sEmp[i].mEmpNo, sEmp[i].mEName.arr, sJob[i], sSalary[i]);
        }
    }
    printf("====== ==================== ========== ========\n");
    printf("Record Count = %d\n", sRecordCount);
    printf("====== ==================== ========== ========\n");

    EXEC SQL CLOSE EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }

    EXEC SQL COMMIT WORK RELEASE;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }

    printf("\n\nSUCCESS\n");
    printf("############################\n");
```

```
    return 0;

  fail_exit:

    printf("\n\nFAILURE\n");
    printf("############################\n\n");

    EXEC SQL ROLLBACK WORK RELEASE;

    return 0;
}

int Connect(char *aHostInfo, char *aUserID, char *sPassword)
{
    EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR  sUid[80];
    VARCHAR  sPwd[20];
    VARCHAR  sConnStr[1024];
    EXEC SQL END DECLARE SECTION;
```

- Log on GOLDILOCKS

```
strcpy((char *)sUid.arr, aUserID);
sUid.len = (short)strlen((char *)sUid.arr);
strcpy((char *)sPwd.arr, sPassword);
sPwd.len = (short)strlen((char *)sPwd.arr);
strcpy((char *)sConnStr.arr, aHostInfo);
sConnStr.len = (short)strlen((char *)sConnStr.arr);
```

- DB connection

```
EXEC SQL CONNECT :sUid IDENTIFIED BY :sPwd USING :sConnStr;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    return SUCCESS;

  fail_exit:
```

```
    PRINT_SQL_ERROR("[ERROR] Connection Failure!");

    return FAILURE;
}
```

Handling Run-time Errors

Overview

In case when the application can not get the expected result during execution, a preparation is required f or this case when developing an embedded SQL application. This chapter explains how to detect the resu lts returned after the SQL execution.

Detecting Run-time Error

SQLCA

All types of errors which occur in an embedded SQL are reported in the area called as SQL Communicatio n Area (SQLCA). Therefore, the application can identify the success of the current operation and the error type by checking the information of SQLCA.

SQLCA is a data structure which stores errors, warnings, SQL statement execution states. SQLCA will only have the results of the last SQL execution which the data structure is combined, but it does not have infor mation about the history of executed SQL statement. If an embedded SQL statement is executed, the exis ting contents of SQLCA disappears. Therefore, it is necessary to immediately check SQLCA and to perfor m the exception handling after executing the SQL statement.

Using SQLCA

The following syntax is used to use SQLCA.

```
EXEC SQL INCLUDE SQLCA;
```

The syntax above is replaced with the following statement in the precompile process.

```
#include "sqlca.h"
```

This statement should be used before using the first embedded SQL statement, and it is typically recomm ended to be positioned at the top of the source code.

The embedded SQL application of GOLDILOCKS generally has a global sqlca. In a single thread program, s qlca can be used without any declaration. However, in multi thread program, sqlca is required to be decla

red separately because the simultaneous accesses to sqlca cause the concurrency problems. For more info rmation, refer to **Multithread Application**.

SQLCA Structure

The following describes the structure of sqlca.

```
struct sqlca
{
    char    sqlcaid[8];    ❶ It is initialized to the string SQLCA.
    int     sqlabc;        ❷ It is the size of sqlca structure.

    /*
     * ❸ It is the error code which occurred in the most recent statement execution.
     * ❹ If it is 0, it is successful. If it is a positive number, it is a warning. If it is
a negative number, it is an error.
     */
    int     sqlcode;

    /*
     * ❺ It stores the error message for sqlcode
     * ❻ .sqlerrml is the length of sqlerrmc.
     * ❼ .sqlerrmc stores the error message in a string form.
     */
    struct
    {
        unsigned short sqlerrml;
        char           sqlerrmc[SQLERRMC_LEN];
    } sqlerrm;

    char    sqlerrp[8];   /* unused                          */
    int     sqlerrd[6];
    /* 0: empty                                             */
    /* 1: empty                                             */
    /* 2: ❽ It is the number of rows processed after INSERT, UPDATE, DELETE.        */
    /* 3: empty                                             */
    /* 4: empty                                             */
    /* 5: empty                                             */
    char    sqlwarn[8];
    /* 0: ❾ If any warning occurs, it is 'W'.
     * 1: ❿ If the result string is truncated in SELECT, FETCH, it is 'W'.
     * 2: unused
```

```
     * 3: unused
     * 4: unused
     * 5: unused
     * 6: unused
     * 7: unused
     */
    char    sqlext[8];    /* unused                          */
    char    sqlstate[8];  /* SQLSTATE                        */
    unsigned short  *rowstatus;    /* fetched row status array*/
};
```

The next chapter describes the content of each component.

SQLCODE

SQLCODE is defined as follows.

```
#define SQLCODE          (sqlca.sqlcode)
```

SQLCODE executes an embedded SQL statement and then returns the result code. SQLCODE was proposed early in ISO/IEC-9075, but it is deprecated in SQL-92. However, it is provided for the backward compatibility because it is being used in many applications. The result code is as follows.

Table 33-16 Execution result of SQLCODE

SQLCODE	Result
0	Success
> 0	Warning
SQL_NO_DATA	No result
< 0	Error

sqlcode is checked as follows. sqlca.sqlcode or SQLCODE can be used.

```
EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;

    EXEC SQL OPEN EMP_CUR;
    if(SQLCODE != 0)
    {
        goto fail_exit;
    }
    while( 1 )
```

```
    {
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            goto fail_exit;
        }

        ...
    }
```

SQLSTATE

SQLSTATE is defined as follows.

```
#define SQLSTATE         (sqlca.sqlstate)
```

SQLCODE was deprecated in ISO/IEC-9075, and SQLSTATE is proposed instead. SQLSTATE consists of five characters(number, English uppercase alphabet), and the first two digits are called as class, and the rear 3 digits are called as subclass. The result of SQLSTATE are as follows.

Table 33-17 Execution result of SQLSTATE

SQLSTATE	Result
00000	Success
01xxx	Warning
02000	No result
All other states	Error

The code is modified by checking SQLSTATE instead of SQLCODE in the example above as follows. sqlca.sqlstate or SQLSTATE can be used.

```
EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;

    EXEC SQL OPEN EMP_CUR;
```

```
    if(strcmp(SQLSTATE, "00000") != 0)
    {
        goto fail_exit;
    }
    while( 1 )
    {
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
        if(strcmp(sqlca.sqlstate, "02000") == 0)
        {
            break;
        }
        else if(strcmp(sqlca.sqlstate, "00000") != 0)
        {
            goto fail_exit;
        }

        ...
    }
```

Number of Processed Rows

When executing update, delete statements or insert, select info, fetch statement using array, it informs a user the number of the processed rows. The information is stored in sqlca.sqlerrd[2]. The application refe rs to the field value and finds out the number of the processed rows. The following is an example of usin g sqlca.sqlerrd[2].

```
EXEC SQL BEGIN DECLARE SECTION;
    typedef struct rsEmp
    {
        int          mEmpNo;
        varchar      mEName[20 + 1];
    } rsEmp;
    rsEmp     sEmp[5];
    char      sJob[5][20 + 1];
    long      sSalary[5];
EXEC SQL END DECLARE SECTION;
    EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;
```

```
EXEC SQL OPEN EMP_CUR;
if(SQLCODE != 0)
{
    goto fail_exit;
}
while( 1 )
{
    EXEC SQL
        FETCH EMP_CUR
        INTO  :sEmpNo, :sEName, :sJob, :sSalary;
    if(sqlca.sqlcode == SQL_NO_DATA)
    {
        break;
    }
    else if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    sRecordCount += sqlca.sqlerrd[2];
    ...
}
```

sqlca.sqlerrd[2] value in fetch statement can be processed as the accumulated number of rows. For more information, refer to --**cumulative** of gpec(Precompiler) option.

Status of Processed Rows

sqlca.row status indicates the row status which is currently processed. When the row is updated or delete d by using the scroll sensitive cursor or Where CURRENT OF, then the row status can be updated. When using SQL statement with array, It has row status as many as the array size.

Table 33-18 Referring to the row status

Number of rows	Row status
1	*sqlca.rowstatus
Array size n	sqlca.rowstats[0] sqlca.rowstats[1] sqlca.rowstats[2] ... sqlca.rowstats[n-1]

Table 33-19 Value of row status

Row status	Description
SQL_ROW_SUCCESS	The row status is normal.
SQL_ROW_DELETED	The row is deleted.
SQL_ROW_UPDATED	The row is updated.
SQL_ROW_NOROW	The row does not exist.
SQL_ROW_ADDED	The row is added.
SQL_ROW_ERROR	The row status is not normal.

The following is an example of referring to the row status.

```
EXEC SQL BEGIN DECLARE SECTION;
    typedef struct rsEmp
    {
        int          mEmpNo;
        varchar      mEName[20 + 1];
    } rsEmp;
    rsEmp     sEmp[5];
    char      sJob[5][20 + 1];
    long      sSalary[5];
EXEC SQL END DECLARE SECTION;
    EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;

    EXEC SQL OPEN EMP_CUR;
    if(SQLCODE != 0)
    {
        goto fail_exit;
    }
    while( 1 )
    {
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
```

```
        {
            goto fail_exit;
        }

        sRecordCount += sqlca.sqlerrd[2];

        for( i = 0; i < sqlca.sqlerrd[2]; i ++ )
        {
            if( sqlca.rowstatus[i] == SQL_ROW_SUCCESS )
            {
                printf("%6d %20s %10s %8ld\n",
                       sEmp[i].mEmpNo, sEmp[i].mEName.arr, sJob[i], sSalary[i]);
            }
        }

        ...
    }
```

Error Message Text

When an error or warning occurs as a result of the embedded SQL statement, the message can be transf erred in a text form. The error message is stored in sqlca.sqlerrm, and sqlca.sqlerrm.sqlerrml is the length of the text. The actual message is stored in sqlca.sqlerrm.sqlerrmc. The error message text is useful to out put information to a user when anomalies occur in the application. The following is an example of using an error message text.

```
EXEC SQL INSERT INTO EMP VALUES ( :sEmp );
if( SQLCODE != 0 )
{
    printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",
           SQLCODE,
           SQLSTATE,
           sqlca.sqlerrm.sqlerrmc );
}
```

Warning Flags

When a waring occurs after executing the embedded SQL, sqlca.sqlwarn is used as the flag which marks the warning. It consists of eight char arrays, and the mark of 'W' is used when the warning occurs.

Table 33-20 Warning flags

Warning flag	Description
sqlca.sqlwarn[0]	If any warning occurs, it is 'W'.
sqlca.sqlwarn[1]	If the result string is truncated in select into, fetch, then it is 'W'.
sqlca.sqlwarn[2]	reserved
sqlca.sqlwarn[3]	reserved
sqlca.sqlwarn[4]	reserved
sqlca.sqlwarn[5]	reserved
sqlca.sqlwarn[6]	reserved
sqlca.sqlwarn[7]	reserved

Handling Implicit Error

After executing the embedded SQL statement, a user should check SQLCA and take action into the execution result. However, when treating the same exception occurs after executing the embedded SQL statement, it can be automated by using WHENEVER indicator.

Using WHENEVER Statement

WHENEVER statement has the following syntax.

```
EXEC SQL WHENEVER conditions actions;
```

WHENEVER Condition

Conditions of WHENEVER statement are as follows.

```
<conditions> ::=
      SQLERROR
    ¦ SQLWARNING
    ¦ NOT FOUND
    ¦ SQLSTATE <sqlstate class value>[<sqlstate subclass value>]
    ;

<sqlstate_char> ::= [0-9A-Z];
<sqlstate class value> ::= <sqlstate_char><sqlstate_char>;
<sqlstate subclass value> ::= <sqlstate_char><sqlstate_char><sqlstate_char>;
```

Table 33-21 Conditions of WHENEVER statement

Conditions	Descriptions
SQLERROR	An error occurs while an embedded SQL is executed.
SQLWARNING	A warning occurs while an embedded SQL is executed.

Conditions	Descriptions
NOT FOUND	A result row does not exist.
SQLSTATE <sqlstate>	SQLSTATE <sqlstate> occurs while an embedded SQL is executed.

WHENEVER Action

When actions meet the conditions described above, it describes the action actually performed, and its syn tax is as follows.

```
<actions> ::=
      CONTINUE
    ¦ GOTO <label>
    ¦ STOP
    ¦ DO <c statements>
    ;
```

Table 33-22 Actions of WHENEVER statement

Actions	Description
CONTINUE	An action is not performed. It ignores the given conditions.
GOTO <label>	It branches the program flow with <label>.
STOP	It terminates the program execution.
DO <c statements>	It executes <c statements>.

Scope of WHENEVER Statement

WHENEVER statement describes actions for conditions, and only one action can be described for one con dition. When using WHENEVER statement, the same action is used for all embedded SQL statements unti l the definition of another condition comes after the current condition.

Maximum four WHENEVER statements can be applied for a specific point because WHENEVER statement s are separately managed by each condition. If a new WHENEVER statement is applied for the same condi tion, the existing action is canceled and a new action may be applied afterwards. The following is an exa mple.

```
EXEC SQL WHENEVER SQLERROR STOP;
EXEC SQL INSERT INTO emp VALUES ( :emp_number, :emp_name, :salary ); ❶
...
EXEC SQL WHENEVER SQLERROR CONTINUE;
EXEC SQL UPDATE emp SET sal = sal * 1.1 WHERE sal < :sal_bound; ❷
...
EXEC SQL WHENEVER SQLERROR GOTO exit_label;
EXEC SQL WHENEVER NOT FOUND DO break;
```

```
EXEC SQL DECLARE EMP_CURSOR FOR
         SELECT empno, ename, sal
         FROM   emp;

EXEC SQL OPEN EMP_CURSOR; ❸

EXEC SQL WHENEVER SQLERROR GOTO close_label;
while( 1 )
{
    EXEC SQL FETCH EMP_CURSOR
              INTO   :emp_number, :emp_name, :salary; ❹

    printf( "emp number : %d, emp name : %s, salary : %lf\n",
            emp_number, emp_name, salary );
}
close_label:
EXEC SQL WHENEVER SQLERROR DO sql_error();
EXEC SQL CLOSE EMP_CURSOR; ❺
...
exit_label:
...
```

The application is stopped when an error occurs during executing ❶ because the stop operation is specified for SQLERROR in line 1. SQLERROR action is changed to proceed without performing any action because CONTINUE is indicated for SQLERROR in line 4 . Therefore, it proceeds to the next even when an error occurs during executing ❷. It branches to exit_label when an error occurs during executing ❸ because SQLERROR action is set to branch to exit_label in line 7. It is specified to perform break for NOT FOUND in line 8, and SQLERROR action is reassigned as close_label in line 15. Therefore, two conditions are applied to ❹. When an error occurs during FETCH, it branches to close_label, and if the FETCH result does not exist, then the break statement is executed. sql_error() function is called when an error occurs during executing ❺ because SQLERROR action is specified to execute sql_error() in line 26.

Notice for WHENEVER statement

WHENEVER statement should be used carefully after understanding the operation principle. The followings should be considered when using the WHENEVER statement.

- The position of WHENEVER statement on the source code: WHENEVER statement is an indicator which informs to automatically insert the exception handling code to precompiler, and it is not an logically executable code. WHENEVER should be at the beginning of the embedded SQL statements to be applied on the source code. CONTINUE action should be used to initialize not to affect the following embedded SQL.
- Using the break, continue keywords: If DO break, DO continue are used in an action clause, the loop

scope should be checked and used. The following is an example.

```
EXEC SQL WHENEVER SQLERROR GOTO fail_exit;
EXEC SQL WHENEVER NOT FOUND DO break; ❶
EXEC SQL DECLARE EMP_CURSOR FOR
         SELECT empno, ename, sal
         FROM   emp;

EXEC SQL OPEN EMP_CURSOR;
while( 1 )
{
    EXEC SQL FETCH EMP_CURSOR
             INTO   :emp_number, :emp_name, :salary;  ❷
    printf( "emp number : %d, emp name : %s, salary : %lf\n",
            emp_number, emp_name, salary );
}
EXEC SQL CLOSE EMP_CURSOR;

EXEC SQL
    SELECT MAX(sal)
    INTO   :max_salary
    FROM   emp;          ❸
...
```

break; may be performed for NOT FOUND in subsequent SQL statements because the action for NOT FOUND is defined as DO break; in ❶. When NOT FOUND occurs in ❷ during FETCH, break is performed and it exits the while loop. However, break can not be performed when NOT FOUND occurs in ❸ because it is not a loop. In this case, the compile error occurs when building the source program and developing the application

- Avoiding infinite loop

If it is misused when branching to the action, it causes the infinite loop. The following is an example.

```
EXEC SQL WHENEVER SQLERROR GOTO sql_error;
...
EXEC SQL INSERT INTO emp VALUES ( :emp_number, :emp_name, :salary );
...
sql_error:
    EXEC SQL ROLLBACK WORK RELEASE;
```

When an error occurs during executing the SQL statement, it branches to sql_error label. When an error

occurs during executing the embedded SQL statement, it branches to sql_error. However, when the error s repeatedly occurs during executing another embedded SQL statement in an error processing, the applic ation infinitely loops. In this case, the following is recommended to safely initialize the error handling.

```
EXEC SQL WHENEVER SQLERROR GOTO sql_error;
...
EXEC SQL INSERT INTO emp VALUES ( :emp_number, :emp_name, :salary );
...
sql_error:
    EXEC SQL WHENEVER SQLERROR CONTINUE;
    EXEC SQL ROLLBACK WORK RELEASE;
```

- Scope of branch label

If it is branched in an action, its label should be located in an accessible position. The following is an exa mple.

```
func1()
{

    EXEC SQL WHENEVER SQLERROR GOTO labelA;
    EXEC SQL DELETE FROM emp WHERE deptno = :dept_number;
    ...
labelA:
...
}
func2()
{

    EXEC SQL INSERT INTO emp (job) VALUES (:job_title);
    ...
}
```

In func1(), the branching the labelA is specified for SQLERROR. However, the complile error occurs becau se labelA exists in func1() but it does not exist in func2(). In this case, the same labelA should be created i n func2() or the action should be initilaized as follows.

```
func1()
{

    EXEC SQL WHENEVER SQLERROR GOTO labelA;
    EXEC SQL DELETE FROM emp WHERE deptno = :dept_number;
```

```
    ...
labelA:
...
}
func2()
{
    EXEC SQL WHENEVER SQLERROR CONTINUE;
    EXEC SQL INSERT INTO emp (job) VALUES (:job_title);
    ...
}
```

33.3 Advanced Topic

Embedded Dynamic SQL

Overview

Most of the embedded SQL applications perform the specific operations on GOLDILOCKS. They are to insert, update, delete, retrieve rows and they are specified by using the database language called as SQL. When SQL is directly specified on the embedded SQL source code for this purpose, the precompiler interpretes the SQL, and converts it to an API call available to GOLDILOCKS on the state of knowing all the given SQL and input/output host variables.

However, some applications do not know the SQL in advance when developing the applications. For example, if static SQL is used in an application such as GUI tool when the user wants to query by selecting the operation type, the table name, condition, the user should specify all SQL statement of possible combination in advance. However, it is impossible or it is very inefficient even when it is possible. In this case, if the user generates and executes the SQL statement with an user selectable option, it might be very flexible and efficient. The dynamic SQL is the SQL which is not defined on the source code in advance and is changed at run-time. GOLDILOCKS supports the embedded dynamic SQL feature.

The advantage of embedded dynamic SQL application provides more flexible usage compared to the static SQL, but the disadvantage is that the development of the source code is difficult and it has poor performance compared to the static SQL when performing the same query.

It is recommended to compare the static SQL and the dynamic SQL, then select one of them considering these features carefully when developing applications.

This chapter describes how to develop the embedded dynamic SQL program.

Dynamic SQL Types

The dynamic SQLs are classified according the usage as follows.

Table 33-23 Dynamic SQL type

Method	Description	Support
Method 1	It is a non-query and a host variable does not exist.	O
Method 2	It is a non-query and a host variable may know the number and type.	O
Method 3	It is a query and a host variable may know the number and type.	O
Method 4	It is a query, and the existence of host variable, the number and type are unknown.	X

Currently, GOLDILOCKS supports until the method 3.

Method 1

It is the simplest form of the dynamic SQL, and it is a non-query and can be used when a host variable do es not exist. Typically, it is used for the DDL or for the DML in which the host variable does not exist.

- EXECUTE IMMEDIATE

The SQL statement can be immediately executed because the method1 is a non-query and it does not ha ve the host variable at the same time. The syntax of the immediate execution of SQL is as follows.

```
EXEC SQL EXECUTE IMMEDIATE { :host_variable ¦ <string_literal> };
<string_literal> ::=
      ' <sql_statement> '
    ¦ " <sql_statement> "
    ¦ <sql_statement>
    ;
```

The method 1 is used as follows.

```
sprintf(sSqlStmt, "CREATE TABLE EMP_RND (\n"
            "EMPNO NUMBER(4) CONSTRAINT PK_EMP_RND PRIMARY KEY,\n"
            "ENAME VARCHAR2(10),\n"
            "JOB VARCHAR2(9),\n"
            "SAL NUMBER(7,2),\n"
            "DEPTNO NUMBER(2) )\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    sprintf(sSqlStmt, "INSERT INTO EMP_RND\n"
            "SELECT *\n"
            "FROM   EMP\n"
            "WHERE  JOB = 'RND'\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
```

Method 2

The method 2 is used for the non-query with an existence of input host variable. The number of input ho st Variables and the data type should be known, and it is performed through preparation step and the ex ecution step.

- Prepare

In the prepare step, the SQL statement is analyzed, and the name is given to this statement. The syntax of prepare is as follows.

```
EXEC SQL PREPARE <statement_name> FROM { :host_variable ¦ <string_literal> };
<string_literal> ::=
      ' <sql_statement> '
    ¦ " <sql_statement> "
    ¦ <sql_statement>
    ;
```

<statement_name> is an identifier notifying to the precompiler. It does not require a separate type or any declaration of a variable because it is not the host variable.

- Execute

The analyzed statement is executed in the execute step. The syntax of execute statement is as follows.

```
EXEC SQL EXECUTE <statement_name> [ USING <host_variable_list> ];
<host_variable_list> ::= <host_variable_entry> [ , <host_variable_list> ];
<host_variable_entry> ::= :host_variable [ [ INDICATOR ] :host_indicator ];
```

If an input host variable exist, USING clause is used. If the host variable does not exist, USING clause is om itted. It is bound to the host variable of the prepared SQL statement according to the sequence of host va riables in USING clause.

When the same SQL statements are repeatedly executed in method 2, execute may be repeatedly perfor med after performing prepare only once. The prepared statement is valid in the current source code until another SQL statement is prepared with the same statement name or it is disconnected.

Method 3

The method 3 is an extended form of the method 2 to support the query. The statements of declare, ope n, fetch, close are added for the cursor because generally a statement is analyzed in the query prepare pr ocess and the cursor should be handled for the query.

- Prepare

The prepare step analyzes the SQL statement as like the method 2, and gives the name to the statement. The syntax of prepare is as follows.

```
EXEC SQL PREPARE <statement_name> FROM { :host_variable ¦ <string_literal> };
<string_literal> ::=
      ' <sql_statement> '
    ¦ " <sql_statement> "
    ¦ <sql_statement>
    ;
```

<statement_name> is an identifier notifying to the precompiler. It does not require a separate type or any declaration of a variable because it is not the host variable.

- Declare cursor

Declare statement declares the cursor for the prepared statement. When declaring the cursor, the cursor property which is as same as the standing cursor can be used. The syntax is as follows.

```
EXEC SQL <dynamic declare cursor>;

<dynamic declare cursor> ::=
    DECLARE <cursor_name> <cursor properties> { FOR ¦ IS } <statement_name>
    ;
<cursor properties> ::=
      [ <cursor sensitivity> ] [ <cursor scrollability>] ] CURSOR [ <cursor holdability> ]
    ¦ [ <odbc cursor type] CURSOR [ <cursor holdability> ]
    ;
<cursor sensitivity> ::=
      INSENSITIVE
    ¦ SENSITIVE
    ¦ ASENSITIVE
    ;
<cursor scrollability> ::=
      NO SCROLL
    ¦ SCROLL
    ;
<cursor holdability> ::=
      WITH HOLD
    ¦ WITHOUT HOLD
    ;
<odbc cursor type> ::=
      STATIC
```

```
    ¦ KEYSET
    ;
```

The meaning and used name of <cursor properties> is as same as the standing cursor.

<statement_name> is the name specified in PREPARE statement. <cursor name> and <statement name> a re the identifiers notifying to the precompiler. It does not require a separate type or any declaration of a v ariable because it is not the host variable.

Only one cursor can be declared per one statement. If another cursor is declared when there is a cursor al ready declared in the statement, then the existing cursor is closed.

- Open cursor

It opens the cursor. It is generally same with the **Open Cursor** of the standing cursor, but there is a signific ant and typical difference in opening the dynamic cursor. The host variable is determined depending on t he declared SQL statement because the dynamic cursor updates and uses the SQL statement freely at the run-time. Therefore, when opening the dynamic cursor, it transfers the host variable by using the USING clause at the time of opening. The cursor should be closed at the time of opening the standing cursor, bu t the dynamic cursor is opened after closing the cursor.

Open syntax of dynamic cursor is as follows.

```
EXEC SQL <dynamic cursor open>;

<dynamic cursor open> ::=
    OPEN <cursor_name> [ USING <host_variable_list> ]
    ;

<host_variable_list> ::= <host_variable_entry> [ , <host_variable_list> ];
<host_variable_entry> ::= :host_variable [ [ INDICATOR ] :host_indicator ];
```

- Fetch cursor

It fetches from the cursor. Fetching dynamic cursor is as same as **fetching standing cursor**.

- Close cursor

It closes the cursor. Closing dynamic cursor is as same as **closing standing cursor**.

Example Program

The following is a sample program of using the dynamic method 1, 2, 3.

```
/*
 * dyn2.gc
 *  : dynamic method 1
 *  : dynamic method 2
 *  : dynamic method 3
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1
#define  PRINT_SQL_ERROR(aMsg)                                          \
    {                                                                   \
        printf("\n");                                                   \
        printf(aMsg);                                                   \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
               sqlca.sqlcode,                                           \
               SQLSTATE,                                                \
               sqlca.sqlerrm.sqlerrmc );                                \
    }

EXEC SQL BEGIN DECLARE SECTION;
typedef struct Record
{
    int          mEmpNo;
    varchar      mEName[20 + 1];
    char         mJob[20];
    char         mSalary[10];
} Record;
EXEC SQL END DECLARE SECTION;

int Connect(char *aHostInfo, char *aUserID, char *sPassword);
int CreateEmpTempTable();
int DropEmpTempTable();
int UpdateSalary(char *aJob, int aBound, double aRatio);

int main(int argc, char **argv)
{
```

```
    EXEC SQL BEGIN DECLARE SECTION;
    EXEC SQL END DECLARE SECTION;
    printf("Connect GOLDILOCKS ...\n");
    if(Connect("DSN=GOLDILOCKS", "test", "test") != SUCCESS)
    {
        goto fail_exit;
    }

    if(CreateEmpTempTable() != SUCCESS)
    {
        goto fail_exit;
    }
```

- Print RND employee increate 20% salary where salary < 2000

```
printf("print RND employee increate 20%% salary where salary < 2000\n");
UpdateSalary( "RND", 2000, 1.2 );
printf("\n\n");
```

- Print SUPPORT employee increate 10% salary where salary < 3000

```
printf("print SUPPORT employee increate 10%% salary where salary < 3000\n");
UpdateSalary( "SUPPORT", 3000, 1.1 );
printf("\n\n");

if(DropEmpTempTable() != SUCCESS)
{
     goto fail_exit;
}

printf("Disconnect GOLDILOCKS ...\n");
EXEC SQL COMMIT WORK RELEASE;
if(sqlca.sqlcode != 0)
{
    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    goto fail_exit;
}

printf("SUCCESS\n");
printf("############################\n");

return 0;
```

```
  fail_exit:

    printf("\n\nFAILURE\n");
    printf("############################\n\n");
    EXEC SQL ROLLBACK WORK RELEASE;

    return 0;
}

int Connect(char *aHostInfo, char *aUserID, char *sPassword)
{
    EXEC SQL BEGIN DECLARE SECTION;
    VARCHAR  sUid[80];
    VARCHAR  sPwd[20];
    VARCHAR  sConnStr[1024];
    EXEC SQL END DECLARE SECTION;
```

- Log on GOLDILOCKS

```
strcpy((char *)sUid.arr, aUserID);
    sUid.len = (short)strlen((char *)sUid.arr);
    strcpy((char *)sPwd.arr, sPassword);
    sPwd.len = (short)strlen((char *)sPwd.arr);
    strcpy((char *)sConnStr.arr, aHostInfo);
    sConnStr.len = (short)strlen((char *)sConnStr.arr);
```

- DB connection

```
EXEC SQL CONNECT :sUid IDENTIFIED BY :sPwd USING :sConnStr;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    return SUCCESS;

  fail_exit:

    PRINT_SQL_ERROR("[ERROR] Connection Failure!");

    return FAILURE;
```

```
}
```

- Create table

```
int CreateEmpTempTable()
{
    EXEC SQL BEGIN DECLARE SECTION;
    char   sSqlStmt[8192];
    EXEC SQL END DECLARE SECTION;
    sprintf(sSqlStmt, "DROP TABLE IF EXISTS EMP_RND" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    sprintf(sSqlStmt, "CREATE TABLE EMP_RND (\n"
            "EMPNO NUMBER(4) CONSTRAINT PK_EMP_RND PRIMARY KEY,\n"
            "ENAME VARCHAR2(10),\n"
            "JOB VARCHAR2(9),\n"
            "SAL NUMBER(7,2),\n"
            "DEPTNO NUMBER(2) )\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    sprintf(sSqlStmt, "INSERT INTO EMP_RND\n"
            "SELECT *\n"
            "FROM   EMP\n"
            "WHERE  JOB = 'RND'\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    sprintf(sSqlStmt, "DROP TABLE IF EXISTS EMP_SUPPORT" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
```

```
    {
        goto fail_exit;
    }

    sprintf(sSqlStmt, "CREATE TABLE EMP_SUPPORT (\n"
            "EMPNO NUMBER(4) CONSTRAINT PK_EMP_SUPPORT PRIMARY KEY,\n"
            "ENAME VARCHAR2(10),\n"
            "JOB VARCHAR2(9),\n"
            "SAL NUMBER(7,2),\n"
            "DEPTNO NUMBER(2) )\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    sprintf(sSqlStmt, "INSERT INTO EMP_SUPPORT\n"
            "SELECT *\n"
            "FROM   EMP\n"
            "WHERE  JOB = 'SUPPORT'\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    EXEC SQL COMMIT WORK;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    return SUCCESS;

  fail_exit:

    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    EXEC SQL ROLLBACK WORK;

    return FAILURE;
}
```

- Drop table

```
int DropEmpTempTable()
{
    EXEC SQL DROP TABLE EMP_RND;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    EXEC SQL DROP TABLE EMP_SUPPORT;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    EXEC SQL COMMIT WORK;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    return SUCCESS;

  fail_exit:

    PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
    EXEC SQL ROLLBACK WORK;

    return FAILURE;
}

int UpdateSalary(char *aJob, int aBound, double aRatio)
{
    EXEC SQL BEGIN DECLARE SECTION;
    Record       sRecord;
    char         sSelectSql[128];
    char         sUpdateSql[128];
    int          sBound = aBound;
    double       sRatio = aRatio;
    EXEC SQL END DECLARE SECTION;
```

```
    int  sRecordCount = 0;
    int  i;
    int  sIsOpenCur = 0;

    sprintf( sSelectSql, "SELECT EMPNO, ENAME, JOB, SAL FROM EMP_%s WHERE sal < :v1 FOR
UPDATE", aJob );
    sprintf( sUpdateSql, "UPDATE EMP_%s SET sal = sal * :v1 WHERE CURRENT OF DYN_CUR", aJob);

    EXEC SQL PREPARE SELECT_STMT FROM :sSelectSql;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }

    EXEC SQL DECLARE DYN_CUR KEYSET CURSOR FOR SELECT_STMT;

Multithread Application

The multithreaded application is an application including multiple execution units in a single process. The multithreaded application can process multiple tasks such as running multiple applications at the same time in parallel, and it has the advantage of being able to share the same address scope because it is a single process.

Sharing the same address scope means sharing the global variables and static variables. When accessing these variables, the concurrency control for each thread should be considered. Therefore, the application should be developed very carefully.

GOLDILOCKS supports the run-time context. The run-time context has a slight difference between Direct Attach (D/A) mode and Client/Server (C/S) mode. The next chapter describes the run-time context and the guideline for developing the multithreaded application.

Run-time Context

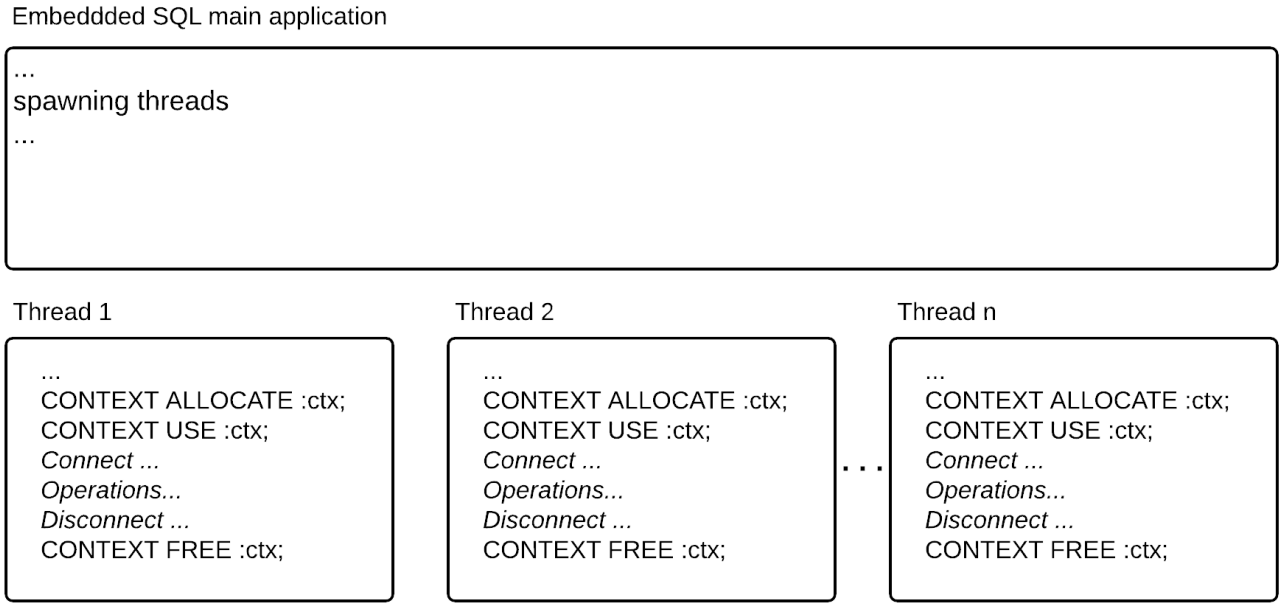
The run-time context in an embedded SQL of GOLDILOCKS is used for the purpose of managing the connection from the application to GOLDILOCKS. The relationship between the run-time context and connection is 1:1, and the run-time context is regarded as the connection itself.

GOLDILOCKS structurally allows only a single connection in a thread in D/A mode. The multithreaded application is required for multiple connections. However, it is the connection with the server via network in C/S mode, so a single thread may have multiple connections.

Direct Attach (D/A) Mode

A single thread has only a single connection in D/A mode. Therefore, n threads are required when developing an application with n connections.

Figure 2 In case when each thread has its own connection in D/A mode



Client/Server (C/S) Mode

An extra restriction for the connection does not exist when operating in C/S mode. A single thread may h ave multiple connections or multiple threads may share a single connection. N threads can share m conne ctions.

Figure 3 In case when multiple threads share a single connection

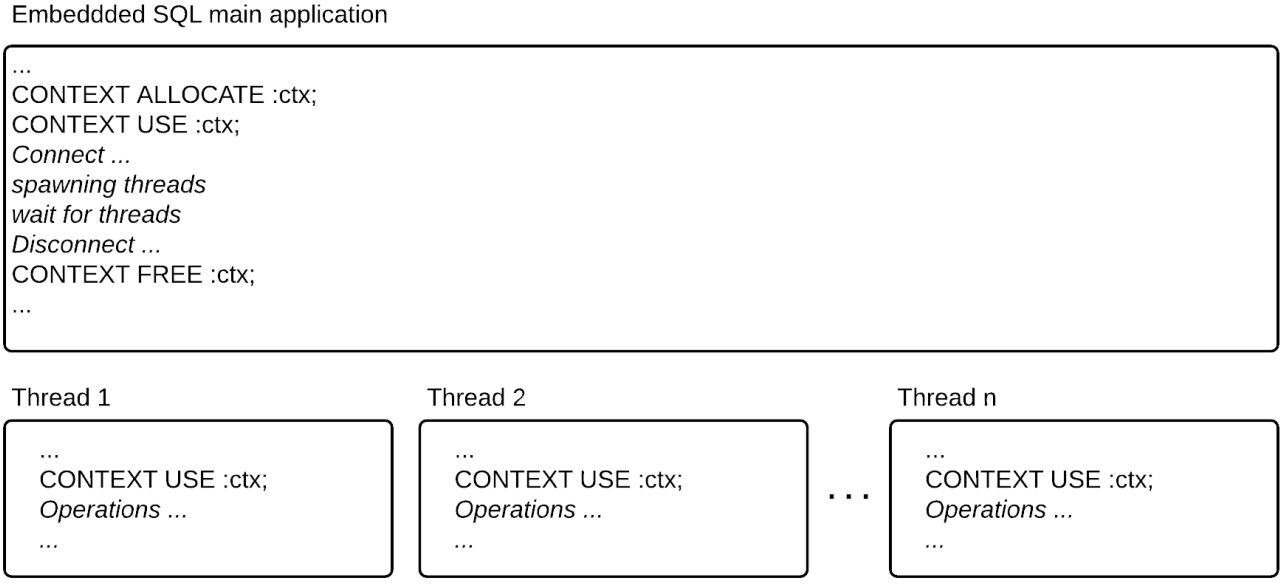


Figure 4 In case when a single thread has multiple connections

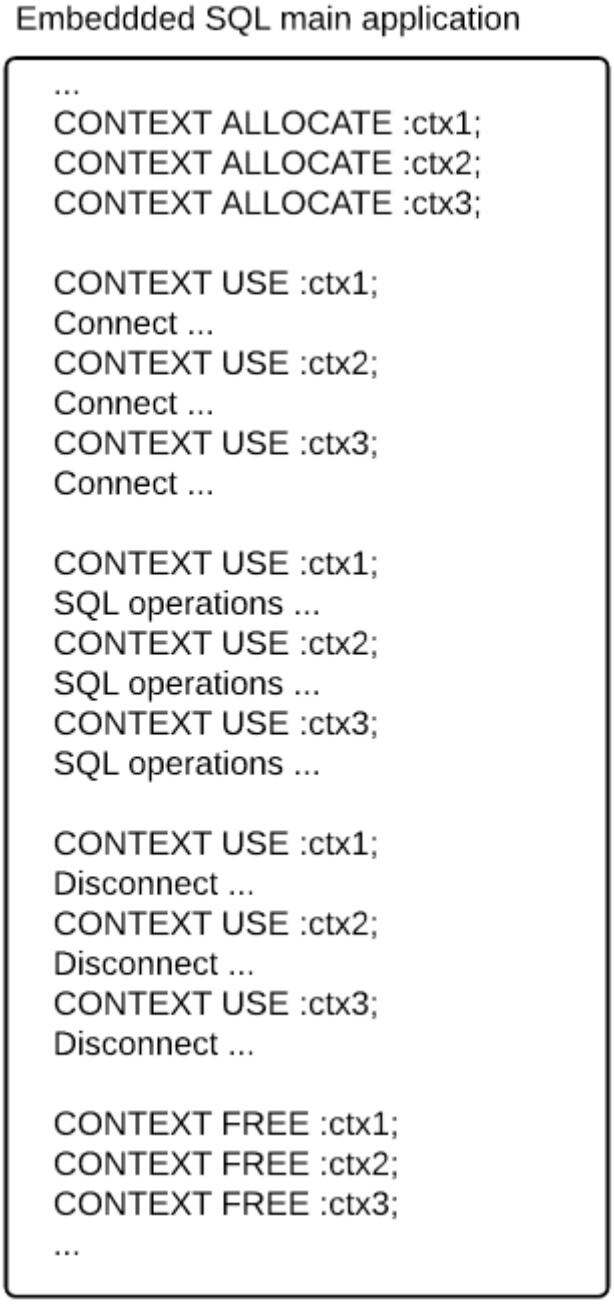

Guidelines

The followings should be considered to develop the multithreaded application.

- The SQLCA variable should be declared thread-safely. It is recommended to declare as a stack variabl e in each thread, and to refer to the example program of the next chapter.
- The static variables or the global variables are shared because the multithread has the same address s cope in a single process. The concurrency control should be considered when using these variables.
- A single run-time context should not be allowed to be used at the same time in multiple threads. The concurrency control of run-time context should also be considered.

Example Program

The following is a sample program of a multithreaded application.

```
/*
 * thread1.gc
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <pthread.h>

EXEC SQL INCLUDE SQLCA;

#define  SUCCESS  0
#define  FAILURE  -1

#define  PRINT_SQL_ERROR(aMsg)                                    \
    {                                                             \
        printf("\n");                                             \
        printf(aMsg);                                             \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",  \
               sqlca.sqlcode,                                     \
               SQLSTATE,                                          \
               sqlca.sqlerrm.sqlerrmc );                          \
    }

}
```

Multi-process Application

A multi-process application is an application program which creates and executes multiple processes by u sing a single process.

GOLDILOCKS embedded SQL does not support a multi-process application. Use a fork function to write a multi-process application. If the application does not execute a new program but continues to executing the existing program after calling the fork function, then be aware of the followings.

- It is difficult to predict which error would occur because the context connected from the parent proc ess is copied to the child process after forking.
- Each OS has a different semaphore management policy. Some OS does not allow both the parent pr ocess and child process clear the semaphore created from the parent process.

If writing a multi-process application, then execute forking without any connection. Also, it is required to check the semaphore management policy of the corresponding OS.

C++ Application

Extension of Output Filename

Precompiler (gpec) of GOLDILOCKS generates C code by precompiling the embedded SQL source code. T he extension of the output file is .c by default. The general C++ source code has various file extensions de pending on the compiler types.

-o option which is the output file specification option of gpec is used to specify the file extension. For exa mple, testfile.gc is converted to testfile.cpp as follows.

```
gpec $(GPEC_OPT) testfile.gc -o testfile.cpp
```

SQLCA_STORAGE_CLASS

When the same symbol is declared as a global variable, the conflict on the symbol is occurred in C++ appl ication. The embedded SQL of GOLDILOCKS has the sqlca variable by default, and the conflict of these va

riables causes a problem when linking multiple C++ files.

SQLCA_STORAGE_CLASS macro should be defined for all other files except for one file to avoid this probl em. For example, if a single application is generated by linking 3 files, SQLCA_STORAGE_CLASS macro is defined for two of three files as follows.

```
#define SQLCA_STORAGE_CLASS extern
EXEC SQL INCLUDE SQLCA;
```

SQLCA_STORAGE_CLASS macro definition should be positioned ahead of the following statement.

```
EXEC SQL INCLUDE SQLCA;
```

XA

Definition of xa_open string

xa_open string includes information for connecting to Resource Manager (RM). For more information, re fer to **SQLDriverConnect attributes**.

The following is an example of xa_open string.

```
DSN=GOLDILOCKS;UID=test;PWD=test;CONN_NAME=XA_CONN
```

Using XA in Precompiler

A user can choose one of the followings when using XA in the precompiler.

- Using the default connection
- Using the named connection

Using Default Connection

It uses the connection connected only with the access information in xa_open string.
The following is an example of xa_open string for the default connection.

```
DSN=GOLDILOCKS;UID=test;PWD=test
```

It is described as follows when using the embedded SQL with the default connection.

```
EXEC SQL
        UPDATE Deposit
        Set InterestRates = :value :value_ind
        WHERE AccountNumber = :account_number;
```

Any connection should not exist in the default context before executing xa open to use XA with the default context.
Do not create multiple XA connections with xa_open string which does not have CONN_NAME.
When creating multiple connections without CONN_NAME, then the first created connection is matched with the default context.

Using Named Connection

It uses the connection name together with the connection information in xa_open string.
The following is an example of xa_open string for the named connection.

```
DSN=GOLDILOCKS;UID=test;PWD=test;CONN_NAME=XA_CONN
```

The connection name should be specified as follows in an embedded SQL which uses the named connect ion.

```
EXEC SQL AT XA_CONN
        UPDATE Deposit
        Set InterestRates = :value :value_ind
        WHERE AccountNumber = :account_number;
```

Example Program

- GOLDILOCKS Sample - XA

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
```

- Include GOLDILOCKS ODBC header

```
#include <goldilocks.h>
EXEC SQL INCLUDE SQLCA;
#define  SUCCESS  0
#define  FAILURE  -1
```

```
#define  PRINT_SQL_ERROR(aMsg)                                          \
    {                                                                   \
        printf("\n");                                                   \
        printf(aMsg);                                                   \
        printf("\nSQLCODE : %d\nSQLSTATE : %s\nERROR MSG : %s\n",   \
               sqlca.sqlcode,                                           \
               SQLSTATE,                                                \
               sqlca.sqlerrm.sqlerrmc );                                \
    }
```

- User-specific definitions

```
#define  BUF_LEN 101
#define GOLDILOCKS_SQL_THROW( aLabel )              \
    goto aLabel;
#define GOLDILOCKS_SQL_TRY( aExpression )           \
    do                                          \
    {                                           \
        if( !(SQL_SUCCEEDED( aExpression ) ) )  \
        {                                       \
            goto GOLDILOCKS_FINISH_LABEL;           \
        }                                       \
    } while( 0 )
#define GOLDILOCKS_FINISH                           \
    goto GOLDILOCKS_FINISH_LABEL;                   \
    GOLDILOCKS_FINISH_LABEL:
```

- Print diagnostic record to console

```
void PrintDiagnosticRecord( SQLSMALLINT aHandleType, SQLHANDLE aHandle )
{
    SQLCHAR       sSQLState[6];
    SQLINTEGER    sNaiveError;
    SQLSMALLINT   sTextLength;
    SQLCHAR       sMessageText[SQL_MAX_MESSAGE_LENGTH];
    SQLSMALLINT   sRecNumber = 1;
    SQLRETURN     sReturn;
```

- SQLGetDiagRec returns the current values which includes an error, warning.

```
while( 1 )
    {
        sReturn = SQLGetDiagRec( aHandleType,
                                 aHandle,
                                 sRecNumber,
                                 sSQLState,
                                 &sNaiveError,
                                 sMessageText,
                                 100,
                                 &sTextLength );
        if( sReturn == SQL_NO_DATA )
        {
            break;
        }
        GOLDILOCKS_SQL_TRY( sReturn );
        printf("\n=============================================\n" );
        printf("SQL_DIAG_SQLSTATE     : %s\n", sSQLState );
        printf("SQL_DIAG_NATIVE       : %d\n", sNaiveError );
        printf("SQL_DIAG_MESSAGE_TEXT : %s\n", sMessageText );
        printf("=============================================\n" );
        sRecNumber++;
    }
    return;
    GOLDILOCKS_FINISH;
    printf("SQLGetDiagRec failure.\n" );
    return;
}
```

- Create table

```
int testCreateTable()
{
    EXEC SQL AT XA_CONN
        DROP TABLE IF EXISTS DEPOSIT;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    EXEC SQL AT XA_CONN

            sEnv = NULL;
        default:
            break;
```

```
    }
    return EXIT_FAILURE;
}
```

33.4 Embedded SQL Reference

This chapter describes the SQL statements which are available only in the embedded SQL applications of GOLDILOCKS. The embedded SQL statements on the source code should have the following syntax.

```
<statement> ::= EXEC SQL <exec sql statement>;
<exec sql statement> ::=
      <embedded SQL statement>
    ¦ <embedded get group_id statement>
    ¦ <embedded specific statement>
    ;

<embedded SQL statement> ::=
    [ AT <db_name> ] [ ATOMIC ] [ FOR <iteration_count> ] <sql statement>
    ;
<embedded get group_id statement> ::=
    [ AT <db_name> ]  <get group_id statement> <sql statement>
<embedded specific statement> ::=
      <autocommit statement>
    ¦ <declare section statement>
    ¦ <include statement>
    ¦ <exception statement>
    ¦ <context statement>
    ¦ <option statement>
    ¦ <allocate statement>
    ¦ <free statement>
    ;

<autocommit statement> ::= [ AT <db_name> ] AUTOCOMMIT { ON ¦ OFF };
<declare section statement> ::= { BEGIN ¦ END } DECLARE SECTION;
<include statement> ::= INCLUDE { SQLCA ¦ <identifier> };
<exception statement> ::= WHENEVER <exception_condition> <exception_action>;
<context statement> ::= CONTEXT <context action>;
<context action> ::=
      ALLOCATE :context_name
    ¦ FREE :context_name
    ¦ USE :context_name
    ¦ USE DEFAULT
    ;
<option statement> ::= OPTION ( <option> );
```

```
<get group_id statement> :: GET GROUPID INTO :group_id;
<allocate statement> ::= [AT <db_name>] ALLOCATE :cursor_variable;
<free statement> ::= [AT <db_name>] FREE :cursor_variable;
```

EXEC SQL ALLOCATE

Feature

It allocates the cursor variable in the embedded SQL.

Syntax

```
EXEC SQL [ AT <db_name> ] ALLOCATE :hostvar
<db_name> ::=
       <identifier>
    | :hostvar
    ;
```

Description

It allocates the memory of the run-time cursor variable. This variable should be allocated after declaring SQL_CURSOR type variable in DECLARE SECTION to allocate the run-time cursor variable. This statement not only allocates the memory but also allocates the client's statement, so it is related to the context. In other words, it can be used only in the context where the cursor variable is allocated.

Example

```
{
    EXEC SQL BEGIN DECLARE SECTION;
    SQL_CURSOR empCursor;
    EXEC SQL END DECLARE SECTION;
    ...
    EXEC SQL AT CONN1 ALLOCATE :empCursor;
    ...
}
```

EXEC SQL AT

Feature

It specifies the connection name applied to the embedded SQL statement.

Syntax

```
EXEC SQL [ AT <db_name> ] ...
<db_name> ::=
      <identifier>
    ¦ :hostvar
    ;
```

Description

The connection name can be specified when connected in the embedded SQL application. The name is used when the embedded SQL statement is performed by using the certain connection.

Example

```
{
    ...
    EXEC SQL AT :conn_name CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL AT :conn_name
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';

    ...
}
```

For More Information

Refer to **Connection**.

EXEC SQL ATOMIC INSERT

Feature

It performs the atomic array insert.

Syntax

```
EXEC SQL ATOMIC <insert_statement>;
```

Description

Atomic array insert is performed in an embedded SQL application. Atomic array insert is for inserting mult iple rows at once. It succeeds only when the entire row is inserted. If any row fails to be inserted, the inse rtion of the entire row is failed.
It has a better performance than the individual insertion because the insertion is performed with a single command.

Example

```
{
    EXEC SQL BEGIN DECLARE SECTION;
    int    emp_number[20];
    char   emp_name[20][10];
    int    dept_number[20];
    EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting the values of emp_number, emp_name, dept_number

```
EXEC SQL ATOMIC INSERT INTO emp (empno, ename, deptno)
                            VALUES (:emp_number, :emp_name, :dept_number);
}
```

For More Information

Refer to **Atomic Insert**.

EXEC SQL AUTOCOMMIT

Feature

It changes the autocommit setting.

Syntax

```
EXEC SQL AUTOCOMMIT { ON | OFF };
```

Description

It sets the autocommit as follows.

Table 33-24 Setting the autocommit

Flag	Description
ON	Statement is executed and then autocommit is performed.
OFF	Commit is not performed until the explicit commit statement comes.

Example

```
{
    ...
    EXEC SQL AT :conn_name CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL AUTOCOMMIT ON;
    EXEC SQL AT :conn_name
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';

    ...
}
```

For More Information

Refer to **Auto Commit**.

EXEC SQL BEGIN DECLARE SECTION

Feature

It is a precompiler indicator, and it specifies the host variable declaration area.

Syntax

```
EXEC SQL BEGIN DECLARE SECTION;
```

Description

It is a precompiler indicator which specifies the host variable declaration section, and it is always used together with EXEC SQL END DECLARE SECTION. When precompiler encounters this statement, it is regarded as the start of declare section, and the variable thereafter is processed as the host variable.

Example

```
{
    EXEC SQL BEGIN DECLARE SECTION;
    int    emp_number[20];
    char   emp_name[20][10];
    int    dept_number[20];
    EXEC SQL END DECLARE SECTION;

    ...
}
```

For More Information

Refer to the followings.

- **Declaring Host Variable**
- **EXEC SQL END DECLARE SECTION**

EXEC SQL COMMIT RELEASE

Feature

It commits the transaction and terminates the current connection.

Syntax

```
EXEC SQL [ AT <db_name> ] COMMIT [ WORK ] RELEASE;
```

Description

It commits the transaction and terminates the current connection.

```
EXEC SQL AT :conn_name COMMIT RELEASE;
```

The statement above is as same as the following.

```
EXEC SQL AT :conn_name COMMIT;
EXEC SQL AT :conn_name DISCONNECT;
```

Example

```
{
    ...
    EXEC SQL AT :conn_name CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL AT :conn_name
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';
    EXEC SQL AT :conn_name COMMIT RELEASE;
    ...
}
```

For More Information

Refer to **RELEASE Option**.

EXEC SQL CONNECT

Feature

It connects to GOLDILOCKS.

Syntax

```
EXEC SQL [ AT <db_name> ] CONNECT <user_name> IDENTIFIED BY <password> [ AT <db_name> ] [
USING <conn_string> ]
<db_name> ::=
      <identifier>
    ¦ :hostvar
    ;
<user_name> ::=
      <identifier>
    ¦ :hostvar
    ;
<password> ::=
      <identifier>
    ¦ :hostvar
    ;
<conn_string> ::= :hostvar;
```

Description

It sets the connection to GOLDILOCKS.

Example

```
{
    ...
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    ...
}
```

For More Information

Refer to **Connecting to Database**.

EXEC SQL CONTEXT ALLOCATE

Feature

It allocates the run-time context memory.

Syntax

```
EXEC SQL CONTEXT ALLOCATE :context;
```

Description

It allocates run-time context memory. It should be allocated for variable of SQL_CONTEXT type after the v ariable of SQL_CONTEXT type is declared in declare section to allocate the run-time context. This stateme nt allocates the memory only, so to use it, USE should be specified and perform the connect.

Example

```
{
    ...
    EXEC SQL BEGIN DECLARE SECTION;
    SQL_CONTEXT ctxt;
    EXEC SQL END DECLARE SECTION;
    EXEC SQL CONTEXT ALLOCATE :ctxt;

    EXEC SQL CONTEXT USE :ctxt;
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';
    EXEC SQL DISCONNECT;
    EXEC SQL CONTEXT FREE :ctxt;

    ...
}
```

For More Information

Refer to **SQL_CONTEXT**.

EXEC SQL CONTEXT FREE

Feature

It frees the run-time context memory.

Syntax

```
EXEC SQL CONTEXT FREE :context;
```

Description

It frees run-time context memory. Disconnect should be performed before freeing the run-time context s o that the connection will not be used any more. Otherwise, an unexpected error may occur.

Example

```
{
    ...
    EXEC SQL BEGIN DECLARE SECTION;
    SQL_CONTEXT ctxt;
    EXEC SQL END DECLARE SECTION;
    EXEC SQL CONTEXT ALLOCATE :ctxt;

    EXEC SQL CONTEXT USE :ctxt;
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';
    EXEC SQL DISCONNECT;
    EXEC SQL CONTEXT FREE :ctxt;

    ...
}
```

For More Information

Refer to **SQL_CONTEXT**.

EXEC SQL CONTEXT USE

Feature

It informs the use of run-time context.

Syntax

```
EXEC SQL CONTEXT USE { :context ¦ DEFAULT };
```

Description

It is an indicator which informs the precompiler of the use of run-time context, and it specifies the run-time context to be used. The run-time context which is declared and allocated by a user can be used by using SQL_CONTEXT variable in USE statement, and the default context in the application is used when performing the USE DEFAULT statement.

Example

```
{
    ...
    EXEC SQL BEGIN DECLARE SECTION;
    SQL_CONTEXT ctxt;
    double      max_sal;
    EXEC SQL END DECLARE SECTION;
    EXEC SQL CONTEXT ALLOCATE :ctxt;

    EXEC SQL CONTEXT USE :ctxt;
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';
    EXEC SQL COMMIT RELEASE;
    EXEC SQL CONTEXT FREE :ctxt;

    EXEC SQL CONTEXT USE DEFAULT;
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;
```

```
    EXEC SQL
        SELECT MAX(sal)
        INTO   max_sal
        FROM   EMP
        WHERE  JOB = 'SALES';
    EXEC SQL DISCONNECT;
    ...
}
```

For More Information

Refer to **SQL_CONTEXT**.

EXEC SQL DISCONNECT

Feature

It disconnects from GOLDILOCKS.

Syntax

```
EXEC SQL [ AT <db_name> ] DISCONNECT [ ALL ]
```

Description

It disconnects from GOLDILOCKS. A specific connection can be freed with AT clause, and the current connection is freed if AT clause is not used. All connections which are used in the current application are freed by using DISCONNECT ALL.

Example

```
{
    ...
    EXEC SQL AT :conn_name DISCONNECT;

    ...
}
```

For More Information

Refer to **Disconnecting Database**.

EXEC SQL END DECLARE SECTION

Feature

It is a precompiler indicator, and it specifies the the host variable declaration section.

Syntax

```
EXEC SQL END DECLARE SECTION;
```

Description

It is a precompiler indicator which specifies the host variable declaration section, and it is always used tog ether with EXEC SQL BEGIN DECLARE SECTION. When precompiler encounters this statement during ana lyzing the declare section, it is regarded as the end of the declare section.

Example

```
{
    EXEC SQL BEGIN DECLARE SECTION;
    int    emp_number[20];
    char   emp_name[20][10];
    int    dept_number[20];
    EXEC SQL END DECLARE SECTION;

    ...
}
```

For More Information

Refer to the followings.

- **Declaring Host Variable**
- **EXEC SQL BEGIN DECLARE SECTION**

EXEC SQL FOR

Feature

It specifies the number of arrays in array operation.

Syntax

```
EXEC SQL FOR { :array_count ¦ integer_constant } <sql statement>;
```

Description

If the host variable of the SQL statement is an array, it is a precompiler indicator which specifies the array count. When FOR clause is given, the array count of the host array is ignored and the arrays as many as th e number specified in FOR clause are performed.

The constant or variable which refers to array count should be an integer.

Example

```
EXEC SQL BEGIN DECLARE SECTION;
int    emp_number[20];
char   emp_name[20][10];
int    dept_number[20];
int    record_cnt;
EXEC SQL END DECLARE SECTION;
```

- Setting the values of emp_number, emp_name, dept_number

```
...
```

- Inserting emp_number, emp_name, dept_number

```
record_cnt = 10;
EXEC SQL FOR :record_cnt INSERT INTO emp (empno, ename, deptno)
    VALUES (:emp_number, :emp_name, :dept_number);
```

For More Information

Refer to **Using FOR Clause**.

EXEC SQL FREE

Feature

It frees the cursor variable in the embedded SQL.

Syntax

```
EXEC SQL [ AT <db_name> ] FREE :hostvar
<db_name> ::=
       <identifier>
    ¦ :hostvar
    ;
```

Description

It frees the memory of the run-time cursor variable. If the cursor variable is not explicitly freed, then it is fr eed when the context is disconnected or the program is terminated. The cursor variable is related to the a llocated context, so FREE command is also related to it.

Example

```
{
    EXEC SQL BEGIN DECLARE SECTION;
    SQL_CURSOR empCursor;
    EXEC SQL END DECLARE SECTION;
    ...
    EXEC SQL AT CONN1 FREE :empCursor;
    ...
}
```

EXEC SQL GET GROUPID INTO

Feature

It obtains the group ID of the SQL statement.

Syntax

```
EXEC SQL [ AT <db_name> ] GET GROUPID INTO :group_id { delete_stmt ¦ insert_stmt ¦ select_stmt
¦ update_stmt };
```

Description

It obtains the the group ID of the SQL statement in the cluster environment which uses the global connection. Only the signed numeric type is allowed for the host variable :group_id. The group ID can be obtained only for the delete, insert, select, update SQL statement, and the shard key should be set in the table in advance.

The SQL statement which obtained the group ID is internally cached in SQLPrepare status without executing SQLExecute.

-1 which is an invalid group ID value can be returned.

Example

```
{
EXEC SQL BEGIN DECLARE SECTION;
int  group_id[10];
int  emp_no[10];
char emp_name[10][20];
int  dept_no[10];
EXEC SQL END DECLARE SECTION;
```

- Set emp_no, emp_name, dept_no values

```
...
```

- Obtain the group id.

```
EXEC SQL GET GROUPID INTO :group_id
         INSERT INTO emp (empno, ename, deptno) VALUES (:emp_no, :emp_name, :dept_no);
```

- INSERT emp_no, emp_name, dept_no.

```
EXEC SQL INSERT INTO emp (empno, ename, deptno) VALUES (:emp_no, :emp_name, :dept_no);
}
```

EXEC SQL INCLUDE

Feature

It includes the embedded SQL header file.

Syntax

```
EXEC SQL INCLUDE <Header file name>;
```

Description

It includes the embedded SQL header file. If the header file is included with #include of C language, the p recompiler does not interpret it, so the precompiler can not recognize it even when the information whic h the precompiler should recognize such as declare section in the header file is included in it. Therefore, t he EXEC SQL INCLUDE statement should be used when the embedded SQL statement which the precom piler should recognize is used.

Example

```
EXEC SQL INCLUDE decl.h;
```

For More Information

Refer to **Precompiled Header File**.

EXEC SQL INCLUDE SQLCA

Feature

It includes sqlca.h header file.

Syntax

```
EXEC SQL INCLUDE SQLCA;
```

Description

It is a special type of EXEC SQL INCLUDE statement, and it includes sqlca.h header file supported by GOL DILOCKS. This header file is required for run-time exception handling in the embedded SQL application.

Example

```
EXEC SQL INCLUDE SQLCA;
```

For More Information

Refer to **Detecting Run-time Error**.

EXEC SQL OPTION

Feature

It applies the option to the process of precompiling the embedded SQL source code.

Syntax

```
EXEC SQL OPTION ( <option_desc> );
<option_desc> ::=
      INCLUDE = <directory path>
    ;
```

Description

It describes the option which is applied to the process of precompiling the embedded SQL source code. It supports only specifying INCLUDE path in the current version, and the option specifies the directory of the header file to be precompiled in EXEC SQL INCLUDE.

Example

```
EXEC SQL OPTION ( INCLUDE = include );
```

For More Information

Refer to **Specifying Header File Path**.

EXEC SQL ROLLBACK RELEASE

Feature

It rolls back the transaction, then releases the connection.

Syntax

```
EXEC SQL [ AT <db_name> ] ROLLBACK [ WORK ] RELEASE;
```

Description

It rolls back the transaction, then releases the current connection.

```
EXEC SQL AT :conn_name ROLLBACK RELEASE;
```

The statement above is as same as the following.

```
EXEC SQL AT :conn_name ROLLBACK;
EXEC SQL AT :conn_name DISCONNECT;
```

Example

```
{
    ...
    EXEC SQL AT :conn_name CONNECT :uid IDENTIFIED BY :pwd USING :conn_str;

    EXEC SQL AT :conn_name
        UPDATE EMP
        SET    sal = sal * 1.1
        WHERE  JOB = 'SALES';
    EXEC SQL AT :conn_name ROLLBACK RELEASE;
    ...
}
```

For More Information

Refer to **RELEASE Option**.

EXEC SQL WHENEVER

Feature

It executes run-time exception handling in the embedded SQL application.

Syntax

```
EXEC SQL WHENEVER <conditions> <actions>;
<conditions> ::=
      SQLERROR
    ¦ SQLWARNING
    ¦ NOT FOUND
    ¦ SQLSTATE <sqlstate class value>[<sqlstate subclass value>]
    ;
<sqlstate_char> ::= [0-9A-Z];
<sqlstate class value> ::= <sqlstate_char> <sqlstate_char>;
<sqlstate subclass value> ::= <sqlstate_char> <sqlstate_char> <sqlstate_char>;
<actions> ::=
      CONTINUE
    ¦ GOTO <label>
    ¦ STOP
    ¦ DO <c statements>
    ;
```

Description

It automates and processes the run-time exception handling in an embedded SQL application. There are f our conditions, a single action can be specified per each condition. The action can be reassigned as neede d. For more information, refer to **Handling Implicit Error**.

Example

```
EXEC SQL WHENEVER SQLERROR STOP;
EXEC SQL WHENEVER SQLERROR CONTINUE;
EXEC SQL WHENEVER SQLERROR GOTO exit_label;
EXEC SQL WHENEVER NOT FOUND DO break;
EXEC SQL WHENEVER SQLERROR GOTO close_label;
EXEC SQL WHENEVER SQLERROR DO sql_error();
```

```
EXEC SQL WHENEVER SQLWARNING CONTINUE;
EXEC SQL WHENEVER SQLSTATE HY000 DO sql_error();
```

For More Information

Refer to **Handling Implicit Error**.

34.

PDO

34.1 Overview of PDO

GOLDILOCKS PDO (PDO_GOLDILOCKS) driver provides PDO interface to access GOLDILOCKS database in PDO, and it is provides in a package.

PDO_GOLDILOCKS is built based on GOLDILOCKS CLI driver.

34.2 Installation /Configuration

Requirement

The client package of GOLDILOCKS should be installed in the system which is as same as that of PHP, and environment variables of $GOLDILOCKS_HOME should be set.

Installation

Installation by Using PECL

Create the package file if PDO_GOLDILOCKS package file does not exist.

```
% pecl pickle
Attempting to process the second package file
Package PDO_GOLDILOCKS-3.2.0.tgz done
```

Install the package by using PECL if PDO_GOLDILOCKS package file exists.

```
% sudo -E pecl install PDO_GOLDILOCKS-3.2.0.tgz
```

Installation by Building the Source

1. Decompress PDO_GOLDILOCKS.

```
% tar xvzf PDO_GOLDILOCKS-3.2.0.tgz
% cd PDO_GOLDILOCKS-3.2.0
```

2. Create the environment for the build.

Create the build environment for PDO_GOLDILOCKS expanded module by using phpize command.
If phpize command can not be found, PHP devel package in an appropriate version should be installed.

```
% whereis phpize
phpize: /usr/bin/phpize /usr/share/man/man1/phpize.1.gz
```

```
% /usr/bin/phpize
Configuring for:
PHP Api Version:         20121113
Zend Module Api No:      20121212
Zend Extension Api No:   220121212
```

3. Build it.

Execute *configure* by adding the path of *$GOLDILOCKS_HOME* to *--with-pdo-goldilocks* option and addi ng the path of *php-config* to *--with-php-config* option, then build it.

```
% whereis php-config
php-config: /usr/bin/php-config /usr/share/man/man1/php-config.1.gz
```

```
% ./configure --with-php-config=/usr/bin/php-config
--with-pdo-goldilocks=/home/goldilocks/goldilocks_home/
```

```
% make
```

4. Install it.

```
% sudo -E make install
```

Altering PHP Configuration File

When using CentOS 6.0 or higher or Fedora 15 or higher, the pdo_goldilocks.ini file should be created in /etc/php.d directory and extension property should be added as follows.

```
extension=pdo_goldilocks.so
```

When using other OS extension_dir should be appropriately set in php.ini file and add extension property should be added as follows.

```
extension=pdo_goldilocks.so
```

Restarting Web Server

Restart the web server.

Checking Installation of PDO_GOLDILOCKS

Check whether PDO_GOLDILOCKS is activated by using phpinfo().

```
% php -i | grep PDO
PDO
PDO support => enabled
PDO drivers => goldilocks, sqlite
PDO Driver for GOLDILOCKS => enabled
PDO Driver for SQLite 3.x => enabled
```

34.3 Usage

Data Source Name (DSN)

Data Source Name (DSN) of PDO_GOLDILOCKS is configured as follows.

Property	Description
DSN prefix	goldilocks
DSN	ODBC Data Source Name (DSN)
HOST	IP address of a server
PORT	PORT number of server
UID	User ID
PWD	User password

34.4 Examples

- Connecting to GOLDILOCKS

```
print "\n[Connecting to GOLDILOCKS]\n";
$db = new PDO('goldilocks:HOST=192.168.0.16;PORT=22581', 'test', 'test');
//$db = new PDO('goldilocks:DSN=GOLDILOCKS;UID=test;PWD=test');
$db->setAttribute(PDO::ATTR_ERRMODE, PDO::ERRMODE_EXCEPTION);
```

- Set test data

```
$result = $db->exec('DROP TABLE IF EXISTS t1');
$result = $db->exec('CREATE TABLE t1 ( id INTEGER GENERATED BY DEFAULT AS IDENTITY, name
VARCHAR(32) )');
$result = $db->exec("INSERT INTO t1(name) VALUES ('Carol')");
$result = $db->exec("INSERT INTO t1(name) VALUES ('Ted')");
$result = $db->exec("INSERT INTO t1(name) VALUES (null)");
$result = $db->exec("INSERT INTO t1(name) VALUES ('William')");
$result = $db->exec("INSERT INTO t1(name) VALUES ('Chelsea')");
$result = $db->exec("INSERT INTO t1(name) VALUES ('Colin')");
$result = $db->exec('DROP TABLE IF EXISTS t2');
$result = $db->exec('CREATE TABLE t2 ( id INTEGER, name VARCHAR(32) )');
$result = $db->exec("INSERT INTO t2 VALUES (1, 'John')");
$result = $db->exec("INSERT INTO t2 VALUES (1, 'John')");
$result = $db->exec("INSERT INTO t2 VALUES (1, 'John')");
$result = $db->exec("INSERT INTO t2 VALUES (2, 'Smith')");
$result = $db->exec("INSERT INTO t2 VALUES (2, 'Smith')");
$result = $db->exec('DROP TABLE IF EXISTS images');
$result = $db->exec('CREATE TABLE images ( id INTEGER, contenttype VARCHAR(256), imagedata
LONG VARBINARY )');
$result = $db->exec('DROP PROCEDURE IF EXISTS sp_out_string');
$result = $db->exec("CREATE OR REPLACE PROCEDURE sp_out_string( v1 OUT VARCHAR(32) ) ".
                    "IS ".
                    "BEGIN ".
                    "  v1 := 'WORLD'; ".
                    "END; ");
$result = $db->exec('DROP PROCEDURE IF EXISTS sp_inout_string');
$result = $db->exec("CREATE OR REPLACE PROCEDURE sp_inout_string( v1 INOUT VARCHAR(32) ) ".
                    "IS ".
                    "BEGIN ".
```

```
                    "  v1 := V1 || ' WORLD'; ".
                    "END; ");
```

- Quoting a normal string

```
print "\n[Quoting a normal string]\n";
$string = 'Nice';
print "Unquoted string: $string\n";
print "Quoted string  : " . $db->quote($string) . "\n";
```

- Quoting a dangerous string

```
print "\n[Quoting a dangerous string]\n";
$string = 'Naughty \' string';
print "Unquoted string: $string\n";
print "Quoted string  :" . $db->quote($string) . "\n";
```

- Quoting a complex string

```
print "\n[Quoting a complex string]\n";
$string = "Co'mpl''ex \"st'\"ring";
print "Unquoted string: $string\n";
print "Quoted string  : " . $db->quote($string) . "\n";
```

- Handling an error

```
print "\n[Error Handling]\n";
try
{
    //connect as appropriate as above
    $db->query('invalid query'); //invalid query!
}
catch(PDOException $ex)
{
    print "ERROR:".$ex->getMessage()."\n";
}
```

- Retrieving column metadata

```
print "\n[Retrieving column metadata]\n";
$stmt = $db->query('SELECT * FROM t1');
foreach(range(0, $stmt->columnCount() - 1) as $column_index)
```

```
{
    $meta = $stmt->getColumnMeta($column_index);
    var_dump($meta);
}
```

- Running simple select statements

```
print "\n[Running Simple Select Statements]\n";
print "\n#1\n";
foreach($db->query('SELECT * FROM t1') as $row)
{
    print $row['ID'].' '.$row['NAME']."\n";
}
print "\n#2\n";
$stmt = $db->query('SELECT * FROM t1');

while($row = $stmt->fetch(PDO::FETCH_ASSOC))
{
    print $row['ID'].' '.$row['NAME']."\n";
}
```

- Fetching rows using different fetch styles

```
print "\n[Fetching rows using different fetch styles]\n";
$stmt = $db->prepare("SELECT id, name FROM t1");
$stmt->execute();
print("PDO::FETCH_ASSOC: ");
print("Return next row as an array indexed by column name\n");
$result = $stmt->fetch(PDO::FETCH_ASSOC);
print_r($result);
print("\n");
print("PDO::FETCH_BOTH: ");
print("Return next row as an array indexed by both column name and number\n");
$result = $stmt->fetch(PDO::FETCH_BOTH);
print_r($result);
print("\n");
print("PDO::FETCH_LAZY: ");
print("Return next row as an anonymous object with column names as properties\n");
$result = $stmt->fetch(PDO::FETCH_LAZY);
print_r($result);
print("\n");
print("PDO::FETCH_OBJ: ");
```

```
print("Return next row as an anonymous object with column names as properties\n");
$result = $stmt->fetch(PDO::FETCH_OBJ);
print $result->NAME;
print("\n");
```

- Fetching rows with a scrollable cursor

```
print "\n[Fetching rows using different fetch styles]\n";
print "\n[Fetching rows with a scrollable cursor]\n";
$sql = 'SELECT id, name FROM t1 ORDER BY id';
print "Reading forwards:\n";
try
{
    $stmt = $db->prepare($sql, array(PDO::ATTR_CURSOR => PDO::CURSOR_SCROLL));
    $stmt->execute();
    while( $row = $stmt->fetch(PDO::FETCH_NUM, PDO::FETCH_ORI_NEXT) )
    {
        $data = $row[0] . "\t" . $row[1] . "\n";
        print $data;
    }
    $stmt = null;
}
catch (PDOException $e)
{
    print $e->getMessage();
}
print "Reading backwards:\n";
try
{
    $stmt = $db->prepare($sql, array(PDO::ATTR_CURSOR => PDO::CURSOR_SCROLL));
    $stmt->execute();
    $row = $stmt->fetch(PDO::FETCH_NUM, PDO::FETCH_ORI_LAST);
    do
    {
        $data = $row[0] . "\t" . $row[1] . "\n";
        print $data;
    } while( $row = $stmt->fetch(PDO::FETCH_NUM, PDO::FETCH_ORI_PRIOR) );
    $stmt = null;
}
catch (PDOException $e)
{
```

```
    print $e->getMessage();
}
```

- Constructing an order

```
print "\n[Construction order]\n";
class Person
{
    private $NAME;
    public function __construct()
    {
        $this->tell();
    }
    public function tell()
    {
        if (isset($this->NAME))
        {
            print "I am {$this->NAME}.\n";
        }
        else
        {
            print "I don't have a name yet.\n";
        }
    }
}
$stmt = $db->query("SELECT name FROM t1");
$stmt->setFetchMode(PDO::FETCH_CLASS, 'Person');
$person = $stmt->fetch();
$person->tell();
$stmt->setFetchMode(PDO::FETCH_CLASS¦PDO::FETCH_PROPS_LATE, 'Person');
$person = $stmt->fetch();
$person->tell();
```

- Running simple INSERT, UPDATE, or DELETE statements

```
print "\n[Running Simple INSERT, UPDATE, or DELETE statements]\n";
$affected_rows = $db->exec("INSERT INTO t1(name) VALUES ('John'), ('Marry')");
print $affected_rows." were affected\n";
```

- Getting the last insert id

```
print "\n[Getting the Last Insert Id]\n";
$affected_rows = $db->exec("INSERT INTO t1(name) VALUES ('Smith')");
$insertId = $db->lastInsertId();
print "last insert id : ".$insertId."\n";
```

- Running statements with parameters

```
print "\n[Running Statements With Parameters]\n";
print "\n#1 array\n";
$id = 1;
$name = 'John';
$stmt = $db->prepare("SELECT * FROM t2 WHERE id=? AND name=?");
$stmt->execute(array($id, $name));
$rows = $stmt->fetchAll(PDO::FETCH_ASSOC);
var_dump($rows);
print "\n#2 bindValue\n";
$id = 2;
$name = 'Smith';
$stmt = $db->prepare("SELECT * FROM t2 WHERE id=? AND name=?");
$stmt->bindValue(1, $id, PDO::PARAM_INT);
$stmt->bindValue(2, $name, PDO::PARAM_STR);
$stmt->execute();
$rows = $stmt->fetchAll(PDO::FETCH_ASSOC);
var_dump($rows);
```

- Named placeholders

```
print "\n[Named Placeholders]\n";
print "\n#1 array\n";
$id = 1;
$name = 'John';
$stmt = $db->prepare("SELECT * FROM t2 WHERE id=:id AND name=:name");
$stmt->execute(array(':name' => $name, ':id' => $id));
$rows = $stmt->fetchAll(PDO::FETCH_ASSOC);
var_dump($rows);
print "\n#2 bindValue\n";
$id = 2;
$name = 'Smith';
$stmt = $db->prepare("SELECT * FROM t2 WHERE id=:id AND name=:name");
$stmt->bindValue(':id', $id, PDO::PARAM_INT);
$stmt->bindValue(':name', $name, PDO::PARAM_STR);
```

```
$stmt->execute();
$rows = $stmt->fetchAll(PDO::FETCH_ASSOC);
var_dump($rows);
```

- Executing prepared statements in a loop

```
print "\n[Executing prepared statements in a loop]\n";
$values = array('bob', 'alice', 'lisa', 'john');
$name = '';
$stmt = $db->prepare("INSERT INTO t1(name) VALUES(:name)");
$stmt->bindParam(':name', $name, PDO::PARAM_STR);
foreach($values as $name)
{
   $stmt->execute();
}
foreach($db->query('SELECT * FROM t1') as $row)
{
    print $row[0].' '.$row[1]."\n";
}
```

- Calling a stored procedure with an output parameter

```
print "\n[Calling a stored procedure with an output parameter]\n";
$stmt = $db->prepare("CALL sp_out_string(?)");
$stmt->bindParam(1, $value, PDO::PARAM_STR, 32);
$stmt->execute();
print "procedure returned $value\n";
```

- Calling a stored procedure with an input/output parameter

```
print "\n[Calling a stored procedure with an input/output parameter]\n";
$stmt = $db->prepare("CALL sp_inout_string(?)");
$value = 'HELLO';
$stmt->bindParam(1, $value, PDO::PARAM_STR¦PDO::PARAM_INPUT_OUTPUT, 32);
$stmt->execute();
print "procedure returned $value\n";
```

- Transactions

```
print "\n[Transactions]\n";
print "\n#1 commit\n";
try
```

```
{
    $db->beginTransaction();

    $db->exec("INSERT INTO t1(name) VALUES('kim')");
    $name = 'lee';
    $stmt = $db->prepare("INSERT INTO t1(name) VALUES(?)");
    $stmt->execute(array($name));

    $id = 3;
    $name = 'park';
    $stmt = $db->prepare("INSERT INTO t2 VALUES(?, ?)");
    $stmt->execute(array($id, $name));

    $db->commit();
}
catch(PDOException $ex)
{
    //Something went wrong rollback!
    $db->rollBack();
    print $ex->getMessage()."\n";
}
print "\nT1\n";
foreach($db->query('SELECT * FROM t1') as $row)
{
    print $row[0].' '.$row[1]."\n";
}
print "\nT2\n";
foreach($db->query('SELECT * FROM t2') as $row)
{
    print $row[0].' '.$row[1]."\n";
}
print "\n#2 rollback\n";
try
{
    $db->beginTransaction();

    $db->exec("INSERT INTO t1(name) VALUES('KIM')");
    $name = 'LEE';
    $stmt = $db->prepare("INSERT INTO t1(name) VALUES(?)");
    $stmt->execute(array($name));
```

```
    $id = 3;
    $name = 'PARK';
    $stmt = $db->prepare("INSERT INTO invalid VALUES(?, ?)");
    $stmt->execute(array($id, $name));

    $db->commit();
}
catch(PDOException $ex)
{
    //Something went wrong rollback!
    $db->rollBack();
    print $ex->getMessage()."\n";
}
print "\nT1\n";
foreach($db->query('SELECT * FROM t1') as $row)
{
    print $row[0].' '.$row[1]."\n";
}
print "\nT2\n";
foreach($db->query('SELECT * FROM t2') as $row)
{
    print $row[0].' '.$row[1]."\n";
}
```

- Inserting an image into a database

```
print "\n[Inserting an image into a database]\n";
try
{
    $stmt = $db->prepare("INSERT INTO images (id, contenttype, imagedata) VALUES (?, ?, ?)");
    $id = 1;
    $type = "image/png";
    $fp = fopen("logo.png", "rb");
    $stmt->bindParam(1, $id, PDO::PARAM_INT);
    $stmt->bindParam(2, $type, PDO::PARAM_STR, 256);
    $stmt->bindParam(3, $fp, PDO::PARAM_LOB);
    $db->beginTransaction();
    $stmt->execute();
    $db->commit();
}
catch(PDOException $ex)
```

```
{
    $db->rollBack();
    print $ex->getMessage()."\n";
}
foreach($db->query('SELECT id, contenttype, lengthb(imagedata) FROM images') as $row)
{
    print $row[0].' '.$row[1].' '.$row[2]."\n";
}
```

- Displaying an image from a database

```
print "\n[Displaying an image from a database]\n";
try
{
    $stmt = $db->prepare("SELECT contenttype, imagedata FROM images WHERE id = ?");
    $id = 1;
    $stmt->execute(array($id));
    $stmt->bindColumn(1, $type, PDO::PARAM_STR, 256);
    $stmt->bindColumn(2, $lob, PDO::PARAM_LOB);
    $stmt->fetch(PDO::FETCH_BOUND);
    print 'Content-Type: '.$type."\n";
    print 'size: '.file_put_contents($id.".png", $lob)."\n";
}
catch(PDOException $ex)
{
    print $ex->getMessage()."\n";
}
```

35.

PyDBC

35.1 GOLDILOCKS PyDBC

Overview

PyDBC programs Python accessing GOLDILOCKS database by using API which complies with **Python Database API Specification v2.0(PEP 249)**.

PyDBC requires the Python standard library, and the internal operation which connects to and operate GOLDILOCKS database requires ODBC library because it calls ODBC API. PyDBC uses gdlcs in ODBC library *$GOLDILOCKS_HOME/lib* by default, and the user can modify it by updating *setup.py*.

The internal operation of PyDBC uses ODBC driver, so it is as same as **Overview of ODBC Components**. There are an architecture of which an application links to the driver manager, and an architecture of which an application links to GOLDILOCKS ODBC driver library.

Version

The information of GOLDILOCKS PyDBC version can be viewed by executing *pygoldilocks.so* file as follows.

```
shell>python
>>> import pygoldilocks
>>> print pygoldilocks.version
3.2.0
```

The current version of GOLDILOCKS PyDBC driver is 3.2.0 according to GOLDILOCKS version, and this driver complies with the standard Python database API 2.0. PyDBC driver supports Python 2.7, 3.4, 3.5, 3.6 versions, and PyDBC driver library should be installed according to each Python version.

Installation

The source should be built to install PyDBC. PyDBC links gdlcs library in GOLDILOCKS_HOME/lib and it includes *goldilocks.h* header file in GOLDILOCKS_HOME/include, so the environment variable GOLDILOCKS_HOME should be set in an appropriate position.

When installing PyDBC, the bit of Python should be as same as that of GOLDILOCKS library. Therefore, if GOLDILOCKS is built in 32 bit, then PyDBC should be installed by using Python 32 bit.

Installation on Linux

Linux requires the gcc compiler, and it is built as follows.

```
shell> sudo python setup.py install
```

It does not support HP-UX nor AIX platform.

Installation on Windows

It is built on Windows as follows.

```
shell> python setup.py install
```

An appropriate Microsoft Visual C++ compiler according to python version is required to compile PyDBC For more information, refer to **https://wiki.python.org/moin/WindowsCompilers**.

- Visual Studio 2003.NET compiler is required to build Python version 2.4 or 2.5, and there is not a free ware for this version.
- Visual C++ 2008 compiler is required to build Python version 2.6, 2.7, 3.0, 3.2, and the freeware for t his version is Visual C++ 2008 Express.
- Visual C++ 2010 compiler is required to build Python version 3.3, 3.4, and the freeware for this versi on is Visual C++ 2010 Express.
- Visual C++ 2014 or VC 2017 compiler is rerquired to build Python version 3.5, 3.6.
- Visual C++ 2017 compiler is required to build Python version 3.7.

Examples

Obtaining Connection Class

PyDBC implicitly calls ODBC library. Therefore, **the data source** should be configured to obtain the connec tion.

- Obtain the connection as follows.

```
import pygoldilocks
cnxn = pygoldilocks.connect( 'DSN=GOLDILOCKS;UID=test;PWD=test' )
```

Call connect which is an internal function of pygoldilocks, a module of PyDBC, to obtain the connection.

Data Source should be configured in advance to use DSN.

If CHARSET is not set in DSN, then ODBC library sets it to Console Character Set. PyDBC implicitly perform s the basic encoding for the character set used by ODBC. If the character set used in GOLDILOCKS server i s different from that in ODBC library, then the data conversion occurs and it degrades the performance. F or example, CP949 is used as a basic character set in Windows. If nothing is set, PyDBC implicitly uses CP 949(UHC) when encoding, and ODBC library also uses UHC when processing the character set.

The followings are how to alter the character set of the client.

- Alter CHARSET property in **Data Source Configuration**.
- Add CHARSET property to the connection string.
- Use attrs_before keyword in connect method of pygoldilocks module.

All of the three methods above alter the connection property of ODBC, SQL_ATTR_CHARACTER_SET, an d set the encoding of PyDBC library as well.

Using Cursor and Row Class

A cursor and a row class can be used as follows.

```
cursor = cnxn.cursor()
cursor.execute( "SELECT NAME, ADDRESS FROM EMP" )
rows = cursor.fetchall()
for row in rows:
    print row.A, row.B
cursor.close()
cnxn.close()
```

35.2 API Reference

pygoldilocks Module

pygoldilocks object complies with **Python Database API Specification v2.0**.
For more information, refer to **Python DB API module**.

Properties

- version
  - The version of pygoldilocks module follows that of GOLDILOCKS database. The version is a string in a form of major.minor.patch.

- apilevel
  - It indicates DB API level 2.0, and the value is "2.0" character string constant.

- lowercase
  - It controls whether to convert the column name from the row object of the result value to lowerc ase. The default value is false. It is useful when the case of database column does not conform.

- threadsafety
  - It is constant 1, and it does not share the connection even when threads share the module.

- paramstyle
  - It indicates a parameter and the value is the character string constant "qmark" which means a qu estion mark.

connect

It newly connects to the database.

```
connect( *connectionstring, **kwargs )
```

It inputs the ODBC connect string and keywords. The keywords are as follows.

Keyword	Description	Default value
attrs_before	It sets properties which should be set before the connection. It receives the value in dictionary type.	-
autocommit	It sets whether to auto commit. If it is false, connection.commit should be c alled to reflect it in the database.	False

Keyword	Description	Default value
readonly	If it is true, the connection is set to readonly.	False
timeout	It sets the timeout for the connection. SQL_ATTR_LOGIN_TIMEOUT is set.	-

- attrs_before
  - It sets options which is to be set before the connection. These options are set by using **SQLSetConnectAttr**. It receives the properties and values in dictionary type. For more information about configuration, refer to **ODBC attributes**.

```
cnxn =  pygoldilocks.connect( "DSN=GOLDILOCKS", attr_before={ pygoldilocks.SQL_ATTR_MAX_ROWS : 1000 })
```

Date

```
>>> print pygoldilocks.Date(1984,11,23),  type(pygoldilocks.Date(1984,11,23))
1984-11-23 <type 'datetime.date'>
```

It creates a date object corresponding to the given value.

Time

```
>>> print pygoldilocks.Time(11,23,23), type(pygoldilocks.Time(11,23,23))
11:23:23 <type 'datetime.time'>
```

It creates a time object corresponding to the given value.

Timestamp

```
>>> print pygoldilocks.Timestamp(1984,11,23,11,23,23),
type(pygoldilocks.Timestamp(1984,11,23,11,23,23))
1984-11-23 11:23:23 <type 'datetime.datetime'>
```

It creates a datetime object corresponding to the given value.

DATETIME

```
>>> print pygoldilocks.DATETIME(1984,11,23,11,23,23),
type(pygoldilocks.DATETIME(1984,11,23,11,23,23))
1984-11-23 11:23:23 <type 'datetime.datetime'>
```

It creates a datetime object corresponding to the given value. It is as same as **Timestamp**.

Binary

```
>>> print pygoldilocks.Binary('binary'), type(pygoldilocks.Binary('binary'))
binary <type 'bytearray'>
```

It creates a bytearray object corresponding to the given value. It is as same as **BINARY**.

BINARY

```
>>> print pygoldilocks.BINARY('binary'), type(pygoldilocks.BINARY('binary'))
binary <type 'bytearray'>
```

It creates a bytearray object corresponding to the given value.

STRING

```
>>> print pygoldilocks.STRING('str'), type(pygoldilocks.STRING('str'))
str <type 'str'>
```

It creates an str object corresponding to the given value.

NUMBER

```
>>> print pygoldilocks.NUMBER(100.001), type(pygoldilocks.NUMBER(100.001))
100.001 <type 'float'>
```

It creates a float object corresponding to the given value.

ROWID

```
>>> print pygoldilocks.ROWID('AA'), type(pygoldilocks.ROWID('AA'))
AA <type 'str'>
```

It is used to describe the row ID column of the database, and returns an str object.

TimeFromTicks

```
>>> print pygoldilocks.TimeFromTicks( 10 )
09:00:10
```

It returns a datetime.time object which is set as an argument value.

DateFromTicks

```
>>> print pygoldilocks.DateFromTicks( 360000 )
1970-01-05
```

It returns a datetime.date object which is set as an argument value.

TimestampFromTicks

```
>>> print pygoldilocks.DateFromTicks( 360000 )
1970-01-05
```

It returns a datetime.timestamp object which is set as an argument value.

setDecimalSeparator

It sets the decimal point delimiter in NUMERIC type obtained from the database. The default value uses a period (.).

getDecimalSeparator

It obtains the set decimal point delimiter in NUMERIC type.

Connection

It is an object managing the connection with the database, and it is created with connect() function of py goldilocks module.

Properties

- autocommit
  - It can set the autocommit mode of the connection.
- searchescape
  - It obtains an escape character of ODBC. pygoldilocks uses '/'.
- timeout
  - It sets SQL_ATTR_QUERY_TIMEOUT by using SQLSetConnectAttr function.

함수

- cursor()
  - It returns a new cursor object.
- commit()
  - It commits the executed SQL statement.
- rollback()
  - It rolls back the executed SQL statement.
- close()
  - It closes the connection. If the autocommit is false, then the SQL statement which was not comm itted is rolled back.
- getinfo(info)
  - It can obtain the connection properties by using SQLGetInfo function of ODBC. For more informa tion, refer to **SQLGetInfo**.

```
dns_name = cnxn.getinfo( pygoldilocks.SQL_DATA_SOURCE_NAME )
```

- execute(sql, [*params])
  - It creates a new cursor object, and executes execute function of this object, then returns a cursor object.

```
cursor = cnxn.execute( "SELECT COUNT(*) FROM EMP" )
```

For more information, refer to Cursor.execute() function. This function does not exist in Python API, but i t is provided for the convenience. Whenever this function is called, a cursor object is allocated, so it is not recommended to use it when it is required to execute one or more SQL statements.

- set_attr(attr_id, value)

- The connection properties can be set by executing SQLSetConnectAttr function.
- The following is an example of controlling the transaction isolation level of the database by using set_attr function.

```
connection.set_attr( pygoldilocks.SQL_ATTR_TXN_ISOLATION, pygoldilocks.SQL_TXN_SERIALIZABLE )
```

Cursor

Generally, a cursor object means the database cursor which is used to manage the fetch operation. The database cursor is mapped to ODBC statement handle (HSTMT). The cursor objects which is created by the same connection are not separated. In other words, all updates executed by a cursor to the database are also applied to other cursors.

Cursor does not manage the database transaction, but the connection commits or rolls back the transaction.

Properties

Description

It is the read-only property, and it includes the contents for each column which was returned by SELECT statement executed last with tuple type. Each tuple includes the followings.

1. Column name (or alias)
2. Type code
3. Display size
4. Internal size
5. Precision
6. Scale
7. Nullable

When SELECT statement is not called, then the description is none.

rowcount

It is the number of rows which were updated by SQL statement which was executed last.

arraysize

It is the number of rows which can be fetched per one time by using **fetchmany([size = cursor.arraysize])** function. The default value 1.

connection

It is the read-only property, and it indicates the connection object which created the corresponding curso r object.

fast_executemany

If it is set to true, then makes the parameters in array and executes them at once when executing **execute many(sql, [*params])** function. If it is set to false, it separately executes each parameter.

Function

execute(sql, [*params])

It executes SQL statement through SQLPrepare and SQLExecute functions, then returns a cursor which ca lled this function.
The parameter option can be used as follows.

```
cursor.execute( "SELECT A FROM TEST WHERE B=? AND C=?", x, y )
```

```
cursor.execute( "SELECT A FROM TEST WHERE B=? AND C=?", (x, y) )
```

executemany(sql, [*params])

It executes SQL statement for each parameter and returns *none*. Parameter *params* should be a sequence type of a sequence or a sequence generator.

```
params = [ ( 1, 'A' ), ( 2, 'B' ) ]
cursor.executemany("INSERT INTO TEST( C1, C2 ) VALUES ( ?, ? )", params)
```

SQL statement is executed twice in the example above. In other words, it is separately executed for (1, 'A') and (2, 'B') each. The operation of executemany depends on whether fast_executemany of a cursor object is set to true or false.

The example above is as same as follows.

```
params = [ ( 1, 'A' ), ( 2, 'B' ) ]
for p in params:
    cursor.execute( "INSERT INTO TEST( C1, C2 ) VALUES ( ?, ? )", p )
```

If fast_executemany is set to true, executemany processes the operation with only a single execute. For th at, data in the same index location in items of parameter *params* should be the same data type.

```
params = [ ( 1, 'A' ), ( '2', 'B' ) ]
cursor.executemany("INSERT INTO TEST( C1, C2 ) VALUES ( ?, ? )", params)
```

In the example above, the data type of the first item among two items of parameter params is different. L ikewise, the data type on the same index location between items are different, then executemany does n ot process SQL statement at once, but separately processes it.

If the autocommit of a connection object is true, then SQL statement is processed being splited and each SQL statement is separately committed. If an error occurs while sequentailly processing records, then only some records are committed to the database and the operation is completed leaving some records are no t committed. Therefore, it is recommended to set autocommit to false to check if all records are committ ed to the database when using executemany().

fetchone()

It returns the next row of the query. If the next data does not exist, it is *none*.

fetchall()

It returns all rows left in the query. Be cautious when using it because it reads all rows to the memory.

fetchmany([size = cursor.arraysize])

It returns rows which were left as many as size or cursor.arraysize. The next data returns an empty sequen ce data. The default value of cursor.arraysize is 1.

commit()

It commits SQL statement. It is a function executed by a connection object which created a cursor object, and it is applied to all cursor which were created in the same connection object. It is as same as commit o f the connection object.

rollback()

It rolls back SQL statement. It is a function executed by a connection object which created a cursor object, and it is applied to all cursor which were created in the same connection object. It is as same as rollback o f the connection object.

skip(count)

It passes through the record through SQLFetchScroll and SQL_FETCH_NEXT as many times as it is set in c ount.

nextset()

It returns false because GOLDILOCKS ODBC does not support SQLMoreResults.

close()

It closes a cursor object.

setinputsizes(size_list)

It is an optional function, and receives sequence type as a parameter. It sets INPUT parameter size of SQL BindParameter.

setoutputsize(size)

It is an optional function, and is used for a purpose which is different from that of DB API, and it allocates the buffer size of OUTPUT parameter.

callproc(procname [, params])

It calls the storage procedure corresponding to procname. The parameter should be a sequence type, and it includes the output parameter. However, data located in the output parameter when inputting is mean ingless. callproc function updates data corresponding to INOUT, OUT of the input parameter data, and re turns it in sequence type.

```
create_proc = """CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 OUT CHAR(10) )
IS
  V1 CHAR(10);
BEGIN
  SELECT T1.I1
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A1;
  A2 := V1;
END;\
"""
cursor.execute( create_proc )
result = cursor.callproc( 'PROC1', ( 1, 0 ) )
```

callfunc(funcname [, params])

It calls a function corresponding to funcname. callfunc() returns the function data.

```
create_func = """
CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
  RETURN INTEGER
  IS
    V1 INTEGER;
  BEGIN
    SELECT COUNT(*)
      INTO V1
      FROM T1
      WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    RETURN V1;
  END;\
"""
cursor.execute( create_func )
cursor.commit()
result = cussr.callfunc( 'FUNC1', ( 1,  4) )
```

tables(table=None, catalog=None, schema=None, tableType=None)

It returns the table information of the database which satisfies the given condition. The character '_' and '%' are translated as a wild card. Each row has the following column information. For more information, refer to **SQLTables**.

1. table_cat: It is the name of the catalog.
2. table_schem: It is the name of the schema.
3. table_name: It is the name of the table.
4. table_type: 'TABLE', 'VIEW', 'SYSTEM TABLE', 'GLOBAL TEMPORARY', 'LOCAL TEMPORARY', 'IMMUTABLE TABLE', 'ALIAS', 'SYNONYM' or a specific type name can be a table type.
5. remarks: It is a description of a table.

```
print cursor.tables( table= 'TEST' ).fetchone()
#print table name
for row in cursor.tables():
 print row.table_name
```

If a parameter is empty, information of all table of which a user has a privilege is returned.

columns(table=None, catalog=None, schema=None, tableType=None)

It obtains the column information of the specified table through **SQLColumns** function. Each row includes the following column information.

1. table_cat
2. table_schem
3. table_name
4. column_name
5. data_type
6. type_name
7. column_size
8. buffer_length
9. decimal_digits
10. num_prec_radix
11. nullable
12. remarks
13. column_def
14. sql_data_type
15. sql_datetime_sub
16. char_octet_length
17. ordinal_position
18. is_nullable: SQL_NULLABLE, SQL_NO_NULLS or SQL_NULLS_UNKNOWN.

```
#print column name of table TEST
for r in cursor.columns( table = 'TEST' ):
    print r.column_name
```

statistics(table, catalog=None, schema=None, unique=False, quick=True)

It obtains the information about the specified table through **SQLStatistics** function.
If unique is true, it returns an unique index, and if it is false, it returns all indexes.
If quick is true, CARDINALYTIY and PAGES are returned only when it is instantly available, otherwise, NUL L is returned to the corresponding column.

1. table_cat
2. table_schem
3. table_name
4. non_unique
5. index_qualifier
6. index_name
7. type
8. ordinal_position
9. column_name
10. asc_or_desc
11. cardinality
12. pages

13. filter_condition

A wildcard character is not allowed.

rowIdColumns(table, catalog=None, schema=None, nullable=True)

It returns the result set of columns which uniquely identifies a row by executing **SQLSpecialColumns** with SQL_BEST_ROWID. Each row includes the following column information.

1. scope: SQL_SCOPE_CURROW, SQL_SCOPE_TRANSACTION, or SQL_SCOPE_SESSION
2. column_name
3. data_type: SQL type constant of ODBC
4. type_name
5. column_size
6. buffer_length
7. decimal_digits
8. pseudo_column: SQL_PC_UNKNOWN, SQL_PC_NOT_PSEUDO or SQL_PC_PSEUDO

rowVerColumns(table, catalog=None, schema=None, nullable=True)

It returns the result set of columns which are automatically updated when a row is updated by executing **SQLSpecialColumns** with SQL_ROWVER. Each row includes the following column information.

1. scope: SQL_SCOPE_CURROW, SQL_SCOPE_TRANSACTION, or SQL_SCOPE_SESSION
2. column_name
3. data_type: SQL type constant of ODBC
4. type_name
5. column_size
6. buffer_length
7. decimal_digits
8. pseudo_column: SQL_PC_UNKNOWN, SQL_PC_NOT_PSEUDO, or SQL_PC_PSEUDO

primaryKeys(table, catalog=None, schema=None)

It returns the result set of columns which configures major keys of a table by executing **SQLPrimaryKeys** f unction. Each row includes the following column information.

1. table_cat
2. table_schem
3. table_name
4. column_name
5. key_seq
6. pk_name

foreignKeys(table=None, catalog=None, schema=None, foreignTable=None, foreignCatalog=None, foreignSchema=None)

It creates the result set of column names of a specified table, or the result set of column names which are foreign keys of another table referring to the basic key of the specified table, by executing **SQLForeignKeys** function. Each row includes the following column information.

1. pktable_cat
2. pktable_schem
3. pktable_name
4. pkcolumn_name
5. fktable_cat
6. fktable_schem
7. fktable_name
8. fkcolumn_name
9. key_seq
10. update_rule
11. delete_rule
12. fk_name
13. pk_name
14. deferrability

procedures(procedure=None, catalog=None, schema=None)

It creates the result set of the information about the procedure by executing **SQLProcedures**. Each row includes the following column information.

1. procedure_cat
2. procedure_schem
3. procedure_name
4. num_input_params
5. num_output_params
6. num_result_sets
7. remarks
8. procedure_type

getTypeInfo(sqlType=None)

It creates the result set of the information about the specified data type or about all data types which are supported by GOLDILOCKS ODBC, by executing **SQLGetTypeInfo** function. Each row includes the following column information.

1. type_name

2. data_type
3. column_size
4. literal_prefix
5. literal_suffix
6. create_params
7. nullable
8. case_sensitive
9. searchable
10. unsigned_attribute
11. fixed_prec_scale
12. auto_unique_value
13. local_type_name
14. minimum_scale
15. maximum_scale
16. sql_data_type
17. sql_datetime_sub
18. num_prec_radix
19. interval_precision

Row

A row object is returned with fetch function of a cursor object. It is processed as a tuple type as described in DB API.

```
row = cursor.fetchone()
for column in row:
    print column
```

The following features are added to pygoldilocks.

- It can access the data by using a column name.
- It can access the value of cursor.description through a row even after a cursor object is closed.
- It can update the value of a row.

Accessing to a row by using a column name is not only convenient but it also improves the readability. Ho wever, if a column name includes Python reserved name or a whitespace, then it be accessed only throug h row.__getattribute__().

```
cursor.execute( "select c1 from test")
print cursor.description
```

```
row = cursor.fetchone()
print row.C1
```

```
(('C1', <type 'str'>, 10, 10, 10, 0, True),)
test
```

Basically, the identifier of GOLDILOCKS database is uppercase. However, sometimes it is required to be specified in lowercase, so be cautious of using uppercase or lowercase when accessing to a row by using a column name.

Properties

- cursor_description

It is the copy of property description of a cursor object which created the corresponding row. For more information, refer to **Cursor.description**.

35.3 Exception

Python exceptions occur by pygoldilocks when GOLDILOCKS ODBC detects an error. The exception classes are as follows, which are as same as **Python DB API**.

- Error
  - DatabaseError
    - DataError
    - OperationalError
    - IntegrityError
    - InternalError
    - ProgrammingError
    - NotSupportedError

If an error occurs, generally, the exception is processed based on SQLSTATE value provided by the database.

SQLSTATE	Exception
0A000	NotSupportedError
01002	OperationalError
08001	OperationalError
08003	OperationalError
08004	OperationalError
08007	OperationalError
08S01	OperationalError
28000	InterfaceError
40002	IntegrityError
22***	DataError
23***	IntegrityError
24***	ProgrammingError
25***	ProgrammingError
42***	ProgrammingError

35.4 Data Type

Transferring Python Parameter to GOLDILOCKS

The data is converted as follows when transferring Python parameter to GOLDILOCKS ODBC.

Table 35-1 Python 3

Python datatype	Description	ODBC datatype
None	-	SQL_VARCHAR
str	UTF-8	SQL_VARCHAR or SQL_LONGVARCHAR
bytes, bytearray	binary	SQL_VARBINARY or SQL_LONGVARBINARY
bool	bit	SQL_BIT
datetime.date	date	SQL_TYPE_DATE
datetime.time	time	SQL_TYPE_TIME
datetime.datetime	timestamp	SQL_TYPE_TIMESTAMP
int	integer	SQL_BIGINT
float	floating point	SQL_DOUBLE
decimal	numeric	SQL_NUMERIC

Table 35-2 Python 2

Python datatype	Description	ODBC datatype
None		SQL_VARCHAR
str	UTF-8	SQL_VARCHAR or SQL_LONGVARCHAR
bytearray	binary	SQL_VARBINARY or SQL_LONGVARBINARY
buffer	binary	SQL_VARBINARY or SQL_LONGVARBINARY
bool	bit	SQL_BIT
datetime.date	date	SQL_TYPE_DATE
datetime.time	time	SQL_TYPE_TIME
datetime.datetime	timestamp	SQL_TYPE_TIMESTAMP
int	integer	32 bit: SQL_INTEGER, 64 bit: SQL_BIGINT
long	bigint	SQL_BIGINT
float	floating point	SQL_DOUBLE
decimal	numeric	SQL_NUMERIC

SQL Value Received from GOLDILOCKS

The data is converted as follows when transferring the data of GOLDILOCKS database to Python.

Table 35-3 Python 3

ODBC datatype	Description	Python datatype
any	NULL	None
SQL_CHAR, SQL_VARCHAR, SQL_LONGVARCHAR	text	text
SQL_BINARY_SQL_VARBINARY, SQL_LONGVARBINARY	binary	bytes
SQL_NUMERIC	decimal, numeric	decimal.Decimal
SQL_BOOLEAN	bit, bool	bool
SQL_SMALLINT, SQL_INTEGER	integers	int
SQL_BIGINT	long	long
SQL_REAL, SQL_FLOAT, SQL_DOUBLE	floating point	float
SQL_TYPE_TIME	time	datetime.time
SQL_TYPE_DATE	date	datetime.date
SQL_TYPE_TIMESTAMP	timestamp	datetime.timestamp
SQL_TYPE_TIME_WITH_TIMEZONE	time with timezone	text
SQL_TYPE_TIMESTAMP_WITH_TIMEZONE	timestamp with timezone	text
SQL_C_INTERVAL_***	interval	text

Table 35-4 Python 2

ODBC datatype	Description	Python datatype
any	NULL	None
SQL_CHAR, SQL_VARCHAR, SQL_LONGVARCHAR	text	text
SQL_BINARY_SQL_VARBINARY, SQL_LONGVARBINARY	binary	bytes
SQL_NUMERIC	decimal, numeric	decimal.Decimal
SQL_BOOLEAN	bit, bool	bool
SQL_SMALLINT, SQL_INTEGER	integers	int
SQL_BIGINT	long	long
SQL_REAL, SQL_FLOAT, SQL_DOUBLE	floating point	float
SQL_TYPE_TIME	time	datetime.time
SQL_TYPE_DATE	date	datetime.date
SQL_TYPE_TIMESTAMP	timestamp	datetime.timestamp
SQL_TYPE_TIME_WITH_TIMEZONE	time with timezone	text
SQL_TYPE_TIMESTAMP_WITH_TIMEZONE	timestamp with timezone	text
SQL_C_INTERVAL_***	interval	text

The text of Python data type is converted to unicode in Python 3. It is converted to the unicode or a string according to the character set of the database in Python 2.

Table 35-5 Python 2 text

DB character set	Python type
UTF-8	str
SQL_ASCII	str
UHC	unicode
GB18030	unicode

36.

Ruby

36.1 Overview

GOLDILOCKS ruby is a driver which enables to use GOLDILOCKS database in an application created with r uby, and it is provided as a RubyGem package.
GOLDILOCKS ruby driver is created based on GOLDILOCKS CLI driver.

36.2 Installation

Requirement

The client package of GOLDILOCKS should be installed in the same system as that of Ruby, and $GOLDIL OCKS_HOME environment variable should be set.

Installing/ Removing

GOLDILOCKS ruby driver can be installed/ removed by using gem.

Removing

Remove the installed GOLDILOCKS ruby driver.

```
% sudo -E gem uninstall ruby-goldilocks
```

Installating

Create the package file when GOLDILOCKS ruby driver package file does not exist.

```
% gem build goldilocks.gemspec
  Successfully built RubyGem
  Name: ruby-goldilocks
  Version: 3.2.0
  File: ruby-goldilocks-3.2.0.gem
```

Install the package file by using gem when GOLDILOCKS ruby driver package file exists.

```
% sudo -E gem install ruby-goldilocks-3.2.0.gem
Building native extensions.  This could take a while...
Successfully installed ruby-goldilocks-3.2.0
Parsing documentation for ruby-goldilocks-3.2.0
Installing ri documentation for ruby-goldilocks-3.2.0
Done installing documentation for ruby-goldilocks after 0 seconds
1 gem installed
```

36.3 Examples

Connecting

Connecting by Using DSN

```
require 'goldilocks'
$c = GOLDILOCKS.connect("GOLDILOCKS")
```

Connecting by Using DSN, UID, PWD

```
require 'goldilocks'
$c = GOLDILOCKS.connect("GOLDILOCKS", "test", "test")
```

Connecting by Using Connecting String

```
$c = GOLDILOCKS::Database.new.drvconnect("DSN=GOLDILOCKS")
```

```
$c = GOLDILOCKS::Database.new.drvconnect("HOST=192.168.0.1;PORT=22581;UID=test;PWD=test")
```

Creating Table

```
$c.run("create table test (id int not null, str varchar(32) not null)")
```

Inserting Data

```
$q = $c.run("insert into test (id, str) values (1, 'foo')")
$q.run("insert into test (id, str) values (2, 'bar')")
$p = $c.proc("insert into test (id, str) values (?, ?)") {}
$p.call(3, "FOO")
$p[4, "BAR"]
```

Retrieving Data

```
$q = $c.prepare("select id,str from test order by id")
if $q.column(0).name.upcase != "ID" then raise "fetch failed" end
if $q.column(1).name.upcase != "STR" then raise "fetch failed" end
$q.execute
if $q.fetch != [1, "foo"] then raise "fetch: failed" end
if $q.fetch != [2, "bar"] then raise "fetch: failed" end
if $q.fetch != [3, "FOO"] then raise "fetch: failed" end
if $q.fetch != [4, "BAR"] then raise "fetch: failed" end
if $q.fetch != nil then raise "fetch: failed" end
$q.close
if $q.execute.entries != [[1, "foo"], [2, "bar"], [3, "FOO"], [4, "BAR"]] then
  raise "fetch: failed"
end
$q.close
if $q.execute.fetch_all != [[1, "foo"], [2, "bar"], [3, "FOO"], [4, "BAR"]] then
  raise "fetch: failed"
end
$q.close
$q.execute
if $q.fetch_many(2) != [[1, "foo"], [2, "bar"]] then raise "fetch: failed" end
if $q.fetch_many(3) != [[3, "FOO"], [4, "BAR"]] then raise "fetch: failed" end
if $q.fetch_many(99) != nil then raise "fetch: failed" end
```

```
$q.close
a = []
$q.execute {|r| a=r.entries}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash(true) {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash(:key=>:Symbol) {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash(:key=>:Symbol,:table_names=>true) {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash(:key=>:String,:table_names=>false) {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
a = []
$q.execute.each_hash(:key=>:Fixnum,:table_names=>false) {|r| a.push(r)}
if a.size != 4 then raise "fetch: failed" end
$q.close
```

Updating Data

```
$q = $c.run("update test set id=0, str='hoge'")
if $q.nrows != 4 then
  $stderr.print "update row count: expected 4, got ", $q.nrows, "\n"
```

```
end
```

Deleting Data

```
$count = $c.do("delete from test where 1 = 1")
if $count != 4
  $stderr.print "delete row count: expected 4, got ", $count, "\n"
end
$count = $c.do("delete from test where 1 = 1")
if $count != 0
  $stderr.print "delete row count: expected 0, got ", $count, "\n"
end
```

Arranging All Created Statement

```
$c.drop_all
```

Dropping Table

```
$c.do("drop table test")
```

Disconnecting

```
$c.disconnect
```

36.4 Examples of ActiveRecord

The following table is created in advance as an example.

```
CREATE TABLE members
(
  id         INTEGER GENERATED BY DEFAULT AS IDENTITY PRIMARY KEY,
  name       VARCHAR(255),
  email      VARCHAR(255),
  created_at TIMESTAMP,
  updated_at TIMESTAMP
);
```

Connecting

```
require 'rubygems'
require 'active_record'
require 'goldilocks'
ActiveRecord::Base.establish_connection(
    :adapter => "goldilocks",
    :host => "192.168.0.1",
    :port => "22581",
    :uid => "TEST",
    :pwd => "test",
    :option => "" )
```

The property values for the connection are as follows.

Property	Description
:adapter	goldilocks
:dsn	ODBC data source name (DSN)
:host	IP address of a server
:port	PORT number of a server
:uid	User ID
:pwd	User password
:opt	Connection string

Inserting Data

```
class Members < ActiveRecord::Base
end
```

```
Members.create(:name => "David",  :email => "David@mail.com")
Members.create(:name => "Olivia", :email => "Olivia@mail.com")
Members.create(:name => "Amelia", :email => "Amelia@mail.com")
Members.create(:name => "Hazel",  :email => "Hazel@mail.com")
Members.create(:name => "Lily",   :email => "Lily@mail.com")
```

Retrieving Data

```
require 'pp'
puts "\nfind(1)"
puts '-'*80
David = Members.find(1)
pp(David)
puts '-'*80
puts "\nwhere(:name => \"Amelia\")"
puts '-'*80
Amelia = Members.where(:name => "Amelia")
pp(Amelia)
puts '-'*80
puts "\nfind_each"
puts '-'*80
Members.find_each do |member|
  pp(member)
end
puts '-'*80
```

Updating Data

```
puts "\nupdate Lily -> Harry"
puts '-'*80
Members.transaction do
 Lily = Members.where(:name => 'Lily')[0]
 Lily.name = 'Harry'
 Lily.save
end
puts "\nfind_each"
Members.find_each do |member|
```

```
 pp(member)
end
puts '-'*80
```

Deleting Data

```
puts "\ndelete Harry"
puts '-'*80
Members.transaction do
 Harry = Members.where(:name => 'Harry')[0]
 Harry.destroy
end
puts "\nfind_each"
Members.find_each do |member|
 pp(member)
end
puts '-'*80
```

37.

Hibernate

37.1 Overview

Hibernate is a Object-Replation Mapping (ORM) framework of which Java Persistent API (JPA) model is a pplied to the database. It maps the relationship between DB table and Java object so that it helps the per sistent logic processing. In other words, when using hibernate, it is easy to access and control DB without using SQL.

37.2 Interworking with Hibernate

Downloading Hibernate

Hibernate can be downloaded at **https://sourceforge.net/projects/hibernate/**. When the downloaded file is decompressed, many jar files are found in lib directory. These files are used to interwork with hibernate.

Hibernate of GOLDILOCKS is created based on Hibernate version 5.2.

Interworking with GoldilocksDialect Class

GOLDILOCKS provides GoldilocksDialect.java file which is appropriate to Hibernate ORM version. When u sing Goldilocks.java 5 version file in Hibernate ORM 4 version, then a compile error occurs. Therefore, use GoldilocksDialect.java file which is appropriate for Hibernate version.

Especially, Hibernate ORM 4 version provides each different api according to the patch version, so GOLDI LOCKS provides GoldilocksDialect.java according to it. For example, Goldilocks.java 4.0.0 version is used i n Hibernate ORM 4.1.4 version, and GoldilocksDialect.java 4.1.5 version is used in Hibernate ORM 4.1.9 version.

GOLDILOCKS provides GoldilocksDialect.java in the directory under $GOLDILOCKS_HOME/app_dev/Hiber nate/.

Porting to Hibernate jar File

It should be ported to the downloaded Hibernate jar file to interwork with Hibernate. GoldilocksDialect.class file and GoldilocksDialect$1.class file can be included in Hibernate jar file as follows.

1. Create a class file by compiling GoldilocksDialect.java file using javac. (The class file is differently created per each version.)
2. Decompress Hibernate jar file.
3. Move GoldilocksDialect.class file and GoldilocksDialect$1.class file to the decomprressed org/hibernate/dialect directory.
4. Compress it again with Hibernate jar file.
5. Add the newly created jar file to classpath.

```
$ javac -cp hibernate-cor-5.2.11.Final.jar GoldilocksDialect.java
$ jar -xvf hibernate-core-5.2.11.Final.jar
$ pwd
hibernate-release-5.2.11.Final/lib/required/
$ mv GoldilocksDialect*.class org/hibernate/dialect/
$ jar -cvf hibernate.5.2.11.jar  META-INF/MANIFEST.MF .
```

Porting to Program Source

Interworking is available by directly using the source file without porting the class file to jar file. Create org.hibernate.dialect package in the user project, then insert GoldilocksDialect.java file into this package.

37.3 Examples

Configuration

hibernate-configuration XML file and hibernate-mapping XML file are required to interqork Hibernate an d DB.

Hibernate Configuration File

Configuration XML file sets the connect information to access the dialect class and DB, and sets Hibernat e-mapping files.
For more information, refer to **Configuration**.

The following is an example of hibernate.conf.xml file.

```
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE hibernate-configuration PUBLIC
"-//Hibernate/Hibernate Configuration DTD 3.0//EN"
"http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">

<hibernate-configuration>
    <session-factory>
        <property
name="hibernate.connection.driver_class">sunje.goldilocks.jdbc.GoldilocksDriver</property>
        <property
name="hibernate.connection.url">jdbc:goldilocks://192.168.0.21:22581/test</property>
        <property name="hibernate.connection.username">test</property>
        <property name="hibernate.connection.password">test</property>
        <property name="hibernate.dialect">org.hibernate.dialect.GoldilocksDialect</property>
        <property name="show_sql">true</property>
        <property name="format_sql">true</property>
        <property name="hbm2ddl.auto"> create </property>
        <mapping resource="SampleTable.mapping.xml" />
    </session-factory>
</hibernate-configuration>
```

Set the DB connecting information on <session-factory> tag, and specifies the dialect class name of DB to connect to hibernate.dialect property. Also, specify hibernate-mapping files by using <mapping-resource> tag.

Hibernate Mapping File

Mapping XML is a configuration file including mapping information about DB table and Java object.
For more information, refer to **Mapping**.

The following is an example of SampleTable.mapping.xml file which was used in the example above.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE hibernate-mapping PUBLIC
"-//Hibernate/Hibernate Mapping DTD 3.0//EN"
"http://hibernate.sourceforge.net/hibernate-mapping-3.0.dtd">
<hibernate-mapping>
    <class name="SampleTable" table="SAMPLETABLE">
        <id column="ID" name="id" type="long">
            <generator class="increment" />
        </id>
        <property column="STUDENT_NAME" name="name" type="string" />
        <property column="BIGINT_VALUE" name="bigintValue" type="long" />
        <property column="INT_VALUE" name="intValue" type="int" />
        <property column="SMALL_VALUE" name="smallValue" type="short" />
        <property column="FLOAT_VALUE" name="floatValue" type="float" />
        <property column="DOUBLE_VALUE" name="doubleValue" type="double" />
        <property column="NUMERIC_VALUE" name="numericValue" type="big_integer" precision="10"
scale="5" />
        <property column="DATE_VALUE" name="dateValue" type="date" />
        <property column="TIME_VALUE" name="timeValue" type="time" />
        <property column="TIMESTAMP_VALUE" name="timestampValue" type="timestamp" />
        <property column="VARBINARY_VALUE" name="binaryValue" type="byte[]" />
    </class>
</hibernate-mapping>
```

The mapping information about Java class and DB table are described on <class> tag. Data type used in a table column and Java are specified on <property> tag.

Examples of Application

Java class to be mapped to DB table should be described. The following is an example of SampleTable.jav
a which is described above.

```
import java.math.BigInteger;
import java.sql.Date;
import java.sql.Time;
import java.sql.Timestamp;
public class SampleTable {
    private long id;
    private String     name;
    private long       bigintValue;
    private int        intValue;
    private short      smallValue;
    private float      floatValue;
    private double     doubleValue;
    private BigInteger numericValue;
    private Date       dateValue;
    private Time       timeValue;
    private Timestamp  timestampValue;
    private byte[]     binaryValue;
    private String     longvarcharValue;
    private byte[]     longvarbinaryValue;

    public SampleTable() {
        this.name = null;
    }

    public SampleTable( String name ) {
        this.name = name;
    }
    public long getId() {
        return id;
    }

    public void setId( long id ) {
        this.id = id;
    }

    public String getName() {
        return name;
    }

    public void setName( String name ) {
        this.name = name;
```

```
    }
....
```

get/ set function of a variable corresponding to a column of SampleTable table should be described.

The data is processed in SamleTable table as follows.

1. It obtains org.hibernate.SessionFactory object through a configuraion file.
2. It obtains org.hibernate.Session object through SessionFactory object.
3. It processes the desired operation by calling a method of a session object.

The following is an example of inserting, updating, retrieving, deleting data in SampleTable table of DB. It obtains SessionFactory object through org.hibernate.Configuration class.

```
public class HibernateSample
{
    private static SessionFactory mFactory;
    public static void main( String[] args ) {
        try {
            mFactory = new Configuration().configure( "hibernate.conf.xml"
).buildSessionFactory();
        } catch( Throwable ex ) {
            System.err.println( "Failed to create sessionFactory object." + ex);
            throw new ExceptionInInitializerError(ex);
        }
        HibernateSample sHibernateSample = new HibernateSample();
```

- Insert 3 records

```
Long sRecord1 = sHibernateSample.addSample( "RECORD_1" );
Long sRecord2 = sHibernateSample.addSample( "RECORD_2" );
Long sRecord3 = sHibernateSample.addSample( "RECORD_3" );
```

- Update record 1

```
sHibernateSample.updateSample( sRecord1, ....
```

- Fetch table

```
sHibernateSample.fetchSample( 0, 3 );
```

- Delete record 2

```
sHibernateSample.deleteSample( sRecord2 );
sHibernateSample.closeFactory();
    }
public void closeFactory() {
        mFactory.close();
    }
....
```

The following is an example of a method inserting a record to HibernateSample class. First, it obtains a se ssion object through SessionFactory class, then obtains org.hibernate.Transaction object. It can be commi tted or rolled back after starting a transaction by using a transaction class and inserting a record.

```
public Long addSample( String name ) {
    Session session = mFactory.openSession();
    Transaction tx = null;
    Long id = null;

    try{
```

- Begin transaction

```
tx = (Transaction) session.beginTransaction();
SampleTable sample = new SampleTable( name );
```

- Insert

```
id = (Long) session.save(sample);
```

- Commit transaction

```
tx.commit();

        System.out.println("add success");
    } catch( HibernateException e) {
        if( tx != null ) {
            tx.rollback();
        }
        System.out.println("add fail");
        e.printStackTrace();
    } finally {
        session.close();
    }
```

```
    return id;
}
```

The following is an example of a method retrieving SampleTable table. It obtains org.hibernate.Query obj ect through a session class. fetchSample method retrieves SampleTable from offset to count.

```
public void fetchSample( int offset, int count ) {
    Session session = mFactory.openSession();
    Query query = null;

    try{
        query = session.createQuery( "FROM SampleTable" );
        query.setFirstResult( offset );
        query.setMaxResults( count );
        query.setFetchSize( 20 );

        @SuppressWarnings( "unchecked" )
        List<SampleTable> samples = (List<SampleTable>) query.list();
        for( Iterator<SampleTable> iter = samples.iterator(); iter.hasNext(); ) {
            SampleTable sample = (SampleTable) iter.next();
            System.out.print( "id: " + sample.getId() );
           ... Ellipsis ...
        }
    } catch ( HibernateException e ) {
        e.printStackTrace();
    } finally {
        session.close();
    }
}
```

The following is an exampel of a method updating SampleTable table. After altering to a set method des cribed in SampleTable class, then it is updated by calling an update method of a session class.

```
public void updateSample( long id, ... ) {
    Session session = mFactory.openSession();
    Transaction tx = null;
    try {
        tx = session.beginTransaction();
        SampleTable sample = (SampleTable)session.get(SampleTable.class, id);
        sample.setName( name );
        ...
        session.update( sample );
```

```
        tx.commit();
        System.out.println( "update success" );
        } catch ( HibernateException e ) {
            if( tx != null ){
                tx.rollback();
            }
            System.out.println("update fail");
            e.printStackTrace();
        } finally {
    session.close();
    }
}
```

The following is an example of deleting a record. It can be deleted by using a delete method of a session class.

```
public void deleteSample( long id ) {
    Session session = mFactory.openSession();
    Transaction tx = null;

    try {
        tx = session.beginTransaction();
        SampleTable sample = (SampleTable) session.get( SampleTable.class, id );
        session.delete( sample );
        tx.commit();

        System.out.println( "delete success" );
    } catch ( HibernateException e ) {
        if( tx != null ) {
            tx.rollback();
        }
        System.out.println("delete fail");
        e.printStackTrace();
    } finally {
        session.close();
    }
}
```

Part VI.

Utility Manual

38.

gcreatedb

38.1 Overview of gcreatedb

Definition

gcreatedb is a database creation utility provided by GOLDILOCKS.

Feature

A new database is created by using DB_Name, comment, time zone, character set specified by a user.

Usage

```
gcreatedb [options]
```

Option

```
--cluster             cluster system (if not specified, stand-alone system)
--db_name             database name
--db_comment          database comment
--timezone            timezone ( {+/-}{TZH:TZM} )
--character_set       character set
                           SQL_ASCII
                           UTF8
                           UHC
                           GB18030
--char_length_units   char length units
                           OCTETS
                           CHARACTERS
--home                home directory
--member              local member name
--host                host address
--port                host port
--silent              suppersses the display of the result message
```

```
--help                print help message
```

Example

```
$ gcreatedb --db_name="goldilocks" --db-comment="goldilocks database" --timezone="+09:00"
--character_set="UTF8" --silent
```

38.2 Command Option

--cluster

It creates the database of a cluster environment.
If this option is not used, then it creates the database of a stand alone environment.

--db_name

It specifies the database name which a user wants to create.
The default value is "goldilocks".
The maximum length of database name is 128.

--db_comment

It specifies the database comment which a user wants to create.
The default value is "goldilocks database".
The maximum length of database comment is 1024.

--timezone

It is the time zone value of database.
The default value is the **TIMEZONE** value of the property.
The property is applied when database is created and it has a value in range of '-14:00' ~ '+14:00'.

--character_set

It is the database character set.
The default value is the **CHARACTER_SET** value of the property.

The property is applied when database is created, and its value is set to one of the followings.

- GB18030

- SQL_ASCII
- UHC
- UTF8

--char_length_units

It is the char length unit value which is used when defining the string column type such as CHAR, VARCHAR and omitting its char length unit as follows.

```
CREATE TABLE t1
(
    id   CHAR( 10 OCTETS ),          ❶ It refers to 10 bytes.
    name VARCHAR( 128 CHARACTERS ),  ❷ It refers to 128 characters.
    addr VARCHAR( 1024 )             ❸ char length unit is omitted.
```

The default value is the **CHAR_LENGTH_UNITS** value of the property.

The property is applied when database is created, and its value is set to one of the followings.
- OCTETS: It is the number of bytes.
- CHARACTERS: It is the number of characters.

The default value of char length unit is defined as CHARACTERS in the SQL standard and it is defined as follows in other DBMS.

- OCTETS is used in Oracle, DB2.
- CHARACTERS is used in MS-SQL, MySQL, PostgreSQL.

--home

It sets the home directory of the database.
The default value uses $GOLDILOCKS_HOME environment variable.

--member

It sets the name of a local database in a cluster environment.

--host

It sets the host address of a local database in a cluster environment.

--port

It sets the port number of a local database in a cluster environment.

--silent

Result messages are not displayed.

--help

Help messages are displayed.

```
$ gcreatedb --help
Usage
    gcreatedb [options]
Options:
    --db_name                database name
    --db_comment             database comment
    --timezone               timezone ( {+/-}{TZH:TZM} )
    --character_set          character set
                               SQL_ASCII
                               UTF8
                               UHC
                               GB18030
    --char_length_units      char length units
                               OCTETS
                               CHARACTERS
    --silent                 suppresses the display of the result message
    --help                   print help message
examples:
    gcreatedb --db_name="goldilocks" --db_comment="goldilocks database" --timezone="+09:00"
```

```
--character_set="UTF8" --char_length_units="OCTETS" --silent
```

39.

glsnr

39.1 Overview of glsnr

glsnr is a listener which GOLDILOCKS enables remote access through the network in the client/ server env ironment. glsnr should be run on the server for the network access to GOLDILOCKS.

glsnr is used as follows.

```
$ glsnr [options]
```

39.2 Command Options

The followings are cell prompt options for using glsnr.

--silent

Description

It does not display the message for execution.

Example

```
$ glsnr --start --silent
```

--start

Description

It starts running glsnr. If glsnr is already running, an error occurs.

Example

```
$ glsnr --start
Listener is started successfully.
```

--stop

Description

It stops the currently running glsnr.

Example

```
$ glsnr --stop
Listener is stopped.
```

--status

Description

It displays the message about glsnr status.

Example

```
$ glsnr --status
Listener is not running.
$ glsnr --start
Listener is started successfully.
$ glsnr --status
Listener process ID : 27880
Listener configuration file : /home/goldilocks/goldilocks_home/conf/goldilocks.listener.conf
Unix Domain Path : /tmp/unix-glsnr.22581
TCP Listen Host : 0.0.0.0, Port : 22581
default C/S mode : Dedicated
Connection Timeout(second) : 100
Listener is running.
```

--home

Description

It sets db home.

Example

```
$ glsnr --start --home Gliese/home/g1n1_home
Listener is started successfully.
$ glsnr --status
```

```
Listener process ID : 20777
Listener configuration file :
/home/goldilocks/Gliese/home/g1n1_home/conf/goldilocks.listener.conf
Unix Domain Path : /tmp/unix-glsnr.22581
TCP Listen Host : 0.0.0.0, Port : 22581
default C/S mode : Dedicated
Connection Timeout(second) : 100
Listener is running.
```

--help

Description

It displays the help message.

Example

```
$ glsnr --help

Usage:
  glsnr [options]

Options:

  --silent       don't print message
  --start        start listener
  --stop         stop listener
  --status       show listener status
  --help         show listner help messages
```

39.3 Listener Configuration

Configuration File and Environment Variables

glsnr uses the configuration file or environment variables for setting the configuration.

The environment variable is specified by using the name which 'GOLDILOCKS_' is added to the property name of the configuration as a prefix. For example, setting the LISTEN_PORT in configuration file is as same as specifying $GOLDILOCKS_LISTEN_PORT.

The contents of configuration file precedes the environment variable settings. (In other words, environment variables are applied only if the configuration file is not set.)

The environment file of glsnr is $GOLDILOCKS_DATA/conf/goldilocks.listener.conf. If the corresponding file is changed or the environment variables are set and glsnr is started to run, then the glsnr driving environment is modified.

If a user want to modify and apply the glsnr environment during running glsnr, a user should stop glsnr and change the content of configuration file or set the environment variable and then restart glsnr.

If a user stops the glsnr, a problem does not occur for the client which is already connected, but the problem occurs when being connected from a new client.

LISTEN_PORT

It is the port on which the glsnr waits for the connection.

Item	Description
Name	LISTEN_PORT
Description	It is the port on which the glsnr waits for a connection.
Data type	INT
Default value/ range	22581 / 1024 ~ 49151

Description

The client who wants a TCP connection should try to connect to the specified port.
The port is available from 1024 to 49151.

TCP_HOST

It is an IP address of NIC of which glsnr waits for the connection.

Item	Description
Name	TCP_HOST
Description	It is the IP address which the glsnr binds.
Data type	ip address
Default value	0.0.0.0

Description

The client who wants a TCP connection should access the IP address specified above. The IP address is us ed in IPv4 or IPv6 format.

BACKLOG

It is the number of clients which the glsnr can handle when multiple clients simultaneously access.

Item	Description
Name	BACKLOG
Description	It is the number of client of which glsnr waits for the connection.
Data type	INT
Default value/ range	1024 / 1 ~ 32768

Description

This setting value does not guarantee the number of concurrent connector of the client.

DEFAULT_CS_MODE

It sets the access mode when the access mode is not designated as dedicated or shared on the client.

Item	Description
Name	DEFAULT_CS_MODE
Description	It sets the default access mode.

Item	Description
Data type	String (dedicated | shared)
Default value	dedicated

Description

- The client/ server mode connected via glsnr supports two modes, which are dedicated and shared.
- Generally, the access mode is set as dedicated or shared on the client (It is .odbcini for ODBC), then it accesses. However, if it is not set on the client, the access mode is determined by setting DEFAULT_CS_MODE.

TCP_VALIDNODE_CHECKING

It sets whether to check the validity of the client attempting to access.

Item	Description
Name	TCP_VALIDNODE_CHECKING
Description	It sets whether to check the client validity.
Data type	String (NO | INVITED | EXCLUDED)
Default value	NO

Description

- If the value is set to *NO*, the client validity is not checked.
- If the value is set to *INVITED* and the file set in TCP_INVITED_FILE exists, then only the client having the IP address of the file set in TCP_INVITED_FILE is set to be valid.
- If the value is set to *EXCLUDED* and the file set in TCP_EXCLUDED_FILE exists, then only the client excluding the client who has IP address of the file set in TCP_EXCLUDED_FILE is set to be valid.

TCP_INVITED_FILE

It is used only when the value of TCP VALIDNODE_CHECKING is *INVITED*.

Item	Description
Name	TCP_INVITED_FILE
Description	It is the file with the valid user (IP address) list.
Data type	String

Item	Description
Default value	'goldilocks.invited.conf'

Description

If the set file exists, only the user (IP address) within the file is allowed to access.

TCP_EXCLUDED_FILE

It is used only when the value of TCP VALIDNODE_CHECKING is *EXCLUDED*.

Item	Description
Name	TCP_EXCLUDED_FILE
Description	It is the file with the invalid user (IP address) list.
Data type	String
Default value	'goldilocks.excluded.conf'

Description

If the set file exists, anyone except for the user (IP address) within the file is allowed to access.

TIMEOUT

It is the glsnr timeout value and its unit is second.

Item	Description
Name	TIMEOUT
Description	glsnr timeout
Data type	INT
Default value/ range	100 / (0 ~ 2147483647)

Description

If the response is too slow or there is not a response from the client when glsnr communicates with the cl ient, the connection is released by the specified timeout.

LISTENER_LOG_DIR

It sets the directory which stores the log to be display from the glsnr.

Item	Description
Name	LISTENER_LOG_DIR
Description	It sets the directory which stores the log of the glsnr.
Data type	String
Default value	'<GOLDILOCKS_DATA>/trc'

Description

<GOLDILOCKS_DATA> of the setting value is replaced with the value of the environment variable $GOLDILOCKS_DATA.

UDS_DIR

It sets the directory in which the Unix Domain Socket file used in glsnr is stored.

Item	Description
Name	UDS_DIR
Description	It sets the directory in which the Unix Domain Socket file used in glsnr is stored.
Data type	String
Default value/ range	'/tmp' / Maximum 60 byte

Description

The maximum length of the directory should be set within 60 bytes. The absolute path of the Unix Domain Socket file (directory name + file name) depends on OS, but usually it is around 100 bytes.

40.

gsql/gsqlnet (Interactive SQL Tool)

40.1 Overview of gsql

The followings are execution files.

Table 40-1 Execution files

Execution file name	Description
gsql	It is used in Direct Attach (D/A) environment.
gsqlnet	It is used in Client/ Server (C/S) environment.

All commands supported by gsql are equally supported by gsqlnet.

Definition

gsql is an interactive utility for processing SQL statements provided by GOLDILOCKS.

Using gsql, a user can query the results of the SELECT statement as well as execute SQL statements without any application.

gsql program executes the SQL statement, and queries a brief information of the objects such as tables and indexes through the gsql specific commands beginning with \, and it provides various features such as startup or shutdown of the server, controlling the output, and querying the execution plan of SQL statement.

Examples

This chapter describes the method of creating/dropping the table, manipulating data, performing a query by using gsql.

gsql is operated in an interactive mode as follows. When connecting normally, it waits for entering the SQL statement or gsql command with *gSQL>* prompt.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL>
```

Create a table by executing **CREATE TABLE** statement and commit the transaction as follows.

```
gSQL> CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) );
Table created.
gSQL> COMMIT;
Commit complete.
```

Insert the data into the created table by executing **INSERT INTO** statement, then commit the transaction a s follows. The second INSERT statement is an example of inserting two rows.

```
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
```

- Two rows are inserted.

```
gSQL> INSERT INTO t1 VALUES ( 2, 'mkkim' ), ( 3, 'xcom73' );
2 rows created.
gSQL> COMMIT;
Commit complete.
```

The column addr is added to the table and data is updated by executing **UPDATE** statement as follows.

```
gSQL> ALTER TABLE t1 ADD COLUMN ( addr VARCHAR(1024) );
Table altered.
gSQL> UPDATE t1 SET addr = 'Seoul, Korea' WHERE id = 1;
1 row updated.
gSQL> UPDATE t1 SET addr = 'Inchon, Korea' WHERE id = 3;
1 row updated.
gSQL> COMMIT;
Commit complete.
```

The inserted data is queried by using **SELECT** query as follows. The query result consists of the header rep resenting column names and the information of each row in a single line. NULL is expressed in lowercase null.

```
gSQL> SELECT * FROM t1 ORDER BY 1;
ID NAME   ADDR
-- ------ -------------
 1 leekmo Seoul, Korea
 2 mkkim  null
 3 xcom73 Inchon, Korea
3 rows selected.
```

A host variable is declared, and the value is put in the host variable then a query using the host variable is

performed as follows.

```
gSQL> \var v_id INTEGER
gSQL> \exec :v_id := 1
gSQL> SELECT * FROM t1 WHERE id = :v_id;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
```

The SQL statement is prepared by using **\prepare sql** and the SELECT statement above is repeatedly perf ormed by using **\exec**, changing the value of host variable. ODBC and JDBC simulate prepare/ execute op eration in gsql interactive mode as follows.

```
gSQL> \var v_id INTEGER
gSQL> \prepare sql SELECT * FROM t1 WHERE id = :v_id;
SQL prepared.
gSQL> \exec :v_id := 2
gSQL> \exec
ID NAME  ADDR
-- ----- ----
 2 mkkim null
1 row selected.
gSQL> \exec :v_id := 3
gSQL> \exec
ID NAME   ADDR
-- ------ -------------
 3 xcom73 Inchon, Korea
1 row selected.
```

A scrollable cursor is declared in an embedded SQL, ODBC, JDBC, and the data retrieval using the cursor i s simulated via gsql as follows. The cursor cur1 declared by using **DECLARE cursor_name** is the scrollable KEYSET cursor and various fetch orientations may be used by using **FETCH cursor_name**.

```
gSQL> \var v_id INTEGER
gSQL> \var v_name VARCHAR(128)
gSQL> DECLARE cur1 KEYSET CURSOR FOR SELECT id, name FROM t1 ORDER BY id;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> FETCH cur1 INTO :v_id, :v_name;
V_ID V_NAME
```

```
---- ------
   1 leekmo
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_name;
V_ID V_NAME
---- ------
   2 mkkim
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_name;
V_ID V_NAME
---- ------
   3 xcom73
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_name;
no rows fetched.
gSQL> FETCH ABSOLUTE 2 cur1 INTO :v_id, :v_name;
V_ID V_NAME
---- ------
   2 mkkim
1 row fetched.
gSQL> FETCH PRIOR cur1 INTO :v_id, :v_name;
V_ID V_NAME
---- ------
   1 leekmo
1 row fetched.
gSQL> CLOSE cur1;
Cursor closed.
```

The created table t1 is dropped and the gsql interactive mode is terminated as follows.

```
gSQL> DROP TABLE t1;
Table dropped.
gSQL> COMMIT;
Commit complete.
gSQL> \q
%
```

40.2 Executing gsql

Information of gsql

Refer to the following options.

Table 40-2 Options

Option	Description
--help	Option list
--version	gsql version information

A user can view the gsql command options which are executable at the shell prompt via **--help** option as follows.

```
% gsql --help
Usage
    gsql [user_name [password]] [options]
Arguments:
    user_name       user name
    password        password
Options:
    --version                    print version information and exit
    --import       FILE          import sql FILE
... Ellipsis ...
%
```

gsql program has a version separate from GOLDILOCKS server version, and the version is viewed by using **--version** option as follows. It is recommended to use the gsql program in the same version as the GOLDIL OCKS server.

```
% gsql --version
%
```

The version of GOLDILOCKS server can be view via **VERSION** function as follows.

```
gSQL> SELECT version() FROM dual;
VERSION()
-----------------------------------
1 row selected.
```

Server Connection

Refer to the following options.

Table 40-3 Options

Option	Description
Username Password	It is the user and password of connection.
--as {SYSDBA|ADMIN}	It specifies the connection role.
--conn-string	It specifies the connection string.
--dsn	It specifies Data Source Name (DSN).

User Connection

Using gsql program, it can be connected to GOLDILOCKS server in various ways.

The simplest way to connect is using a username and password as follows. The following is an example t hat the test user connects to it by using the test password. When successfully connected, it operates in an interactive mode and the *gSQL>* prompt waits for the user command.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL>
```

The following is an example that an error occurs when using an invalid username or password. When the login is failed, an error message is displayed and then the gsql program is terminated.

```
% gsql test invalid_password
ERR-28000(16004): invalid username/password; logon denied
%
```

The following is an example that an error occurs when the GOLDILOCKS server does not run. The gsql pr ogram is terminated with the error message as follows.

```
% gsql test test
ERR-HY000(11031): Unable to attach the shared memory segment
%
```

In addition, it can be connected via the following options. For more details, refer to the respective link.

- **--conn-string**
- **--dsn**

SYSDBA Connection

The **--as {SYSDBA|ADMIN}** option is used to drive the server or to connect to SYSDBA role which has full access privilege on the database.

The following is an example of connecting with --as sysdba in the state of when the GOLDILOCKS server is not driven. *gSQL>* prompt is waiting in the state which is ready to drive GOLDILOCKS with the message *Connected to an idle instance*.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL>
```

The following is an example of connecting with --as sysdba when the GOLDILOCKS server is already driven.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL>
```

For more information, refer to **Startup and Shutdown Server**.

Quit gsql

gsql is quit by using `\quit` or `\q` command as follows.
For more information, refer to **`\quit`**.

```
gSQL> \quit
%
```

Controlling Interactive Mode

Refer to the following options.

Table 40-4 Options

Option	Description
--prompt	It specifies the prompt.
--no-prompt	It removes the prompt.
--import	It executes the SQL file with input.
--silent	When executing the SQL file, the command and the result are not displayed.

Option	Description
--enable-color	The query result is displayed by grouping per row.

Controlling Prompt

When starting an interactive mode, the prompt may be changed by using --prompt option as follows. Th e following is an example that the prompt is changed to *GOLDILOCKS>* prompt, not to *gSQL>* prompt.

```
% gsql test test --prompt GOLDILOCKS
Connected to GOLDILOCKS Database.
GOLDILOCKS>
```

For more information about controlling the prompt, refer to the following options.

- --prompt
- --no-prompt

Executing from File

When processing batch operation by using gsql program, the SQL statement included in the file may be e xecuted by using --import option. The following is an example of executing PerformanceViewSchema.sql file in the $GOLDILOCKS_HOME/admin directory. The example uses --silent option not to output the exec ution results.

```
% cd $GOLDILOCKS_HOME/admin
% gsql --as SYSDBA --import 'PerformanceViewSchema.sql' --silent
%
```

For more information about executing gsql from the file, refer to the following options.

- --import
- --silent
- --enable-color

Storing gsql configuration

gsql Configuration File (gsql.ini)

The gsql configuration file (.gsql.ini) consists of options which is automatically applied when gsql starts u p, and it should be in the directory $HOME.

A user can set multiple dsn in the configuration file, and can specify different options for each dsn. If a us er do not enter dsn when gsql starts up, the options in GOLDILOCKS are applied.

Example

```
[GOLDILOCKS]
AUTOCOMMIT = OFF
AUTOTRACE = OFF
LINESIZE = 80
PAGESIZE = 20
VERTICAL = OFF
TIME = OFF
TIMING = OFF
ERROR = ON
COLSIZE = 8192
NUMSIZE = 20
DDLSIZE = 10000
HISTORY = 128
```

Table 40-5 Options

Option	Minimum value	Maximum value	Default value
AUTOCOMMIT	OFF	ON	OFF
AUTOTRACE	OFF	ON/TRACEONLY	OFF
LINESIZE	1	10000	80
PAGESIZE	1	10000	20
VERTICAL	OFF	ON	OFF
TIME	OFF	ON	OFF
TIMING	OFF	ON	OFF
ERROR	ON	OFF	ON
COLSIZE	1	10485760	8192
NUMSIZE	1	50	20
DDLSIZE	1	10485760	10000
HISTORY	0	100000	128

If .gsql.ini does not exist or the option value is invalid, it is ignored.

glogin.sql

glogin.sql is a global configuration file and it is positioned in $GOLDILOCKS_DATA/conf/glogin.sql. If glogin.sql file exists when driving gsql, then it reads the file and executed the statement included in the file. In this way, all gsql sessions are set (e.g.line size).

login.sql

login.sql is a user configuration file. If login.sql file exists in the current directory when driving gsql, then it reads the file and executed the statement included in the file.
The login.sql configuration takes precedence over the glogin.sql configuration.

40.3 Using Interactive Command

gsql Interactive Mode Commnad

Refer to the following commands.

Table 40-6 Commands

gsql command	Description
\help	gsql command list

gsql program operates in an interactive mode through **Server Connection** as follows.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL>
```

A user may enter the SQL statement on the prompt line then execute it or enter the unique command wh ich is executable in an gsql interactive mode then execute it. The gsql command begins with back-slash (\) to distinguish it from the SQL statement. The gsql command which begins with back-slash(\) can no t be used in the application, while SQL statement can be directly used in the application.

The gsql interactive mode command begins with \.

The following is an example of executing SQL statement in an interactive mode.

```
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
```

The following is an example of executing the same SELECT statement by using **\exec sql**, gsql command. \exec sql command is a unique gsql command although the syntax of \ exec sql is as same as the synta x of EXEC SQL referring to the beginning of SQL statement in an **Embedded SQL**.

```
gSQL> \exec sql SELECT * FROM dual;
DUMMY
-----
```

```
X
1 row selected.
```

The current time can be output on the prompt by setting via **\set time**.

```
gSQL> \set time on
12:45:34 gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
12:45:37 gSQL>
```

The unique commands of gsql interactive mode can be queried with the command **\help** as follows.

```
gSQL> \help
\help
\q[uit]
\i[mport] {'FILE'}                Import SQL
\ed[it] [{'FILE'|[HISTORY] num}] Edit SQL statement
\\                                Executes the most recent history entry
\{n}                              Executes n'th history entry
\hi[story]                        Show history entries
\desc     {[schema.]table_name}   Show table description
\idesc    {[schema.]index_name}   Show index description
\spo[ol]  ['filename' | OFF]      Stores query results in a file
\ho[st]   [command]               Executes an operating system command
\set vertical     {ON|OFF}
\set time         {ON|OFF}
\set timing       {ON|OFF}
\set color        {ON|OFF}
\set error        {ON|OFF}
\set autocommit   {ON|OFF}
\set autotrace    {ON|TRACEONLY|OFF}
\set serveroutput {ON|OFF}
\set heading      {ON|OFF}
\set linesize     {n}      0 < n <= 100000
\set pagesize     {n}      0 < n <= 100000
\set colsize      {n}      0 < n <= 104857600
\set numsize      {n}      0 < n <= 50
\set ddlsize      {n}      0 < n <= 100000
\set history      {n}      n <= 100000 ( if n < 0, clear history buffer )
```

```
\set sqlprompt    "prompt_sql"
\var              {host_var_name} {INTEGER|BIGINT|VARCHAR(n)}
\exec             [{:host_var_name} := {constant}]
\exec sql         {sql string}
\prepare sql      {sql string}
\dynamic sql      {host_var_name}
\explain plan     [{ON|ONLY}] {sql string}
\print            [{host_var_name}]
\ddl_cluster
\ddl_db
\ddl_tablespace    {name}
\ddl_profile       {name}
\ddl_auth          {name}
\ddl_schema        {name}
\ddl_table         {[schema.]name}
\ddl_constraint    {[schema.]name}
\ddl_index         {[schema.]name}
\ddl_view          {[schema.]name}
\ddl_sequence      {[schema.]name}
\ddl_synonym       {[schema.]name}
\ddl_public_synonym {name}
\ddl_procedure     {[schema.]name}
\ddl_package       {[schema.]name}
\startup          {[nomount|mount|open]}
\shutdown         {[abort|immediate|transactional|normal]}
\cstartup         {[nomount|mount|open]}
\cshutdown        {[abort|immediate|transactional|normal]}
\connect          userid password [as {sysdba|admin}]
```

Startup and Shutdown Server

Refer to the following commands.

Table 40-7 Commands

gsql Commad	Description
\startup	It starts up the server.
\shutdown	It shuts down the server.
\cstartup	It starts up the server for the cluster environment.
\cshutdown	It shuts down the server for the cluster environment.

Standalone

It should be connected by using SYSDBA role or ADMIN role as follows to startup or shutdown the server.

- SYSDBA role
  - It has all privileges related to DBA such as the server startup or shutdown.
- ADMIN role
  - It has the same privileges as SYSDBA but it is allowed to connect only one session.
  - It is the role for when a valid session does not exist or for emergency connection under abnormal circumstances.

The following is an example of connecting by using SYSDBA role when the GOLDILOCKS server is not driven.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL>
```

gsql is connected to an idle instance in the state of when GOLDILOCKS server does not exist. gsql drives the GOLDILOCKS server on the specific step through **\startup** and connects to the server. The following is an example of driving the GOLDILOCKS server on NOMOUNT phase.

```
gSQL> \startup NOMOUNT
Startup success
gSQL>
```

\startup command is used only when initially driving GOLDILOCKS. Each step of the GOLDILOCKS server is switched by using **ALTER SYSTEM {MOUNT | OPEN} DATABASE** after driving the GOLDILOCKS server and connecting to the server.

```
gSQL> ALTER SYSTEM MOUNT DATABASE;
System altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
System altered.
gSQL>
```

\startup command is executed without any extra option as follows when GOLDILOCKS server is driven on OPEN phase whose service is available without switching the step.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup
Startup success
```

```
gSQL>
```

If the server is already driven on a certain step, \startup command outputs an error message as follows. Unless the server is driven up to OPEN phase, it may be driven on OPEN phase by using ALTER SYSTEM as follows.

```
% gsql sys gliese--as sysdba
Connected to GOLDILOCKS Database.
gSQL> \startup
ERR-HY000(11029): shared memory segment exists
gSQL> ALTER SYSTEM MOUNT DATABASE;
System altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
System altered.
gSQL>
```

For more information about the server startup, refer to the followings.

- Step of the server startup: **Multi-level Startup**
- Command for the initial server startup: **\startup**
- Altering the server step: **ALTER SYSTEM {MOUNT | OPEN} DATABASE**

\shutdown command is used as follows to shutdown the server. For more information about the server shutdown, refer to **\shutdown**.

```
gSQL> \shutdown
Shutdown success
gSQL>
```

Cluster

LOCATOR_DSN property should be defined in odbc.ini file to startup or shutdown the server by using \cstartup command and \cshutdown command, and it should be connected with SYSDBA role or ADMIN role by using gsqlnet.

The following is an example of connecting with SYSDBA role by using gsqlnet when GOLDILOCKS server is not driven.

```
% gsqlnet sys gliese --as sysdba
Connected to an idle instance.
gSQL>
```

The following is an example of driving GOLDILOCKS server on LOCAL OPEN phase by using \cstartup co

mmand. Then it switches the server to OPEN phase.

```
gSQL> \cstartup LOCAL OPEN
Startup success
gSQL> ALTER SYSTEM OPEN GLOBAL DATABASE;
System altered.
gSQL>
```

\cstartup command and \cshutdown command are used in C/S environment, so glsnr should be on servic e on all servers to startup or shutdown the server.

The following is an example of trying to drive GOLDILOCKS server when glsnr is not on service.

```
gSQL> \cstartup
ERR-HY000(58000): MEMBER(G1N1): the sender failed to connect to the member(1)
ERR-HY000(11067): MEMBER(G1N1): fail to connect to an host with a socket : connect() :
stnConnect() returned errno(111)
gSQL>
```

The following is an example of defining LOCATOR_DSN property and LOCATOR DSN property in **odbc.ini file**.

```
% cat .odbc.ini
# Edit the SYSTEM or USER DSN ini file (/etc/odbc.ini or ~/.odbc.ini) and add a data source
using the syntax:
[GOLDILOCKS]
HOST=127.0.0.1
PORT=20101
UID=test
PWD=test
LOCATOR_DSN=LOCATOR
[LOCATOR]
FILE=/home/test/.locator.ini
```

The following is an example of trying to drive the server when LOCATOR_DSN property is not defined in odbc.ini file.

```
gSQL> \cstartup
ERR-HY000(40057): not specified valid location information
gSQL>
```

Commands excluding \CSTARTUP {LOCAL | GLOBAL} OPEN are applied only to the corresponding GOLDI LOCKS server. Therefore, other servers should be started up to LOCAL OPEN phase for multi-level startup

by using **ALTER SYSTEM {MOUNT | OPEN} DATABASE** after `\CSTARTUP NOMOUNT, MOUN` commands.

The following is an example of trying multi-level startup after `\CSTARTUP MOUNT`. The corresponding server i s started on MOUNT phase, but the other server is not started up to LOCAL OPEN phase, so an error occu rs.

```
gSQL> \CSTARTUP MOUNT
Startup success
gSQL> ALTER SYSTEM OPEN LOCAL DATABASE;
System altered.
gSQL> ALTER SYSTEM OPEN GLOBAL DATABASE;
ERR-HY000(58000): MEMBER(G1N1): the sender failed to connect to the member(1)
ERR-HY000(11067): MEMBER(G1N1): fail to connect to an host with a socket : connect() :
stnConnect() returned errno(111)
gSQL>
```

For more information about the server startup, refer to the followings.

- Step of the server startup: **Multi-level Startup**
- Command for the initial server startup: **\cstartup**
- Altering the server step: **ALTER SYSTEM {MOUNT | OPEN} DATABASE**

\cshutdown command is used as follows to shutdown the entire server. For more information about the e ntire server shutdown, refer to **\cshutdown**.

```
gSQL> \cshutdown
Shutdown success
gSQL>
```

Executing SQL Statements

Refer to the following commands.

Table 40-8 Commands

gsql commad	Description
\import	It executes SQL file.
\set autocommit	It automatically COMMITs whenever executing the SQL statement.
SQL References	It is a type of SQL statement.

Entering SQL Statement

In an interactive mode, gsql outputs the interactive mode prompt gSQL> and waits for a user input. After entering the SQL statement, gsql performs the SQL statement by transferring it to the server. In an interactive mode, the SQL statement is completed by entering semi-colon (;), then entering `enter`. After executing the SQL statement, gsql outputs the result and the prompt gSQL>, and then waits for user input.

The following is an example of entering the SQL statement on a single line and executing it.

```
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
gSQL>
```

The following is an example of entering SQL statement across multiple lines and executing it. If `enter` is used in the state of which the SQL statement is not completed, gsql outputs the line number, moves to the next line and waits for user input.

```
gSQL> SELECT id, name
2
```

When a user continuously completes entering all SQL statements, then enters semicolon (;) and `enter` as follows, the SQL statement is executed and *gSQL>* prompt waits for the next command.

```
gSQL> SELECT id, name
2 FROM t1
3 WHERE id > 0;
ID NAME
-- ------
 1 leekmo
 2 mkkim
 3 xcom73
3 rows selected.
gSQL>
```

The SQL statement is not recognized to be completed of input because the semi-colon (;) within the single quote (') is recognized as a string.

```
gSQL> SELECT id, ';'
2 FROM t1
3 WHERE id = 1;
```

```
ID ';'
-- ---
 1 ;
1 row selected.
gSQL>
```

Entering SQL Statement from File

In an interactive mode, `\import` is used to execute the SQL statement from the file, not to execute it by dir ectly entering the SQL statement. The following is an example of executing multiple SQL statements by re ading the file sample.sql. For more information, refer to **`\import`**.

```
gSQL> \import 'sample.sql'
```

- Drop table

```
DROP TABLE IF EXISTS t1;
Table dropped.
```

- Create table

```
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
```

- Create index

```
CREATE INDEX t1_idx_name ON t1(name);
Index created.
```

- Insert three rows

```
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
3 rows created.
```

- Commit transaction

```
COMMIT;
Commit complete.
gSQL>
```

gsql Comment

The comments in an interactive mode are as same as those in the SQL statement. The comments input fr om the file via the **--import** option is also as same as those in the SQL statement. For more information ab out comments on SQL statement, refer to **Comments**.

The following is an example of using the line comment in an interactive mode.

```
gSQL> -- outside line-comment
gSQL> SELECT id, name
2 FROM t1 -- inside line-comment
3 WHERE id = 1;
ID NAME
-- ------
 1 leekmo
1 row selected.
gSQL>
```

The following is an example of executing the file content with the `\import` command. It is treated in the s ame way as the comment in an interactive mode. And *gSQL>* prompt waits for the next SQL statement af ter all contents of the file are executed.

```
gSQL> \import 'sample.sql'
```

- Drop table

```
DROP TABLE IF EXISTS t1;
Table dropped.
```

- Create table

```
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    addr VARCHAR(128)
```

```
);
Table created.
```

- Create index

```
CREATE INDEX t1_idx_name ON t1(name);
Index created.
```

- Insert three rows

```
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
3 rows created.
```

- Commit transaction

```
COMMIT;
Commit complete.
gSQL>
```

The following is an example of using the multi-line comment in an interactive mode.

```
gSQL> SELECT id, name
2     /*
3     multi-line
4     comment
5     */
6     FROM t1
7     WHERE id = 1;
ID NAME
-- ------
 1 leekmo
1 row selected.
gSQL>
```

The comments which is available in gsql interactive mode are as same as those in the SQL statement. For more information about the comments, refer to **Comments** of SQL statement.

SQL Execution Result

When a user performs a query such as SELECT statement in an interactive mode, gsql outputs the query results. The query result consists of the header with the column names, the data of the query result, and summary the query results at the end.

The following is an example of executing the SELECT statement.

```
gSQL> SELECT * FROM t1;
ID NAME   ADDR
-- ------ -------------
 1 leekmo Seoul, Korea
 2 mkkim  Seoul, Korea
 3 xcom73 Inchon, Korea
3 rows selected.
gSQL>
```

In the example above, the header of output results consists of the column name and the hyphen (-) which distinguishes it from data. The query result is displayed in the middle of the output result, each row of query result is displayed on a single line, and each column value is separated with the space. The summary of the query result is displayed at the end. In this case, it refers that three rows are retrieved.

Data Definition Language, **Data Manipulation Language**, **Control Language** statements (except for SQL query) displays the summarized information of the execution result corresponding to the SQL statements characteristics.

The followings are the examples of respectively executing the DDL, DML, Control Language, displaying the results.

- DDL statement

```
gSQL> CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) );
Table created.
```

- DML statement

```
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
```

- Transaction control statement

```
gSQL> COMMIT;
Commit complete.
gSQL>
```

SQL Execution Error

The error which occurs during executing the SQL statement consists of the following information when it.

- SQLSTATE information: SQLSTATE value of SQL standard
- Error code: Unique error code value of GOLDILOCKS
- Error message: An error message describing the cause of error

The following is an example of an error when executing the SELECT statement. The error message consist s of that value of ERR-42000 corresponds to SQLSTATE and the unique error code of GOLDILOCKS is the value of (16040) and a table or view corresponding to invalid_table does not exist at line 2.

```
gSQL> SELECT id, name
2       FROM invalid_table
3      WHERE id > 0;
ERR-42000(16040): table or view does not exist :
      FROM invalid_table
           *
ERROR at line 2:
gSQL>
```

Interactive Command Execution Result

The interactive commands used together with SQL statements displays the same results and errors as tho se executing SQL statements.

The following is an example of preparing the SQL statement by using **`\prepare sql`** and executing it by u sing **`\exec`**.

```
gSQL> \prepare sql SELECT * FROM t1;
SQL prepared.
gSQL> \exec
ID NAME   ADDR
-- ------ -------------
 1 leekmo Seoul, Korea
 2 mkkim  Seoul, Korea
 3 xcom73 Inchon, Korea
3 rows selected.
gSQL>
```

The following is an example of an error occurred in the SQL statement when using **`\prepare sql`**. It displa ys an error which is as same as that occurs when executing the SQL statement.

- An error of \prepare sql command

```
gSQL> \prepare sql SELECT * FROM invalid_table;
ERR-42000(16040): table or view does not exist :
SELECT * FROM invalid_table
              *
ERROR at line 1:
```

- An error of the same SQL statement

```
gSQL> SELECT * FROM invalid_table;
ERR-42000(16040): table or view does not exist :
SELECT * FROM invalid_table
              *
ERROR at line 1:
gSQL>
```

If the gsql commands in an interactive mode do not include the SQL statement or when the command do es not have any result to display, only *gSQL>* prompt is displayed without any extra message when the co mmand is successfully performed.

The following is an example of successfully performing the interactive command without a message. The error message is displayed when an error occurs.

- When the interactive gsql command is normally performed

```
gSQL> \var v1 INTEGER
gSQL> \exec :v1 := 1
```

- When the interactive gsql command causes an error

```
gSQL> \var v2 INVALID TYPE
ERR-42000(40000): syntax error
\var v2 INVALID TYPE
........^     ^
Error at line 1
gSQL>
```

For more information about the performance result of the interactive command, refer to the description and example of the interactive command in **Interactive Command References**.

Autocommitting SQL statement

The SQL statements in the gsql interactive mode may commit or roll back the transaction by using the **COMMIT** or **ROLLBACK** statement.

The following is an example of performing COMMIT or ROLLBACK after performing multiple INSERT statements. Whereas the first INSERT statement is successfully committed by COMMIT, the second and third INSERT statements are rolled back by ROLLBACK in the following example.

```
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO t1 VALUES ( 2, 'mkkim' );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 3, 'xcom73' );
1 row created.
gSQL> ROLLBACK;
Rollback complete.
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
gSQL>
```

If a user wants to automatically COMMIT every transaction whenever performing the SQL statements, it can be controlled by using the **`\set autocommit`** as follows. When performing the same SQL statement as the example above, each SQL statement is automatically committed, so the transaction of the second and the third INSERT statements are completed regardless of ROLLBACK.

```
gSQL> \set autocommit on
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO t1 VALUES ( 2, 'mkkim' );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 3, 'xcom73' );
1 row created.
gSQL> ROLLBACK;
Rollback complete.
```

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
 2 mkkim
 3 xcom73
3 rows selected.
gSQL>
```

For more information about controlling automatic COMMIT, refer to **\set autocommit**.

Forced Termination of SQL Statement Being Executed

SQL statements being executed in an interactive mode is forcibly terminated by entering Ctrl+C.

The following is an example of which the SELECT statement being executed for a long time is forcibly ter minated. If Ctrl+C is entered by using a keyboard during performing the SQL statement, the error messag e, operation canceled, is displayed and the SQL statement is forcibly terminated.

```
gSQL> SELECT COUNT(*)
  FROM
       t1 AS v01,
       t1 AS v02,
       t1 AS v03,
       t1 AS v04,
       t1 AS v05,
       t1 AS v06,
       t1 AS v07,
       t1 AS v08,
       t1 AS v09,
       t1 AS v10,
       t1 AS v11,
       t1 AS v12,
       t1 AS v13,
       t1 AS v14,
       t1 AS v15,
       t1 AS v16,
       t1 AS v17,
       t1 AS v18,
       t1 AS v19,
       t1 AS v20;
```

```
2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22
^C
ERR-HY008(13043): operation canceled
gSQL>
```

Controlling Output Result

Refer to the following commands.

Table 40-9 Commands

gsql command	Description
\set color	It identifies each row with different color.
\set colsize	It controls the maximum size of the column results.
\set error	It controls whether an error message is displayed.
\set linesize	It controls the maximum output length of the row.
\set numsize	It controls the maximum number of digit of the numeric value.
\set pagesize	It controls the number of row to be included in a page.
\set timing	It outputs the execution time of the SQL statement.
\set vertical	It displays each column in a single line.

Controlling Page Configuration

As described in **SQL Execution Result**, the query results display the column names in the header, displays t he data, then the summary information at the end.

If there are many query results, they are divided into the unit of pagesize (default value is 20), and each p age outputs the column names and data set. When the output of all pages is completed, the summary in formation is displayed at the end.

The following is an example of the output of query results by changing the pagesize to 5. For more infor mation about controlling the pagesize, refer to **\set pagesize**.

```
gSQL> \set pagesize 5
gSQL> SELECT table_schema, table_name FROM dictionary WHERE table_name like 'ALL_%' FETCH 20;
TABLE_SCHEMA      TABLE_NAME
----------------- ------------------
DICTIONARY_SCHEMA ALL_ALL_TABLES
DICTIONARY_SCHEMA ALL_COL_COMMENTS
DICTIONARY_SCHEMA ALL_COL_PRIVS
DICTIONARY_SCHEMA ALL_COL_PRIVS_MADE
```

```
DICTIONARY_SCHEMA ALL_COL_PRIVS_RECD
TABLE_SCHEMA      TABLE_NAME
----------------- -----------------
DICTIONARY_SCHEMA ALL_CONSTRAINTS
DICTIONARY_SCHEMA ALL_CONS_COLUMNS
DICTIONARY_SCHEMA ALL_DB_PRIVS
DICTIONARY_SCHEMA ALL_DB_PRIVS_MADE
DICTIONARY_SCHEMA ALL_DB_PRIVS_RECD
TABLE_SCHEMA      TABLE_NAME
----------------- -----------------
DICTIONARY_SCHEMA ALL_INDEXES
DICTIONARY_SCHEMA ALL_IND_COLUMNS
DICTIONARY_SCHEMA ALL_SCHEMAS
DICTIONARY_SCHEMA ALL_SCHEMA_PATH
DICTIONARY_SCHEMA ALL_SCHEMA_PRIVS
TABLE_SCHEMA      TABLE_NAME
----------------- ---------------------
DICTIONARY_SCHEMA ALL_SCHEMA_PRIVS_MADE
DICTIONARY_SCHEMA ALL_SCHEMA_PRIVS_RECD
DICTIONARY_SCHEMA ALL_SEQUENCES
DICTIONARY_SCHEMA ALL_SEQ_PRIVS
DICTIONARY_SCHEMA ALL_SEQ_PRIVS_MADE
20 rows selected.
gSQL>
```

Each row of the query result is output in linesize unit (default value is 80). If the row length of the result i s bigger than linesize, it is output on the next line.

The following is an example of the query result before and after the linesize is adjusted to 200. For more i nformation about controlling linesize, refer to **`\set linesize`**.

```
gSQL> SELECT * FROM dict_columns WHERE table_name = 'USER_TABLES' FETCH 3;
TABLE_SCHEMA      TABLE_NAME  COLUMN_NAME
----------------- ----------- ---------------
COMMENTS
----------------------------------------
DICTIONARY_SCHEMA USER_TABLES TABLE_SCHEMA
Schema of the table
DICTIONARY_SCHEMA USER_TABLES TABLE_NAME
Name of the table
DICTIONARY_SCHEMA USER_TABLES TABLESPACE_NAME
Name of the tablespace containing the table
```

```
3 rows selected.
```

- Set the linesize to 200.

```
gSQL> \set linesize 200
gSQL> SELECT * FROM dict_columns WHERE table_name = 'USER_TABLES' FETCH 3;
TABLE_SCHEMA      TABLE_NAME  COLUMN_NAME     COMMENTS
----------------- ----------- --------------- ----------------------------------------
DICTIONARY_SCHEMA USER_TABLES TABLE_SCHEMA    Schema of the table
DICTIONARY_SCHEMA USER_TABLES TABLE_NAME      Name of the table
DICTIONARY_SCHEMA USER_TABLES TABLESPACE_NAME Name of the tablespace containing the table
3 rows selected.
gSQL>
```

To increase the readability of each row on the terminal by differentiating rows, each row can be output b y varying the color through **\set color** as described below. For more information, refer to **\set color**.

```
gSQL> \set color on
gSQL> SELECT table_schema, table_name FROM dictionary WHERE table_name like 'ALL_%' FETCH 10;
TABLE_SCHEMA      TABLE_NAME
----------------- ------------------
DICTIONARY_SCHEMA ALL_ALL_TABLES
DICTIONARY_SCHEMA ALL_COL_COMMENTS
DICTIONARY_SCHEMA ALL_COL_PRIVS
DICTIONARY_SCHEMA ALL_COL_PRIVS_MADE
DICTIONARY_SCHEMA ALL_COL_PRIVS_RECD
DICTIONARY_SCHEMA ALL_CONSTRAINTS
DICTIONARY_SCHEMA ALL_CONS_COLUMNS
DICTIONARY_SCHEMA ALL_DB_PRIVS
DICTIONARY_SCHEMA ALL_DB_PRIVS_MADE
DICTIONARY_SCHEMA ALL_DB_PRIVS_RECD
10 rows selected.
gSQL>
```

To output the query result rows in the column unit on a single line, not in the line unit, `\set vertical on` i s used. The following is an example of displaying the query results in a column unit. For more information, refer to **\set vertical**.

```
gSQL> SELECT * FROM v$system_stat FETCH 5;
STAT_NAME             STAT_VALUE COMMENTS
--------------------- ---------- ------------------------------------------------------------
SYSTEM_SAR                     3 system available resource( 0:none, 1:session 2:database )
```

```
MAX_ENVIRONMENT_COUNT        128 maximum environment count
FREE_ENVIRONMENT_ID            3 available environment identifier
MAX_SESSION_COUNT            128 maximum session count
FREE_SESSION_ID                4 available session identifier
5 rows selected.
gSQL> \set vertical on
gSQL> SELECT * FROM v$system_stat FETCH 5;
               STAT_NAME # SYSTEM_SAR
              STAT_VALUE # 3
                COMMENTS # system available resource( 0:none, 1:session 2:database )
               STAT_NAME # MAX_ENVIRONMENT_COUNT
              STAT_VALUE # 128
                COMMENTS # maximum environment count
               STAT_NAME # FREE_ENVIRONMENT_ID
              STAT_VALUE # 3
                COMMENTS # available environment identifier
               STAT_NAME # MAX_SESSION_COUNT
              STAT_VALUE # 128
                COMMENTS # maximum session count
               STAT_NAME # FREE_SESSION_ID
              STAT_VALUE # 4
                COMMENTS # available session identifier
5 rows selected.
gSQL>
```

Controlling Data Output

gsql converts all data included in the query result to a string, then outputs it.

For a numeric data type, numsize (default value is 20) is output in the digit unit, and a numeric value bigg er than numsize is output in an exponent form. The following is an example of controlling the output by using the numsize. For more information, refer to **`\set numsize`**.

```
gSQL> SELECT num, ( num * num ) AS result FROM t1;
          NUM               RESULT
------------- --------------------
1234567890123 1.52415787532276E+24
1 row selected.
gSQL> \set numsize 50
gSQL> SELECT num, ( num * num ) AS result FROM t1;
          NUM                    RESULT
------------- -------------------------
```

```
1234567890123 152415787532275580095129
1 row selected.
gSQL>
```

The output of the numeric value may be controlled in various ways by using the **TO_CHAR(number)** fun ction as the following example.

```
gSQL> SELECT num, TO_CHAR( num * num, '$999,999,999,999,999,999,999,999,999' ) AS result FROM
t1;
          NUM RESULT
------------- -----------------------------------
1234567890123    $1,524,157,875,322,755,800,955,129
1 row selected.
gSQL>
```

For the date/ time data types such as DATE/ TIME/ TIMESTAMP, gsql determines the output type by using the property information as follows.

- **NLS_DATE_FORMAT**
- **NLS_TIMESTAMP_FORMAT**
- **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**
- **NLS_TIME_FORMAT**
- **NLS_TIME_WITH_TIME_ZONE_FORMAT**

The property is used when the format information is not entered in the functions such as TO_CHAR(), TO _DATE(). When connected for the first time, gsql acquires the property information and uses it to output the date/ time data value, whereas the property above is used only when the application using ODBC or J DBC uses the functions such as TO_CHAR(), TO_DATE() in SQL statement. When the property is changed to the following SQL statement in an interactive mode, gsql uses the updated property information.

- **ALTER SESSION SET property_name**
- **ALTER SYSTEM SET property_name**

The following is an example of controlling the output for the DATE column.

```
gSQL> SELECT enter_date FROM t1;
ENTER_DATE
----------
2014-08-26
1 row selected.
gSQL> ALTER SESSION SET NLS_DATE_FORMAT = 'DD-MON-YYYY';
Session altered.
gSQL> SELECT enter_date FROM t1;
```

```
ENTER_DATE
-----------
26-AUG-2014
1 row selected.
gSQL>
```

The output of the date/ time value can be controlled by using **TO_CHAR(datetime)** function without alte ring property as follows.

```
gSQL> SELECT TO_CHAR( enter_date, 'DD-MON-YYYY' ) as result FROM t1;
RESULT
----------------
26-AUG-2016
1 row selected.
gSQL>
```

A binary string such as BINARY or VARBINARY is output as hex values as follows.

```
gSQL> select * from t1;
BINARY_VALUE
--------------------
A010002F370000000000
1 row selected.
gSQL>
```

The data of the LONG VARCHAR, LONG VARBINARY type may include a very long string, so it outputs th e data as much as colsize (default value is 8192). The following is an example of outputting the part of th e TEXT column data of LONG VARCHAR data type by reducing the colsize. The whole data may be outpu t by increasing the colsize. For more information, refer to **`\set colsize`**.

```
gSQL> \set colsize 100
gSQL> SELECT view_name, text FROM all_views WHERE view_name = 'ALL_ALL_TABLES';
VIEW_NAME      TEXT
-------------- ----------------------------------------------------
ALL_ALL_TABLES SELECT
                     auth.AUTHORIZATION_NAME               ❶ OWNER
                   , sch.SCHEMA_NAME
1 row selected.
gSQL>
```

Execution Time of SQL Statement

The execution time of the SQL statement is output by using `\set timing on` as follows. For more information, refer to **`\set timing`**.

```
gSQL> \set timing on
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
Elapsed time: 0.08500 ms
```

Logging Output Result

All results performed in gsql are simultaneously logged to the file when they are output on the terminal.

Table 40-10 Commands

gsql command	Description
`\spool`	It logs the output result to a file.

For more information about the features related to logging output results, refer to the commands of **`\spool`**.

The output result is logged as the following example.

- Start to log the execution result on result.txt

```
gSQL> \SPOOL 'result.txt'
```

- Check the spool status

```
gSQL> \SPOOL

currently spooling to result.txt
gSQL> SELECT * FROM T1 WHERE C1 < 10;
```

- Stop the spool feature

```
gSQL> \SPOOL OFF
```

Querying SQL Object Information

The information about SQL objects may be queried with the views of **DICTIONARY_SCHEMA**, **INFORMATION_SCHEMA**.

Table 40-11 Commands

gsql command	Description
\desc	It queries the table information.
\idesc	It queries the index information.

For example, there are the table and index created as follows.

```
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    addr VARCHAR(128)
);
CREATE INDEX t1_idx_name ON t1(name);
```

A user may query the information related to the table by performing a series of SQL statements as follows.

```
gSQL> SELECT table_schema, table_name FROM user_tables WHERE table_name = 'T1';
TABLE_SCHEMA TABLE_NAME
------------ ----------
PUBLIC       T1
1 row selected.
gSQL> SELECT column_name, data_type, nullable FROM user_tab_columns WHERE table_schema =
'PUBLIC' AND table_name = 'T1';
COLUMN_NAME DATA_TYPE         NULLABLE
----------- ----------------- --------
ID          NUMBER            N
NAME        CHARACTER VARYING Y
ADDR        CHARACTER VARYING Y
3 rows selected.
gSQL> SELECT index_name FROM user_indexes WHERE table_schema = 'PUBLIC' AND table_name = 'T1';
INDEX_NAME
--------------------
T1_PRIMARY_KEY_INDEX
T1_IDX_NAME
```

```
2 rows selected.
gSQL>
```

gsql may easily query the information related to the table by using \desc as follows. For more information about the output, refer to **\desc**.

```
gSQL> \desc t1
COLUMN_NAME TYPE                   IS_NULLABLE
----------- ---------------------- -----------
ID          NUMBER(10,0)           FALSE
NAME        VARCHAR(128)           TRUE
ADDR        VARCHAR(128)           TRUE
INDEX_NAME           TABLESPACE_NAME INDEX_TYPE IS_UNIQUE COLUMNS
-------------------- --------------- ---------- --------- -------
T1_PRIMARY_KEY_INDEX MEM_TEMP_TBS    BTREE      TRUE      ID
T1_IDX_NAME          MEM_TEMP_TBS    BTREE      FALSE     NAME
CONSTRAINT_NAME CONSTRAINT_TYPE ASSOCIATED_INDEX     COLUMNS
--------------- --------------- -------------------- -------
T1_PRIMARY_KEY  PRIMARY KEY     T1_PRIMARY_KEY_INDEX ID
gSQL>
```

\idesc describes the information related to the index as the following example. For more information, refer to **\idesc**.

```
gSQL> \idesc t1_idx_name
COLUMN_NAME ORDINAL_POSITION IS_ASCENDING_ORDER IS_NULLS_FIRST
----------- ---------------- ------------------ --------------
NAME                       1 TRUE               FALSE
gSQL>
```

Output DDL Statement of SQL Object

The following gsql commands output the DDL statement corresponding to the current state of the SQL object. As well as the CREATE statement which creates the SQL object, DDL statement of the related object may be output through the various options.

The objects stored in the recycle bin are not output.

Table 40-12 Commands

gsql command	Description
\ddl_cluster	It outputs the cluster-related DDL.
\ddl_db	It outputs the database-related DDL.
\ddl_tablespace	It outputs the tablespace-related DDL.
\ddl_profile	It outputs the profile-related DDL.
\ddl_audit_policy	It outputs the audit policy-related DDL.
\ddl_auth	It outputs the account-related DDL.
\ddl_schema	It outputs the schema-related DDL.
\ddl_public_synonym	It outputs the public synonym-related DDL.
\ddl_table	It outputs the table-related DDL.
\ddl_constraint	It outputs the constraint-related DDL.
\ddl_index	It outputs the index-related DDL.
\ddl_view	It outputs the view-related DDL.
\ddl_sequence	It outputs the sequence-related DDL.
\ddl_synonym	It outputs the synonym-related DDL.
\ddl_procedure	It outputs the procedure-related DDL.
\ddl_package	It outputs the package-related DDL.
\set ddlsize	It controls the size of the DDL output buffer.

For example, the orders table is created as follows.

```
gSQL>
CREATE TABLE ORDERS
(
    O_ID         INTEGER,
    O_D_ID       INTEGER,
    O_W_ID       INTEGER,
    O_C_ID       INTEGER,
    O_ENTRY_D    TIMESTAMP,
    O_CARRIER_ID INTEGER,
    O_OL_CNT     NUMERIC(8),
    O_ALL_LOCAL  NUMERIC(1),
    PRIMARY KEY(O_W_ID, O_D_ID, O_ID) INDEX ORDERS_PK_IDX
);
Table created.
```

The CREATE TABLE statement which created the orders table in the example above is output by using \ddl_table as follows.

```
gSQL> \ddl_table orders CREATE
SET SESSION AUTHORIZATION "TEST";
CREATE TABLE "PUBLIC"."ORDERS"
    (
        "O_ID" NUMBER( 10, 0 )
      , "O_D_ID" NUMBER( 10, 0 )
      , "O_W_ID" NUMBER( 10, 0 )
      , "O_C_ID" NUMBER( 10, 0 )
      , "O_ENTRY_D" TIMESTAMP( 6 ) WITHOUT TIME ZONE
      , "O_CARRIER_ID" NUMBER( 10, 0 )
      , "O_OL_CNT" NUMBER( 8, 0 )
      , "O_ALL_LOCAL" NUMBER( 1, 0 )
    )
    PCTFREE  10
    PCTUSED  60
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "MEM_DATA_TBS"
;
```

From the example above, SET AUTHORIZATION statement refers to the owner who performed CREATE TABLE statement. The CREATE TABLE statement is output together with the information that the user does not input such as the schema name to which the table belongs, the tablespace name in which the table is stored and the physical information of the table.

DDL corresponding to the constraints generated in the table is output by using the CONSTRAINT option of \ddl_table as follows.

```
gSQL> \ddl_table orders CONSTRAINT
SET SESSION AUTHORIZATION "TEST";
ALTER TABLE "PUBLIC"."ORDERS"
    ADD CONSTRAINT "PUBLIC"."ORDERS_PRIMARY_KEY"
    PRIMARY KEY
    (
        "O_W_ID" ASC NULLS LAST
```

```
      , "O_D_ID" ASC NULLS LAST
      , "O_ID" ASC NULLS LAST
    )
    INDEX "ORDERS_PK_IDX"
    PCTFREE  10
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "MEM_TEMP_TBS"
    NOT DEFERRABLE
    INITIALLY IMMEDIATE
;
```

For more information, refer to the gsql command corresponding to the SQL object.

> ⚠ If a user uses the command such as `\ddl_table` and simultaneously performs DDL on the relevant SQL object, it may output different results, so DDL should not be simultaneously performed.

Controlling History

gsql controls the history of executed SQL statements in an interactive mode.

Table 40-13 Commands

gsql command	Description
****	It executes the previous SQL.
\{n}	It executes the SQL statement corresponding to the history number.
\history	It queries the SQL execution history.
\set history	It controls the number of history buffer.

The following is an example of executing SQL statement which has already been performed may be performed again.

- The most recent successfully executed SQL statement is executed again.

```
gSQL> \\
DUMMY
-----
X
1 row selected.
gSQL> \history
ID SQL
-- ---------------------------------------------
 1 DROP TABLE IF EXISTS t1
 2 CREATE TABLE t1
   (
       id   INTEGER PRIMARY KEY,
       name VARCHAR(128),
       addr VARCHAR(128)
   )
 3 CREATE INDEX t1_idx_name ON t1(name)
 4 INSERT INTO t1
          VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
                 ( 2, 'mkkim' , 'Seoul, Korea'  ),
                 ( 3, 'xcom73', 'Inchon, Korea' )
 5 COMMIT
 6 select * from t1
```

- The first SQL in the history is executed.

```
gSQL> \1
Table dropped.
```

For more information about the history related features of gsql, refer to **Commands** .

Editing SQL

It edits the SQL statement by using the text editor. The text editor to be used may be specified in the environment variable EDITOR. If the environment variable EDITOR does not exist, vi is used by default.

Table 40-14 Command

gsql command	Description
\edit	It edits the SQL statement by using the text editor.

When using the editing features, gsql runs the editor and hands over control to it. The user can freely edit

the SQL statements with the editor. When the editor ends, the control is handed over to gsql, and its con tent will be added as the last history.

The SQL statement edited by the editor may be executed through the last history execution command \\.

> ⚠ Only a single SQL statement can be edited with the SQL editor. An error occurs when executing multiple SQL statements.

The followings may be edited by using \edit.

- The most recently performed SQL statement
- The SQL statement stored in a file
- The SQL statement stored in the gsql history

For more information about the edit-related features in gsql, refer to **\edit**.

The SQL statement may be edited as the following example.

- The most recently performed SQL statement is edited.

```
gSQL> SELECT * FROM T1;
C1
--
 1
11
2 rows selected.
gSQL> \EDIT
SELECT * FROM T1 WHERE C1 < 10;
```

- The edited SQL statement is executed.

```
gSQL> \\
C1
--
 1
1 row selected.
```

Controlling Connection

Refer to the following commands.

Table 40-15 Commands

gsql command	Description
\connect	It connects with a new user.
\quit	It quits the connection.

It is connected with a new user by using \connect in an interactive mode as follows. The existing session is terminated and a new session is created by using \connect. For more information, refer to **\connect**.

```
gSQL> \connect test test
gSQL>
```

The user may be changed by using the **SET SESSION AUTHORIZATION user_identifier** statement as follows. \connect commits all transactions being executed and creates a new session whereas the SET SESSION AUTHORIZATION statement changes the user while keeping intact the existing sessions.

```
gSQL> SET SESSION AUTHORIZATION test;
Session set.
gSQL>
```

Interactive mode is terminated by using \quit as follows. For more information, refer to **\quit**.

```
gSQL> \quit
%
```

Using Host Variable

gsql declares a host variable in an interactive mode, and assigns a value to the host variable, then uses the host variable together with the SQL statement.

Table 40-16 Commands

gsql command	Description
\var	It declares the host variable.
\exec :var := value	It assigns the value to the host variable.
\print	It outputs the value of the host variable.
\dynamic sql :var	It executes SQL statements stored in the host variable.

The following is an example of declaring the host variable by using **\var**, and assigning the value to the host variable by using **\exec :var := value**, and querying the value of the host variable by using **\print**. For more information, refer to each command.

```
gSQL> \var v_id INTEGER
gSQL> \exec :v_id := 1
gSQL> \print v_id
V_ID
----
   1
gSQL>
```

The variable declared in an interactive mode may be used as the input parameter in the SQL statement as follows.

```
gSQL> SELECT * FROM t1 WHERE id = :v_id;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
gSQL>
```

The variable declared in an interactive mode may be used as the output parameter in the SQL statement as follows.

```
gSQL> SELECT id INTO :v_id FROM t1 WHERE name = 'mkkim';
V_ID
----
   2
1 row selected.
gSQL>
```

Controlling Method of Treating SQL Statement

The SQL process methods which are frequently used when processing the SQL such as the execution of p repare/ execute statement or the retrieval by using the cursor may be simulated by using the gsql interacti ve mode command before developing the application.

Table 40-17 Commands

gsql command	Description
\exec sql	It directly executes the SQL statement.
\prepare sql	It prepares the SQL statement.
\exec	It executes the prepared SQL statement.
	It executes the SQL statement stored in the host variable.

gsql command	Description
\dynamic sql :var	

The following Java application is a part of code in $GOLDILOCKS_HOME/sample/JDBC/JdbcSample.java.

```
public static void main(String[] args) throws SQLException
    {
        Connection con = createConnectionByDriverManager("TEST", "test");
        Statement stmt = con.createStatement();
        stmt.execute("CREATE TABLE SAMPLE_TABLE ( ID INTEGER, NAME CHAR(20) )");
        PreparedStatement pstmt = con.prepareStatement("INSERT INTO SAMPLE_TABLE VALUES (?,
?)");
        pstmt.setInt(1, 100);
        pstmt.setString(2, "Tom");
        pstmt.executeUpdate();
        pstmt.setInt(1, 200);
        pstmt.setString(2, "Jerry");
        pstmt.executeUpdate();
        ResultSet rs = stmt.executeQuery("SELECT * FROM SAMPLE_TABLE");
        while (rs.next())
        {
            System.out.println("ID = " + rs.getInt(1) + ": " + rs.getString(2));
        }
        rs.close();
        stmt.close();
        pstmt.close();
        con.close();
        Connection con2 = createConnectionByDataSource("TEST", "test");
        Statement stmt2 = con2.createStatement();
        stmt2.execute("DROP TABLE SAMPLE_TABLE");
        stmt2.close();
        con2.close();
    }
```

The implementation above which used the PreparedStatement class of Java code may be simulated by using **\prepare sql** and **\exec** as follows.

```
gSQL> \connect test test
gSQL> \var v_int INTEGER
gSQL> \var v_string VARCHAR(128)
gSQL> CREATE TABLE SAMPLE_TABLE ( ID INTEGER, NAME CHAR(20) );
```

```
Table created.
gSQL> \prepare sql INSERT INTO SAMPLE_TABLE VALUES (:v_int, :v_string);
SQL prepared.
gSQL> \exec :v_int := 100
gSQL> \exec :v_string := 'Tom'
gSQL> \exec
1 row created.
gSQL> \exec :v_int := 200
gSQL> \exec :v_string := 'Jerry'
gSQL> \exec
1 row created.
gSQL> SELECT * FROM SAMPLE_TABLE;
 ID NAME
--- --------------------
100 Tom
200 Jerry
2 rows selected.
gSQL> \connect test test
gSQL> DROP TABLE SAMPLE_TABLE;
Table dropped.
gSQL> \quit
%
```

The following embedded SQL program is a part of code in $GOLDILOCKS_HOME/sample/EmbeddedSQL/sample2.gc.

```
int main(int argc, char **argv)
{
    EXEC SQL BEGIN DECLARE SECTION;
    int          sEmpNo;
    varchar      sEName[20 + 1];
    char         sJob[20];
    long         sSalary;
    EXEC SQL END DECLARE SECTION;
    ... Ellipsis ...
```

- Retrieve employee

```
EXEC SQL
        DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;
```

```
    EXEC SQL OPEN EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }
    printf(" EMPNO    ENAME                JOB       SALARY\n");
    printf("====== ==================== ========== ========\n");
    while( 1 )
    {
        EXEC SQL
            FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
        if(sqlca.sqlcode == SQL_NO_DATA)
        {
            break;
        }
        else if(sqlca.sqlcode != 0)
        {
            PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
            goto fail_exit;
        }
        sRecordCount ++;
        printf("%6d %20s %10s %8ld\n",
               sEmpNo, sEName.arr, sJob, sSalary);
    }
    printf("====== ==================== ========== ========\n");
    printf("Record Count = %d\n", sRecordCount);
    printf("====== ==================== ========== ========\n");
    EXEC SQL CLOSE EMP_CUR;
    if(sqlca.sqlcode != 0)
    {
        PRINT_SQL_ERROR("[ERROR] SQL ERROR -");
        goto fail_exit;
    }

    ... Ellipsis ...
}
```

The query processing which uses the cursor in an embedded SQL program above may be simulated in gsq
l interactive mode as follows.

```
gSQL> \var sEmpNo INTEGER
gSQL> \var sEName VARCHAR(20)
gSQL> \var sJob CHAR(20)
gSQL> \var sSalary BIGINT
gSQL> DECLARE EMP_CUR CURSOR FOR
        SELECT empno, ename, job, sal
        FROM   EMP;
Cursor declared.
gSQL> OPEN EMP_CUR;
Cursor is open.
gSQL> FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
SEMPNO SENAME SJOB                SSALARY
------ ------ -------------------- -------
  2854 Park   RND                      800
1 row fetched.
gSQL> FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
SEMPNO SENAME SJOB                SSALARY
------ ------ -------------------- -------
  2098 Kim    SALESMAN                1600
1 row fetched.
gSQL> FETCH EMP_CUR
            INTO  :sEmpNo, :sEName, :sJob, :sSalary;
SEMPNO SENAME SJOB                SSALARY
------ ------ -------------------- -------
  2175 Choi   SALESMAN                1250
1 row fetched.
gSQL> CLOSE EMP_CUR;
Cursor closed.
gSQL>
```

The following statements are limitedly used in an embedded SQL in other DBMS. On the other hand, in GOLDILOCKS, the followings are used not only in an embedded SQL but also can be us ed as an argument of SQL processing functions when developing the application of ODBC or JD BC.

- **SELECT .. INTO**
- **DECLARE cursor_name**
- **OPEN cursor_name**

- FETCH cursor_name
- CLOSE cursor_name

Information of SQL Execution Plan

Refer to the following commands.

Table 40-18 Command

gsql Command	Description
\explain plan	It outputs the execution plan for the SQL statement.
\set autotrace	It sets whether to output the execution plan.

The execution plan of the SQL statement is viewed in an interactive mode by using `\explain plan` or `\set autotrace` as follows. For more information about the command, refer to **\explain plan** or **\set autotrace**, and for more information about the analysis of execution plan, refer to **SQL Execution Plan**.

The following is an example of executing the query No.4 of TPC-H benchmark by using the `\explain plan`.

```
\explain plan
select
    o_orderpriority,
    count(*) as order_count
from
    orders
where
      o_orderdate >= date '1993-07-01'
  and o_orderdate < date '1993-07-01' + interval '3' month
  and exists (
              select
                    *
                from
                    lineitem
               where
                    l_orderkey = o_orderkey
                 and l_commitdate < l_receiptdate
            )
group by
    o_orderpriority
order by
```

```
    o_orderpriority;
O_ORDERPRIORITY ORDER_COUNT
--------------- -----------
1-URGENT              10594
2-HIGH                10476
3-MEDIUM              10410
4-NOT SPECIFIED       10556
5-LOW                 10487
5 rows selected.
>>>  start print plan
< Execution Plan >

<<<  end print plan
```

40.4 Command Option Reference

This chapter describes the options for performing gsql command at the shell prompt.

Username Password

Description

It connects to GOLDILOCKS by using the username and password.

Examples

The following is an example of connecting to GOLDILOCKS with the test user.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL>
```

The following is an example of failing to connect to GOLDILOCKS with the invalid username or password.

```
% gsql invalid_user invalid_password
ERR-28000(16004): invalid username/password; logon denied
%
```

--as {SYSDBA|ADMIN}

Description

It connects to GOLDILOCKS with SYSDBA role or ADMIN role.
For more information about the description of the role, refer to **Startup and Shutdown Server**.

```
% gsql sys gliese --as sysdba
```

Example

The following is an example of connecting to GOLDILOCKS with SYSDBA role.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL>
```

--conn-string

Description

It connects to GOLDILOCKS by using the connection string.
The details of the connection string to be described should used in a form as same as the input string of t he ODBC function, **SQLDriverConnect**. For more information about the connection string, refer to **SQLDri verConnect** function.

Example

The following is an example of connecting to GOLDILOCKS with --conn-string.

```
% gsql --conn-string 'DSN=GOLDILOCKS;UID=test;PWD=test'
Connected to GOLDILOCKS Database.
gSQL>
```

--dsn

Description

It connects to GOLDILOCKS by using Data Source Name (DSN) defined in the file odbc.ini.
DSN should be defined in the odbc.ini file. For more information about the odbc.ini file, refer to **DSN Con figuration on UNIX**.
If DSN is omitted, the default value is GOLDILOCKS.

Examples

The following is an example of connecting to GOLDILOCKS with DSN.

```
% gsql test test --dsn GOLDILOCKS
Connected to GOLDILOCKS Database.
gSQL>
```

The content of odbc.ini file used in the example above is as follows.

```
[GOLDILOCKS]
DATE_FORMAT = YYYY-MM-DD
TIME_FORMAT = HH24:MI:SS.FF6
```

gsql does not recognize HOST, PORT of odbc.ini file property.

--enable-color

Description

It outputs each row of query results in a different color on the terminal to easily distinguish them.
Each row of the query results is output with a different color in an interactive mode, and it is also applied to the results of the SELECT statement included in the file by using the **--import** option.

Examples

The following is an example of performing gsql by using the --enable-color option, then outputting the query results in an interactive mode.

```
% gsql test test --enable-color
Connected to GOLDILOCKS Database.
gSQL> SELECT id, addr FROM t1;
ID ADDR
-- -------------
 1 Seoul, Korea
 2 Seoul, Korea
 3 Inchon, Korea
3 rows selected.
gSQL>
```

The following is an example of executing a SELECT query included in the file by using the --import option.

```
% gsql test test --import 'sample_select.sql' --enable-color
SELECT id, addr FROM t1;
ID ADDR
-- -------------
 1 Seoul, Korea
 2 Seoul, Korea
 3 Inchon, Korea
3 rows selected.
%
```

--help

Description

It briefly displays the option list of gsql program.

Example

The following is an example of using the --help option.

```
% gsql --help
Usage
    gsql [user_name [password]] [options]
Arguments:
    user_name       user name
    password        password
Options:
    --version                     print version information and exit
    --import       FILE           import sql FILE
    --no-prompt                   suppresses the display of the banner and prompts
    --dsn          DSN            dsn string (default is GOLDILOCKS)
    --conn-string  'CONN-STRING'  connection string
    --prompt       STRING         change prompt string
    --enable-color                enable colored text
    --as           {SYSDBA|ADMIN} privilege
    --silent                      suppresses the display of the result message and echoing of
commands
    --help                        print help message
%
```

--import

Description

It performs the SQL statement which is not an interactive mode in the file in batch.
The file name is enclosed in a single quote ('), and it can use an absolute or relative path.

Examples

The following is an example of executing the SQL statement by using the absolute path of the file.

```
% gsql test test --import '/home/goldilocks/sample.sql'
DROP TABLE IF EXISTS t1;
Table dropped.
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
CREATE INDEX t1_idx_name ON t1(name);
Index created.
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
3 rows created.
COMMIT;
Commit complete.
%
```

The following is an example of executing the SQL statement by using the relative path of the file.

```
% gsql test test --import 'sample.sql'
DROP TABLE IF EXISTS t1;
Table dropped.
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
```

```
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
CREATE INDEX t1_idx_name ON t1(name);
Index created.
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
3 rows created.
COMMIT;
Commit complete.
%
```

--no-prompt

Description

It does not output the prompt when performing an interactive mode.

Example

The following is an example of using --no-prompt.

```
% gsql test test --no-prompt
SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
```

--prompt

Description

It sets the gsql prompt when performing an interactive mode.
The default value is gSQL.
The special characters or spaces are enclosed in double quotes (") as follows.

```
% gsql test test --prompt "GOLDILOCKS Venus.3.2"
```

Example

The following is an example of which the prompt is changed to GOLDILOCKS in an interactive mode by u sing the --prompt option.

```
% gsql test test --prompt GOLDILOCKS
Connected to GOLDILOCKS Database.
GOLDILOCKS> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
GOLDILOCKS>
```

--silent

Description

It does not output the results of SQL statement.
It is useful when executing large amounts of SQL statements by reading the file with **--import** command.
The --silent option is also applied when operating in an interactive mode.

Example

The following is an example of executing the DictionarySchema.sql file in the $GOLDILOCKS_HOME/adm in directory by using the --silent option.

```
% gsql sys gliese --as sysdba --import 'DictionarySchema.sql' --silent
%
```

--version

Description

It outputs the version information of the gsql program.
It is recommended to use the gsql program with the version as same as the version of GOLDILOCKS. The GOLDILOCKS version can be viewed via the SQL function **VERSION** as follows.

```
gSQL> SELECT version() FROM dual;
VERSION()
-----------------------------------
Release Name.X.X.X revision(XXXXX)
1 row selected.
```

Example

The following is an example of using the --version option.

```
% gsql --version
%
```

40.5 Interactive Command References

All gsql-specific commands start with backslash (\) in an interactive mode.

\\

Syntax

```
\\
```

Description

It executes the most recent successfully executed SQL statement.

Examples

```
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
```

- It executes the most recent successfully executed SQL statement.

```
gSQL> \\
DUMMY
-----
X
1 row selected.
gSQL> SELECT * FROM invalid_table;
ERR-42000(16040): table or view does not exist :
SELECT * FROM invalid_table
              *
ERROR at line 1:
```

- It executes the most recent successfully executed SQL statement rather than executing the failed SQL s tatement.

```
gSQL> \\
DUMMY
-----
X
1 row selected.
```

\connect

Syntax

```
\connect username password [as sysdba]
```

Description

It is newly connected with the entered username and password.
If any uncommitted transaction exists, it performs COMMIT.

Examples

The following is an example of connecting with the test account.

```
gSQL> \connect test test
gSQL>
```

An error occurs if the password is invalid as follows.

```
gSQL> \connect test invalid_password
ERR-28000(16004): invalid username/password; logon denied
gSQL> SELECT * FROM dual;
ERR-08003(40044): connection does not exist
```

The following is an example of connecting with the SYSDBA role.

```
gSQL> \connect sys gliese as sysdba
gSQL>
```

\cstartup

Syntax

```
\cstartup
\cstartup nomount
\cstartup mount
\cstartup open
\cstartup local open
\cstartup global open
```

Description

It starts up GOLDILOCKS server in a cluster environment.

To execute \cstartup command, it should connect with SYSDBA role or ADMIN role. For more informatio n about how to connect with SYSDBA role, refer to **startup and shutdown server**.

- \cstartup nomount
  - It starts up the corresponding server on NOMOUNT phase.
- \cstartup mount
  - It starts up the corresponding server on MOUNT phase.
- \cstartup local open
  - It starts up the corresponding server and other servers on LOCAL OPEN phase.
- \cstartup global open
  - It startsup all servers on GLOBAL OPEN phase.
- \cstartup open
  - It is as same as \cstartup global open.
- \cstartup
  - It is as same as \cstartup global open.

\cstartup local open command and \cstartup global open command startup the corresponding server and other servers to the corresponding phase. Other commands are applied only to the corresponding se rver, so the server should be started up to LOCAL OPEN phase for the multi-level startup using **ALTER SYS TEM {MOUNT | OPEN} DATABASE**.

The server startup phases are classified as NOMOUNT, MOUNT, LOCAL OPEN, GLOBAL OPEN. For more i nformation, refer to **multi-level startup**.

ALTER SYSTEM {MOUNT | OPEN} DATABASE should be performed to move on to the next phase after ex ecuting \cstartup command.

\cstartup using glocator can be viewed via **CSTARTUP and CSHUTDOWN**.

- It is command used only in a C/S environment. It can be used only in gsqlnet.
- Commands other than \cstartup nomount/ mount affects on the corresponding server and o ther servers. Therefore, if LOCATOR_DSN is not specified in **odbc.ini file**, then an error occur s.

Example

The following is an example of starting up GOLDILOCKS.

```
% gsqlnet sys gliese --as sysdba
Connected to an idle instance.
gSQL> \cstartup
Startup success
```

\cshutdown

Syntax

```
\cshutdown
\cshutdown abort
\cshutdown immediate
\cshutdown transactional
\cshutdown normal
```

Description

It shuts down GOLDILOCKS server in a cluster environment.

To execute \cshutdown command, it should connect with SYSDBA role or ADMIN role. For more informati on about how to connect with SYSDBA role, refer to **startup and shutdown server**.

- \cshutdown normal
  - It blocks the connection from the new session and waits for all currently connected sessions to be terminated, then performs the checkpoint and shuts down the server.
- \cshutdown transactional
  - It blocks the start of a new transaction and waits for all currently running transactions to be termi nated, then performs the checkpoint and shuts down the server.

- \cshutdown immediate
  - It blocks the execution of a new unit operation (e.g. FETCH, EXECUTE), waits for all currently running unit operations to be terminated, then rolls back all transactions and performs the checkpoint and shuts down the server.
- \cshutdown abort
  - The server is forcibly shut down immediately regardless of the status of the currently connected session.
- \cshutdown
  - It is as same as \cshutdown normal.

\cshutdown using glocator can be viewed via **CSTARTUP and CSHUTDOWN**.

- It is command used only in a C/S environment. It can be used only in gsqlnet.
- Commands other than \cshutdown affects on the corresponding server and other servers. Therefore, if LOCATOR_DSN is not specified in **odbc.ini file**, then an error occurs.

Example

The following is an example of shutting down GOLDILOCKS.

```
% gsqlnet sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \cshutdown
Shutdown success
gSQL>
```

\ddl_cluster

Syntax

```
\ddl_cluster
```

Description

It outputs a cluster DDL corresponding to the current status of a cluster system.
This statement is valid in a cluster system.

Example

The following is an example of executing \ddl_cluster command for a cluster system consisting as 3 x 2.

```
gSQL> \ddl_cluster
SET SESSION AUTHORIZATION "SYS";
CREATE CLUSTER GROUP "G1"
       CLUSTER MEMBER "G1N1" HOST '127.0.0.1' PORT '10110'
;
COMMIT;
SET SESSION AUTHORIZATION "SYS";
ALTER CLUSTER GROUP "G1" ADD
      CLUSTER MEMBER "G1N2" HOST '127.0.0.1' PORT '10120'
;
COMMIT;
SET SESSION AUTHORIZATION "SYS";
CREATE CLUSTER GROUP "G2"
       CLUSTER MEMBER "G2N1" HOST '127.0.0.1' PORT '10210'
;
COMMIT;
SET SESSION AUTHORIZATION "SYS";
ALTER CLUSTER GROUP "G2" ADD
      CLUSTER MEMBER "G2N2" HOST '127.0.0.1' PORT '10220'
;
COMMIT;
SET SESSION AUTHORIZATION "SYS";
CREATE CLUSTER GROUP "G3"
       CLUSTER MEMBER "G3N1" HOST '127.0.0.1' PORT '10310'
;
COMMIT;
SET SESSION AUTHORIZATION "SYS";
ALTER CLUSTER GROUP "G3" ADD
      CLUSTER MEMBER "G3N2" HOST '127.0.0.1' PORT '10320'
;
```

\ddl_db

Syntax

```
\ddl_db
\ddl_db GRANT
\ddl_db COMMENT
```

Description

It outputs the DDL statements corresponding to the current state of the database object.

The objects stored in the recycle bin are not output.

Table 40-19 `\ddl_db` commands

Command	Description
`\ddl_db`	It outputs the DDL statements of all objects created in the database.
`\ddl_db GRANT`	It outputs the GRANT .. ON DATABASE statement corresponding to the privilege information on the database object.
`\ddl_db COMMENT`	It outputs the COMMENT ON DATABASE statement corresponding to the comment information on the database object.

The result of `\ddl_db` command without any option outputs the DDL statements in the following order.

- Database DDL
- Tablespace DDL
- Profile DDL
- Authorization DDL
- Schema DDL
- Authorization schema path DDL
- Database privilege DDL
- Tablespace privilege DDL
- Schema privilege DDL
- Public synonym DDL
- Table DDL
- Table privilege DDL
- Table option DDL
- Constraint DDL
- Index DDL
- View DDL
- View privilege DDL
- Sequence DDL

- Sequence privilege DDL
- Synonym DDL
- Stored procedure/ function DDL
- Package DDL
- Audit policy DDL

However, the information related to the following schemas which include the dictionary information are not output.

- DICTIONARY_SCHEMA
- INFORMATION_SCHEMA
- PERFORMANCE_VIEW_SCHEMA
- DEFINITION_SCHEMA
- FIXED_TABLE_SCHEMA

The DDL statement for the schema above which includes the dictionary information can be output by using **`\ddl_schema`**.

Examples

The following is an example of executing `\ddl_db`.

```
gSQL> \ddl_db
```

- Database DDL

```
SET SESSION AUTHORIZATION "SYS";
COMMENT
    ON DATABASE
    IS 'goldilocks database'
;
```

- Tablespace DDL

```
SET SESSION AUTHORIZATION "SYS";
CREATE MEMORY DATA TABLESPACE "TEST_TBS"
    DATAFILE '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test1.dbf'
        SIZE 10477568 REUSE
    ONLINE
    LOGGING
    EXTSIZE 262144
;
```

```
SET SESSION AUTHORIZATION "SYS";
ALTER TABLESPACE "TEST_TBS"
    ADD DATAFILE '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test2.dbf'
        SIZE 10477568 REUSE
;
SET SESSION AUTHORIZATION "SYS";
ALTER TABLESPACE "TEST_TBS"
    ADD DATAFILE '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test3.dbf'
        SIZE 10477568 REUSE
;
SET SESSION AUTHORIZATION "SYS";
COMMENT
    ON TABLESPACE "TEST_TBS"
    IS 'comment tablespace TPC data'
;
SET SESSION AUTHORIZATION "SYS";
CREATE MEMORY TEMPORARY TABLESPACE "TEMP_TBS"
    MEMORY 'test_mem'
        SIZE 10477568
    EXTSIZE 262144
;
... Ellipsis ...
```

- Sequence privilege DDL

```
SET SESSION AUTHORIZATION "H_USER";
GRANT
    USAGE ON SEQUENCE "H_USER"."H_SEQ"
    TO "PUBLIC"
;
SET SESSION AUTHORIZATION "H_USER";
GRANT
    USAGE ON SEQUENCE "H_USER"."H_SEQ"
    TO "TEST"
    WITH GRANT OPTION
;
SET SESSION AUTHORIZATION "H_USER";
GRANT
    USAGE ON SEQUENCE "H_USER"."H_SEQ"
    TO "C_USER"
;
```

```
SET SESSION AUTHORIZATION "C_USER";
GRANT
    USAGE ON SEQUENCE "C_USER"."C_SEQ"
    TO "TEST"
;
SET SESSION AUTHORIZATION "C_USER";
GRANT
    USAGE ON SEQUENCE "C_USER"."C_SEQ"
    TO "H_USER"
;
```

The following is an example of executing `\ddl_db GRANT`.

```
gSQL> \ddl_db GRANT
SET SESSION AUTHORIZATION "SYS";
GRANT
    ALTER DATABASE ON DATABASE
    TO "TEST"
    WITH GRANT OPTION
;
SET SESSION AUTHORIZATION "SYS";
GRANT
    ALTER SYSTEM ON DATABASE
    TO "TEST"
    WITH GRANT OPTION
;
... Ellipsis ...
```

\ddl_tablespace

Syntax

```
\ddl_tablespace name
\ddl_tablespace name CREATE
\ddl_tablespace name ALTER
\ddl_tablespace name TABLE
\ddl_tablespace name CONSTRAINT
\ddl_tablespace name INDEX
\ddl_tablespace name GRANT
```

```
\ddl_tablespace name COMMENT
```

Description

It outputs the DDL statements for the current state of the tablespace object.

The objects stored in the recycle bin are not output.

Table 40-20 \ddl_tablespace commands

Command	Description
\ddl_tablespace name	It performs all options below.
\ddl_tablespace name CREATE	It outputs the CREATE TABLESPACE statement of the tablespace object.
\ddl_tablespace name ALTER	It outputs the ALTER TABLESPACE statements for the datafile or memory added to the tablespace.
\ddl_tablespace name TABLE	It outputs the CREATE TABLE statements of the tables stored in the tablespace.
\ddl_tablespace name CONSTRAINT	It outputs the ALTER TABLE statements of the constraints stored in the tablespace.
\ddl_tablespace name INDEX	It outputs the CREATE INDEX statements of the indexes stored in the tablespace.
\ddl_tablespace name GRANT	It outputs the GRANT .. ON TABLESPACE statement for the privilege information on the tablespace.
\ddl_tablespace name COMMENT	It outputs the COMMENT ON TABLESPACE statement corresponding o the comment on the tablespace.

Examples

The following is an example of executing \ddl_tablespace CREATE.

```
gSQL> \ddl_tablespace test_tbs CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE MEMORY DATA TABLESPACE "TEST_TBS"
    DATAFILE '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test1.dbf'
        SIZE 10477568 REUSE
    ONLINE
    EXTSIZE 262144
;
```

The following is an example of executing \ddl_tablespace ALTER.

```
gSQL> \ddl_tablespace test_tbs ALTER
SET SESSION AUTHORIZATION "SYS";
```

```
ALTER TABLESPACE "TEST_TBS"
    ADD DATAFILE
        '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test2.dbf'
        SIZE 10477568 REUSE
      ,
        '/home/GOLDILOCKS/workspace/product/Gliese/home/db/test3.dbf'
        SIZE 10477568 REUSE
;
```

\ddl_profile

Syntax

```
\ddl_profile name
\ddl_profile name CREATE
\ddl_profile name COMMENT
```

Description

It outputs the DDL statement for the current state of the profile object.

Table 40-21 `\ddl_profile` commands

Command	Description
`\ddl_profile name`	It performs all options below.
`\ddl_profile name CREATE`	It outputs the CREATE PROFILE statement of the profile object.
`\ddl_profile name COMMENT`	It outputs the COMMENT ON PROFILE statement corresponding to the comment on the profile.

Example

The following is an example of executing `\ddl_profile CREATE`.

```
gSQL> \ddl_profile prof1 CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE PROFILE "PROF1" LIMIT
    FAILED_LOGIN_ATTEMPTS   DEFAULT
    PASSWORD_LOCK_TIME   1/86400
    PASSWORD_LIFE_TIME   UNLIMITED
    PASSWORD_GRACE_TIME   100
```

```
    PASSWORD_REUSE_MAX    DEFAULT
    PASSWORD_REUSE_TIME    DEFAULT
    PASSWORD_VERIFY_FUNCTION    KISA_VERIFY_FUNCTION
;
COMMIT;
```

\ddl_audit_policy

Syntax

```
\ddl_audit_policy name
\ddl_audit_policy name CREATE
\ddl_audit_policy name AUDIT
\ddl_audit_policy name COMMENT
```

Description

It outputs the DDL statement for the current state of the audit policy object.

The objects stored in the recycle bin are not output.

Table 40-22 \ddl_audit_policy commands

Command	Description
\ddl_audit_policy name	It perform all options below.
\ddl_audit_policy name CREATE	It outputs CREATE AUDIT POLICY statement of the audit policy object.
\ddl_audit_policy name AUDIT	It outputs AUDIT POLICY statement of the audit policy object.
\ddl_audit_policy name COMMENT	It outputs the COMMENT ON AUDIT POLICY statement corresponding to the comment on the audit policy.

Examples

The following is an example of executing \ddl_audit_policy CREATE.

```
gSQL> \ddl_audit_policy p1 CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE AUDIT POLICY "P1"
```

```
       ACTIONS SELECT ON "PUBLIC"."T1"
             , INSERT ON "PUBLIC"."T1"
             , UPDATE ON "PUBLIC"."T2"
             , ALL ON "PUBLIC"."SEQ1"
             , SELECT ON "PUBLIC"."SEQ2"
             , EXECUTE ON "PUBLIC"."FUNC2"
;
COMMIT;
```

\ddl_auth

Syntax

```
\ddl_auth name
\ddl_auth name CREATE
\ddl_auth name SCHEMA PATH
\ddl_auth name SCHEMA
\ddl_auth name TABLE
\ddl_auth name CONSTRAINT
\ddl_auth name INDEX
\ddl_auth name VIEW
\ddl_auth name SEQUENCE
\ddl_auth name SYNONYM
\ddl_auth name PROCEDURE
\ddl_auth name PACKAGE
\ddl_auth name COMMENT
```

Description

It outputs the DDL statements for the current state of the account object.

The objects stored in the recycle bin are not output.

Table 40-23 \ddl_auth commands

Command	Description
\ddl_auth name	It performs all options below.
\ddl_auth name CREATE	It outputs the CREATE USER statement of the user object.
\ddl_auth name SCHEMA	It outputs the CREATE SCHEMA statement of schemas owned by a user.

Command	Description
\ddl_auth name SCHEMA PATH	It outputs the ALTER USER statement corresponding to the schema path of the account.
\ddl_auth name TABLE	It outputs the CREATE TABLE statements of tables owned by a user.
\ddl_auth name CONSTRAINT	It outputs the ALTER TABLE statements of constraints owned by a user.
\ddl_auth name INDEX	It outputs the CREATE INDEX statements of indexes owned by a user.
\ddl_auth name VIEW	It outputs the CREATE VIEW statements of views owned by a user.
\ddl_auth name SEQUENCE	It outputs the CREATE SEQUENCE statements of sequences owned by a user.
\ddl_auth name SYNONYM	It outputs the CREATE SYNONYM statements of sequences owned by a user.
\ddl_auth name PROCEDURE	It outputs the CREATE PROCEDURE/ FUNCTION statements of sequences owned by a user.
\ddl_auth name PACKAGE	It outputs the CREATE PACKAGE/PACKAGE BODY statements of packages owned by a user.
\ddl_auth name COMMENT	It outputs the COMMENT ON AUTHORIZATION statement corresponding to comments on the account.

Examples

The following is an example of executing \ddl_auth CREATE.

```
gSQL> \ddl_auth h_user CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE USER "H_USER"
    IDENTIFIED BY H_USER
    DEFAULT TABLESPACE "TEST_TBS"
    TEMPORARY TABLESPACE "TEMP_TBS"
    WITHOUT SCHEMA
;
```

The following is an example of executing \ddl_auth SCHEMA.

```
gSQL> \ddl_auth h_user SCHEMA
SET SESSION AUTHORIZATION "SYS";
CREATE SCHEMA "H_USER"
    AUTHORIZATION "H_USER"
;
```

The following is an example of executing \ddl_auth TABLE.

```
gSQL> \ddl_auth h_user TABLE
SET SESSION AUTHORIZATION "H_USER";
```

```
CREATE TABLE "H_USER"."REGION"
    (
        "R_REGIONKEY" NUMBER( 10, 0 )
      , "R_NAME" CHARACTER( 25 OCTETS )
      , "R_COMMENT" CHARACTER VARYING( 152 OCTETS )
    )
    PCTFREE  10
    PCTUSED  60
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "TEST_TBS"
;
SET SESSION AUTHORIZATION "H_USER";
CREATE TABLE "H_USER"."NATION"
    (
        "N_NATIONKEY" NUMBER( 10, 0 )
      , "N_NAME" CHARACTER( 25 OCTETS )
      , "N_REGIONKEY" NUMBER( 10, 0 )
      , "N_COMMENT" CHARACTER VARYING( 152 OCTETS )
    )
    PCTFREE  10
    PCTUSED  60
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (

        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "TEST_TBS"
;
```

\ddl_schema

Syntax

```
\ddl_schema name
\ddl_schema name CREATE
\ddl_schema name TABLE
\ddl_schema name CONSTRAINT
\ddl_schema name INDEX
\ddl_schema name VIEW
\ddl_schema name SEQUENCE
\ddl_schema name SYNONYM
\ddl_schema name PROCEDURE
\ddl_schema name PACKAGE
\ddl_schema name GRANT
\ddl_schema name COMMENT
```

Description

It outputs the DDL statements for the current state of the schema object.

The objects stored in the recycle bin are not output.

Table 40-24 \ddl_schema commands

Command	Description
\ddl_schema name	It performs all options below.
\ddl_schema name CREATE	It outputs the CREATE SCHEMA statement of the schema object.
\ddl_schema name TABLE	It outputs the CREATE TABLE statements of the tables which belong to the schema.
\ddl_schema name CONSTRAINT	It outputs the ALTER TABLE statements of the constraints which belong to the schema.
\ddl_schema name INDEX	It outputs the CREATE INDEX statements of the indexes which belong to the schema.
\ddl_schema name VIEW	It outputs the CREATE VIEW statements of the views which belong to the schema.
\ddl_schema name SEQUENCE	It outputs the CREATE SEQUENCE statements of the sequences which belong to the schema.
\ddl_schema name SYNONYM	It outputs the CREATE SYNONYM statements of the sequences which belong to the schema.
\ddl_schema name PROCEDURE	It outputs the CREATE PROCEDURE/ FUNCTION statements of the sequences which belong to the schema.
\ddl_schema name PACKAGE	It outputs the CREATE PACKAGE/PACKAGE BODY statements of the package which

Command	Description
	belong to the schema.
\ddl_schema name GRANT	It outputs the GRANT .. ON SCHEMA statement for the privilege information on the schema.
\ddl_schema name COMMENT	It outputs the COMMENT ON SCHEMA statement corresponding to the comment on the schema.

Examples

The following is an example of executing \ddl_schema CREATE.

```
gSQL> \ddl_schema h_user CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE SCHEMA "H_USER"
    AUTHORIZATION "H_USER"
;
```

The following is an example of executing \ddl_schema CONSTRAINT.

```
gSQL> \ddl_schema h_user CONSTRAINT
SET SESSION AUTHORIZATION "H_USER";
ALTER TABLE "H_USER"."REGION"
    ADD CONSTRAINT "H_USER"."REGION_PK"
    PRIMARY KEY
    (
        "R_REGIONKEY" ASC NULLS LAST
    )
    INDEX "REGION_PK_INDEX"
    PCTFREE  10
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288

    )
    TABLESPACE "TEMP_TBS"
    NOT DEFERRABLE
    INITIALLY IMMEDIATE
```

```
;
SET SESSION AUTHORIZATION "H_USER";
ALTER TABLE "H_USER"."NATION"
    ADD CONSTRAINT "H_USER"."NATION_PK"
    PRIMARY KEY
    (
        "N_NATIONKEY" ASC NULLS LAST
    )
    INDEX "NATION_PK_INDEX"
    PCTFREE  10
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "TEMP_TBS"
    NOT DEFERRABLE
    INITIALLY IMMEDIATE
;
SET SESSION AUTHORIZATION "H_USER";
ALTER TABLE "H_USER"."SUPPLIER"
    ADD CONSTRAINT "H_USER"."SUPPLIER_PK"
    PRIMARY KEY
    (
        "S_SUPPKEY" ASC NULLS LAST
    )
    INDEX "SUPPLIER_PK_INDEX"
    PCTFREE  10
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144

        MAXSIZE 35184372088832
    )
```

```
    TABLESPACE "TEMP_TBS"
    NOT DEFERRABLE
    INITIALLY IMMEDIATE
;
```

\ddl_public_synonym

Syntax

```
\ddl_public_synonym name
\ddl_public_synonym name CREATE
```

Description

It outputs the DDL statements for the current state of the public synonym object.

Table 40-25 `\ddl_public_synonym` commands

Command	Description
`\ddl_public_synonym`	It performs all options below.
`\ddl_public_synonym name CREATE`	It outputs the CREATE PUBLIC SYNONYM statement of the public synonym object.

Example

The following is an example of executing `\ddl_public_synonym CREATE`.

```
gSQL> \ddl_public_synonym pubsyn CREATE
SET SESSION AUTHORIZATION "SYS";
CREATE PUBLIC SYNONYM "PUBSYN" FOR "PUBLIC"."T1"
;
COMMIT;
```

\ddl_table

Syntax

```
\ddl_table name
\ddl_table name CREATE
\ddl_table name CONSTRAINT
\ddl_table name INDEX
\ddl_table name IDENTITY
\ddl_table name SUPPLEMENTAL
\ddl_table name GRANT
\ddl_table name COMMENT
```

Description

It outputs the DDL statements for the current state of the table object.

The objects stored in the recycle bin are not output.

Table 40-26 `\ddl_table` commands

Command	Description
`\ddl_table name`	It performs all options below.
`\ddl_table name CREATE`	It outputs the CREATE TABLE statement of the table object.
`\ddl_table name CONSTRAINT`	It outputs the ALTER TABLE statements of the constraints created in the table.
`\ddl_table name INDEX`	It outputs the CREATE INDEX statements of the indexes created in the table.
`\ddl_table name IDENTITY`	It outputs the ALTER TABLE statement for the restart value if the table has an identity column.
`\ddl_table name SUPPLEMENTAL`	It outputs the ALTER TABLE statement if the supplemental log option is set on the table.
`\ddl_table name GRANT`	It outputs the GRANT .. ON TABLE statement for the privilege information on the table.
`\ddl_table name COMMENT`	It outputs the COMMENT ON TABLE statement corresponding to the comment on the table.

Examples

The following is an example of executing `\ddl_table CREATE`.

```
gSQL> \ddl_table h_user.orders CREATE
SET SESSION AUTHORIZATION "H_USER";
CREATE TABLE "H_USER"."ORDERS"
    (
```

```
        "O_ORDERKEY" NUMBER( 10, 0 )
      , "O_CUSTKEY" NUMBER( 10, 0 )
      , "O_ORDERSTATUS" CHARACTER( 1 OCTETS )
      , "O_TOTALPRICE" NUMBER( 12, 2 )
      , "O_ORDERDATE" DATE
      , "O_ORDERPRIORITY" CHARACTER( 15 OCTETS )
      , "O_CLERK" CHARACTER( 15 OCTETS )
      , "O_SHIPPRIORITY" NUMBER( 10, 0 )
      , "O_COMMENT" CHARACTER VARYING( 79 OCTETS )
    )
    PCTFREE  10
    PCTUSED  60
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "TEST_TBS"
;
```

The following is an example of executing `\ddl_table GRANT`.

```
gSQL> \ddl_table h_user.nation GRANT
SET SESSION AUTHORIZATION "H_USER";
GRANT
    DELETE ON TABLE "H_USER"."NATION"
    TO "TEST"
;
SET SESSION AUTHORIZATION "H_USER";
GRANT
    SELECT ( "N_NATIONKEY" ) ON TABLE "H_USER"."NATION"
    TO "C_USER"
;
SET SESSION AUTHORIZATION "H_USER";
GRANT
    SELECT ( "N_NAME" ) ON TABLE "H_USER"."NATION"
    TO "C_USER"
```

```
;
```

\ddl_constraint

Syntax

```
\ddl_constraint name
\ddl_constraint name ALTER
\ddl_constraint name COMMENT
```

Description

It outputs the DDL statements for the current state of the constraint object.

The objects stored in the recycle bin are not output.

Table 40-27 `\ddl_constraint` commands

Command	Description
`\ddl_constraint name`	It performs all options below.
`\ddl_constraint name ALTER`	It outputs the ALTER TABLE statement of the constraint object.
`\ddl_constraint name COMMENT`	It outputs the COMMENT ON CONSTRAINT statement corresponding to the comment on the constraint.

Example

The following is an example of executing `\ddl_constraint ALTER`.

```
gSQL> \ddl_constraint h_user.lineitem_pk ALTER
SET SESSION AUTHORIZATION "H_USER";
ALTER TABLE "H_USER"."LINEITEM"
    ADD CONSTRAINT "H_USER"."LINEITEM_PK"
    PRIMARY KEY
    (
        "L_ORDERKEY" ASC NULLS LAST
      , "L_LINENUMBER" ASC NULLS LAST
    )
    INDEX "LINEITEM_PK_INDEX"
    PCTFREE  10
```

```
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "TEMP_TBS"
    NOT DEFERRABLE
    INITIALLY IMMEDIATE
;
```

\ddl_index

Syntax

```
\ddl_index name
\ddl_index name CREATE
\ddl_index name COMMENT
```

Description

It outputs the DDL statements for the current state of the index object.

The objects stored in the recycle bin are not output.

Table 40-28 \ddl_index commands

Command	Description
\ddl_index name	It performs all options below.
\ddl_index name CREATE	It outputs the CREATE INDEX statement of the index object.
\ddl_index name COMMENT	It outputs the COMMENT ON INDEX statement corresponding to the comment on the index.

Example

The following is an example of executing `\ddl_index CREATE`.

```
gSQL> \ddl_index public.idx2 CREATE
SET SESSION AUTHORIZATION "TEST";
CREATE INDEX "PUBLIC"."IDX2"
    ON "PUBLIC"."T1"
    (
        "C3" ASC NULLS LAST
      , "C1" DESC NULLS FIRST
    )
    PCTFREE  10
    INITRANS 4
    MAXTRANS 8
    STORAGE
    (
        INITIAL 524288
        NEXT    262144
        MINSIZE 524288
        MAXSIZE 35184372088832
    )
    TABLESPACE "MEM_TEMP_TBS"
;
```

\ddl_view

Syntax

```
\ddl_view name
\ddl_view name CREATE
\ddl_view name GRANT
\ddl_view name COMMENT
```

Description

It outputs the DDL statements for the current state of the view object.

Table 40-29 \ddl_view commands

Command	Description
\ddl_view name	It performs all options below.
\ddl_view name CREATE	It outputs the CREATE VIEW statement of the view object.
\ddl_view name GRANT	It outputs the GRANT .. ON TABLE statement for the privilege information on the view.
\ddl_view name COMMENT	It outputs the COMMENT ON TABLE corresponding to the comment on the view.

Example

The following is an example of executing \ddl_view CREATE.

```
gSQL> \ddl_view h_user.revenue CREATE
SET SESSION AUTHORIZATION "H_USER";
CREATE OR REPLACE FORCE VIEW "H_USER"."REVENUE"
    (supplier_no, total_revenue)
    AS SELECT
    l_suppkey,
    ROUND( sum(l_extendedprice * (1 - l_discount)), 2)
FROM
    lineitem
WHERE
      l_shipdate >= date '1996-01-01'
  AND l_shipdate < date '1996-01-01' + interval '3' month
GROUP BY
    l_suppkey
;
```

\ddl_sequence

Syntax

```
\ddl_sequence name
\ddl_sequence name CREATE
\ddl_sequence name RESTART
\ddl_sequence name GRANT
\ddl_sequence name COMMENT
```

Description

It outputs the DDL statements for the current state of the sequence object.

Table 40-30 \ddl_sequence commands

Command	Description
\ddl_sequence name	It performs all options below.
\ddl_sequence name CREATE	It outputs the CREATE SEQUENCE statement of the sequence object.
\ddl_sequence name RESTART	It outputs the ALTER SEQUENCE statement corresponding to the restart value of the sequence object.
\ddl_sequence name GRANT	It outputs the GRANT .. ON SEQUENCE statement for the privilege information on t he sequence.
\ddl_sequence name COMMENT	It outputs the COMMENT ON SEQUENCE statement corresponding to the comment on the sequence.

Examples

The following is an example of executing \ddl_sequence CREATE.

```
gSQL> \ddl_sequence h_user.h_seq CREATE
SET SESSION AUTHORIZATION "H_USER";
CREATE SEQUENCE "H_USER"."H_SEQ"
    START WITH 1
    INCREMENT BY 1
    MAXVALUE 9223372036854775807
    MINVALUE 1
    NO CYCLE
    CACHE 20
;
```

The following is an example of executing \ddl_sequence RESTART.

```
gSQL> \ddl_sequence h_user.h_seq RESTART
SET SESSION AUTHORIZATION "H_USER";
ALTER SEQUENCE "H_USER"."H_SEQ"
    RESTART WITH 21
;
```

\ddl_synonym

Syntax

```
\ddl_synonym name
\ddl_synonym name CREATE
```

Description

It outputs the DDL statements for the current state of the synonym object.

Table 40-31 `\ddl_synonym` commands

Command	Description
`\ddl_synonym`	It performs all options below.
`\ddl_synonym name CREATE`	It outputs the CREATE SYNONYM statement of the synonym object.

Example

The following is an example of executing `\ddl_synonym CREATE`.

```
gSQL> \ddl_synonym syn CREATE
SET SESSION AUTHORIZATION "TEST";
CREATE SYNONYM "PUBLIC"."SYN" FOR "PUBLIC"."T1"
;
COMMIT;
```

\ddl_procedure

Syntax

```
\ddl_procedure name
\ddl_procedure name CREATE
```

Description

It outputs the DDL statements for the current state of the stored procedure or the function object.

Table 40-32 \ddl_procedure commands

Command	Description
\ddl_procedure	It performs all options below.
\ddl_procedure name CREATE	It outputs CREATE PROCEDURE/ FUNCTION statement of the stored procedure/ function object.

Example

The following is an example of executing \ddl_procedure CREATE.

```
gSQL> \ddl_procedure proc1 CREATE
SET SESSION AUTHORIZATION "TEST";
CREATE OR REPLACE PROCEDURE "PUBLIC"."PROC1"
is
begin
 null;
end;
/
COMMIT;
```

\ddl_package

Syntax

```
\ddl_package name
\ddl_package name CREATE
```

Description

It outputs the DDL statements for the current state of the package spec or the package body object.

Table 40-33 \ddl_package commands

Command	Description
\ddl_package	It performs all options below.
\ddl_package name CREATE	It outputs CREATE PACKAGE/PACKAGE BODY statement of the package spec and the package body object.

Examples

The following is an example of executing `\ddl_package CREATE`.

```
gSQL> \ddl_package pkg1 CREATE
SET SESSION AUTHORIZATION "TEST";
CREATE OR REPLACE PACKAGE "PUBLIC"."PKG1"
is
  v1 integer;
  procedure proc1( a1 integer );
 end;
/
CREATE OR REPLACE PACKAGE BODY "PUBLIC"."PKG1"
is
  procedure proc1( a1 integer )
  is
  begin
    null;
  end;
end;
/
COMMIT;
```

\desc

Syntax

```
\desc table_name
\desc schema_name.table_name
```

Description

It queries the structure information of the table.

A table may be described only with the table name as follows or described together with the schema na me. If the schema name is not specified, the schema name of the table is determined by the **Schema Path** of the user.

- \desc t1
- \desc public.t1

If a table name is created by using **Identifiers** when creating a table as follows, the double quotes (") is used to describe it.

- Creating a table
  - CREATE TABLE "TaBle#@^*" (id INTEGER);
- \desc "TaBle#@^*"
- \desc "PUBLIC"."TaBle#@^*"

The execution result includes the following information of the table.

- Column information
  - Column name
  - Data type
  - Whether NULL is allowed
- Index information
  - Index name
  - Storage space for index
  - Index type
  - Whether UNIQUE is allowed
  - Key column name
- Constraint information
  - Constraint name
  - Constraint type
  - The related index
  - Constraint column

Examples

The following is an example of querying the information of the t1 table.

```
gSQL> \desc t1
COLUMN_NAME TYPE                    IS_NULLABLE
----------- ----------------------- -----------
ID          NUMBER(10,0)            FALSE
NAME        CHARACTER VARYING(128)  TRUE
ADDR        CHARACTER VARYING(1024) TRUE
INDEX_NAME           TABLESPACE_NAME INDEX_TYPE IS_UNIQUE COLUMNS
-------------------- --------------- ---------- --------- -------
T1_PRIMARY_KEY_INDEX MEM_TEMP_TBS    BTREE      TRUE      ID
T1_IDX_NAME          MEM_TEMP_TBS    BTREE      FALSE     NAME
CONSTRAINT_NAME CONSTRAINT_TYPE ASSOCIATED_INDEX     COLUMNS
--------------- --------------- -------------------- -------
```

```
T1_PRIMARY_KEY  PRIMARY KEY     T1_PRIMARY_KEY_INDEX ID
```

The following is an example of querying the information of the t1 table by describing together with the s chema name public.

```
gSQL> \desc public.t1
COLUMN_NAME TYPE                    IS_NULLABLE
----------- ----------------------- -----------
ID          NUMBER(10,0)            FALSE
NAME        CHARACTER VARYING(128)  TRUE
ADDR        CHARACTER VARYING(1024) TRUE
INDEX_NAME           TABLESPACE_NAME INDEX_TYPE IS_UNIQUE COLUMNS
-------------------- --------------- ---------- --------- -------
T1_PRIMARY_KEY_INDEX MEM_TEMP_TBS    BTREE      TRUE      ID
T1_IDX_NAME          MEM_TEMP_TBS    BTREE      FALSE     NAME
CONSTRAINT_NAME CONSTRAINT_TYPE ASSOCIATED_INDEX     COLUMNS
--------------- --------------- -------------------- -------
T1_PRIMARY_KEY  PRIMARY KEY     T1_PRIMARY_KEY_INDEX ID
```

The following is an example of querying the information of the table created by using the delimited identi fier.

```
gSQL> CREATE TABLE "TaBle#@^*" ( id INTEGER );
Table created.
gSQL> \desc "TaBle#@^*"
COLUMN_NAME TYPE         IS_NULLABLE
----------- ------------ -----------
ID          NUMBER(10,0) TRUE
```

If the delimited identifier is not used as follows, then an error occurs.

```
gSQL> \desc TaBle#@^*
ERR-42000(40000): syntax error
\desc TaBle#@^*
...........^  ^
Error at line 1
```

\dynamic sql :var

Syntax

```
\dynamic sql :var
```

Description

It executes the SQL statement stored in the host variable var.
It is similar in concept to **Embedded Dynamic SQL** which executes SQL statements that are not defined in an embedded SQL, but It is used when performing SQL statement which is not defined.

It is performed in the following order.

1. Declare a host variable. (Refer to **\var**.)
   \var var_stmt VARCHAR(1024)
2. Assign an SQL statement as the value of the host variable. (Refer to **\exec :var := value**.)
   \exec :var_stmt := 'SELECT # FROM t1'
3. Execute the dynamic SQL.
   \dynamic sql :var_stmt

Examples

The following is an example of declaring the var_stmt host variable and executing the dynamic SQL by ass igning an SQL statement.

- Assigning the SELECT statement to the host variable

```
gSQL> \exec :var_stmt := 'SELECT * FROM t1'
```

- Executing the dynamic SQL

```
gSQL> \dynamic sql :var_stmt
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
```

Two single quote (') are described like as the usage of the **\exec :var := value** command when a string exists in an SQL statement as the INSERT statement below.

- Declaring a host variable

```
gSQL> \var var_stmt VARCHAR(1024)
```

- Assigning the INSERT statement to the host variable

```
gSQL> \exec :var_stmt := 'INSERT INTO t1(id, name, addr) VALUES ( 1, ''leekmo'', ''Seoul, Korea'' )'
```

- Executing the dynamic SQL.

```
gSQL> \dynamic sql :var_stmt
1 row created.
```

\edit

Description

It edits the SQL statement by using the text editor. The used text editor is specified in the EDITOR environment variable, and if the EDITOR environment variable does not exist, vi is used by default.

When using the editing feature, gsql hands over control by executing the editor. The user can freely edit the SQL statements with the editor. When the editor ends, the control is handed over to gsql, and its content will be added as the last history.

The SQL statement edited by the editor may be executed through the last history execution command \\.

> ⚠ Only a single SQL statement can be edited with the SQL editor. An error occurs when executing multiple SQL statements.

The followings can be edited by using \edit.

- The most recently performed SQL statement
- the SQL statement stored in a file
- The SQL statement stored in the gsql history

The following chapter describes the usage.

\edit

Syntax

```
\edit
\ed
```

Description

It edits the most recently executed SQL statement by using the text editor. If any SQL statement has not b
een executed, the text editor is run without any content.

Example

The following is an example of editing the most recently executed SQL statement.

- Editing the most recently executed SQL statement

```
gSQL> SELECT * FROM T1;
C1
--
 1
11
2 rows selected.
gSQL> \EDIT
SELECT * FROM T1 WHERE C1 < 10;
```

- Executing the edited SQL statement

```
gSQL> \\
C1
--
 1
1 row selected.
```

\edit 'file_name'

Syntax

```
\edit 'file_name'
\ed   'file_name'
```

Description

It edits the given file_name by using the text editor.
The file_name is enclosed with the single quote (').
file_name can use either an absolute path or a relative path as follows. When file_name uses a relative pa th, it searches for the file_name based on the path of gsql execution.

- Using the absolute path

```
gSQL> \edit '/home/goldilocks/sample.sql'
```

- Using the relative path

```
gSQL> \edit 'sample.sql'
```

Example

The following is an example of editing the SQL statement stored in the file.

- Editing the most recently executed SQL statement

```
gSQL> SELECT * FROM T1;
C1
--
 1
11
2 rows selected.
gSQL> \EDIT 'sample.sql'
SELECT * FROM T1 WHERE C1 < 10;
```

- Executing the edited SQL statement

```
gSQL> \\
C1
--
 1
1 row selected.
```

\edit [history] {n}

Syntax

```
\edit [history] {n}
\ed   [history] {n}
```

Description

It edits the SQL statement corresponding to the number from the SQL execution history which can be qu eried by using **\history**.
The value of number should be the ID value which is the result of executing **\history**.

Example

The following is an example of editing the SQL statement stored in the gsql history.

```
gSQL> SELECT * FROM T1;
C1
--
 1
11
2 rows selected.
gSQL> \history
ID SQL
-- ----------------
 1 SELECT * FROM T1
```

- Editing the SQL statement whose ID value is 1 from the stored history

```
gSQL> \edit 1
SELECT * FROM T1 WHERE C1 < 5;
```

- Executing the edited SQL statement

```
gSQL> \\
C1
--
 1
1 row selected.
```

\exec

Syntax

```
\exec
```

Description

It executes the SQL statement which is prepared by **\prepare sql**.
\exec operates similarly to the **SQLExecute** function of ODBC and PreparedStatement::**execute** function of JDBC.
The prepared SQL statements can be repeatedly executed by using \exec.

Examples

The following is an example of preparing an INSERT statement and repeatedly executing it.

- Preparing the INSERT statement

```
gSQL> \prepare sql INSERT INTO t1(id, addr) VALUES ( seq.NEXTVAL, 'N/A' );
SQL prepared.
```

- Executing the prepared statement

```
gSQL> \exec
1 row created.
```

- Executing the prepared statement

```
gSQL> \exec
1 row created.
```

- The results of querying the table are as follows.

```
gSQL> SELECT * FROM t1;
ID ADDR
-- ----
 1 N/A
 2 N/A
2 rows selected.
```

The following is an example of preparing the SELECT statement with the host variable and repeatedly exe cuting it by changing the host variable value.

- Declaring the host variable

```
gSQL> \var v_id INTEGER
```

- Preparing the SELECT statement which used the host variable

```
gSQL> \prepare sql SELECT * FROM t1 WHERE ID = :v_id;
SQL prepared.
```

- Assigning the value 1 to the host variable

```
gSQL> \exec :v_id := 1
```

- Executing the prepared SELECT statement

```
gSQL> \exec
ID ADDR
-- ----
 1 N/A
1 row selected.
```

- Assigning the value 2 to the host variable

```
gSQL> \exec :v_id := 2
```

- Executing the prepared SELECT statement

```
gSQL> \exec
ID ADDR
-- ----
 2 N/A
1 row selected.
```

\exec :var := value

Syntax

```
\exec :variable := <value expression>
```

Description

It assigns the value to the host variable.
This command assigns a value to the host variable in the same way as executing **SELECT .. INTO** as follows.

```
gSQL> \exec :v_value := 1234
gSQL> SELECT 1234 INTO :v_value FROM DUAL;
```

The host variable must have been declared with **\var**.

The host variable must be used together with colon (:), and the assignment operator (:=) is not allowed to omit (:). Simple values or operators may appear in <value expression> entered to the host variable. For more information, refer to **Expressions**.

The value assigned to the host variable should be compatible with the data type of the host variable. For more information, refer to **Type Conversion**.

The value assigned to the host variable may be queried by using **\print**.

```
\exec :v_value := 1234
\print v_value
```

The string should be enclosed in the single quote (') as follows when inserting the string into the host variable.

- Simple string
  - Value: abcd
  - \exec :v_value := 'abcd'
- The string which includes the single quote
  - Value: Tom's House
  - The single quote within the string is represented with the two single quotes ('') as follows.
  - \exec :v_value := 'Tom''s House'
- The SQL statement including the single quote
  - Value: INSERT INTO t1 VALUES (1, 'Tom''s House')
  - The single quote within the string is represented with the two single quotes ('') as follows.
  - \exec :v_value := 'INSERT INTO t1 VALUES (1, ''Tom''s House'')'

Examples

The following is an example of assigning the various types of string to the host variable.

- Declaring the host variable

```
gSQL> \var v_value VARCHAR(1024)
```

- Assigning the simple string

```
gSQL> \exec :v_value := 'abcd'
gSQL> \print v_value
V_VALUE
-------
abcd
```

- Assigning the string including the single quote (')

```
gSQL> \exec :v_value := 'Tom''s House'
gSQL> \print v_value
V_VALUE
-----------
Tom's House
```

- Assigning the SQL statement including the single quote (')

```
gSQL> \exec :v_value := 'INSERT INTO t1 VALUES ( 1, ''Tom''s House'' )'
gSQL> \print v_value
V_VALUE
----------------------------------------
INSERT INTO t1 VALUES ( 1, 'Tom's House' )
```

The following is an example of using the operation result when assigning the value to the host variable.

- Declaring the host variable

```
gSQL> \var v1 INTEGER
gSQL> \var v2 INTEGER
```

- Assigning the value to v1

```
gSQL> \exec :v1 := 100
```

- Assigning the result of operation with v1 to v2

```
gSQL> \exec :v2 := :v1 + 1000
```

- Querying the value of host variables v1 and v2

```
gSQL> \print v1
 V1
---
100
gSQL> \print v2
  V2
----
1100
```

The following is an example of assigning the value to the host variable and using the host variable in the SELECT statement.

- Declaring the host variable

```
gSQL> \var v_id INTEGER
```

- Assigning the value to the host variable

```
gSQL> \exec :v_id := 1
```

- Executing the SELECT statement by using the host variable

```
gSQL> SELECT * FROM t1 WHERE id = :v_id;
ID ADDR
-- ----
 1 N/A
1 row selected.
```

The following is an example of obtaining the value to the host variable via **SELECT .. INTO**.

- Declaring the host variable

```
gSQL> \var v_id INTEGER
```

- A value is not specified.

```
gSQL> \print v_id
V_ID
----
```

```
null
```

- Assigning the value to v_id by executing the SELECT INTO statement

```
gSQL> SELECT MAX(id) INTO :v_id FROM t1;
V_ID
----
   2
1 row selected.
```

- Checking the host variable value

```
gSQL> \print v_id
V_ID
----
   2
```

\exec sql

Syntax

```
\exec sql <sql_statement>
```

Description

It executes the SQL statement described in <sql_statement>.
It operates as same as the execution of the SQL statement at the prompt as follows.

```
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
gSQL> \exec sql SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
```

The SQL statement is executed with the PREPARE/EXECUTE method using **\prepare sql** and **\exec**. On the other hand, \exec sql executes the SQL statement with the DIRECT EXECUTE method corresponding to **SQLExecDirect** function of ODBC and to Statement::**execute** function of JDBC.

Example

The following is an example of executing the SELECT statement.

```
gSQL> \exec sql SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
```

\explain plan

Syntax

```
\explain plan <sql_statement>
\explain plan on <sql_statement>
\explain plan only <sql_statement>
```

Description

It outputs the execution plan of the SELECT statement described in <sql_statement>.

- \explain plan on
  - It executes the SQL statement and outputs the execution plan along with the query results.
- \explain plan only
  - It does not execute the SQL statement and outputs the execution plan without the query results.
- \explain plan
  - If on or only is not specified, the default value is on.

For more information about the execution plan, refer to **SQL Execution Plan**.

Examples

If it is used together with ON as follows, it executes the SQL statement and outputs the execution plan wi
th the query results.

```
gSQL> \explain plan on SELECT * FROM t1 WHERE id = 1;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                ¦       ROWS ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                ¦            ¦
¦    1  ¦    TABLE ACCESS ("T1")                         ¦          1 ¦
================================================================================
     1  -  READ COLUMNS : ID, NAME, ADDR
             PHYSICAL FILTER : ID = 1
<<<  end print plan
```

If it is used together with ONLY as follows, it does not execute the SQL statement and outputs the execut ion plan without the query results.

```
gSQL> \explain plan only SELECT * FROM t1 WHERE id = 1;
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                ¦       ROWS ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                ¦            ¦
¦    1  ¦    TABLE ACCESS ("T1")                         ¦          0 ¦
================================================================================
     1  -  READ COLUMNS : ID, NAME, ADDR
             PHYSICAL FILTER : ID = 1
<<<  end print plan
```

\help

Syntax

```
\help
```

Description

It briefly displays the list of commands which begin with (\) in gsql interactive mode.

Examples

The following is an example of using \help.

```
gSQL> \help
\help
\q[uit]
\i[mport] {'FILE'}               Import SQL
\ed[it] [{'FILE'|[HISTORY] num}] Edit SQL statement
\\                               Executes the most recent history entry
\{n}                             Executes n'th history entry
\hi[story]                       Show history entries

\cstartup        {[nomount|mount|open]}
\cshutdown       {[abort|normal]}
\connect         [userid password] [as {sysdba|admin}]
```

\host

Syntax

```
\host [command]
\ho [command]
```

Description

It executes the command of the operational system without terminating gsql program.
If HOST is input without command, then the prompt of the operational system is displayed and it is able t o continuously input the command of the operational system.
Instead of HOST, "$" is input in Windows, and "!" is input in UNIX.

Example

The following is an example of executing ls *.sql statement which is a command of UNIX operational syst em.

```
gSQL> \host ls *.sql
DictionarySchema.sql  InformationSchema.sql  PerformanceViewSchema.sql
```

\history

Syntax

```
\history
\hi
```

Description

It displays the list of the SQL statements executed after executing gsql program.
It manages only the successfully executed SQL statements and it does not include the failed SQL statemen t nor the interactive command which begins with gsql(\).
The previously executed SQL statements can be executed again referring to the list through **** or **\{n}**.
The number of manageable SQL statements is controlled by using **\set history**.

Example

The following is an example of querying the SQL statement execution history and executing the SQL state ment of number 8 again.

```
gSQL> \history
ID SQL
-- ------------------------------------------------------------------
 1 drop table t1
 2 create table t1 ( id integer, name varchar(128), addr varchar(1024) )
 3 create index t1_idx on t1(id)
 4 insert into t1 values ( 1, 'leekmo', 'Seoul, Korea' )
 5 insert into t1 values ( 2, 'mkkim', 'Seoul, Korea' )
 6 insert into t1 values ( 3, 'xcom73', 'Inchon, Korea' )
 7 commit
 8 select * from dual
gSQL> \8
DUMMY
-----
X
1 row selected.
```

\import

Syntax

```
\import 'file_name'
\i 'file_name'
```

Description

It imports the SQL statement included in file_name.
The file_name is enclosed with the single quote (').
file_name can use either an absolute path or a relative path as follows. When file_name uses a relativepat
h, it searches for the file_name based on the path of gsql execution.

- Using the absolute path

```
gSQL> \import '/home/GOLDILOCKS/sample.sql'
```

- Using the relative path

```
gSQL> \import 'sample.sql'
```

Examples

The following is an example of importing the SQL statement from the file by using the absolute path.

```
gSQL> \import '/home/GOLDILOCKS/sample.sql'
DROP TABLE IF EXISTS t1;
Table dropped.
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
```

```
3 rows created.
COMMIT;
Commit complete.
```

The following is an example of importing the SQL statement from the file by using the relative path.

```
gSQL> \import 'sample.sql'
DROP TABLE IF EXISTS t1;
Table dropped.
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
INSERT INTO t1
       VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
              ( 2, 'mkkim' , 'Seoul, Korea'  ),
              ( 3, 'xcom73', 'Inchon, Korea' );
3 rows created.
COMMIT;
Commit complete.
```

\idesc

Syntax

```
\idesc index_name
\idesc schema_name.index_name
```

Description

It queries the structure information of the index.

An index can be described alone as follows or it can be described together with the schema name. If the schema name is not specified, the schema name of the index is determined by the user's **Schema Path**.

- \idesc t1_idx_name
- \idesc public.t1_idx_name

The execution result includes the following key column information of the index.

- Key column name
- Key column location
- Key column sort order (ascending/ descending)
- NULL position of the key column(FIRST/ LAST)

Example

The following is an example of querying the information of the index t1_idx_name.

```
gSQL> \idesc t1_idx_name
COLUMN_NAME ORDINAL_POSITION IS_ASCENDING_ORDER IS_NULLS_FIRST
----------- ---------------- ------------------ --------------
NAME                       1 TRUE               FALSE
```

\{n}

Syntax

```
\number
```

Description

It executes the SQL statement corresponding to the number from the SQL execution history which can be queried by using **`\history`**.
The value of number should be the ID value which is the result of executing **`\history`**.

Examples

The following is an example of executing SQL statement which used `\history`, then executing the DROP TABLE statement whose ID value is 1.

```
gSQL> \history
ID SQL
-- --------------------------------------------
 1 DROP TABLE IF EXISTS t1
 2 CREATE TABLE t1
   (
```

```
       id   INTEGER PRIMARY KEY,
       name VARCHAR(128),
       addr VARCHAR(128)
   )
 3 CREATE INDEX t1_idx_name ON t1(name)
 4 INSERT INTO t1
          VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
                 ( 2, 'mkkim' , 'Seoul, Korea'  ),
                 ( 3, 'xcom73', 'Inchon, Korea' )
 5 COMMIT
 6 select * from t1
gSQL> \1
Table dropped.
```

\prepare sql

Syntax

```
\prepare sql <sql_statement>
```

Description

It prepares the SQL statement described in <sql_statement>. The prepared SQL statement can be execute d repeatedly with **\exec**.

\prepare sql operates similarly to the **SQLPrepare** functions of ODBC and Connection::**prepareStatement** function of JDBC.

Example

The following is an example of preparing the SELECT statement and repeatedly executing it.

- Preparing the SELECT statement

```
gSQL> \prepare sql SELECT * FROM t1 WHERE id > 2;
SQL prepared.
```

- Executing the prepared SQL statement

```
gSQL> \exec
ID NAME   ADDR
-- ------ -------------
 3 xcom73 Inchon, Korea
1 row selected.
gSQL> INSERT INTO t1 VALUES ( 4, 'GOLDILOCKS', 'Better Place' );
1 row created.
```

- Executing the prepared SQL statement again

```
gSQL> \exec
ID NAME   ADDR
-- ------ -------------
 3 xcom73 Inchon, Korea
 4 goldilocks  Better Place
2 rows selected.
```

\print

Syntax

```
\print
\print variable
```

Description

It queries the value of host variable declared with **\var** as follows. If the value of host variable is not set, it is NULL.

```
gSQL> \var v1 INTEGER
gSQL> \print v1
  V1
----
null
```

If the name of host variable is not specified as follows, it queries all declared host variables. VAR_ELAPSED_TIME_ is a built-in host variable which manages the execution time of SQL statement as follows.

```
gSQL> \print
NAME                VALUE
------------------- -----
VAR_ELAPSED_TIME__  null
V1                    21
V2                    10
```

Example

The following is an example of declaring the host variable, assigning the value to the host variable then querying it.

- Declaring the host variable

```
gSQL> \var v1 INTEGER
gSQL> \var v2 INTEGER
gSQL> \var v3 INTEGER
```

- Querying all host variables

```
gSQL> \print
NAME                VALUE
------------------- -----
VAR_ELAPSED_TIME__  null
V1                  null
V2                  null
V3                  null
```

- Assigning the value to the host variable

```
gSQL> \exec :v1 := 10
gSQL> \exec :v2 := 20
gSQL> \exec :v3 := :v1 + :v2
```

- Querying the host variable v3

```
gSQL> \print v3
V3
--
30
```

- Querying all host variables

```
gSQL> \print
NAME                VALUE
------------------- -----
VAR_ELAPSED_TIME__  null
V1                    10
V2                    20
V3                    30
```

\quit

Syntax

```
\quit
\q
```

Description

It quits gsql.
When quitting gsql, all uncommitted transactions are committed.

Example

```
gSQL> \quit
%
```

\set autocommit

Syntax

```
\set autocommit on
\set autocommit off
```

Description

It sets whether to automatically commit after executing the SQL statement.

- `\set autocommit on`
  - It automatically commits after executing the SQL statement.
- `\set autocommit off`
  - It does not automatically commit after executing the SQL statement.
- The default value of autocommit is OFF.

Examples

The following is a usage example when setting the AUTOCOMMIT value to ON.

- Setting the autocommit to on

```
gSQL> \set autocommit on
```

- The INSERT statement is automatically committed.

```
gSQL> INSERT INTO t1 ( id, name, addr ) VALUES ( 1, 'leekmo', 'Seoul, Korea' );
1 row created.
```

- It is not affected by rollback.

```
gSQL> ROLLBACK;
Rollback complete.
gSQL> SELECT * FROM t1;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
```

The following is a usage example when setting the AUTOCOMMIT value to OFF.

- Setting the autocommit to off

```
gSQL> \set autocommit off
```

- The transaction in not committed after executing the INSERT statement.

```
gSQL> INSERT INTO t1 ( id, name, addr ) VALUES ( 1, 'leekmo', 'Seoul, Korea' );
1 row created.
```

- The transaction is rolled back.

```
gSQL> ROLLBACK;
Rollback complete.
```

- The INSERT statement is rolled back without any result.

```
gSQL> SELECT * FROM t1;
no rows selected.
```

\set autotrace

Syntax

```
\set autotrace on
\set autotrace traceonly
\set autotrace off
```

Description

It sets whether to output the execution plan.

- `\set autotrace on`
  - It executes SQL statement, and outputs the execution plan together with the query result.
- `\set autotrace traceonly`
  - It does not execute SQL statement, and outputs the execution plan without the query result.
- `\set autotrace off`
  - It does not output the execution plan.
  - The default value is off.

For more information, refer to **SQL execution plan**.

Example

When using ON as follows, it executes SQL statement and outputs the execution plan together with the query result.

```
gSQL> \set autotrace on
gSQL> SELECT * FROM t1 WHERE id = 1;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
```

```
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                |       ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                |            |
|    1  |    TABLE ACCESS ("T1")                           |          1 |
================================================================================
     1  -  READ COLUMNS : ID, NAME, ADDR
              PHYSICAL FILTER : ID = 1
<<<  end print plan
```

When using TRACEONLY as follows, it does not execute SQL statement, and outputs the execution plan without the query result.

```
gSQL> \set autotrace traceonly
gSQL> SELECT * FROM t1 WHERE id = 1;
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                |       ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                |            |
|    1  |    TABLE ACCESS ("T1")                           |          0 |
================================================================================
     1  -  READ COLUMNS : ID, NAME, ADDR
              PHYSICAL FILTER : ID = 1
<<<  end print plan
```

\set color

Syntax

```
\set color on
\set color off
```

Description

It sets whether to output each row of the query results in a different color on the terminal to distinguish t hem.

- `\set color on`
  - Each row is output in a different color.
- `\set color off`
  - Each row is output in the same color.
- The default value is OFF.

If the length of each row is too long so that it overflows the terminal window, then the row is output ove r multiple lines. In this case, each row is hard to be distinguished, so it reduces the readability It is used to distinguish between the rows and increase the readability on the terminal.

Example

The following is an example of setting the color to ON.

```
gSQL> \set color on
gSQL> SELECT id, addr FROM t1;
ID ADDR
-- -------------
 1 Seoul, Korea
 2 Seoul, Korea
 3 Inchon, Korea
3 rows selected.
```

\set colsize

Syntax

```
\set colsize number
```

Description

It sets the maximum length of the data when outputting LONG VARCHAR, LONG VARBINARY data.

- The colsize value is a positive integer between 1 and 104,857,600.(100M, the maximum length of L ONG VARCHAR)

- The default value of colsize is 8,192.

The string length of the LONG VARCHAR column is too long, so the readability of the query execution is l ow as follows. In this case, the readability of LONG VARCHAR column can be increased by reducing the c olsize, or it may be output as long as the desired length by enlarging the colsize.

```
gSQL> SELECT view_name, text FROM all_views WHERE view_name LIKE 'ALL_%' FETCH 3;
VIEW_NAME
----------------
TEXT
--------------------------------------------------------------------------------
ALL_ALL_TABLES
SELECT
       auth.AUTHORIZATION_NAME                ❶ OWNER
     , sch.SCHEMA_NAME                        ❷ TABLE_SCHEMA

... Ellipsis ...
                                                    WHERE      , pvcol.GRANTOR_ID
     , pvcol.GRANTEE_ID
     , pvcol.PRIVILEGE_TYPE_ID

3 rows selected.
```

Example

The following is an example of increasing the readability of the LONG VARCHAR column by reducing the colsize.

```
gSQL> \set colsize 200
gSQL> SELECT view_name, text FROM all_views WHERE view_name LIKE 'ALL_%' FETCH 3;
VIEW_NAME        TEXT
---------------- ------------------------------------------------------------
ALL_ALL_TABLES   SELECT
                         auth.AUTHORIZATION_NAME                ❶ OWNER
                       , sch.SCHEMA_NAME                        ❷ TABLE_SCHEMA
                       , tab.TABLE_NAME                         ❸ TABLE_NAME
                       , spc.TAB
ALL_COL_COMMENTS SELECT
                         auth.AUTHORIZATION_NAME
                       , sch.SCHEMA_NAME
                       , tab.TABLE_NAME
```

```
                      , col.COLUMN_NAME
                      , col.COMMENTS
                   FROM
                        DICTIONARY_SCHEMA.WHOLE_COLUMNS AS col
                      , DICTIONARY_S
ALL_COL_PRIVS    SELECT
                        grantor.AUTHORIZATION_NAME
                      , grantee.AUTHORIZATION_NAME
                      , owner.AUTHORIZATION_NAME
                      , sch.SCHEMA_NAME
                      , tab.TABLE_NAME
                      , col.COLUMN_NAME
                      , pvcol.PRIVILEGE_TY
3 rows selected.
```

\set ddlsize

Syntax

```
\set ddlsize number
```

Description

It sets the buffer size to output the statement when outputting the DDL statements by using the followin g commands.

- \ddl_db
- \ddl_tablespace
- \ddl_auth
- \ddl_schema
- \ddl_table
- \ddl_constraint
- \ddl_index
- \ddl_view
- \ddl_sequence
- \ddl_synonym
- \ddl_public_synonym
- \ddl_procedure
- \ddl_package

- The value of ddlsize is a positive integer between 1 and 1,0485,760 (10M).
- The default value of ddlsize is 10,000.

If an error occurs due to the lack of buffer space as follows, DDL statement may be output by increasing t he value of ddlsize.

```
gSQL> \set ddlsize 1000
gSQL> \ddl_view dictionary_schema.all_tables
ERR-HY000(40052): not enough DDLSIZE.
use command: \set ddlsize {n}
gSQL> \set ddlsize 100000
gSQL> \ddl_view dictionary_schema.all_tables
SET SESSION AUTHORIZATION "SYS";
CREATE OR REPLACE FORCE VIEW "DICTIONARY_SCHEMA"."ALL_TABLES"
... Ellipsis ...
```

Example

The following is an example of changing the ddlsize.

```
gSQL> \set ddlsize 100000
gSQL>
```

\set error

Syntax

```
\set error on
\set error off
```

Description

It sets whether to output the error message.

- `\set error on`
  - It outputs the error message.
- `\set error off`
  - It does not output the error message.
- The default value of error is ON.

If an error occurs during executing the SQL statement, gsql outputs the following information.

- SQLSTATE: SQL standard state code
- Error code: GOLDILOCKS error code
- Error message

The following example describes that the error of the SQL statement occurs, the SQLSTATE value in ERR-42000(16040) is 42000, and the error code is 16040 within ().

```
gSQL> SELECT * FROM invalid_table;
ERR-42000(16040): table or view does not exist :
SELECT * FROM invalid_table
              *
ERROR at line 1:
```

Example

The following is an example of disabling the error message.

- Disabling the error message

```
gSQL> \set error off
```

- Outputting only the value of SQLSTATE and the error code

```
gSQL> SELECT * FROM invalid_table;
ERR-42000(16040)
```

\set heading

Syntax

```
\set heading {ON|OFF}
```

Description

It sets whether to output the header in the query result.

Example

- Set not to output the header message.

```
gSQL> \set heading off
```

- The following is an example of a query result in which the header message is not output.

```
gSQL> select * from dual;
X
1 row selected.
```

\set history

Syntax

```
\set history number
```

Description

It sets the number of SQL statements to manage the history information.

- The history value is a positive integer between 1 and 100,000.
- If the history value is set to a negative value, all SQL history are removed.
- The default value of history is 128.

If the history value is reduced, the old SQL statement is removed.
The history information is used when executing the previously executed SQL statement again through **** and **\{n}**.

Example

The following is an example of setting the number of history to 100.

```
gSQL> \set history 100
gSQL>
```

The following is an example of setting the number of history to smaller than the number of stored SQL st
atements.

- Five SQL statements are stored.

```
gSQL> \history
ID SQL
-- ---------------------------------------------
 1 DROP TABLE IF EXISTS t1
 2 CREATE TABLE t1
   (
       id   INTEGER PRIMARY KEY,
       name VARCHAR(128),
       addr VARCHAR(128)
   )
 3 CREATE INDEX t1_idx_name ON t1(name)
 4 INSERT INTO t1
         VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
                ( 2, 'mkkim' , 'Seoul, Korea'  ),
                ( 3, 'xcom73', 'Inchon, Korea' )
 5 COMMIT
```

- The history value is reduced to 3.

```
gSQL> \set history 3
```

- Three SQL statements are stored.

```
gSQL> \history
ID SQL
-- ---------------------------------------------
 3 CREATE INDEX t1_idx_name ON t1(name)
 4 INSERT INTO t1
         VALUES ( 1, 'leekmo', 'Seoul, Korea'  ),
                ( 2, 'mkkim' , 'Seoul, Korea'  ),
                ( 3, 'xcom73', 'Inchon, Korea' )
 5 COMMIT
```

The following is an example of removing all SQL statements stored in the history.

```
gSQL> \history
ID SQL
-- -------------------------
 1 SELECT * FROM dual
 2 SELECT * FROM user_tables
```

- All SQL history are removed by using a negative value.

```
gSQL> \set history -1
gSQL> \history
gSQL>
```

\set linesize

Syntax

```
\set linesize number
```

Description

It sets the maximum size of a single line when outputting the query result.

- The value of linesize is a positive integer between 1 and 10,000.
- The default value of linesize is 80.

Each row of the query result is output on a single line basis. If there are many columns in a row or the ro w length is bigger than linesize, a row is output to the multiple lines so the readability is decreased.

```
gSQL> SELECT * FROM dict_columns WHERE table_name = 'USER_TABLES' FETCH 3;
TABLE_SCHEMA      TABLE_NAME  COLUMN_NAME
----------------- ----------- ---------------
COMMENTS
----------------------------------------
DICTIONARY_SCHEMA USER_TABLES TABLE_SCHEMA
Schema of the table
DICTIONARY_SCHEMA USER_TABLES TABLE_NAME
Name of the table
DICTIONARY_SCHEMA USER_TABLES TABLESPACE_NAME
Name of the tablespace containing the table
3 rows selected.
```

In this case, a row may be controlled to be output in a single line by changing the linesize value.

Example

The following is an example of increasing the readability by setting the linesize larger.

```
gSQL> \set linesize 400
gSQL> SELECT * FROM dict_columns WHERE table_name = 'USER_TABLES' FETCH 3;
TABLE_SCHEMA      TABLE_NAME  COLUMN_NAME     COMMENTS
----------------- ----------- --------------- ----------------------------------------
DICTIONARY_SCHEMA USER_TABLES TABLE_SCHEMA    Schema of the table
DICTIONARY_SCHEMA USER_TABLES TABLE_NAME      Name of the table
DICTIONARY_SCHEMA USER_TABLES TABLESPACE_NAME Name of the tablespace containing the table
3 rows selected.
```

\set numsize

Syntax

```
\set numsize number
```

Description

It sets the maximum number of digit for the output of a numeric value.

- The numsize value is a positive integer between 1 and 50.
- The default value of numsize is 20.

If the number of digit of a numeric value exceeds the numsize range as follows, it is output in an expone ntial form.

```
gSQL> SELECT num, ( num * num ) AS result FROM t1;
          NUM               RESULT
------------- --------------------
1234567890123 1.52415787532276E+24
1 row selected.
```

By changing the value of numsize, these numeric value is output in a numeric form, not in an exponent f orm.

Example

The following is an example of outputting all digits of the numeric value by setting the numsize larger.

```
gSQL> \set numsize 50
gSQL> SELECT num, ( num * num ) AS result FROM t1;
          NUM                   RESULT
------------ ------------------------
1234567890123 15241578753227558009551 29
1 row selected.
```

\set pagesize

Syntax

```
\set pagesize number
```

Description

It sets the number of the rows which is to be consisted in a single page.

- The value of pagesize is a positive integer between 1 and 10,000.
- The default value of pagesize is 20.

It is set when there are many rows of the query results or when a page should consist of a certain number of row.

Example

The following is an example of consisting a page in 10 rows unit.

```
gSQL> \set linesize 120
gSQL> \set pagesize 10
gSQL> SELECT column_name, comments FROM dict_columns  WHERE table_name = 'SEQUENCES';
COLUMN_NAME       COMMENTS
----------------- ------------------------------------------------------------------------
OWNER_ID          authorization identifier who owns the table of the sequence generator
SCHEMA_ID         schema identifier of the sequence generator
SEQUENCE_ID       sequence generator identifier
SEQUENCE_TABLE_ID table id of sequence for naming resolution
```

```
TABLESPACE_ID     tablespace identifier of the sequence generator
PHYSICAL_ID       physical identifier of the sequence generator
SEQUENCE_NAME     sequence generator name
DTD_IDENTIFIER    unsupported feature
START_VALUE       the start value of the sequence generator
MINIMUM_VALUE     the minimum value of the sequence generator
COLUMN_NAME      COMMENTS
---------------- ----------------------------------------------------------------
MAXIMUM_VALUE    the maximum value of the sequence generator
INCREMENT        the increment of the sequence generator
CYCLE_OPTION     The values of CYCLE_OPTION have the following meanings:
                 - TRUE : The cycle option of the sequence generator is CYCLE.
                 - FALSE : The cycle option of the sequence generator is NO CYCLE.

CACHE_SIZE       number of sequence numbers to cache
CREATED_TIME     created time of the sequence generator
MODIFIED_TIME    last modified time of the sequence generator
COMMENTS         comments of the sequence generator
SEQUENCE_CATALOG catalog name of the sequence
SEQUENCE_OWNER   owner name of the sequence
SEQUENCE_SCHEMA  schema name of the sequence
COLUMN_NAME             COMMENTS
----------------------- ------------------------------------------------------------
SEQUENCE_NAME           sequence name
DATA_TYPE               the standard name of the data type
NUMERIC_PRECISION       the numeric precision of the numerical data type
NUMERIC_PRECISION_RADIX the radix ( 2 or 10 ) of the precision of the numerical data type
NUMERIC_SCALE           the numeric scale of the exact numerical data type
START_VALUE             the start value of the sequence generator
MINIMUM_VALUE           the minimum value of the sequence generator
MAXIMUM_VALUE           the maximum value of the sequence generator
INCREMENT               the increment of the sequence generator
CYCLE_OPTION            cycle option
COLUMN_NAME               COMMENTS
------------------------- -------------------------------------------
CACHE_SIZE                number of sequence numbers to cache
DECLARED_DATA_TYPE        the data type name that a user declared
DECLARED_NUMERIC_PRECISION the precision value that a user declared
DECLARED_NUMERIC_SCALE    the scale value that a user declared
CREATED_TIME              created time of the sequence generator
MODIFIED_TIME             last modified time of the sequence generator
```

```
COMMENTS                  comments of the sequence generator
37 rows selected.
```

\set serveroutput

Syntax

```
\set serveroutput on
\set serveroutput off
```

Description

It controls automatic output feature for the message writeten by functions of which DBMS_OUTPUT pack age provides in gsql or gsqlnet

- `\set serveroutput on`
  - It automatically outputs messages accumulated in the server by DBMS_OUTPUT.PUT_LINE after e xecuting SQL.
- `\set serveroutput off`
  - It does not use DBMS_OUTPUT package.
- The default value of serveroutput is OFF.

Basically, the maximum size of accumulated in the server is 20000 bytes.

Example

The following is an example of outputting the messages accumulated in a user defined function which w as used in SQL statement.

```
gSQL> create or replace function my_msg( msg varchar(100) )
return integer
is
begin
  dbms_output.put_line( 'my message is : ' || msg );
  return length( msg );
end;
/
2 3 4 5 6 7 8
Function created.
gSQL> commit;
```

```
Commit complete.
gSQL> \set serveroutput on
gSQL> select my_msg( 'Hello World!' ) from dual;
MY_MSG( 'Hello World!' )
------------------------
                      12
my message is : Hello World!
1 row selected.
```

\set sqlprompt

Syntax

```
\set sqlprompt "prompt_sql"
```

Description

It sets SQL for prompt of gsql or gsqlnet.

- Maximum 127 characters are allowed in SQL statement.
- Maximum 31 characters are allowed in the prompt returning to SQL statement.

Even when SQL is set, the prompt is not changed until connecting to the database.

If SQL statement is incorrect or the returning data is longer than 31 characters, then the user SQL statem ent is output following [SQLPROMPT ERROR] statement.

Example

The following is an example of outputting the user name and the cluster member name in the prompt.

```
gSQL> \set sqlprompt "current_user || '@' || cluster_member_name || '>'"
TEST@G1N1>
```

\set time

Syntax

```
\set time on
\set time off
```

Description

It sets whether to output the current time.

- `\set time on`
  - It outputs the current time.
- `\set time off`
  - It does not output the current time.
- The default value of time is OFF.

Example

The following is an example of outputting the current time.

```
gSQL> \set time on
12:45:34 gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
Elapsed time: 0.07600 ms
```

\set timing

Syntax

```
\set timing on
\set timing off
```

Description

It sets whether to output the execution time of SQL statement.

- `\set timing on`

    - The execution time is output.
- `\set timing off`
    - The execution time is not output.
- The default value of timing is OFF.

The unit of execution time is ms (millisecond).

Example

The following is an example of outputting the execution time of SQL statement.

```
gSQL> \set timing on
gSQL> SELECT * FROM dual;
DUMMY
-----
X
1 row selected.
Elapsed time: 0.07600 ms
```

\set vertical

Syntax

```
\set vertical on
\set vertical off
```

Description

It sets whether to output the value of column in line unit.

- `\set vertical on`
    - A column is output in a line unit.
- `\set vertical off`
    - A row is output in a line unit.
- The default value of vertical is OFF.

If each row has an individual information, the readability can be increased by outputting the query result i n a column unit.

If `\set vertical on` is set, then each row is separated by a blank line, and one line represents a single valu

e, then it is consisted in the following form.

```
column name # data value
```

Example

The following is an example of outputting a query result in a column unit.

```
gSQL> \set vertical on
gSQL> SELECT * FROM v$system_stat FETCH 10;
                STAT_NAME # SYSTEM_SAR
               STAT_VALUE # 3
                 COMMENTS # system available resource( 0:none, 1:session 2:database )
                STAT_NAME # MAX_ENVIRONMENT_COUNT
               STAT_VALUE # 128
                 COMMENTS # maximum environment count
                STAT_NAME # FREE_ENVIRONMENT_ID
               STAT_VALUE # 81
                 COMMENTS # available environment identifier
                STAT_NAME # MAX_SESSION_COUNT
               STAT_VALUE # 128
                 COMMENTS # maximum session count
                STAT_NAME # FREE_SESSION_ID
               STAT_VALUE # 82
                 COMMENTS # available session identifier
                STAT_NAME # MAX_PROCESS_COUNT
               STAT_VALUE # 128
                 COMMENTS # maximum process count
                STAT_NAME # FREE_PROCESS_ID
               STAT_VALUE # 1
                 COMMENTS # available process identifier
                STAT_NAME # CACHE_ALIGNED_SIZE
               STAT_VALUE # 64
                 COMMENTS # cache aligned size
                STAT_NAME # CPU_COUNT
               STAT_VALUE # 8
                 COMMENTS # count of CPUs
                STAT_NAME # SYSTEM_TIME
               STAT_VALUE # 1408676900172925
                 COMMENTS # system time
10 rows selected.
```

\shutdown

Syntax

```
\shutdown
\shutdown abort
\shutdown immediate
\shutdown transactional
\shutdown normal
```

Description

It shuts down the GOLDILOCKS server.
It should be connected as SYSDBA or ADMIN role to perform \shutdown. For more information about con necting as SYSDBA, refer to **Startup and Shutdown Server**.

- \shutdown normal
  - It blocks the connection from the new session and waits for all currently connected sessions to be terminated, then performs the checkpoint and shuts down the server.
- \shutdown transactional
  - It blocks the start of a new transaction and waits for all currently running transactions to be termi nated, then performs the checkpoint and shuts down the server.
- \shutdown immediate
  - It blocks the execution of a new unit operation(ex FETCH or EXECUTE, etc.), waits for all currentl y running unit operations to be terminated, then rolls back all transactions and performs the chec kpoint and shuts down the server.
- \shutdown abort
  - The server is forcibly shut down immediately regardless of the status of the currently connected s ession.
- \shutdown
  - It is as same as \shutdown normal.

In GOLDILOCKS cluster system, if the current phase is GLOBAL OPEN when using \shutdown to shut dow n a single node, then abort is the only option, but if the current phase is LOCAL OPEN or below, then all options are available.
If using an option other than abort on GLOBAL OPEN phase, then the following error occurs.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \shutdown immediate
ERR-42000(16430): in the GLOBAL OPEN phase, the cluster database can be closed only with ABORT
```

```
option :
ALTER SYSTEM CLOSE DATABASE IMMEDIATE
                             *
ERROR at line 1:
gSQL>
```

Example

The following is an example of shutdowning GOLDILOCKS.

```
% gsql --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \shutdown
Shutdown success
gSQL>
```

\spool

Description

It sets all results output by using gsql to be stored in the terminal and file.

\spool 'filename'

Syntax

```
\spool 'filename' [CREATE ¦ REPLACE ¦ APPEND]
\spo   'filename' [CREATE ¦ REPLACE ¦ APPEND]
```

Description

It starts the spool function. All output results performed by gsql are stored in the given filename since exe cuting this statement.

The following options describe how to open the file.

- CREATE: It creates the file. If a file already exists, an error occurs.
- REPLACE: It removes the contents of an existing file, and newly starts storing. If a file does not exist, i t performs as same as CREATE.
- APPEND: It continues to store the contents from the end of an existing file. If a file does not exist, it p

erforms as same as CREATE.

If these options are not given, it is operated in REPLACE mode by default.

When starting a new spool during spooling, the existing spool stops and a new spool starts.

Example

The following is an example of starting spooling.

- Creating the result.txt file and storing the gsql execution result

```
gSQL> \SPOOL 'result.txt' CREATE
gSQL> SELECT * FROM T1 WHERE C1 < 10;
gSQL> \SPOOL OFF
```

- Continuing to store the result at the end of the existing result.txt file

```
gSQL> \SPOOL 'result.txt' APPEND
gSQL> SELECT * FROM T1 WHERE C1 >= 10;
gSQL> \SPOOL OFF
```

- Removing the contents of the existing result.txt file and storing a new result

```
gSQL> \SPOOL 'result.txt' REPLACE
gSQL> SELECT * FROM T1;
gSQL> \SPOOL OFF
```

\spool OFF

Syntax

```
\spool OFF
\spo   OFF
```

Description

It ends the current spool. If the spool is not in use, it does not perform any transaction.

Example

The following is an example of starting the spool then ending it.

```
gSQL> \SPOOL 'result.txt'
gSQL> SELECT * FROM T1;
```

- Ending spooling

```
gSQL> \SPOOL OFF
```

\spool

Syntax

```
\spool
\spo
```

Description

It represents the current spool state. If the spool is in use, it informs which file is spooling. Otherwise, it in forms that the spool is not in use.

Example

The following is an example of editing the SQL statement stored in the gsql history.

```
gSQL> \SPOOL 'a.txt'
```

- It informs that it is spooling in a.txt.

```
gSQL> \SPOOL

currently spooling to a.txt

gSQL> \SPOOL OFF
```

- It informs that it is not spooling.

```
gSQL> \SPOOL

not spooling currently
```

\startup

Syntax

```
\startup
\startup nomount
\startup mount
\startup open
```

Description

It starts up the GOLDILOCKS server.
It should be connected as SYSDBA or ADMIN role to perform \startup.
For more information about connecting as SYSDBA, refer to **Startup and Shutdown Server**.

- \startup nomount
  - It starts up the server on the NOMOUNT phase.
- \startup mount
  - It starts up the server on the MOUNT phase.
- \startup open
  - It starts up the server on the OPEN phase.
- \startup
  - It is as same as \startup open.

The server start up is divided into NOMOUNT, MOUNT, OPEN phase. For more information, refer to **Multi-level Startup**.
Execute **ALTER SYSTEM {MOUNT | OPEN} DATABASE** statement to move on to the next phase after exec uting \startup.

Example

The following is an example of starting up GOLDILOCKS.

```
% gsql --as SYSDBA
Connected to an idle instance.
gSQL> \startup
Startup success
```

\var

Syntax

```
\var variable_name data_type
```

Description

It declares the host variable.
When declaring the host variable which is as same as variable_name, the existing host variable is remove d and a new one is declared. The maximum length of variable_name is 128 bytes.
The data_type of host variable is as same as the data type of GOLDILOCKS.
For more information, refer to **Data Type**.
The host variable assigns the value by using **\exec :var := value** , and its value is queried by using **\prin t**.

```
gSQL> \var v1 INTEGER
gSQL> \exec :v1 := 1
gSQL> \print v1
V1
--
 1
```

The host variable can be used as an input or output parameter in the SQL statement. When the host varia ble is used in the SQL statement or **\exec :var := value**, a colon (:) sign should be put in front of the hos t variable to indicate that it is a host variable.

Example

The following is an example of declaring the host variable and using it as an input argument of the SQL st atement.

```
gSQL> \var v1 INTEGER
gSQL> \exec :v1 := 1
gSQL> SELECT * FROM t1 WHERE id = :v1;
ID NAME   ADDR
-- ------ ------------
 1 leekmo Seoul, Korea
1 row selected.
```

The following is an example of using the host variable as an output argument of the SQL statement.

```
gSQL> \var v_name VARCHAR(128)
gSQL> SELECT name INTO :v_name FROM t1 WHERE id = 1;
V_NAME
------
leekmo
1 row selected.
```

The following is an example of declaring the host variable and using it as the input and output arguments of the SQL statement.

In the following **UPDATE name RETURNING .. INTO** statement, the host variable of SET clause and WHERE clause, :v_id, is used as an input argument and :v_id of INTO clause is used as an output argument.

```
gSQL> \var v_name VARCHAR(128)
gSQL> \var v_id INTEGER
gSQL> \exec :v_id := 1
gSQL> UPDATE t1 SET id = 100 + :v_id WHERE id = :v_id RETURNING id INTO :v_id;
V_ID
----
 101
1 row updated.
gSQL> \print v_id
V_ID
----
 101
```

41.

gloader/gloadernet(Upload/download Tool)

41.1 Overview of gloader and gloadernet

gloader is a utility which downloads or uploads data of GOLDILOCKS in table unit.

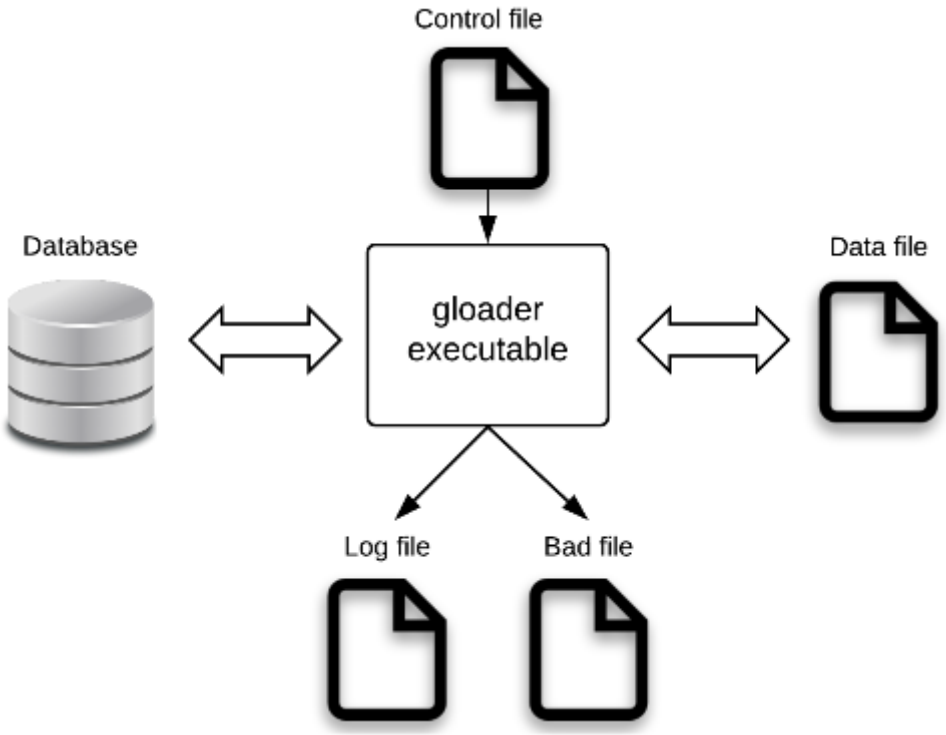
Table 41-1 Execution files

Name	Description
gloader	It is used in Direct Attach (D/A) environment.
gloadernet	It is used in Client/ Server (C/S) environment.

Environment

gloader should be connected to the database and it requires attention to all required files while using glo ader.

Figure 1 gloader environment



The control file and datafile are required to upload the data, then the log file is generated as a result.
The control file is required to download the data, then the datafile, log file, and bad file are generated as the results.

Control File

The control file is a file for operating gloader and it includes the following information. (Refer to **Control File Syntax**.)

- Table name
- Schema name
- The delimiter between columns in a row
- The qualifier notifying the start and end of the data
- The delimiter between rows
- Character set
- Whether to trim the whitespace character
- Where clause

DataFile

The datafile should be prepared when gloader uploads the data, and it is created when gloader downloads the data.
The datafile supports text format and binary format.

- The datafile in text format has an advantage of which the file contents can be checked and directly updated.
- The datafile in binary format can be performed faster comparing to the datafile in text format.

gloader uses direct I/O for the data file by default. gloader arbitrarily adjusts the file size if the file size is not an array appropriate for direct I/O when uploading the data file by using direct I/O.

Log File

Log file is a file which stores the following errors and results which occur while operating gloader.

- The row number and cause of the error
- The operating results of gloader

Bad File

Bad file is a file which stores the rows in which an error occurred while gloader uploads the data. The delimiter between columns and rows, and the qualifier which are used to store the bad file should be user-defined.

Example

The following is an example of downloading and uploading data by using gloader.

A table is created by using the SQL statement as follows.

```
$ cat test.sql
CREATE TABLE TEST
(
TEST_NAME VARCHAR(60),
TEST_NUM  INTEGER,
TEST_TIME TIMESTAMP(0) WITH TIME ZONE
);
INSERT INTO TEST VALUES
( 'NAME', 1, '1999-01-08 04:05:06.789 -8:00' );
INSERT INTO TEST VALUES
( 'NAME', 2, '1999-01-08 04:05:06.789 -8:00' );
INSERT INTO TEST VALUES
( 'NAME', 3, '1999-01-08 04:05:06.789 -8:00' );
COMMIT;
```

The control file is used as follows.

```
$ cat test.ctl
TABLE TEST
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
```

- Export: It downloads the data.

```
$ gloader test test --export --control test.ctl --data test.dat --no-prompt
 COMPLETED IN EXPORTING TABLE: PUBLIC.TEST, 3 RECORDS
$ cat test.dat
"NAME","1","1999-01-08 04:05:07. -08:00"
"NAME","2","1999-01-08 04:05:07. -08:00"
"NAME","3","1999-01-08 04:05:07. -08:00"
$ cat test.log
cat test.log
COMPLETED IN EXPORTING TABLE: PUBLIC.TEST, 3 RECORDS [ Start Time: 2010-1-1 01:01:01 End Time:
2010-1-1 01:01:01 Taken Time: 56496 micro-sec ]
```

- Import: It uploads the data.

```
$ cat import.dat
"NAME","1","1999-01-08 04:05:07. -08:00"
"NAME","2","1999-01-08 04:05:07. -08:00"
"NAME","3","1999-01-08 04:05:07. -08:00"
"FAIL","FAIL","FAIL"
$ gloader test test --import --control test.ctl --data import.dat --no-prompt
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 4 RECORDS, SUCCEEDED 3 RECORDS
$ gsql test test
gSQL> select * from test;
TEST_NAME TEST_NUM TEST_TIME
--------- -------- -------------------------------
NAME             1 1999-01-08 04:05:07.000000 -08:00
NAME             2 1999-01-08 04:05:07.000000 -08:00
NAME             3 1999-01-08 04:05:07.000000 -08:00
NAME             1 1999-01-08 04:05:07.000000 -08:00
NAME             2 1999-01-08 04:05:07.000000 -08:00
NAME             3 1999-01-08 04:05:07.000000 -08:00
6 rows selected.
$ cat import.log
Err Rec(4) Col(2): 22018(12006): data value is not a numeric literal
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 4 RECORDS, SUCCEEDED 3 RECORDS [ Start Time:
2010-1-1 01:01:01 End Time: 2010-1-1 01:01:01 Taken Time: 56496 micro-sec ]
$ cat import.bad
"FAIL","FAIL","FAIL"
```

41.2 Using gloader

Datafile Type

Text Datafile

It is represented with a string which can be checked and edited by the user. A user can directly create, edi t the file, or can download the data from the existing tables in the database. A user also can use the data in a text format downloaded from another DBMS products.
The description for the representation of the text type datafile is recorded in the control file.

Binary Datafile

The file consists of binary data. A user can not directly create or edit the binary datafile. The file is generat ed when downloading the data from the existing tables in the database.

The binary type file is uploaded faster than the text type because the data is written to the file appropriat e to the data structure type defined in GOLDILOCKS.

When GOLDILOCKS databases' versions are different one another, then it is not recommended to upload/ download by using a binary datafile. Also, it may be required to chang a column size when uploading/ downloading data between databases whose string sets are different.

Downloading Data

Downloading in Text File

Simple Download

The following is the structure and data of the table to be downloaded.

```
$ cat test.sql
CREATE TABLE TEST ( I1 INTEGER PRIMARY KEY, I2 VARCHAR(10), I3 VARBINARY(10) );
INSERT INTO TEST VALUES( 1, 'LKH', X'10' );
INSERT INTO TEST VALUES( 2, 'KMM', X'A0' );
INSERT INTO TEST VALUES( 3, 'ksj', X'CD' );
COMMIT;
```

```
$ gsql test test
gSQL> SELECT * FROM TEST;
I1 I2  I3
-- --- --
 1 LKH 10
 2 KMM A0
 3 ksj CD
3 rows selected.
```

The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
```

The data in the table T1 is downloaded through gloader as follows.

```
$ gloader test test --export --control test.ctl --data test.dat
 COMPLETED IN EXPORTING TABLE: PUBLIC.test, 3 RECORDS
```

The data in the table TEST is downloaded to the datafile as follows.

```
$ ls
test.ctl test.dat test.log
$ cat test.dat
1,LKH,10
2,KMM,A0
3,ksj,CD
```

Whitespace Character

The following is the structure and data of the table to be downloaded.

```
$ cat test.sql
CREATE TABLE TEST ( I1 INTEGER PRIMARY KEY, I2 VARCHAR(10), I3 VARBINARY(10) );
INSERT INTO TEST VALUES( 1, ' L K H ', X'10' );
INSERT INTO TEST VALUES( 2, 'KIM
MM', X'A0' );
INSERT INTO TEST VALUES( 3, ' KIM S
J ', X'CD' );
COMMIT;
$ gsql test test
```

```
gSQL> SELECT * FROM TEST;
I1 I2      I3
-- ------- --
 1  L K H  10
 2 KIM     A0
   MM
 3  KIM S  CD
   J
3 rows selected.
```

- The control file without using OPTIONALLY ENCLOSED BY statement
    - The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
```

    - The data in the table TEST is downloaded to the datafile as follows.

```
$ ls
test.ctl test.dat test.log
$ cat test.dat
1, L K H ,10
2,KIM
MM,A0
3, KIM S
J ,CD
```

The control file should be used with the OPTIONALLY ENCLOSED BY statement for the data including the white space to maintain the downloaded data and the uploaded data as same.

- The control file using OPTIONALLY ENCLOSED BY statement
    - The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
```

```
LINES TERMINATED BY '\n'
```

- The data in the table TEST is downloaded to the datafile as follows.

```
$ ls
test.ctl test.dat test.log
$ cat test.dat
"1"," L K H ","10"
"2","KIM
MM","A0"
"3"," KIM S
J ","CD"
```

Time Related Data Type

DATE, TIME, TIME WITH TIME ZONE, TIMESTAMP, TIMESTAMP WITH TIME ZONE are output in the property default format when downloaded.

The following is each data type of DATE, TIME WITH TIME ZONE, TIMESTAMP WITH TIME ZONE.

```
$ gsql test test
gSQL> SELECT PROPERTY_VALUE, INIT_VALUE FROM V$PROPERTY WHERE PROPERTY_NAME LIKE
'NLS_DATE_FORMAT';
PROPERTY_VALUE                   INIT_VALUE
-------------------------------- --------------------------------
YYYY-MM-DD                       YYYY-MM-DD
1 row selected.
gSQL> SELECT PROPERTY_VALUE, INIT_VALUE FROM V$PROPERTY WHERE PROPERTY_NAME LIKE
'NLS_TIME_WITH_TIME_ZONE_FORMAT';
PROPERTY_VALUE                   INIT_VALUE
-------------------------------- --------------------------------
HH24:MI:SS.FF6 TZH:TZM           HH24:MI:SS.FF6 TZH:TZM
1 row selected.
gSQL> SELECT PROPERTY_VALUE, INIT_VALUE FROM V$PROPERTY WHERE PROPERTY_NAME LIKE
'NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT';
PROPERTY_VALUE                   INIT_VALUE
-------------------------------- --------------------------------
YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM
1 row selected.
```

The following is the structure and data of the table to be downloaded.

```
$ cat test.sql
CREATE TABLE TEST ( I1 INTEGER, I2 DATE, I3 TIME WITH TIME ZONE, I4 TIMESTAMP WITH TIME ZONE
);
INSERT INTO TEST VALUES ( 1, '1999-12-31', '01:01:01', '1999-12-31 01:01:01.789 -8:00' );
INSERT INTO TEST VALUES ( 2, '2000-01-01', '23:12:12', '2000-01-01 23:12:06.0 +8:00' );
INSERT INTO TEST VALUES ( 3, '2000-12-31', '23:12:12', '2000-12-31 23:12:12.0 -8:00' );
COMMIT;
$ gsql test test
gSQL> SELECT * FROM T1;
I1 I2         I3                     I4
-- ---------- ---------------------- ---------------------------------
 1 1999-12-31 01:01:01.000000 +09:00 1999-12-31 01:01:01.789000 -08:00
 2 2000-01-01 23:12:12.000000 +09:00 2000-01-01 23:12:06.000000 +08:00
 3 2000-12-31 23:12:12.000000 +09:00 2000-12-31 23:12:12.000000 -08:00
3 rows selected.
```

The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
```

The data in the table TEST is downloaded to the datafile as follows.

```
$ gloader test test -e -c test.ctl -d test.dat
 COMPLETED IN EXPORTING TABLE: PUBLIC.TEST, 3 RECORDS
$ ls
test.ctl test.dat test.log
$ cat test.dat
"1","1999-12-31 00:00:00","01:01:01.000000 +09:00","1999-12-31 01:01:01.789000 -08:00"
"2","2000-01-01 00:00:00","23:12:12.000000 +09:00","2000-01-01 23:12:06.000000 +08:00"
"3","2000-12-31 00:00:00","23:12:12.000000 +09:00","2000-12-31 23:12:12.000000 -08:00"
```

Downloading in Binary File

Simple Download

The following is the structure and data of the table to be downloaded.

```
$ cat test.sql
CREATE TABLE TEST ( I1 INTEGER PRIMARY KEY, I2 VARCHAR(10), I3 VARBINARY(10) );
INSERT INTO TEST VALUES( 1, 'LKH', X'10' );
INSERT INTO TEST VALUES( 2, 'KMM', X'A0' );
INSERT INTO TEST VALUES( 3, 'ksj', X'CD' );
COMMIT;
$ gsql test test
gSQL> SELECT * FROM TEST;
I1 I2  I3
-- --- --
 1 LKH 10
 2 KMM A0
 3 ksj CD
3 rows selected.
```

The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
```

The data in the table TEST is downloaded through gloader as follows.

```
$ gloader test test --export --control test.ctl --data test.dat --format binary
 COMPLETED IN EXPORTING TABLE: PUBLIC.test, 3 RECORDS
```

The following file is generated after executing gloader.

```
$ ls
test.ctl test.dat test.log
```

A user can not directly check or edit the binary file.

Complex Download

The following is the structure and data of the table to be downloaded.

```
$ gsql test test
gSQL>\desc TEST
COLUMN_NAME TYPE                        IS_NULLABLE
----------- --------------------------- -----------
```

```
I1          NUMBER(10,0)               TRUE
I2          DATE                       TRUE
I3          TIME(6) WITH TIME ZONE     TRUE
I4          TIMESTAMP(6) WITH TIME ZONE TRUE
gSQL> SELECT COUNT(*) FROM TEST;
COUNT(*)
--------
 1572864
1 row selected.
```

The following is the contents of the control file which is created to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
```

- Downloading in a single file
    - The data in the table TEST is downloaded through gloader as follows.

```
$ gloader test test --export --control test.ctl --data test.dat --format binary
loaded 1000 records into PUBLIC.TEST
loaded 2000 records into PUBLIC.TEST
... Ellipsis ...
loaded 1571000 records into PUBLIC.TEST
loaded 1572000 records into PUBLIC.TEST
 COMPLETED IN EXPORTING TABLE: PUBLIC.TEST, TOTAL 1572864 RECORDS
```

    - The following file is generated after executing gloader.

```
$ ll test.*
-rw-r--r-- 1 test test       71 2014-08-28 12:13 t1.ctl
-rw-r--r-- 1 test test 59930624 2014-08-28 12:49 t1.dat
-rw-r--r-- 1 test test      159 2014-08-28 12:49 t1.log
```

- Downloading in multiple files
    - The data in the table TEST is downloaded through gloader as follows.

```
$ gloader test test --export --control test.ctl --data test.dat --format binary --filesize
31461376
loaded 1000 records into PUBLIC.TEST
loaded 2000 records into PUBLIC.TEST
```

```
... Ellipsis ...
loaded 1571000 records into PUBLIC.TEST
loaded 1572000 records into PUBLIC.TEST
 COMPLETED IN EXPORTING TABLE: PUBLIC.TEST, TOTAL 1572864 RECORDS
```

- The following file is generated after executing gloader.

```
$ ll test.*
-rw-r--r-- 1 test test       71 2014-08-28 12:13 test.ctl
-rw-r--r-- 1 test test 31461376 2014-08-28 13:02 test.dat
-rw-r--r-- 1 test test 28474880 2014-08-28 13:02 test.dat.001
-rw-r--r-- 1 test test      159 2014-08-28 12:49 test.log
```

Uploading Data

Uploading Text File

Simple Upload

The following is the table to be uploaded.

```
gSQL> \DESC TEST
COLUMN_NAME TYPE                        IS_NULLABLE
----------- --------------------------- -----------
I1          NUMBER(10,0)                TRUE
I2          DATE                        TRUE
I3          TIME(6) WITH TIME ZONE      TRUE
I4          TIMESTAMP(6) WITH TIME ZONE TRUE
gSQL> SELECT * FROM TEST;
no rows selected.
```

The following is the datafile to be uploaded.

```
$ cat test.dat
1,1999-12-31 00:00:00,01:01:01.000000 +09:00,1999-12-31 01:01:01.789000 -08:00
2,2000-01-01 00:00:00,23:12:12.000000 +09:00,2000-01-01 23:12:06.000000 +08:00
3,2000-12-31 00:00:00,23:12:12.000000 +09:00,2000-12-31 23:12:12.000000 -08:00
```

The datafile is uploaded with gloader and the result is output as follows.

```
$ gloader test test --import --control test.ctl --data test.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3 RECORDS, SUCCEEDED 3 RECORDS
$ gsql test test
gSQL> select * from test;
I1 I2         I3                     I4
-- ---------- ---------------------- ---------------------------------
 1 1999-12-31 01:01:01.000000 +09:00 1999-12-31 01:01:01.789000 -08:00
 2 2000-01-01 23:12:12.000000 +09:00 2000-01-01 23:12:06.000000 +08:00
 3 2000-12-31 23:12:12.000000 +09:00 2000-12-31 23:12:12.000000 -08:00
3 rows selected.
```

Whitespace Character

The following is the table to be uploaded.

```
gSQL> \DESC TEST
COLUMN_NAME TYPE                 IS_NULLABLE
----------- -------------------- -----------
I1          NUMBER(10,0)         TRUE
I2          CHARACTER VARYING(10) TRUE
I3          BINARY VARYING(10)   TRUE
gSQL> SELECT * FROM TEST;
no rows selected.
```

- The datafile downloaded without using OPTIONALLY ENCLOSED BY statement in the control file
    - The datafile is downloaded without using OPTIONALLY ENCLOSED BY statement in the control fil e as follows. (Refer to **Downloading in Text File**.)

```
$ cat test.dat
1, L K H ,10
2,KIM
MM,A0
3, KIM S
J ,CD
```

    - The datafile is uploaded with gloader and the result is output as follows. Even though New Line ('\n') exists in the data of the second and third records, but a qualifier notifying the start and end of the column data is not set, so it is recognized as a row identifier.

```
$ gloader test test --import --control test.ctl --data test.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 5 RECORDS, SUCCEEDED 3 RECORDS
$ gsql test test
gSQL> select * from test;
I1 I2     I3
-- ------ ----
 1 L K H  10
 2 KIM    null
 3 KIM S  null
3 rows selected.
```

- The datafile downloaded using OPTIONALLY ENCLOSED BY statement in the control file
    - The datafile is downloaded by using the OPTIONALLY ENCLOSED BY statement of the control file

as follows. (Refer to **Downloading in Text File**.) Differently from the result above, New Line ('\n') i s treated as a part of data in the result below.

```
$ cat test.dat
"1"," L K H ","10"
"2","KIM
MM","A0"
"3"," KIM S
J ","CD"
```

- The datafile is uploaded with gloader and the result is output as follows.

```
$ gloader test test --import --control test.ctl --data test.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 5 RECORDS, SUCCEEDED 3 RECORDS
$ gsql test test
gSQL> select * from test;
I1 I2      I3
-- ------- --
 1  L K H  10
 2 KIM     A0
   MM
 3  KIM S  CD
   J
3 rows selected.
```

Uploading Binary File

Simple Upload

The following is the structure of the table to be uploaded.

```
gSQL> \DESC TEST
COLUMN_NAME TYPE                 IS_NULLABLE
----------- -------------------- -----------
I1          NUMBER(10,0)         TRUE
I2          CHARACTER VARYING(10) TRUE
I3          BINARY VARYING(10)    TRUE
gSQL> SELECT * FROM TEST;
no rows selected.
```

The following is the content of the control file written to download the table data.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
```

The following is a file to be uploaded with gloader. *test.dat* was already downloaded when **Downloading in Binary File**.

```
$ ls
test.dat
```

The datafile is uploaded to the table TEST and the result is output as follows.

```
$ gloader test test --import --control test.ctl --data test.dat --format binary
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3 RECORDS, SUCCEEDED 3 RECORDS
$ gsql test test
gSQL> SELECT * FROM TEST;
I1 I2  I3
-- --- --
 1 LKH 10
 2 KMM A0
 3 ksj CD
3 rows selected.
```

Complex Upload

The following is the structure of the table to be uploaded.

```
gSQL> \DESC TEST
COLUMN_NAME TYPE                  IS_NULLABLE
----------- --------------------- -----------
I1          NUMBER(10,0)          TRUE
I2          CHARACTER VARYING(10) TRUE
I3          BINARY VARYING(10)    TRUE
gSQL> SELECT * FROM TEST;
no rows selected.
```

The following is the datafile to be uploaded.

```
$ ll test.*
 -rw-r--r-- 1 test test       71 2014-08-28 12:13 test.ctl
 -rw-r--r-- 1 test test 31461376 2014-08-28 13:02 test.dat
 -rw-r--r-- 1 test test 28474880 2014-08-28 13:02 test.dat.001
```

```
 -rw-r--r-- 1 test test      159 2014-08-28 12:49 test.log
```

When uploading multiple downloaded files with --filesize, gloader should be separately performed for ea ch datafile.

```
$ gloader test test --import --control test.ctl --data test.dat --format binary
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 860728 RECORDS, SUCCEEDED 2285000 RECORDS,
ERRORED 0 RECORDS
$ gloader test test --import --control test.ctl --data test.dat.001 --format binary
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 860728 RECORDS, SUCCEEDED 860728 RECORDS,
ERRORED 0 RECORDS
```

The upload result is as follows.

```
gSQL> select count(*) from test;
COUNT(*)
--------
 3145728
1 row selected.
```

Controlling Upload Unit

The data can be uploaded faster by using the options which is related to performance.
For more information, refer to **--array**, **--commit**, **--atomic**.

The following is the datafile with approximately 380,000 records.

```
$ ll test.dat
-rw-r--r-- 1 test test 75092480 2014-08-28 15:59 test.dat
```

The following is the control file which is used for uploading.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
```

Array Binding and Commit Cycle

The following gloader command uploads records to be bound in 5,000 unit and uploads records to be co mmitted in 20,000 unit.

```
$ gloader test test --import --control test.ctl --data test.dat --array 5000 --commit 20000
loaded 5000 records into PUBLIC.TEST
loaded 10000 records into PUBLIC.TEST
loaded 15000 records into PUBLIC.TEST
... Ellipsis ...
loaded 3810000 records into PUBLIC.TEST
loaded 3815000 records into PUBLIC.TEST
loaded 3818244 records into PUBLIC.TEST
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3818243 RECORDS, SUCCEEDED 3818243 RECORDS
```

The following is the result of executing gloader.

```
gSQL> SELECT I1, I2, I3 FROM TEST FETCH 3;
I1 I2 I3
-- ------- --
1 L K H 10
2 KIM A0
3 KIM S CD
3 rows selected.
gSQL> SELECT COUNT(*) FROM TEST;
COUNT(*)
--------
3818246
1 row selected.
```

Array Binding and Atomic Option

The following gloader commands uploads records to be bound in 5000 unit with atomic INSERT, and 1,0 00 records are failed.

```
$ gloader test test --import --control test.ctl --data test.dat --array 5000 --atomic
loaded 5000 records into PUBLIC.TEST
loaded 10000 records into PUBLIC.TEST
loaded 15000 records into PUBLIC.TEST
... Ellipsis ...
loaded 38175000 records into PUBLIC.TEST
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3818243 RECORDS, SUCCEEDED 3817243 RECORDS
```

The following is the result of executing gloader.

```
gSQL> SELECT I1, I2, I3 FROM TEST FETCH 3;
I1 I2 I3
```

```
-- ------- --
1 L K H 10
2 KIM A0
3 KIM S CD
3 rows selected.
gSQL> SELECT COUNT(*) FROM TEST;
COUNT(*)
--------
3817243
1 row selected.
```

The following is the result for the cause of the upload failure and they are recorded in the log file. The upl oad is failed because the non-numeric data is stored in the first column of the first record.

```
$ cat test.log
Err Rec(1) Col(1): 22018(12006): data value is not a numeric literal
Err Rec(1) Col(-1): HY000(19041): Failed to atomic execution
Err Rec(1001) Col(1): 22018(12006): data value is not a numeric literal
Err Rec(1001) Col(-1): HY000(19041): Failed to atomic execution
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3818243 RECORDS, SUCCEEDED 3817243 RECORDS [
Start Time: 2014-8-28 16:46:42 End Time: 2014-8-28 16:46:52 Taken Time: 10084582 micro-sec ]
```

The following is the result of the records which failed to upload and they are recorded in the bad file. 100 0 records were stored because it is uploaded in 500 array units.

```
"s1"," L K H ","10"
"2","KIM","A0"
"3"," KIM S J ","CD"
... Ellipsis ...
```

Array, commit options do not affect the execution result, but success or failure of INSERT in the atomic operation is treated in an array unit, so if a record is failed to upload, all records in a unit to which the records belong are treated as INSERT failure.
The cause of the first failed records of the array is recorded in the log file and the causes for fail ed record later is not recorded.

Parallel Upload

gloader improves the performance of GOLDILOCKS by dividing the operation into parts and uploading th em in thread unit. (Refer to --**parallel**.)

The following is the datafile with approximately 380,000 records.

```
$ ll test.dat
-rw-r--r-- 1 test test 75092480 2014-08-28 15:59 test.dat
```

The following is the control file which is used for uploading.

```
$ cat test.ctl
TABLE  PUBLIC.test
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
```

The following gloader commands uploads records which is bound to a thread performing four uploads. It is uploaded in 5000 unit with INSERT, and 100 records are failed.

```
$ gloader test test --import --control test.ctl --data test.dat --array 5000 --parallel 4
loaded 5000 records into PUBLIC.TEST
loaded 10000 records into PUBLIC.TEST
loaded 15000 records into PUBLIC.TEST
... Ellipsis ...
loaded 3810000 records into PUBLIC.TEST
loaded 3815000 records into PUBLIC.TEST
 COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3818243 RECORDS, SUCCEEDED 3818143 RECORDS
```

The following is the result of executing gloader.

```
gSQL> SELECT I1, I2, I3 FROM TEST FETCH 3;
I1 I2 I3
-- ------- --
1 L K H 10
2 KIM A0
3 KIM S CD
3 rows selected.
gSQL> SELECT COUNT(*) FROM TEST;
COUNT(*)
--------
3818143
1 row selected.
```

The cause of failure during the upload is recorded in the log file as follows.

```
$ cat test.log
Err Rec(1) Col(1): 22018(12006): data value is not a numeric literal
Err Rec(3) Col(1): 22018(12006): data value is not a numeric literal
Err Rec(5) Col(1): 22018(12006): data value is not a numeric literal
... Ellipsis ...
Err Rec(1001) Col(1): 22018(12006): data value is not a numeric literal
... Ellipsis ...
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3818243 RECORDS, SUCCEEDED 3818143 RECORDS [
Start Time: 2014-8-28 16:46:42 End Time: 2014-8-28 16:46:52 Taken Time: 10084582 micro-sec ]
```

The following is a result of failed records recorded on the bad file during the upload. 100 records are stor ed.

```
"s1"," L K H ","10"
"s2","KIM","A0"
"s3"," KIM S J ","CD"
... Ellipsis ...
```

When uploading the data with multiple threads, the records in which errors occur after INSERT are stored in the log file and bad file. In this case, the order of records may not be as same as th e order in the data files.

Troubleshooting for Uploading

The record upload failure may occur by various causes. The failed record is stored in the bad file, and the i nformation about the cause of failure is stored in the log file.

Failure due to Redundant Constraint

The redundant data is already in the constrained table to be uploaded. (primary k ey or unique index)

The following is the structure of the table to be uploaded.

```
gSQL>\desc T1
COLUMN_NAME TYPE                  IS_NULLABLE
----------- --------------------- -----------
I1          NUMBER(10,0)          TRUE
I2          CHARACTER VARYING(10) TRUE
I3          BINARY VARYING(10)    TRUE
gSQL> SELECT * FROM T1;
I1 I2  I3
-- --- --
 1 LKH 10
 2 KMM A0
 3 ksj CD
3 rows selected.
```

The following is the datafile to be uploaded.

```
$ cat t1.dat
"1","LKH"
"4","SOS"
"5","OKO"
```

The followings are the upload result by using gloader, and the created log file and bad file.
The upload is failed because the record violated a primary key constraint.

```
$ gloader test test -i -c t1.ctl -d t1.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 2 RECORDS
$
$ cat t1.log
```

```
Err Rec(1) Col(-1): 40002(16057): unique constraint (PUBLIC.T1_PRIMARY_KEY) violated
COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 2 RECORDS [ Start Time:
2014-8-26 16:19:51 End Time: 2014-8-26 16:19:51 Taken Time: 15455 micro-sec ]
$
$ cat t1.bad
"1","LKH"
```

Failure due to Date/time Format

The format can be set for the data type such as DATE, TIME, TIME WITH TIME ZONE, TIMESTAMP, TIMES TAMP WITH TIME ZONE, and it may cause the failure of upload using gloader.

The following is the table to be uploaded.

```
gSQL> \DESC T1
COLUMN_NAME TYPE IS_NULLABLE
----------- ------------------------- -----------
I1 NUMBER(10,0) TRUE
I2 TIMESTAMP(6) WITH TIME ZONE TRUE
gSQL> SELECT * FROM T1;
no rows selected.
```

The format of the TIMESTAMP WITH TIME ZONE on the server is as follows.

```
gSQL> SELECT PROPERTY_VALUE, INIT_VALUE FROM V$PROPERTY WHERE PROPERTY_NAME LIKE
'NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT';
PROPERTY_VALUE                    INIT_VALUE
--------------------------------- ---------------------------------
YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM
```

The following is the datafile to be uploaded.

```
$ cat t1.dat
"4","20000108 00:00:00"
"5","20000108 04:05:06"
"6","20000108 04:05:06"
```

The following is the result of executing upload by using gloader.

```
$ gloader test test -i -c t1.ctl -d t1.dat

 COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 0 RECORDS
```

The cause and records of upload failure are stored in the log file and the bad file as follows.

```
$ cat t1.log
Err Rec(1) Col(2): HY000(12136): literal does not match format string
Err Rec(2) Col(2): HY000(12136): literal does not match format string
Err Rec(3) Col(2): HY000(12136): literal does not match format string
COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 0 RECORDS [ Start Time:
2014-8-27 13:56:29 End Time: 2014-8-27 13:56:29 Taken Time: 20670 micro-sec ]
$ cat t1.bad
"4","20000108 00:00:00"
"5","20000108 04:05:06"
"6","20000108 04:05:06"
```

Troubleshooting

The problem occurs when the data type format of the datafile and that of the data used on the server are different. The data type format of the datafile should be set to solve the problem. In this case, .odbc.ini is used.

The data type format is set in .odbc.ini file as follows.

```
$ cat .odbc.ini
[GOLDILOCKS]
HOST = 127.0.0.1
PORT = 21123
DATE_FORMAT = YYYYMMDD
TIME_FORMAT = HH24MISS
TIME_WITH_TIME_ZONE_FORMAT = HH24MISS TZHTZM
TIMESTAMP_FORMAT = YYYYMMDD HHMISS
TIMESTAMP_WITH_TIME_ZONE_FORMAT = YYYYMMDD HH:MI:SS
```

The following is the result of setting .odbc.ini and performing gloader again.

```
$ gloader test test -i -c t1.ctl -d t1.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 3 RECORDS
```

- The data type format set in .odbc.ini is applied to the entire column, and it can not be separ ately set.
- If the data type format is set in .odbc.ini, it is also applied when downloading to gloader.

Failure Due to Lack of Capacity

gloader is performed and failed as follows.

```
$ gloader test test -i -c t1.ctl -d t2.dat
loaded 4000 records into PUBLIC.T1
COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 4200 RECORDS, SUCCEEDED 0 RECORDS
```

It is failed due to lack of the space for datafile in the tablespace.

```
$ cat t1.log
Err Rec(1) Col(-1): HY000(14015): there is no extendible datafile in tablespace 'MEM_DATA_TBS'
Err Rec(2) Col(-1): HY000(14015): there is no extendible datafile in tablespace 'MEM_DATA_TBS'
... Ellipsis ...
COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 4200 RECORDS, SUCCEEDED 0 RECORDS [ Start Time:
2014-8-27 15:7:28 End Time: 2014-8-27 15:7:29 Taken Time: 317885 micro-sec ]
```

Troubleshooting

The datafile of a tablespace should be extended or added to solve the problem.
For more information, refer to **ALTER TABLESPACE**.

Datafile Analysis Failure

The field terminator, the qualifier, and the line terminator described in the control file may be different in the text datafile because of misuse.

The following is the structure of the table object to be uploaded.

```
gSQL>\desc T1
COLUMN_NAME TYPE                  IS_NULLABLE
----------- --------------------- -----------
I1          NUMBER(10,0)          TRUE
I2          CHARACTER VARYING(10) TRUE
I3          BINARY VARYING(10)    TRUE
```

The following is the control file to be uploaded.

```
$ cat t1.ctl
TABLE  T1
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
```

The following is the datafile to be uploaded.

```
$ cat t1.dat
'1',"LKH","aa"
"2","SOS"","aa"
"5","OKO","00"
```

The following is the result of executing upload by using gloader.

```
$ gloader test test --import --control t1.ctl --data t1.dat
 COMPLETED IN IMPORTING TABLE: PUBLIC.T1, TOTAL 3 RECORDS, SUCCEEDED 1 RECORDS
```

The cause and records of upload failure are as follows.

```
$ cat t1.log
Err Rec(1) Col(1): 22018(12006): data value is not a numeric literal
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3 RECORDS, SUCCEEDED 1 RECORDS [ Start Time:
2014-8-28 18:6:13 End Time: 2014-8-28 18:6:13 Taken Time: 18679 micro-sec ]
$
$ cat t1.bad
"2","SOS"","aa"
'1',"LKH","aa"
```

Troubleshooting

The records fail to analyze the data due to qualifier or delimiter which are used improperly. Therefore, to solve this problem, the field terminator, the qualifier and the delimiter in the control file and the datafile s hould be checked, then the datafile should be edited based on the records of the bad file.

The records which are failed to parse in the data analysis process are stored in the bad file, not i n the log file.

Uploading to Another Database Whose Character Set Is Different

Adjusting the column size may be required when downloading/ uploading data in binary type between d atabases whose character sets are different one another.

The following is the structure of the table object to be uploaded.

```
gSQL>\desc T1
COLUMN_NAME TYPE                 IS_NULLABLE
----------- -------------------- -----------
```

```
I1          NUMBER(10,0)          TRUE
I2          CHARACTER VARYING(36) TRUE
```

The following is the table data, and it is a VARCHAR type, its size is 36 and is completely filled.

```
SELECT * FROM T1;
I1    I2
---- ------------------------------------
   1 일이삼사오육칠팔구십일이삼사오육칠팔
```

The following error occurs when downloading data above from UHC database then uploading to UTF8 d atabase which has the same schema.

```
$ gloader test test -i -f binary -T T1 -d t1.dup
ERR-HY000(42023): byte length of data greater than column length.
ERROR: FAILED TO IMPORT TABLE PUBLIC.T1
```

Troubleshooting

The data upload succeeds when adjusting the length of column I2 as follows.
Declare I2 as VARCHAR(18 CHAR), or declare I2 as VARCAR(54) size.

```
gSQL>\desc T1
COLUMN_NAME TYPE                       IS_NULLABLE
----------- -------------------------- -----------
I1          NUMBER(10,0)               TRUE
I2          CHARACTER VARYING(18 CHAR) TRUE
```

```
gSQL>\desc T1
COLUMN_NAME TYPE                  IS_NULLABLE
----------- --------------------- -----------
I1          NUMBER(10,0)          TRUE
I2          CHARACTER VARYING(54) TRUE
```

41.3 Control File Syntax

```
TABLE [schema_name.]table_name[domain_name.]
FIELDS TERMINATED BY 'Field Terminator'
[OPTIONALLY ENCLOSED BY 'Open Qualifier' [AND 'Close Qualifier']]
[LINES TERMINATED BY 'Line Terminator']
[Characterset characterset_name]
[RTRIM [ON¦OFF]]
[LTRIM [ON¦OFF]]
[WHERE="conditional statement"]
```

A control file describes only one table. Therefore, each item above should be described in the co ntrol file only once, and if it is described redundantly, then the control parsing error occurs.

CHARACTERSET

Syntax

```
CHARACTERSET characterset_name
```

Description

It refers to the character set of the datafile to be downloaded or uploaded.
If the character set is not specified, the UTF8 which is the default character set of CHARACTER_SET in GO LDILOCKS property is used.

Example

The following is an example of which the character set of the datafile to be uploaded or downloaded is t he ASCII code.

```
% cat sample.ctl
CHARACTERSET ASCII
```

TABLE

Syntax

```
TABLE table_name
TABLE schema_name.table_name
TABLE table_name@domain_name
TABLE schema_name.table_name@domain_name
```

Description

It specifies the name of table to which upload or download the data, or specifies the schema name to which the table belongs, or the domain name.
The domain name can be used only for data download, and it downloads only the data of the corresponding member.
The string or double-quoted (") string is used in the table name.
If the table name is given as the command row argument in gloader as well, then the value of the command row argument takes precedence over the value in the control file.

Examples

The following is an example of specifying only the table name.

```
% cat sample.ctl
TABLE lineitem
```

The following is an example of specifying the schema PUBLIC and the table name. It has the same meaning as the example above.

```
% cat sample.ctl
TABLE PUBLIC.lineitem
```

The following is an example of specifying the schema PUBLIC and the table name of G1N1 member. It has the same meaning as the example above.

```
% cat sample.ctl
TABLE PUBLIC.lineitem@G1N1
```

The following is an example of specifying the table name created by the delimited identifier.

```
gSQL> CREATE TABLE "Tab*&^" ( id INTEGER );
```

```
% cat sample.ctl
TABLE "Tab*&^"
```

FIELDS TERMINATED BY

Syntax

```
FIELDS TERMINATED BY 'Field Terminator'
```

Description

The field terminator is used as a delimiter between columns in the record data of the data file. Setting the field terminator in the control file can not be omitted.
The field terminator can be set with one or more strings, and should not be redundant with a qualifier or line terminator, and it should not use the subset string.
There is not any constraintfor the string to be set as a field terminator. However, \ or % should be added to in front of each n, t, r when setting NEW LINE or TAB, CARRIAGE RETURN character.
If the field terminator is given as the command row argument in gloader as well, then the value of the co mmand row argument takes precedence over the value in the control file.

Example

The following is an example of setting the field terminator as COMMA and NEW LINE.

```
% cat sample.ctl
FIELDS TERMINATED BY ',\n'
```

```
% cat sample.ctl
FIELDS TERMINATED BY ',%n'
```

OPTIONALLY ENCLOSED BY

Syntax

```
OPTIONALLY ENCLOSED BY 'Open Qualifier' [AND 'Close Qualifier']
```

Description

Qualifier is used as a delimiter to represent the start and end of the column.
Qualifier is a single character, and the first qualifier is a open qualifier, the last qualifier is a close qualifier.
The same characters can be used to set an open qualifier and a close qualifier, or the different characters can be used to represent the start and end of the column.
Characters set as a qualifier can not be used in a field terminator nor in a line terminator.
If a close qualifier literally belongs to a column data, two close qualifiers are used to represent a single valid data.
If an open qualifier is set omitting a close qualifier, then characters as same as those in an open qualifier is set in a close qualifier.

If OPTIONALLY ENCLOSED BY statement does not exist, the column data is distinguished by the field terminator.
If the qualifier is given as the command row argument in gloader as well, then the value of the command row argument takes precedence over the value in the control file.

If OPTIONALLY ENCLOSED BY statement does not exist, the results of the uploading and downloading data may be different. (Refer to **Troubleshooting Uploading**.)

Example

The following is an example of using double quotes (") and a single quote (') as a open qualifier and a close qualifier each.

```
% cat sample.ctl
OPTIONALLY ENCLOSED BY '"' AND "'"
```

LINES TERMINATED BY

Syntax

```
LINES TERMINATED BY 'Line Terminator'
```

The line terminator is used as a delimiter between records in the data file.
The line terminator can be set with one or more strings, and should not be redundant with a qualifier or a field terminator, and it should not use the subset string.

When omitting the line terminator setting, then NEW LINE ('\n' or '%n') is used by default.
If the line terminator is given as the command row argument in gloader as well, then the value of thecom mand row argument takes precedence over the value in the control file.

Description

• Differently from Unix, CARRIAGE RETURN and NEW LINE are written together instead of a si ngle NEW LINE in the data file exported from Windows OS. When importing data by using this data file, LINES TERMINATED BY in the control file should be explicitly set like as '\r\n' so that t he data is normally imported.

• It is recommended to set a field terminator and a line terminator with a different string each. The more mutual string including the first character exist the poorer the import performance du e to the internal comparing. In other words, when a field terminator and a line terminator are s et with different strings each, then the shorter the string the better the performnace.

Example

The following is an example of using '^^\t\r\n' as a line terminator

```
% cat sample.ctl
LINES TERMINATED BY '^^\t\r\n'
```

LTRIM

Syntax

```
LTRIM ON¦OFF
```

Description

It determines a left trim.
The default value is OFF, and when it is set to OFF, then the left WHITESPACE is considered data.
When it is set to ON, then the left WHITESPACE is ignored.

> OPTIONALLY ENCLOSED BY is applied only when the syntax does not exist.
> If OPTIONALLY ENCLOSED BY is used and the column is enclosed with delimiters in the data file, then RTRIM and LTRIM is OFF.

Example

The following is an example of setting LTRIM to ON.

```
% cat sample.ctl
LTRIM ON
```

RTRIM

Syntax

```
RTRIM ON¦OFF
```

Description

It determines a right trim.
The default value is OFF, and when it is set to OFF, then the right WHITESPACE is considered data.
When it is set to ON, then the right WHITESPACE is ignored.

> OPTIONALLY ENCLOSED BY is applied only when the syntax does not exist.
> If OPTIONALLY ENCLOSED BY is used and the column is enclosed with delimiters in the data file, then RTRIM and LTRIM is OFF.

Example

The following is an example of setting RTRIM to ON.

```
% cat sample.ctl
RTRIM ON
```

WHERE

Syntax

```
WHERE="conditional_statement"
```

Description

It uses a conditional clause when downloading data.

Example

The following is an example of using WHERE.

```
% cat sample.ctl
WHERE="I2 > 3"
```

41.4 gloader Argument References

Usage

```
$ gloader --help
Usage
    gloader user password mode data [control] [format] [options]
    user                user name
    password            password
mode: gloader's mode.
  --export              export data
  --import              import data
data:
  --data                data file
options:
  --control             control file
  --format              file format(text¦binary, Default text)
  --log                 log file
  --bad                 bad file
  --dsn                 dsn string
  --array               number of rows in bind array(Default 1000)
  --filesize            max file size
  --commit              number of commit unit(Default 5000)
  --comment             commenting on commit
  --atomic              use atomic function
  --parallel            use parallel in import
  --propagation         enabling or disabling a redo log propagation(ON¦OFF)
  --errors              number of error count to allow(Default 100)
  --AsTIMESTAMP         bind DATE as TIMESTAMP
  --buffered            buffered disk io(Default direct io)
  --tablename           [schema_name.]table_name[@domain_name]
  --fieldterm           field terminator
  --lineterm            line terminator
  --qualifier           qualifier(column data encloser)
  --where               export only rows selected by given WHERE condition
  --group-id            importing distributed data by group id using global connections in a
clustered environment
  --directio-size       direct io size(Default 512)
```

```
--no-copyright        suppresses the display of the banner
--silent              suppresses the display of the result message
--help                print help message
```

Mandatory Argument

The arguments are entered in an order of username and password to connect to the database.
gloader operation mode, control file, datafile are entered as arguments.

Argument	Description
user_name	It is the user name. The maximum length of user name is 128.
password	It is password. The maximum length of password is 128.

--export

Description

It specifies for gloader to download the data in the database.

Example

```
$ gloader test test --export -c sample.ctl -d sample.dat
```

--import

Description

It specifies for gloader to upload the data in the database.

Example

```
$ gloader test test --import -c sample.ctl -d sample.dat
```

--control

Description

It specifies the control file path.

If --tablename is given as an argument, the control file can be omitted. The table name is mandatory to e

xecute gloader, so the table name should be given via a control file or an argument. If the table name is n ot given as an argument, TABLE item should be set via a control file.

When a control file is omitted, a field terminator, a qualifier, a line terminator can be given as an argume nt. If these delimiters are not given as an argument, then delimiters in CSV form is used by default.

Example

The following is an example of using a control file whose name is sample.ctl.

```
$ gloader test test -i --control sample.ctl -d sample.dat
```

--data

Description

It specifies the data file path to download or upload.

Example

The following is an example of uploading a control file whose name is sample.dat.

```
$ gloader test test -i -c sample.ctl --data sample.dat
```

Optional Argument

--tablename

Description

It specifies the table name in [Schemaname.]Tablename[@domain_name] form.

The table name should be given via setting TABLE of an argument or a control file. In other words, if a co ntrol file is omitted, the table name argument is mandatory.
If a tablename argument is given when TABLE item of a control file is set, then argument value takes prec edence over the value in the control file.

Example

The following is an example of uploading data in CSV form by giving a tablename argument because the control file argument is omitted

```
$ gloader test test -i --tablename PUBLIC.T1 --data sample.dat
```

The following is an argument of omitting a tablename argument because TABLE item is omitted in the co ntrol file.

```
$ cat sample.ctl | grep TABLE
  TABLE T1
$ gloader test test -i -c sample.ctl --data sample.dat
```

--format

Description

It specifies the datafile format.
The datafile format may be text or binary, and the default value is text when the format is not set.

Example

The following is an example of downloading the data to sample.dat in binary form.

```
$ gloader test test --export --control sample.ctl --data sample.dat --format binary
```

The followings are sample.dat and sample.log which are created after executing gloader as above.

```
$ ls
sample.ctl sample.dat sample.log
```

--log

Description

It specifies the logfile path.
gloader records the error and results occurred during the execution.
If the file name is not specified, the name is created as same as the datafile by changing its extension to l og.

Example

The following is an example of when the name of the log file is specified by using --log option.

```
$ gloader test test --export --control sample.ctl --data sample.dat --log SAMPLE.log
```

The followings are sample.dat, SAMPLE.log which are created after executing gloader as above.

```
$ ls
sample.ctl sample.dat SAMPLE.log
```

The following is an example of when the name of the log file is not specified by using --log option.

```
$ gloader test test --export --control sample.ctl --data sample.dat
```

The followings are sample.dat, sample.log which are created after executing gloader as above.

```
$ ls
sample.ctl sample.dat sample.log
```

--bad

Description

It specifies the bad file path.
It is valid only when gloader performs the import operation. Rows which can not be uploaded due to an error are stored in the bad file.
If the file name is not specified, the name is created as same as the datafile by changing its extension to bad.

Example

The following is an example of when the name of the bad file is specified by using --bad option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --bad SAMPLE.bad
```

The followings are sample.dat, sample.log, SAMPLE.bad which are created after executing gloader as above.

```
$ ls
SAMPLE.bad sample.ctl sample.dat sample.log
```

The following is an example of when the name of the bad file is not specified by using --bad option.

```
$ gloader test test --export --control sample.ctl --data sample.dat
```

The followings are sample.dat, sample.log, sample.bad which are created after executing gloader as abov

e.

```
$ ls
sample.bad sample.ctl sample.dat sample.log
```

--dsn

Description

It is the dsn string. The maximum length is 128.
It is used to specify the format of the time-related data type represented in the data file to be downloaded or uploaded.
It is used to specify the server when using gloadernet in the Client/ Server (C/S) environment.
For more information, refer to **odbc.ini File**.

Example

The following is an example of .odbc.ini described to use --dsn option.

```
$ cat .odbc.ini
[GOLDILOCKS]
HOST = 127.0.0.1
PORT = 21123
DATE_FORMAT = YYYYMMDD
TIME_FORMAT = HH24MISS
TIME_WITH_TIME_ZONE_FORMAT = HH24MISS TZHTZM
TIMESTAMP_FORMAT = YYYYMMDD HHMISS
TIMESTAMP_WITH_TIME_ZONE_FORMAT = YYYYMMDD HH:MI:SS
```

The following is an example of uploading the data to the goldilocks server by using --dsn option.

```
$ gloadernet test test --dsn goldilocks --import --control sample.ctl --data sample.dat
```

The following is an example of defining the format of time-related data type of the data file by using --dsn option, and then downloading data.

```
$ gloader test test --dsn goldilocks --export --control sample.ctl --data sample.dat
```

For more information, refer to **Failure due to date/time format**.

--array

Description

It specifies the number of rows to be bound when importing the data.
The amount of memory is required in proportion to the number of array. If not specified, 1,000 rows are used.
The option is applied only when uploading the data.

Example

The following is an example of uploading the data file in 2,000 records unit.

```
$ gloader test test --import --control sample.ctl --data sample.dat --array 2000
```

--filesize

Description

The maximum size of the file can be set when gloader downloads the data. If the amount of data exceeds the maximum size, the file is generated by adding the permutation number to the file extension.
If not specified, the maximum file size is unlimited, and the minimum is 31,461,376 (30 Mbytes).
The option is valid only for the binary type data file.

Example

The following is an example of executing the commands, then the file size exceeds the specified maximum, so new files are generated as results.

```
$ gloader test test --export --control sample.ctl --data sample.dat --filesize 31461376
```

```
$ls -al
-rw-r--r-- 1 test test 31461376 sample.dat
-rw-r--r-- 1 test test 31461376 sample.dat.001
-rw-r--r-- 1 test test  6715392 sample.dat.002
```

--commit

Description

While gloader uploads the data, the transaction is in the no commit state. The commit cycle may be set b
y using --commit option.
If not set, the default value is 5,000 (rows).

Example

The following is an example of using --commit option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --commit 10000
```

--comment

Description

When gloader commits the transaction, it specifies the comment on the transaction.

Example

The following is an example of using --comment option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --comment import_sample
```

--atomic

Description

It is the option for performing array INSERT, and it is useful when uploading the data.
The performance is faster than the existing array insert, because atomic array INSERT processes the insert statements as many as the size of array in a single transaction.

Example

The following is an example of using --atomic option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --array 1000 --atomic
```

--parallel

Description

It specifies the number of threads for parallel processing.
It is useful only when gloader uploads the data, and the performance gets faster when the number of thr

eads is increased by adjusting --parallel option.
The performance gets faster by increasing the number of threads, but it is recommended to set the numb er of threads according to the operational environment.
The default value is 1, and the maximum value is 32.

Example

The following is an example of using eight threads when uploading data. Ten threads are operated toget her including threads analyzing the data files and read only threads, besides the eight uploading threads.

```
$ gloader test test --import --control sample.ctl --data sample.dat --parallel 8
```

--propagation

Description

It determines whether to propagate the upload transaction log to another replicated server.
It can be set to ON or OFF.

Example

The following is an example of which the upload transaction log is not propagated to another replicated server.

```
$ gloader test test --import --control sample.ctl --data sample.dat --propagation off
```

--errors

Description

It sets the number of errors permitted when gloader uploads the data.
If not set, 100 (rows) are used. If it is set to 0, the --errors option is ignored.
If it is smaller than the size of --array option, the number of permitted error is the number of array.

Example

The following is an example of using --errors option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --errors 10000
```

--AsTIMESTAMP

Description

It sets the DATE type data stored in TIMESTAMP format to be operated in TIMESTAMP format for backw ard compatibility.
TIMESTAMP_FORMAT is also applied to the DATE type data when using the --AsTIMESTAMP option.

Example

The following is an example of using --AsTIMESTAMP option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --AsTIMESTAMP
```

--buffered

Description

Only the datafile uses the buffered IO instead of the direct IO.
The log file and bad file use the buffered IO.

Example

The following is an example of using --buffered option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --buffered
```

--fieldterm

Description

It provides a field terminator.
If it is set in a control file as well, then the fieldterm argument value is preferentially used.
% is added in front of n, r, t each for NEW LINE, CARRIAGE RETURN, TAB.
Characters which is used as a shell meta character such as ', ", ₩, & is not recommended to use.

Example

The following is an example of using --fieldterm option.

```
$ gloader test test --i -c sample.ctl -d sample.dat --fieldterm ",,,"
$ gloader test test --i -c sample.ctl -d sample.dat --fieldterm ,,,
```

```
$ gloader test test --i -c sample.ctl -d sample.dat --fieldterm ',,,'
```

--lineterm

Description

It provides a line terminator.
If it is set in a control file as well, then the lineterm argument value is preferentially used.
The detailed usage is as same as that of the fieldterm argument.

Example

The following is an example of using --lineterm option.

```
$ gloader test test --i -T PUBLIC.test -d sample.dat --lineterm ",,,"
$ gloader test test --i -T PUBLIC.test -d sample.dat --lineterm ,,,
$ gloader test test --i -T PUBLIC.test -d sample.dat --lineterm ',,,'
```

--qualifier

Description

It provides a qualifier which is to be added to the start and the end of the column data. Only a single char acter can be set as a qualifier.
If it is set in a control file as well, then the qualifier argument value is preferentially used.
The detailed usage is as same as that of the fieldterm argument.

Example

The following is an example of using --qualifier option.

```
$ gloader test test --i -T PUBLIC.test -d sample.dat --qualifier "¦"
$ gloader test test --i -T PUBLIC.test -d sample.dat --qualifier '"'
```

--where

Description

It downloads the data by setting a conditional clause for export operation.
If the where clause is also set in a control file, then the where argument value is preferentially used.

Example

The following is an example of using --where option.

```
$ gloader test test --i -T PUBLIC.test -d sample.dat --where "I2 > 4"
```

--group-id

Description

It directly uploads the data to the corresponding group after sorting the data by group when uploading t he data in the sharded table in the cluster environment.
If this option is used when uploading the data to the non-sharded table, the option is not valid.
This option is operated only in C/S environment, so it is valid only in gloadernet and it can be used only w hen uploading text files.

--group-id option uses **GLOBAL CONNECTION** of ODBC, so properties related to the **Data Source Configu ration** should be set.

Example

The following is odbc.ini configuration file to use the global connection.

```
$cat .odbc.ini
[GOLDILOCKS]
HOST=127.0.0.1
PORT = 22581
LOCALITY_AWARE_TRANSACTION=1
LOCATOR_DSN = LOCATOR
[LOCATOR]
LOCATOR_FILE=.locator.ini
```

The following is an example of using *--group-id* option in gloadernet.

```
$ gloadernet test test --i -T PUBLIC.test -d sample.dat --group-id
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 20 RECORDS, SUCCEEDED 20 RECORDS
```

The following is an example of an error which occurred due to using *--group-id* option in gloader.

```
$ gloader test test --i -T PUBLIC.test -d sample.dat --group-id
ERR-HY010(19009): Function sequence error : The function should be called only when the
SQL_ATTR_LOCALITY_AWARE_TRANSACTION connection attribute is set.
```

--directio-size

Description

gloader uses direct IO by default. The default value of direct IO is 512, but this size can be modified by using *--directio-size*. The value for the size should be the value of 2 powers of 512.

Example

The following is an example of modifying the direct IO size in gloader.

```
$ gloader test test --i -T PUBLIC.test -d sample.dat --directio-size 1024
```

--no-copyright

Description

It does not output the copyright and version.

Example

The following is the result of executing gloader with --no-copyright option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --no-copyright
COMPLETED IN EXPORTING TABLE: PUBLIC.t1, 3 RECORDS
$
```

--silent

Description

It does not output the results of executing gloader.

Example

The following is the result of executing gloader with --silent option.

```
$ gloader test test --import --control sample.ctl --data sample.dat --silent
$
```

--help

Description

It displays the help messages.
For more information, refer to **Usage**.

42.

gdump

42.1 Overview of gdump

Definition

gdump is a utility provided by GOLDILOCKS, and it dumps the following binary files managed by the data base in text form.

- Control file
- Datafile
- Log file
- Incremental backup file
- Property file
- Commit log file
- Log buffer file
- Pending log buffer file

Argument

gdump usage is divided into the mandatory argument and the optional argument, and the optional arguments are used differently according to the file types to be dumped.

```
gdump file_type file_name [options]
```

Mandatory Argument

The mandatory argument is used in an order of the file type and and the file path.

```
file_type:  CONTROL ¦ LOG ¦ DATA ¦ PROPERTY ¦ BACKUP ¦ COMMIT_LOG ¦ LOG_BUFFER ¦ PEND_BUFFER
file_name:  file name to dump
```

file_type Argument

- CONTROL: It is a control file. It is located in *<GOLDILOCKS_DATA>/wal*, and its file extension is *.ctl*.
- Log: It is a log file (online/archived redo log file). It is located in *<GOLDILOCKS_DATA>/wal* or in *<GOLDILOCKS_DATA>/archive_log*, and its file extension is *.log*.
- DATA: It is a datafile. It is located in *<GOLDILOCKS_DATA>/db*, and its file extension is *.dbf*.
- PROPERTY: It is a binary property file. It is located in *<GOLDILOCKS_DATA>/conf*, and the default file name is *goldilocks.properties.binary*.

- BACKUP: It is an incremental backup file. It is located in *<GOLDILOCKS_DATA>/backup*, and its file extension is *.inc*.
- COMMIT_LOG: It is a commit.log file located in *<GOLDILOCKS_DATA>/wal*.
- LOG_BUFFER: It is a file of which a log buffer located in the memory is stored. The log buffer is stored in a file by executing gsyncher.
- PEND_BUFFER: It is a file of which a pending log buffer located in the memory is stored. The pending log buffer is stored in a file by executing gsyncher.

An attempt to the dump of broken control file fails.

Optional Argument

```
-S  --silent                                silent
   file_type = CONTROL
      -s, --section  sys ¦ log ¦ db ¦ backup ¦ all  dump controlfile section(default all)
   file_type = DATA
      -h, --header                          dump datafile header
      -n, --number   INTEGER ( >= 0 )       (log or page) sequence number
      -f, --fetch    INTEGER ( >= 1 )       dump as much as count
   file_type = LOG
      -h, --header
      -n, --number   INTEGER ( >= 0 )       (log or page) sequence number
      -o, --offset   INTEGER                offset of lsn(usable if set lsn)
      -f, --fetch    INTEGER ( >= 1 )       dump as much as count
      -a, --all
   file_type = BACKUP
      -b, --body     header ¦ all           dump incremental body(default all)
      -t, --tbs                             dump specific tablespace body(usage if set body)
      -n, --number   INTEGER ( >= 0 )       (log or page) sequence number
      -f, --fetch    INTEGER ( >= 1 )       dump as much as count
```

Description

Name	Available file type	Description
--silent	All	It does not output copyright, version, the execution time.
--section	Control file	It refers to the section of control file to be dumped. • sys: System section • log: Log section • db: Database section

Name	Available file type	Description
		• backup: Incremental backup section • all: All sections (The default value)
--header	Datafile	It dumps only the header of the datafile. If not set, it does not display the header.
	Log file	It dumps only the header of the log file.
--number	Datafile	It is a page number to be dumped. (The default value is 0.)
	Log file	It is a log number to be dumped. (The default value is 0, and it dumps the log bigger than the specified number.)
	Incremental backup file	It is a page number to be dumped. (The default value is 0, and it dumps the page bigger than the specified number.)
--fetch	Datafile	It is a number of pages to be dumped. (The default value is 1.)
	Log file	It is a number of logs to be dumped. (The default value is the whole logs.)
	Incremental backup file	It is a number of pages to be dumped. (The default value is the whole pages.)
--offset	Log file	It is valid only when --number option argument is set, and it refers to the position apart as far as offset from the value set in number. (The default value is 0.)
--body	Incremental backup file	It displays the header of page (header) or the header and page (all). If not set, it does not display anything. (The default value is none).
--tbs	Incremental backup file	It is valid only when --body option is set. It specifies the certain tablespace number in the incremental backup file. If not set, it refers to all tablespace.
--all	Logl file	It dumps all including invalid logs.

An option is not used when dumping the property file.

42.2 Examples of Using gdump

Control File

- Dumping system section

```
$ gdump control control_0.ctl --section sys --silent
 [SYSTEM SECTION]
------------------------------------------------------------
  SERVER STATE                      : SERVICE
  DATA STORE MODE                   : TDS
  LAST CHECKPOINT LSN               : 136976
  INCREMENTAL BACKUP CHUNK COUNT    : 1
  INCREMENTAL BACKUP SECTION OFFSET : 512
  LOG  SECTION OFFSET               : 8704
  DB   SECTION OFFSET               : 13312
```

- Dumping log section

```
$ gdump control control_0.ctl --section log --silent
[LOG SECTION]
------------------------------------------------------------
   DATABASE CREATION TIME : 2014-08-25 18:37:11.299610
  [CHECKPOINT]
    LID                              :  0,54834,13
    LSN                              :  136976
    RECOVERY LSN                     :  136976
    ARCHIVELOG MODE                  :  ARCHIVELOG
    LAST INACTIVATED LOGFILE SEQUENCE :  -1
  [LOG STREAM]
    STATE          :  ACTIVE
    GROUP COUNT    :  4
    BLOCK SIZE     :  512
    FILE SEQUENCE  :  0
    [LOG GROUP #0]

43.

tablediff

43.1 Overview of tablediff

Background

The GOLDILOCKS system operator should prepare for the unexpected failure of GOLDILOCKS synchronization of two tables using the tools such as cyclone or LogMirror. An unexpected failure of synchronization refers that a particular row exists only in one table or the column values of rows to be synchronized are different from each other. Cyclone and LogMirror do not notify a user whether synchronization is failed. It is required to verify the synchronization of the table and to perform synchronization, if necessary, at non-operation time.

Features

tablediff is a tool comparing two tables of GOLDILOCKS which was synchronized by using CDC in a row unit. It reports when a particular row exists only in a table or values are different each other, then performs synchronization. The configuration file for controlling various operations is input, and the log files to report the unsynchronized rows and the synchronization results are output.

The constraints are that the schemas of two tables should be same and each of them should have the primary key. It is not recommended to perform the tool for table of the currently executing transaction because the table can be updated in real time. However, it does not matter for the currently executing querying (SELECT statement). This tool is available only for the GOLDILOCKS tables.

This tool has two executing commands, which are TableDiff and TableSync.

TableDiff

```
java sunje.goldilocks.tool.diff.TableDiff [configure file]
```

TableDiff program verifies whether two tables are unsynchronized, and it may output the information(binary file) to perform synchronization for unsynchronized rows immediately or at a later time according to an option. The immediate synchronization can be operated for multiple threads.

TableSync

```
java sunje.goldilocks.tool.diff.TableSync [configure file]
```

Tablesync program performs synchronization by using the sync information which was previously left by T ableDiff. (Row comparison is not performed.) A simultaneous execution can be performed by driving mul ti threads.

Unsynchronized rows of two tables to which the configure file is not applied are stored in a bin file left by TableDiff. TableSync uses this bin file to forcibly synchronize two tables.

Characteristics

This tool is a java application and it is provided in a jar file form, so Java(1.6) is required to execute the to ol. Also, goldilocks6.jar is required because GOLDILOCKS JDBC driver is used. It can be remotely performe d because it is connected to GOLDILOCKS by using TCP/ IP, and it is performed at much faster rate than u sing JDBC, ODBC with the proprietary protocol.

The row comparison and synchronization can be simultaneously performed with multi threads. For multit hreading of the row comparison, equal dividing of the range of the key in the table should be manually p erformed. When the user splits the key range into ten ranges (The user can specify it in the configuration file), then ten threads compare the tables. On the other hand, the synchronization operation is performe d by threads of as many as it is specified.

File Configuration

tablediff program consists of a single file called as $GOLDILOCKS_HOME/bin/tablediff.jar. $GOLDILOCKS _HOME/lib/goldilocks6.jar file is also required for execution. Also, the configuration file is required as an i nput argument, and refer to the sample file, $GOLDILOCKS_HOME/conf/tablediff.conf.

43.2 Usage

Command Usage

Java (JRE 1.6 or JDK1.6) is required because tablediff is a java program. For this, tablediff.jar and goldiloc ks6.jar files should be included in CLASSPATH, or they should be specified with -classpath option of java. tablediff is executed as follows.

```
export
CLASSPATH=$CLASSPATH:$GOLDILOCKS_HOME/bin/tablediff.jar:$GOLDILOCKS_HOME/lib/goldilocks6.jar
java sunje.goldilocks.tool.diff.TableDiff [configure file]
```

Or

```
java -classpath $GOLDILOCKS_HOME/bin/tablediff.jar:$GOLDILOCKS_HOME/lib/goldilocks6.jar
sunje.goldilocks.tool.diff.TableDiff [configure file]
```

The result of executing TableDiff for the simple sample table is as follows.

```
gSQL> create table tab1 ( c1 integer primary key, c2 char(10) );
gSQL> create table tab2 ( c1 integer primary key, c2 char(10) );
gSQL> insert into tab1 values ( 1, 'HELLO');
gSQL> insert into tab2 values ( 1, 'HELLO');
gSQL> insert into tab1 values ( 2, 'WORLD');
gSQL> insert into tab2 values ( 2, 'world');
gSQL> insert into tab1 values ( 3, 'good');
gSQL> insert into tab2 values ( 4, 'good');
gSQL> commit;
shell> java sunje.goldilocks.tool.diff.TableDiff tablediff.conf
Total 4 rows processed
  > row diff            : 1, update target(success/failure): 1/0
  > key diff source only: 1, insert into target(success/failure): 1/0
  > key diff target only: 1, delete from target(success/failure): 1/0
TableDiff completed
elapsed time = 0.229 sec
```

- The contents of tablediff.conf

```
SOURCE_URL      = jdbc:goldilocks://127.0.0.1:22581/test
SOURCE_USER     = TEST
SOURCE_PASSWORD = test
SOURCE_SCHEMA   = PUBLIC
SOURCE_TABLE    = TAB1
TARGET_URL      = jdbc:goldilocks://127.0.0.1:22581/test
TARGET_USER     = TEST
TARGET_PASSWORD = test
TARGET_SCHEMA   = PUBLIC
TARGET_TABLE    = TAB2
OPERATION       = SYNC
TARGET_INSERT = ON
TARGET_UPDATE = ON
TARGET_DELETE = ON
SOURCE_INSERT = OFF
```

Property Option

This chapter describes the available property options in the configuration file of tablediff.

Property Options for SOURCE, TARGET Tables

These property options should necessarily be specified and they define the source and target tables. The s ource and target refer to table to be compared each.

- SOURCE_URL: It is JDBC connection URL of GOLDILOCKS in which the source table exists.
- SOURCE_USER: It is the user account of GOLDILOCKS in which the source table exists.
- SOURCE_PASSWORD: It is the password of GOLDILOCKS in which the source table exists.
- SOURCE_SCHEMA: It is the schema of source table.
- SOURCE_TABLE: It is the name of source table.
- TARGET_URL: It is JDBC connection URL of GOLDILOCKS in which the target table exists.
- TARGET_USER: It is the user account of GOLDILOCKS in which the target table exists.
- TARGET_PASSWORD: It is the password of GOLDILOCKS in which the target table exists.
- TARGET_SCHEMA: It is the schema of target table.
- TARGET_TABLE: It is the name of target table.

The following is an example.

```
SOURCE_URL      = jdbc:goldilocks://192.168.0.100:22581/test
SOURCE_USER     = TEST
SOURCE_PASSWORD = test
SOURCE_SCHEMA   = PUBLIC
SOURCE_TABLE    = T1
TARGET_URL      = jdbc:goldilocks://192.168.0.101:22581/test
TARGET_USER     = TEST
TARGET_PASSWORD = test
TARGET_SCHEMA   = PUBLIC
TARGET_TABLE    = T2
```

Operation

It determines the operations of TableDiff. The DIFF property verifies only the synchronization integrity and reports it, but the SYNC property verifies the integrity and simultaneously performs synchronization.

The integrity result file (whose file name is specified as DIFF_BIN_ FILE property) is generated when operating with DIFF and it is used to execute TableSync.

Synchronization Policy

Four properties are used for controlling the synchronization policy and all of them have the value of either ON or OFF.

- TARGET_INSERT: If the key in the source does not exist in the target, it inserts the key into the target.
- TARGET_UPDATE: If the value of the column which is not a key is different, it updates the target row.
- TARGET_DELETE: If the key does not exist in the source but exists in the target, it deletes the target row.
- SOURCE_INSERT: If the key does not exist in the source but exists in the target, it inserts that row into the source.

Both TARGET_DELETE and SOURCE_INSERT are not allowed to be ON together.

EXCLUDED_COLUMNS

It specifies the columns to be excluded from the comparison. The comma (,) is used as a delimiter and the column name should be specified. The key columns can not be excluded.

WHERE_CLAUSE

It sets the conditions for comparing rows in the table. For example, the condition, WHERE_CLAUSE = SALARY> = 1000000, refers that the integrity is verified only for the rows having the values of their column salary equal to or bigger than 1,000,000.

DISPLAY_ROW_UNIT

TableDiff program displays the progress status of table comparison, and it outputs to the console the number of rows processed each time whenever it processes a certain number of rows. The property sets the number of rows to be output. the default value is 100,000, and it can be omitted.

SYNC_OUT_FILE

It specifies the name of the file in which the synchronization result is to be recorded. If not specified, the result is recorded in tablesync.log. If multiple synchronized threads exist, a number is added at the end of the file name.

DIFF_OUT_FILE

It specifies the name of the file in which the row mismatch result is to be recorded. If not specified, the result is recorded in tablesync.log. This file is in a text form which is human-readable.

DIFF_BIN_FILE

If the operation property is set to DIFF, TableDiff records the synchronization information in a file with a name specified by this property. This file is used as an input argument by TableSync.

PROPAGATE_REDO_LOG

It determines whether to propagate the row synchronization log to another replicated server. The default value is OFF.

LOGGING_ON_SUCCESS

It sets whether to record logs even when DML(INSERT, UPDATE, DELETE) used for the row synchronization is successful. The default value is OFF. If it is OFF, then the synchronization performance becomes poor. If DML is failed, the logging information is recorded regardless of this property.

LOGGING_ON_DIFF

It sets whether to record logs when the mismatch occurs during comparing the row integrity. The default value is OFF.

JOB_QUEUE_SIZE

The row synchronization is performed by the operating thread. The threads perform the synchronization by getting the operation from the JOB QUEUE one by one. The main thread of TableDiff or TableSync ins erts the operation to JOB QUEUE. JOB QUEUE becomes full if the thread slowly performs synchronization. JOB_QUEUE_SIZE property sets the size of JOB QUEUE. If this value is big, JOB QUEUE never becomes full but it wastes a lot of memory. The default value is 100, and 100 is big enough to use without filling of th e queue.
The property is recommended not to change unless it is needed.

JOB_THREAD

It sets the number of threads for synchronization. If not set, the default value is 1. If there are multiple ro ws to be synchronized, the value should be set considering the number of CPU. The bigger the value, the faster the synchronization is performed.

JOB_UNIT_SIZE

The synchronization is performed in batch as much as the size specified by the property. The default value is 100.

DISPLAY_CALL_STACK

It sets whether to display call stack when an error occurs. The default value is OFF.

Replication Settings for Table Comparison

The row comparison of TableDiff is performed by a single thread by default. But multiple threads can perf orm comparisons by specifying the condition clause. The property name is PARTITION_RANGE[n], and if t he range for N properties is set such as the WHERE clause, n threads perform the comparison each.

For example, the following properties are specified for each of 12 threads to perform the comparison wh en the table includes the monthly data.

```
PARTITION_RANGE1 = MONTH=1
PARTITION_RANGE2 = MONTH=2
```

```
PARTITION_RANGE3 = MONTH=3
PARTITION_RANGE4 = MONTH=4
PARTITION_RANGE5 = MONTH=5
PARTITION_RANGE6 = MONTH=6
PARTITION_RANGE7 = MONTH=7
PARTITION_RANGE8 = MONTH=8
PARTITION_RANGE9 = MONTH=9
PARTITION_RANGE10 = MONTH=10
PARTITION_RANGE11 = MONTH=11
PARTITION_RANGE12 = MONTH=12
```

All conditions should be disjointed, and the union of all conditions should be as same as the total set. Als o, the column used in the condition should the front part of the primary key. (It means that the specified condition should be able to use the primary index.)
This property is applied only to TableDiff, and TableSync ignores this property.

44.

gsyncher

44.1 Overview of gsyncher

Definition

gsyncher is a utility provided by GOLDILOCKS, and which synchronizes the log of shared memory and the logfile of disk.
When the server is abnormally terminated, gsyncher synchronizes the latest log of shared memory and th e logfile, then records it.

Features

- gsyncher can not be executed during the server operation.
- The STARTUP stage of the server in which gsyncher can be executed is OPEN phase.
- When executing gsyncher, all other applications of the shared memory should be terminated.
- During gsyncher execution, the logfile can be switched and in this case, the controlfile is generated.
- gsyncher backups the controlfile and logfile in which the logs are reflected, in advance.
- gsyncher can be executed after restoring the damaged controlfile.

Usage

```
gsyncher [options]
```

Options

```
-l  --log              Log trace msg
-s  --silent           Do not print message
-f  --home             home directory
-c  --copy-right       Do not print copy right
-b  --backup-path      Backup directory
-h  --help             Print help message
```

44.2 Examples

- Example 1: gsyncher is executed during the server is normally operating.

```
$ gsyncher -l
[SHARED MEM] Attached to shm - Name(_STATIC), Key(21128)
[SHARED MEM] Detached from shm.
ERR-HY000(53002): gmaster is active
```

- Example 2: The server is not on the STARTUP stage on which gsyncher can be executed.

```
$ gsyncher -l
[SHARED MEM] Attached to shm - Name(_STATIC), Key(21128)
[SHARED MEM] Detached from shm.
ERR-HY000(53000): invalid phase(MOUNT): executable phase is OPEN
```

- Example 3: When executing gsyncher, the progress is displayed. The execution result is total buffer (0) bytes, and all logs are flushed to the logfile, so there is not a log to be synchronized.

```
$ gsyncher --log
[SHARED MEM] Attached to shm - Name(_STATIC), Key(21128)
[CLEAR PROCESS] Process 'gbalancer' is cleared.
[CLEAR PROCESS] Process 'gdispatcher' is cleared.
[CLEAR PROCESS] Process 'gdispatcher' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[CLEAR PROCESS] Process 'gserver' is cleared.
[FLUSH] Log buffer flushed - Log group from id (0) to (0), lsn from (130784) to (130784),
total buffer (0) bytes
[SHARED MEM] Detached from shm.
[FINI] Log sync complete.
```

    - gsyncher operations are recorded in logfile by using --log option.

```
$ cat $GOLDILOCKS_DATA/trc/gsyncher.trc

45.

gmon

45.1 Overview of gmon

Definition

gmon is a database (gmaster) process monitoring utility provided by GOLDILOCKS.

Features

gmon monitors whether database process (gmaster) is operated, and when the process is abnormally ter minated, not by user's SHUTDOWN, then it executes **gsyncher** and terminates the process. It intends to re duce the loss of logs by executing gsyncher.

gmon can be set to be automatically operated by setting the server property GMON_AUTOSTART to 1, or a user can directly executes gmon.

A single gmaster process can monitor only one gmon process.

Usage

```
gmon [options]
```

Options

```
-s  --start        Start gmon
-t  --stop         Stop gmon
-u  --status       Get gmon status
-o  --home         gmaster home path
-d  --uds_dir      unix domain socket directory
-l  --silent       Suppress display message
-r  --no-copyright Suppress display copy right and version
-h  --help         Print help messages
```

start

It starts gmon.

stop

It stops gmon.

status

It checks the status of gmon process.

home

It is the database home directory. If it is omitted, then it uses the value set in GOLDILOCKS_DATA environ ment variable.

uds_dir

It sets the directory in which unix domain socket is created. The maximum length of the directory is 50 by tes. The default value is /tmp.

silent

It does not output the result message.

no-copyright

It does not output copyright and version.

help

It outputs the help message.

45.2 Examples

- Example 1: Execute gmon by using the default path ($GOLDILOCKS_DATA).

```
$ gmon --start
gmon is started.
```

- Example 2: Execute gmon by specifying home path. When a relative path is used, home path is specif ied based on $GOLDILOCKS_DATA.

```
$ gmon --start --home g1n1_home
gmon is started.
```

- Example 3: Execute gmon by specifying home path as an absolute path. When an absolute path is us ed, the specified path is specified as a home path.

```
$ gmon --start --home /g1n1_home
gmon is started.
```

- Example 4: Check the status of gmon process.

```
$ gmon --status --home /g1n1_home
gmon is running(19119).
```

- Example 5: Terminate the gmon process.

```
$ gmon --stop --home /g1n1_home
gmon is stopped.
```

46.

gtrclogger

46.1 Overview of gtrclogger

Definition

gtrclogger is a utility remotely collecting logs of GOLDILOCKS.

GOLDILOCKS basically records events and trace logs which occur in a server, in system.trc file of the speci fied directory of SYSTEM_LOGGER_DIR of property. (The default value is $GOLDILOCKS_DATA/trc)

If multiple different instances are being operated, trace logs occur in each server should be separately mo nitored. For that, gtrclogger makes trace logs of each different GOLDILOCKS instances to be collected in a single spot. gtrclogger receives trace logs of various GOLDILOCKS being operated in a different device with udp, and stores them in a file.

gtrclogger receives trace logs from the remote GOLDILOCKS and records them in a file. For that, the rem ote GOLDILOCKS should have the following transfer properties.

- TRACE_LOGGER
- TRACE_LOGGER_REMOTE_HOST
- TRACE_LOGGER_REMOTE_PORT

Features

- gtrclogger can be operated regardless of server operation.
- Even when it receives trace logs from various servers, it sequentially stores them in a file.
- A trace log is basically stored as $(GOLDILOCKS_DATA)/trc/system.rmt.trc.
- If system.rmt.trc is bigger than 10M bytes , it is backuped as system.rmt.trc_*date*_Index.

Usage

```
gtrclogger [options]
```

Options

```
-s  --start        start gtrclogger
-q  --stop         stop gtrclogger
-p  --port         udp port for receive log (1024 ~ 49151): default 21470
-d  --dir          write file directory: default $(GOLDILOCKS_DATA)/system.rmt.trc
-h  --help         show gtrclogger help messages
```

46.2 Examples

- Example 1: Execute gtrclogger by using the default port (21470) and the default directory($GOLDILOCKS_DATA/trc).

```
$ gtrclogger --start
gtrclogger is started successfully.
```

- Example 2: Receive a trace log with two ports (21471, 21472) and set the directory as $GOLDILOCKS_DATA/rmt_trc, then execute gtrclogger.

```
$ gtrclogger -s -p 21471 -p 21472 -d $GOLDILOCKS_HOME/rmt_trc
ERR-HY000(11040): No such object
(/home/lym1/workspace/product/Gliese/home/rmt_trc/system.rmt.trc)
$ mkdir $GOLDILOCKS_HOME/rmt_trc
$ gtrclogger -s -p 21471 -p 21472 -d $GOLDILOCKS_HOME/rmt_trc
gtrclogger is started successfully.
```

- Example 3: Terminate gtrclogger.

```
$ gtrclogger -q
Stop Done.
```

47.

glocator

47.1 Overview of glocator

Definition

glocator is a utility which provides locations to a client and manages them in GOLDILOCKS cluster system. The location information of cluster member nodes is provided to the glocator program through **gloctl**. glocator communicates with the client and gloctl via UDP, and it communicates with gagent via TCP.

glocator requires the location information such as a listener host, listener port and db home pat h, and this information is provided to the glocator through gloctl.

Usage

```
glocator [options]
```

Options

help

Description

It outputs a help message.

Example

```
$ glocator --help
Usage:
 glocator [options]
Options:
-c  --create       Create glocator environment
-s  --start        Start glocator
-t  --stop         Stop glocator
-f  --conf         Set configure file
-u  --status       Get glocator status
-l  --silent       Suppress display message
```

```
-r  --no-copyright Suppress display copy right and version
-h  --help         Print help message
```

create

Description

It creates the data file of glocator.

Example

```
$ glocator --create
glocator is created.
```

The data file of glocator is created in <GOLDILOCKS_DATA>/db directory.

```
$ ls
README  glocator.dat  system_data.dbf  system_dict.dbf  system_undo.dbf
```

start

Description

It starts glocator. If glocator having the same port already has started, then an error occurs.

Example

```
$ glocator --start
glocator is started.
```

stop

Description

It stops glocator which is in operation. The same port should be set to stop glocator in operation.

Example

```
$ glocator --stop
glocator is stopped.
```

conf

Description

It sets the configure file when starting glocator.

Example

```
$ glocator --start --conf goldilocks.glocator.conf
glocator is started.
```

status

Description

It outputs the status message of glocator which is in operation. The same port should be set to check the status of glocator in operation.

Example

```
$ glocator --status
Process ID: 26058
Configuration file: goldilocks.glocator.conf
Unix domain path: /tmp/unix-glocator.42581
Udp listen host: 0.0.0.0, Port: 42581
glocator is running.
```

sync

Description

It synchronizes the data of glocator set in ALTERNATE_LOCATORS before driving glocator.

There are two methods for the data synchronization, whichare SOURCE and BOTH. SOURCE method brin gs data from ALTERNATE_LOCATORS, and BOTH method merges two glocators.

Example

The following is an example of success of a sync option.

```
$ glocator --start --sync
glocator is started.
```

The following is an example of failure of a sync option. The value is not set in ALTERNATE_LOCATORS pr operty.

```
$ glocator --start --sync
ERR-HY000(60016): Need more alternate locator host information.
```

The following is an example of failure of a sync option. glocator set in ALTERNATE_LOCATORS property d oes not response.

```
$ glocator --start --sync
ERR-HY000(60016): Need more alternate locator host information.
```

silent

Description

It does not output the message of glocator about the execution.

Example

```
$ glocator --start --silent
```

no-copyright

Description

It does not output the message of glocator's copyright and version about the execution.

Example

```
$ glocator --start --no-copyright
glocator is started.
```

47.2 Using glocator

Data File

glocator data file should be created before starting glocator.

```
$ glocator --create
glocator is created.
```

The directory in which glocator data file is stored can be altered by editing configuration **LOCATION_FILE_DIR**. The default value is created in <GOLDILOCKS_DATA>/db. The data file can be altered by editing **LOCATION_FILE_NAME**. The default value is glocator.dat.

The maximum size and initial size of glocator data file can be altered by editing configuration **LOCATION_FILE_MAX_SIZE**and **LOCATION_FILE_SIZE**.

CSTARTUP and CSHUTDOWN

glocator can be used to CSTARTUP and CSHUTDOWN the GOLDILOCKS server.
For that, glocator should be in operation, and CSTARTUP or CSHUTDOWN should be executed through gsqlnet.
However, LOCATOR_DSN and the property should be set in odbc.ini of the device which executes gsqlnet.
For more information, refer to **GOLDILOCKS UNIX ODBC driver libraries**.

The following contents is set in odbc.ini to use glocator.

```
[GOLDILOCKS]
HOST=127.0.0.1
PORT=20101
UID=sys
PWD=gliese
LOCATOR_DSN=GLOCATOR
[GLOCATOR]
HOST=127.0.0.1
PORT=42581
```

If FILE property exists in DSN [GLOCATOR], then the file specified in FILE property takes precedence instead of using glocator. Therefore, FILE property should be excluded.

glocator should know the location information of member nodes to execute CSTARTUP and CSHUTDOWN.

Replication

Overview

glocator replication keeps data consistent, so it enables the stable service through the remote glocator when an error occurs.

Configuration

Each glocator should set ALTERNATE_LOCATORS property in a configure file to use the replication feature. Locator_name should be set in ALTERNATE_LOCATORS property and the specified Locator_name should be set in a configure file together with HOST, PORT properties.

The following is how to set ALTERNATE_LOCATORS property.

```
[LOCATOR]
ALTERNATE_LOCATORS = (locator_name1,locator_name2)
[locator_name1]
HOST= ip_address
PORT = port_num
[locator_name2]
HOST= ip_address
PORT = port_num
```

The following is an example of a configure file which sets ALTERNATE_LOCATORS property.

```
[LOCATOR]
PORT=42581
SYNC_RESPONSE_TIMEOUT = 2
SYNC_RETRY_COUNT = 2
LOCATION_FILE_NAME='glocator_1.dat'
ALTERNATE_LOCATORS=(LOCATOR_2,LOCATOR_3)
[LOCATOR_2]
```

```
HOST=127.0.0.1
PORT=42582
[LOCATOR_3]
HOST=127.0.0.1
PORT=42583
```

- [LOCATOR] is DSN which is read as default by glocator.
- For more information glocator-related ODBC and how to set gagent, refer to **odbc.ini File**, **ALTERNATE_LOCATORS**.

Synchronizing Data

The data should be consistent when the replicated glocator is in service. If glocator in operation does not exist, then all glocator can perform the normal start. If glocator in operation exists, an alternate glocator can be started by synchronizing the data using a **sync** option.

sync option has BOTH and SOURCE. BOTH merges glocator's own data and alternate glocator's data. SOURCE brings the data from the counterpart glocator. The sync operation of glocator is 1 : 1 correspondence task between a glocator and an alternate glocator. Therefore, if A and B are already being operated, and C is operated after syncing by using BOTH for the replication of three (A, B, C) glocators, then the data of A and B glocators may be different.

glocator in service synchronizes only the updated content. If the data synchronization fails due to the packet loss or other reasons, then the data may be different. In this case, update the data within that glocator by using **gloctl** program, or restart glocator with sync option.

47.3 Features of glocator

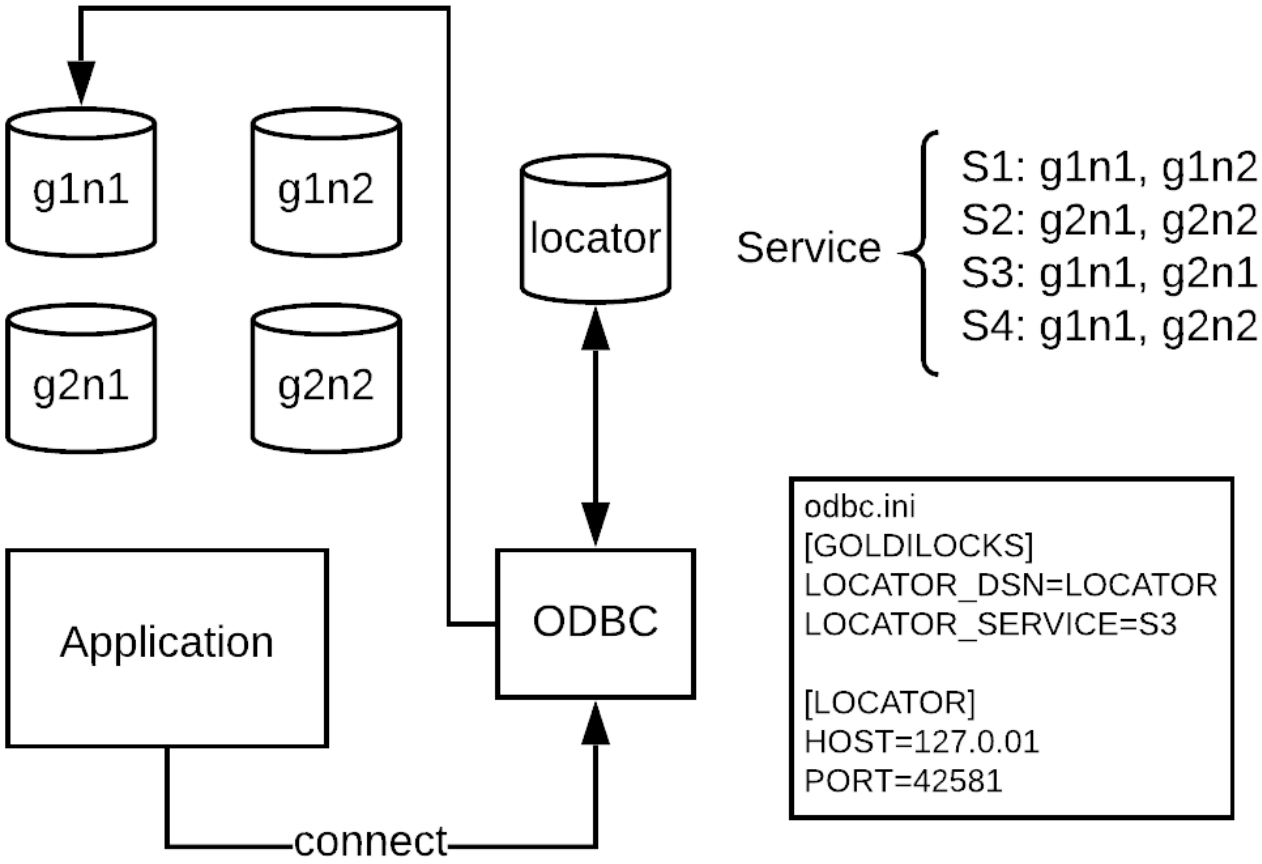
Connection Service

It provides a service feature which enables arbitrarily access any node among user-defined nodes even th ough the location information of a specific node in a cluster environment is unknown.

The service feature is that a user specifies nodes managed by glocator an arbitrary group. This service can be registered by using gloctl program. Service lists managed by glocator can also be viewed by using gloc tl program.

An application should be accessed by using ODBC driver, and LOCATOR_DSN and LOCATOR_SERVICE pr operty should be specified in **odbc.ini file**.

Figure 1 locator_service



The figure above describes that an application accesses to g1n1 belonging to service s3. The connecting s equence of ODBC driver by using the service is as same as the sequence of node registered in the service. If ODBC driver fails to connect to g1n1 in the example above, it will try to connect to the next node g2n1.

To use the service feature, the valid location information of a node should be input in glocator in advance.

Cluster Failover

glocator is helpful when a server proceeds the failover.

When the value of server property **CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY** is set to 1 or 2, and connection between nodes is disconnected in a cluster environment, a failover occurs, then each node proceeds the cluster failover and queries its viability to glocator through gagent.

The glocator which received a query determines the viability between two nodes which were disconnected, and transfer the result to the gagent which enquired the query.

Nodes received the viabilty results are terminated or proceeds the failover.

The cluster failover processing time of the server is relevant to various properties. Server property **LOCATOR_QUERY_TIMEOUT** sets the time waiting for the response after the server enquires to glocator, and the default value is 3 seconds.
Server property **CLUSTER_SPLIT_BRAIN_RETRY_COUNT** sets the number of enquiring again when glocator does not respond, and it is relevant to the cluster failover processing time. The default value is 1.

47.4 glocator Configuration

Configuration File and Environment Variable

glocator can use a file or environment variable to set the configuration.

An environment variable can be set by using the name of which 'LOCATOR_' is added as a prefix to a con figuration property name. For example, setting HOST in the configuration file has the same effect as speci fying $LOCATOR_HOST.

The contents of a configuration file takes precedence over the environment variable setting values.

glocator reads the configuration file by reading DSN as the default value of [LOCATOR].

glocator has $GOLDILOCKS_DATA/conf/goldilocks.glocator.conf file as its environment file. To alter the d riving environment of glocator, the file contents should be altered, or glocator should start after setting t he environment variables.

Configuration Properties

HOST

Item	Description
Name	HOST
Description	It is an IP address of which glocator binds.
Data type	ip address (ip v4)
Default value/ range	0.0.0.0

It is an IP address of which glocator binds for UDP communication.
It uses an IP address in IP v4 form.

PORT

Item	Description
Name	PORT
Description	It is a port of which glocator waits for Recv.
Data type	INT
Default value/ range	42581 / 1024~49151

It is a port of which glocator receives a packet through UDP communication.
The port from 1024 to 49151 can be used.

WORKER_COUNT

Item	Description
Name	WORKER_COUNT
Description	It is the number of threads processing a job.
Data type	INT
Default value/ range	1 / 1~8

It is the number of threads processing packets of which glocator received from a client or an internal proc ess.

MAX_NODE_COUNT

Item	Description
Name	MAX_NODE_COUNT
Description	It is the maximum number of connectable gagent.
Data type	INT
Default value/ range	64 / 1~8192

It is the maximum number of connectable gagent.

MESSAGE_QUEUE_SIZE

Item	Description
Name	MESSAGE_QUEUE_SIZE
Description	It is the queue size in which received packets are stored before processing them.
Data type	INT
Default value/ range	33554432 / 10485760~2147483648

It is the size of queue of which glocator stores packets received from a client or or an internal process bef ore processing them.
A packet is stored in a queue as a single item in message unit.

MESSAGE_ALLOCATOR_SIZE

Item	Description
Name	MESSAGE_ALLOCATOR_SIZE
Description	It is the size of an allocator which allocates an item to be stored in a message queue.
Data type	INT
Default value/ range	33554432 / 10485760~2147483648

It is the size of an allocator which is used to allocate an item (message) to be stored in a message queue.

PACKET_ALLOCATOR_SIZE

Item	Description
Name	PACKET_ALLOCATOR_SIZE
Description	It is the size of an allocator which allocates a packet when receiving packets through UDP c ommunication.
Data type	INT
Default value/ range	33554432 / 10485760~2147483648

It is the size of an allocator for a buffer which is allocated for glocator to receive packets.

SYSTEM_LOGGER_DIR

Item	Description
Name	SYSTEM_LOGGER_DIR
Description	It is the directory path of glocator trace log file.
Data type	String
Default value/ range	<GOLDILOCKS_DATA>/trc

It is the directory path in which system trace log file of glocator is stored. <GOLDILOCKS_DATA> of the de fault value is replaced with the environment variable value of $GOLDILOCKS_DATA.

SYSTEM_UDS_DIR

Item	Description
Name	SYSTEM_UDS_DIR
Description	It is the directory path in which unix domain socket file used in glocator is stored.
Data type	String
Default value/ range	/tmp (Maximum 60 byte)

It sets the directory path in which the unix domain socket file used in glocator is stored. The maximum le ngth of the directory should be set within 60 bytes.

LOCATION_FILE_DIR

Item	Description
Name	LOCATION_FILE_DIR
Description	It is the directory path in which the location file used in glocator is stored.
Data type	String
Default value/ range	<GOLDILOCKS_DATA>/db

It sets the directory path in which the location file used in glocator is stored.

LOCATION_FILE_NAME

Item	Description
Name	LOCATION_FILE_NAME
Description	It is the name of a location file which is used in glocator.
Data type	String
Default value/ range	glocator.dat

It sets the name of a location file which is used in glocator.
The default value is glocator.dat.

LOCATION_FILE_SIZE

Item	Description
Name	LOCATION_FILE_SIZE
Description	It is the initial size of a location file.
Data type	Int
Default value/ range	1048576 / 104576~2147483648

It sets the initial size of a location file used in glocator.

LOCATION_FILE_MAX_SIZE

Item	Description
Name	LOCATION_FILE_MAX_SIZE
Description	It is the maximum size of a location file.

Item	Description
Data type	Int
Default value/ range	10485760 / 104576~2147483648

It sets the maximum size of a location file used in glocator.

MESSAGE_TIMEOUT

Item	Description
Name	MESSAGE_TIMEOUT
Description	It sets the maximum time for glocator to wait to receive packets.
Data type	Int
Default value/ range	100 / 0 ~2147483648(단위 Second)

It sets the maximum time (seconds) for glocator to wait to receive packets. Packets exceeds the maximum time without being processed, are dumped.

ALTERNATE_LOCATORS

Item	Description
Name	ALTERNATE_LOCATORS
Description	It sets an alternate locator and replication of glocator.
Data type	String
Default value/ range	empty / 0 ~ 1024 bytes

It sets **Replication** of glocator.

SYNC_RETRY_COUNT

Item	Description
Name	SYNC_RETRY_COUNT
Description	It sets the number of retry when glocator fails to synchronize with an alternate locator.
Data type	Int
Default value/ range	1 / 0 ~ 5

It sets the number of redelivery of glocator synchronization.

glocator transfers the altered data to alternate locator when the data is altered, and it transfers the data again when it could not get any response.

SYNC_RESPONSE_TIMEOUT

Item	Description
Name	SYNC_RESPONSE_TIMEOUT
Description	It sets the time waits for the response for the synchronization of glocator.
Data type	Int
Default value/ range	5 / 1 ~ 20

It sets the time waits for the response for the synchronization data transferred from glocator.

KEEPALIVE_IDLE_TIME

Item	Description
Name	KEEPALIVE_IDLE_TIME
Description	tcp keepalive idle time for checking dead client session (sec)
Data type	INT
Default value/ range	1 / 1 ~ 16383

It is the (idle) duration which the TCP packet is not sent nor is received before sending a keep alive packet. In other words, if TCP packet is not exchanged during the time set in KEEPALIVE_IDLE_TIME, then it perf orms the keep alive mechanism to detect the dead connection.

KEEPALIVE_COUNT

Item	Description
Name	KEEPALIVE_COUNT
Description	tcp keepalive check count
Data type	INT
Default value/ range	5 / 1 ~ 10

It is the number of performing keep alive mechanism.

KEEPALIVE_INTERVAL

Item	Description
Name	KEEPALIVE_INTERVAL
Description	tcp keepalive packet interval (sec)
Data type	INT
Default value/ range	5

It is the time interval to send the keep alive packet.

48.

gagent

48.1 Overview of gagent

Definition

gagent is a utility communicating with **glocator** by being executed with each member node in GOLDILO CKS cluster system.

When **CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY** server property value of the node to which gagent b elongs is set to 1 or 2, and the connection between nodes is disconnected so the cluster failover is procee ding, then gagent enquires to glocator the validity of the node to which the gagent belongs.
For more information, refer to **Cluster Failover**.

Usage

```
gagent [options]
```

Options

help

Description

It outputs the help message.

Example

```
$ gagent --help
Usage:
 gagent [options]
Options:
-s  --start                     Start gagent
-t  --stop                      Stop gagent
-u  --status                    Get gagent status
-f  --conf                      Set configure file
-o  --home                      gmaster home path
-l  --silent                    Suppress display message
```

```
-r  --no-copyright              Suppress display copy right and version
-h  --help                      Print help message
```

start

Description

It starts gagent. If gagent having the same home directory already has been started, then an error occurs.

Example

```
$ gagent --start
gagent is started.
```

stop

Description

It stops gagent which is in operation. The same home directory should be set to stop gagent in operation.

Example

```
$ gagent --stop
gagent is stopped.
```

status

Description

It outputs the status message of gagent which is in operation. The same home directory should be set to check the status of gagent in operation.

Example

```
$ gagent --status
gagent(31938) is running.
```

conf

Description

It sets the configure file when starting gagent.

Example

```
$ gagent --start --conf goldilocks.gagent.conf
gagent is started.
```

home

Description

It sets the server home directory of GOLDILOCKS when starting gagent.
When a relative path is used, it searchs for the home directory based on <GOLDILOCKS_DATA>.
<GOLDILOCKS_DATA> is replaced with the environment variable value of $GOLDILOCKS_DATA.

Example

```
$ gagent --start --home g1n1_home --conf goldilocks.gagent.conf
gagent is started.
```

In the example above, gagent is started by setting <GOLDILOCKS_DATA>/g1n1_home to home.

silent

Description

It does not output the message of gagent about the execution.

Example

```
$ gagent --start --silent
```

no-copyright

Description

It does not output the message of gagent's copyright and version about the execution.

Example

```
$ gagent --start --no-copyright
gagent is started.
```

48.2 gagent Configuration

Configuration File and Environment Variable

gagent can use a file or environment variable to set the configuration.

An environment variable can be set by using the name of which 'AGENT_' is added as a prefix to a config uration property name. For example, setting HOST in the configuration file has the same effect as specifyi ng $AGENT_HOST.

The contents of a configuration file takes precedence over the environment variable setting values.

gagent has $GOLDILOCKS_DATA/conf/goldilocks.gagent.conf file as its environment file. To alter the driv ing environment of gagent, the file contents should be altered, or gagent should start after setting the en vironment variables.

Configuration Properties

HOST

Item	Description
Name	HOST
Description	It is an IP address of which gagent binds.
Data type	ip address (ip v4)
Default value/ range	0.0.0.0

It is an IP address of which gagent binds for UDP communication.
It uses an IP address in IP v4 form.

REQUEST_PORT

Item	Description
Name	REQUEST_PORT
Description	It is a port which gagent uses for request.
Data type	INT
Default value/ range	43581 / 1024~49151

It is a port of which gagent uses to request to glocator during tcp communication.
The port from 1024 to 49151 can be used.

RESPONSE_PORT

Item	Description
Name	RESPONSE_PORT
Description	It is a port which gagent uses for response.
Data type	INT
Default value/ range	43582 / 1024~49151

It is a port of which gagent uses to receive the response from glocator during tcp communication.
The port from 1024 to 49151 can be used.

LOCATOR_HOST

Item	Description
Name	LOCATOR_HOST
Description	It is an IP address of glocator.
Data type	ip address(ip v4)
Default value/ range	0.0.0.0

It is an IP address of glocator.

LOCATOR_PORT

Item	Description
Name	LOCATOR_PORT
Description	It is a port of which glocator waits for Recv.
Data type	INT
Default value/ range	42581 / 1024~49151

It is the port of glocator of when gagent sends packets to glocator.
The port from 1024 to 49151 can be used.

SYSTEM_LOGGER_DIR

Item	Description
Name	SYSTEM_LOGGER_DIR
Description	It is the directory path of gagent trace log file.
Data type	String
Default value/ range	<GOLDILOCKS_DATA>/trc

It is the directory path in which system trace log file of gagent is stored. <GOLDILOCKS_DATA> of the default value is replaced with the environment variable value of $GOLDILOCKS_DATA.

SYSTEM_UDS_DIR

Item	Description
Name	SYSTEM_UDS_DIR
Description	It is the directory path which stores Unix Domain Socket file of gagent.
Data type	String
Default value/ range	/tmp (Maximum 50 bytes)

It is the directory path which stores Unix Domain Socket file of gagent. The default value is /tmp. The directory length can be set up to 50 bytes.

ALTERNATE_LOCATORS

Item	Description
Name	ALTERNATE_LOCATORS
Description	It sets the alternate locators.
Data Type	String
Default value/ range	empty / 0 ~ 1024

If glocator set in gagent does not respond, then it proceeds to process the operation by replacing with an alternate locator.

The following is an example of a configure file which used ALTERNATE_LOCATOR.

```
[AGENT]
PORT=43581
LOCATOR_HOST=127.0.0.1
LOCATOR_PORT=42581
ALTERNATE_LOCATORS=(LOCATOR1,LOCATOR2)
[LOCATOR1]
```

```
HOST=127.0.0.1
PORT=42582
[LOCATOR2]
HOST=127.0.0.1
PORT=42583
```

KEEPALIVE_IDLE_TIME

Item	Description
Name	KEEPALIVE_IDLE_TIME
Description	tcp keepalive idle time for checking dead client session (sec)
Data type	INT
Default value/ range	1 / 1 ~ 16383

It is the (idle) duration which the TCP packet is not sent nor is received before sending a keep alive packet. In other words, if TCP packet is not exchanged during the time set in KEEPALIVE_IDLE_TIME, then it perf orms the keep alive mechanism to detect the dead connection.

KEEPALIVE_COUNT

Item	Description
Name	KEEPALIVE_COUNT
Description	tcp keepalive check count
Data type	INT
Default value/ range	5 / 1 ~ 10

It is the number of performing keep alive mechanism.

KEEPALIVE_INTERVAL

Item	Description
Name	KEEPALIVE_INTERVAL
Description	tcp keepalive packet interval (sec)
Data type	INT
Default value/ range	5

It is the time interval to send the keep alive packet.

49.

gloctl

49.1 Overview of gloctl

Definition

gloctl is an interactive utility provided by GOLDILOCKS, which provides location to **glocator** and edits it. gloctl communicates with glocator by using User Datagram Protocol (UDP) communication protocol.

Usage

```
gloctl [options]
```

Options

help

Description

It outputs the help message.

Example

```
$ gloctl --help
Usage:
 gloctl [options]
Options:
-c  --conf         User configure file
-i  --ip           Locator host ip
-p  --port         Locator port number
-o  --import       Import control FILE
-l  --silent       Suppress the display of result message and echoing commands
-r  --no-copyright Suppress display copy right and version
-h  --help         Print help message
```

conf

Description

It sets a **Configuration** file to communicate with glocator.
If it is not set, $GOLDILOCKS_DATA/conf/goldilocks.gloctl.conf is used.

Example

```
$ gloctl --conf gloctl.conf
gLoctl>
```

- The contents of gloctl.conf file above is as follows.

```
[GLOCTL]
# Port number (1024 ~ 49151)
PORT = 44581
# Locator address
LOCATOR_HOST = 127.0.0.1
# Locator port number (1024 ~ 49151)
LOCATOR_PORT = 42581
# Time out to receive message from glocator (second)
# second ( 0 ~ 2147483647 )
MESSAGE_TIMEOUT = 10
```

ip

Description

It sets IP address of glocator when starting gloctl. IP set value takes precedence when it is used together with DSN.

Example

```
$ gloctl --ip 127.0.0.1
gLoctl>
```

The port of glocator in the example above is obtained by using DSN default LOCATOR in odbc.ini.

port

Description

It sets the port of glocator when starting gloctl. The port set value takes precedence when it is used toget her with DSN.

Example

```
$ gloctl --port 42581
gLoctl>
```

IP of glocator in the example above is obtained by using DSN default LOCATOR in odbc.ini.

import

Description

It performs gloctl commands in batch within a file, not an interactive mode.

Example

```
$ gloctl --import import.txt
HELP
QUIT
IMPORT       {'FILE'}             Upload FILE to locations
EXPORT       {'FILE'}             Download locations to FILE
ADD MEMBER   {DSN¦{member_name {'host; port; db_home;'}}} Add member location
DROP MEMBER  {member_name}        Drop member location
SET TIMEOUT  {second}             Set time for session timeout
Add member succeeded.
```

- The contents of import.txt above is as follows.

```
HELP
ADD MEMBER G1N3 'HOST=127.0.0.1;PORT=24581;DB_HOME=g1n3_home;'
```

silent

Description

It does not output the message of gloctl about the execution.

Example

```
$ gloctl --silent --import import.txt
```

no-copyright

Description

It does not output the message of gloctl's copyright and version about the execution.

Example

```
$ gloctl --no-copyright
gLoctl>
```

49.2 Interactive Command References

ADD MEMBER

Syntax

```
ADD MEMBER {DSN | member_name {'host; port; db_home;'}}
```

Description

It adds a member to glocator. DSN existing in odbc.ini, a member name, and the required location inform ation should be input.

- The port is that of glsnr.
- ADD MEMBER is used to update the information of an existing member. In this case, if the member is in the process of the failover, then the update fails.

Example

ADD MEMBER by using DSN of odbc.ini.

```
gLoctl> ADD MEMBER G1N1
Add member succeeded.
gLoctl>
```

- The contents of odbc.ini is as follows.

```
[G1N1]
HOST=127.0.0.1
PORT=20101
DB_HOME= g1n1_home
LOCATOR_DSN=LOCATOR
```

- Describe the location of a member, and add it.

```
gLoctl> ADD MEMBER G1N2 'HOST=127.0.0.1; PORT=20201; DB_HOME=g1n2_home;'
Add member succeeded.
gLoctl>
```

ADD SERVICE

Syntax

```
ADD SERVICE service_name {'member_name; ... '}
```

Description

It adds a service to glocator. The node belonging to the service should be managed in **glocator**, and it is i gnored when the same node does not exist in glocator.

Example

Add the service *s1* by using ADD SERVICE.

```
gLoctl> ADD SERVICE S1 'G1N1;G1N2;G2N1'
Add service succeeded.
gLoctl>
```

- The contents of odbc.ini is as follows.

```
[GOLDILOCKS]
HOST=127.0.0.1
PORT=22581
LOCATOR_DSN=LOCATOR
LOCATOR_SERVICE=S1
[LOCATOR]
HOST=127.0.0.1
PORT=42581
```

When describing glocator properties in **odbcinst.ini file** and using **glocator**, then gsqlnet and ot her applications can access one of a server from the service list.

DROP MEMBER

Syntax

```
DROP MEMBER member_name
```

Description

It drops a member corresponding to member_name from glocator.

If a member is in the process of the failover, then the member can not be dropped.

Example

```
gLoctl> DROP MEMBER G1N2
Drop member succeeded.
gLoctl>
```

DROP SERVICE

Syntax

```
DROP MEMBER service_name
```

Description

It drops a service corresponding to service_name from glocator.

Example

```
gLoctl> DROP SERVICE S1
Drop service succeeded.
gLoctl>
```

EXPORT

Syntax

```
EXPORT {'FILE'}
```

Description

It receives the location information from glocator and stores it in a file.

Example

Download the location information in Location.txt file.

```
gLoctl> EXPORT 'Location.txt'
Export file succeeded.
gLoctl>
```

- The contents of Location.txt above is as follows.

```
[G1N1]
PORT = 20101
HOST = 127.0.0.1
DB_HOME = g1n1_home
[G1N3]
PORT = 24581
HOST = 127.0.0.1
DB_HOME = g1n3_home
```

HELP

Syntax

```
HELP
```

Description

It displays the commands list in an interactive mode of gloctl.

Example

```
gLoctl> HELP
HELP
QUIT
IMPORT {'FILE'} Upload FILE to locations
EXPORT {'FILE'} Download locations to FILE
ADD MEMBER {DSN|{member_name {'host; port; db_home;'}}} Add member location
DROP MEMBER {member_name} Drop member location
SET TIMEOUT {second} Set time for session timeout
ADD SERVICE  {service_name {'member_name; ... '} } Add service
DROP SERVICE {service_name}       Drop service
gLoctl>
```

IMPORT

Syntax

```
IMPORT {'FILE'}
```

Description

It transfers the location to glocator by using a file in ini form.

Example

It transfers the contents in Location.txt to glocator.

```
gLoctl> IMPORT 'Location.txt'
Import file succeeded.
gLoctl>
```

- The contents of Location.txt above is as follows.

```
[G1N1]
PORT = 20101
HOST = 127.0.0.1
DB_HOME = g1n1_home
[G1N3]
PORT = 24581
HOST = 127.0.0.1
DB_HOME = g1n3_home
```

QUIT

Description

It quits gloctl.

Syntax

```
QUIT
```

SET TIMEOUT

Description

It sets TIMEOUT of glocator.

Syntax

```
SET TIMEOUT {second}
```

Example

```
gLoctl> set timeout 120
Set timeout.
gLoctl>
```

49.3 Location File

Location file uploads or downloads the location information of a node from gloctl to glocator.

Description

Location file format is similar to that of **Data Source Specification** file.

```
[node_name]
HOST = host_address
PORT = port_no
DB_HOME = db_home_path
[SERVICE]
service_name = node_name {, node_name}*
```

Location keywords of Location file are as follows.

Table 49-1 Location information

Keyword	Description
node_name	It is the name of a node.
HOST	It is the IP address of a node.
PORT	It is the port number of glsnr which was executed in a node.
DB_HOME	It sets the home directory of a node.

[SERVICE] is a fixed keyword which lists the service hints. Service hints which are registered or to be regist ered in glocator are listed below SERVICE keyword.

HOST and PORT keywords should be input, and an error occurs if they are omitted.

The following is an example of configuring a location file.

```
[G1N1]
HOST = 192.168.0.101
PORT = 20101
DB_HOME = g1n1_home
[G1N2]
HOST = 192.168.0.102
PORT = 20102
DB_HOME = g1n2_home
```

```
[G2N1]
HOST = 192.168.0.201
PORT = 20201
DB_HOME = g2n1_home
[G2N2]
HOST = 192.168.0.202
PORT = 20202
DB_HOME = g2n2_home
[SERVICE]
service_1 = G1N1,G2N1
service_2 = G1N1,G1N2
```

49.4 Configuration

The environment file of gloctl is $GOLDILOCKS_DATA/conf/goldilocks.gloctl.conf. The environment file s hould be altered or the environment file should be set with **conf** option and restart gloctl, to alter the driv ing environment for gloctl.

Stop gloctl and alter the driving environment, then restart it to alter the environment of gloctl and to appl y it, while gloctl is being executed.

PORT

Item	Description
Name	PORT
Description	It is a port which is used by gloctl.
Data type	INT
Default value/ range	44581 / 1024 ~ 49151

It sets the port of a socket which is used by gloctl.

LOCATOR_HOST

Item	Description
Name	PORT
Description	It is the host address of glocator with which gloctl communicates.
Data type	STRING
Default value/ range	127.0.0.1

It sets the host address of glocator.

LOCATOR_PORT

Item	Description
Name	PORT
Description	It is the port of glocator with which gloctl communicates.

Item	Description
Data type	INT
Default value/ range	42581 / 1024 ~ 49151

It sets the port of glocator.

MESSAGE_TIMEOUT

Item	Description
Name	MESSAGE_TIMEOUT
Description	It sets the time of which gloctl waits for the response from glocator. (second)
Data type	INT
Default value/ range	10 / 0 ~ 2147483647

It sets the time of which gloctl waits for the response after transferring a packet to glocator.

Part VII.

Replication

50.

Overview

50.1 Overview of GOLDILOCKS Replication

Database replication efficiently and consistently distributes data for data recovery when an error occurs in the original database by using the remote database, so that it enables sustained service. It is also used to build multiple database with same data.

GOLDILOCKS replication supports CYCLONE, which is a tool using Change Data Capture (CDC) method.

> Change Data Capture (CDC)
> This method captures and analyzes the redo log generated during the database operation, and performs the replication.
> Only the asynchronous mode is supported because CYCLONE is available after the changes of t he database are stored in the redo log file.

The interval may occur between the original database and the remote database of the replication becaus e CDC method supports only the asynchronous mode. When the failure of original database or equipmen t occurs in the state of which the replication to the remote database is not completed, the remote databa se is in the state of which the interval is not reflected.

LOGMIRROR can be used to complement the data not reflected due to the interval of the asynchronous mode.

> LOGMIRROR is a tool which replicates the redo log files. It sends and stores the redo logs gener ated from the original database to the remote equipment without any loss of data. Therefore, u sing LOGMIRROR can prevent loss of data.

It provides CYFILE tool storing the transaction data which was processed and committed in the database i n Comma-Separated Values (CSV) format file by using CDC method. A user can directly process the data by using the stored file or converts the data according to its purpose.

> CYFILE directly captures the redo log file by using CDC method and analyzes the transaction in r eal time, then stores the contents in CSV format file.

50.2 Characteristics

CYCLONE

The followings are the characteristics of CYCLONE.

- It is a replication tool which uses Change Data Capture (CDC) method.
- It recognizes, analyzes and applies the changes in redo log files of the original database.
- It is operated being divided into master and slave.
- It supports active-active, active-standby.
- Replication is available in table unit.
- Several options can be set to improve the performance.
- It does not affect GOLDILOCKS in case of failure because it is operated as an independent process.
- Adding or changing the H/W is not required for operation.
- It allows various replication topology
- The operation between master and slave in standalone environment supports the relationship of 1 : 1 or N : N.
- The operation between master and slave in cluster environment supports the relationship of N : 1.

LOGMIRROR

The followings are the characteristics of LOGMIRROR.

- It transfers and stores the redo logs of the original database to the remote machine without any loss.
- It interworks with CYCLONE and replicates without any loss of data.
- Only one LOGMIRROR can be operated in a database.
- It is operated being divided into master and slave.

CYFILE

The followings are features of CYFILE.

- It uses Change Data Capture (CDC) method.
- It recognizes and analyzes updates in the redo log file of the original database.
- It captures in the unit of table.
- The process is independently operated, so GOLDILOCKS is not affected even when an error occurs.

- It supports standalone environment and cluster environment.

51.

CYCLONE

51.1 CYCLONE

CYCLONE is a replication tool which uses the Change Data Capture (CDC) method.

Overview

Database records the data changes which occur during the operation in the redo log file for the recovery. CDC performs the replication by analyzing the information of the recorded redo log file.

CYCLONE is driven being divided into master and slave. Master recognizes the changes of the redo log fil e in the original database and analyzes it, then transfers it to the slave. Slave analyzes the received data a nd performs the replication by using ODBC.

Operational Features

- It is divided into master and slave and is operated as master/slave in group unit.
- Master and slave of CYCLONE uses TCP/ IP communication.
- It can be executed/ terminated in group unit.
- The replication is executed in table unit, and a group may include one or more tables.
- A single table may be operated being included in several groups.
- The original database should have the redo log files, so DATA_STORE_MODE should be operated in T DS.
- The original database should have SUPPLEMENTAL LOGGING.
  - SUPPLEMENTAL LOGGING adds an additional information to the redo log files for the replication of CYCLONE.
- The original database should be operated in ARCHIVE LOG mode.
  - GOLDILOCKS recursively reuses the redo log files. When the redo log files are reused before the r eplication is completed, the replication becomes aborted and the existing replication from the cu rrent point is canceled then restarted. Therefore, the redo log files should be operated in ARCHIV E LOG mode to be archived.
- It does not affect GOLDILOCKS even when it fails to replicate because it is operated as an independe nt process.

Operational Restrictions

- The table participated in the replication should have a PRIMARY KEY.
- Only the committed transaction is allowed to be replicated. Therefore, the content is unknown to the slave before committing the transaction.
- The primary key update is not supported.
  - When the primary key is updated, the table is given up and it is not replicated any more.
- The table participated in the replication can not use the column which has Generated Always As Identity property.
- When Data Definition Language (DDL) is performed on the table in which the replication is being operated, it could be given up.
  - For more information, refer to **The occurrence of give up and whether to allow DDL statement according to DDL category** in table1.
  - If it does not comply with the processing procedure of table DDL of CYCLONE, then even the allowable DDL is given up.
  - It does not affect the replication of other tables.
  - It is same in case of the truncated table.
- The given-up table can be reset only when it was given up with --reset TABLE_NAME
- The columns configuring the table participating in the replication should have the same structure.(data type, order)
- The database performing the replication should have the same character encoding.
- The table stored in the recycle bin is not a replication target.

Table 51-1 The occurrence of give up and whether to allow DDL statement according to DDL category

DDL category	Occurrence of give up	Whether to allow DDL statement	DDL statement
Table DDL	X	-	CREATE TABLE
	O	X	DROP TABLE
	O	X	TRUNCATE TABLE
	O	X	ALTER TABLE .. RENAME
	X	-	ALTER TABLE .. STORAGE
	X	-	ALTER TABLE .. ADD SUPPLEMENTAL LOG
	O	X	ALTER TABLE .. DROP SUPPLEMENTAL LOG
	X	-	ALTER TABLE .. READ { ONLY | WRITE }
Column DDL	O	O	ALTER TABLE .. ADD COLUMN
	O	X	ALTER TABLE .. SET UNUSED COLUMN
	O	-	ALTER TABLE .. RENAME COLUMN
	X	-	ALTER TABLE .. ALTER COLUMN .. SET DEFAULT
	X	-	ALTER TABLE .. ALTER COLUMN .. DROP DEFAULT
	O	X	ALTER TABLE .. ALTER COLUMN .. SET NOT NULL

DDL category	Occurrence of give up	Whether to allow DDL statement	DDL statement
	O	X	ALTER TABLE .. ALTER COLUMN .. DROP NOT NULL
	O	X	ALTER TABLE .. ALTER COLUMN .. ALTER IDENTITY
	O	X	ALTER TABLE .. ALTER COLUMN .. DROP IDENTITY
	O	O	ALTER TABLE .. ALTER COLUMN .. SET DATATYPE
Constraint DDL	O	X	ALTER TABLE .. ADD CONSTRAINT
	O	X	ALTER TABLE .. DROP CONSTRAINT
	O	X	ALTER TABLE .. ALTER CONSTRAINT
	X	-	ALTER TABLE .. RENAME CONSTRAINT
Index DDL	O	X	CREATE UNIQUE INDEX
	X	-	CREATE INDEX
	O	X	DROP INDEX unique_index
	X	-	DROP INDEX non_unique_index
	X	-	ALTER INDEX .. STORAGE
	X	-	ALTER INDEX .. RENAME
Superordinate object of table	O	X	DROP USER
	O	X	DROP SCHEMA
	O	X	DROP TABLESPACE

The server property **DISABLE_DDL_CDC_GIVEUP** can disable the DDL statement which causes th e replication give up to avoid user created errors. Also, the server property **DISABLE_UPDATE_P K_CDC_GIVEUP** can disable primary key update.

DDL Processing during Replication

It should comply with the following procedure when the allowable DDL is performed for the table in whic h the replication is being performed.

1. Terminate all operating CYCLONE in master and slave before executing DDL in master.
   - The process in progress does not need to be terminated.
   - e.g. cyclone --master --stop / cyclone --slave --stop
2. Execute DDL in both master and slave. (It should be the allowable DDL.)
   - For more information, refer to **The occurrence of give up and whether to allow DDL statement ac cording to DDL category**
3. Restart CYCLONE of master and slave.
   - cyclone --master --start ... / cyclone --slave --start ...

- It does not require --reset option.
- It performs the recovery from the termination of the first stage and process DDL when restarting. (Refer to trace log)

Table 51-2 DDL application procedure

Item	MASTER CYCLONE	MASTER DB	SLAVE CYCLONE	SLAVE DB
1	CYCLONE STOP	-	-	-
2	-	-	CYCLONE STOP	-
3	-	Executing DDL	-	-
4	-	-	-	Executing DDL
5	CYCLONE START	-	-	-
6	-	-	CYCLONE START	-

If the table which executed DDL in CYCLONE master is given up after DDL application procedure is normally performed, then the following two should be checked.

1. Check if DDL performed in the master DB and in the slave DB is same, and check if the table structure is same after performing the DDL. (The order of performing DDL does not matter.)
2. Check if the performed DDL is allowable.

If the table is given up due to the reasons above, the given-up table should be replicated again from the current point by using reset in table unit and restarting it. (e.g. cyclone --start --master --reset TABLE_NAME).

Datatype Compatibility When Interworking with Other DBMS

- When target database of CYCLONE slave interworks with other DBMS instead of GOLDILOCKS, the column datatype of GOLDILOCKS table, source database, should be compatible with that of other DBMS table so that it can prevent the data loss or an error.
- Currently, it can interwork with Oracle, MySQL and DB2.
- When interworking with other DBMS, then SYNC and allowable DDL features are not available.

Oracle

Table 51-3 Datatype compatible with Oracle

GOLDILOCKS	Oracle	Remarks
Boolean	X	The corresponding datatype does not exist.
NATIVE_SMALLINT	NUMBER(5)	-
NATIVE_INTEGER	NUMBER(10)	-
NATIVE_BIGINT	NUMBER(19)	-
NATIVE_REAL	BINARY_FLOAT	-
NATIVE_DOUBLE	BINARY_DOUBLE	-
FLOAT	FLOAT	-
SMALLINT	NUMBER(5,0)	-
INTEGER	NUMBER(10,0)	-
BIGINT	NUMBER(19,0)	-
INT2	NUMBER(5,0)	-
INT4	NUMBER(10,0)	-
INT8	NUMBER(19,0)	-
REAL	FLOAT(24)	-
DOUBLE	FLOAT(53)	-
DOUBLE PRECISION	FLOAT(53)	-
FLOAT4	FLOAT(24)	-
FLOAT8	FLOAT(53)	-
DECIMAL	NUMERIC	-
NUMBER	NUMBER	-
NUMERIC	NUMERIC	-
CHAR	CHAR	-
VARCHAR	VARCHAR, VARCHAR2	-
BINARY	RAW	-
VARBINARY	RAW	-
DATE	DATE	-
TIME	X	The corresponding datatype does not exist.
TIMESTAMP	TIMESTAMP	-
TIMESTAMP WITH TIMEZONE	X	It does not support ODBC driver.
INTERVAL	X	It does not support ODBC driver.
LONG VARCHAR	LONG VARCHAR	-
LONG VARBINARY	LONG RAW	-

- The following four datatypes can not be replicated as described in a table above.
  - BOOLEAN
  - TIME
  - TIMESTAMP WITH TIMEZONE

- INTERVAL

MySQL

Table 51-4 Datatype compatible with MySQL

GOLDILOCKS	MySQL	Remarks
Boolean	BOOL, BOOLEAN	The corresponding type in MySQL is a synonym of TINYINT(1).
NATIVE_SMALLINT	SMALLINT	-
NATIVE_INTEGER	INT	-
NATIVE_BIGINT	BIGINT	-
NATIVE_REAL	FLOAT	-
NATIVE_DOUBLE	DOUBLE	The corresponding type in MySQL is a synonym of DOUBLE PRECISION, and it does not support the unsigned.
FLOAT	X	The precision is supported up to 53 in MySQL, and a data error occurs if the precision is bigger.
SMALLINT	SMALLINT	-
INTEGER	INTEGER	-
BIGINT	BIGINT	-
INT2	SMALLINT	-
INT4	INTEGER	-
INT8	BIGINT	-
REAL	REAL	-
DOUBLE	DOUBLE	-
DOUBLE PRECISION	DOUBLE PRECISION	-
FLOAT4	FLOAT(24)	A data error may occur.
FLOAT8	FLOAT(53)	A data error may occur.
DECIMAL	DECIMAL	-
NUMBER	X	-
NUMERIC	NUMERIC	-
CHAR	TEXT	-
VARCHAR	TEXT	-
BINARY	VARBINARY	-
VARBINARY	VARBINARY	-
DATE	DATETIME	-
TIME	TIME(6)	The data is not lost when fractional seconds precision is set.
TIMESTAMP	DATETIME(6)	The data is not lost when fractional seconds precision is set.

GOLDILOCKS	MySQL	Remarks
TIMESTAMP WITH TIMEZONE	X	It does not support ODBC driver.
INTERVAL	X	It does not support ODBC driver.
LONG VARCHAR	TEXT	-
LONG VARBINARY	BLOB	-

- The following four datatypes can not be replicated as described in a table above.
  - FLOAT
  - NUMBER
  - TIMESTAMP WITH TIMEZONE
  - INTERVAL

When 'lower_case_table_names' is set to '0' in Mysql settings, then it is case sensitive in schem a/ table name. Therefore, use a double quotation (") in schema/ table name when specifying th e configuration file.

DB2

Table 51-5 Datatype compatible with DB2

GOLDILOCKS	DB2	비고
Boolean	X	The corresponding datatype does no t exist.
NATIVE_SMALLINT	SMALLINT	-
NATIVE_INTEGER	INT	-
NATIVE_BIGINT	BIGINT	-
NATIVE_REAL	REAL	-
NATIVE_DOUBLE	DOUBLE	-
FLOAT	DOUBLE	-
SMALLINT	DECIMAL(5)	-
INTEGER	DECIMAL(10)	-
BIGINT	DECIMAL(19)	-
INT2	DECIMAL(5)	-
INT4	DECIMAL(10)	-
INT8	DECIMAL(19)	-
REAL	DOUBLE	-
DOUBLE	DOUBLE	-
DOUBLE PRECISION	DOUBLE	-
FLOAT4	DOUBLE	-
FLOAT8	DOUBLE	-

GOLDILOCKS	DB2	비고
DECIMAL	DECIMAL	The significant digit of DB2 is 31.
NUMBER	DECIMAL	The significant digit of DB2 is 31.
NUMERIC	DECIMAL	The significant digit of DB2 is 31.
CHAR	CHAR	The maximum size of DB2 is 254 bytes.
VARCHAR	VARCHAR	-
BINARY	CHAR(n) FOR BIT DATA	The maximum size of DB2 is 254 bytes.
VARBINARY	VARCHAR(n) FOR BIT DATA	-
DATE	DATE / TIMESTAMP(0)	DATE of DB2 is stored only in YYYY/MM/DD format.
TIME	X	-
TIMESTAMP	TIMESTAMP	-
TIMESTAMP WITH TIMEZONE	X	It does not support ODBC driver.
INTERVAL	X	It does not support ODBC driver.
LONG VARCHAR	CLOB	-
LONG VARBINARY	BLOB	-

Others

The replication moments are as follows.

- At the first run, the replication starts after master and slave are performed and the initialization is terminated.
- Even if it is restarted after terminated during the replication, the replication is continuously performed from the termination point. (Recovery feature)
- It should be restarted by using --reset option when giving up the existing replication and restarting from the current point.

51.2 Requirements

Original GOLDILOCKS: It is required to perform GOLDILOCKS preparations, user registration and privilege setting all.
Remote GOLDILOCKS: It is required to perform user registration and privilege setting only.

GOLDILOCKS Requirements

The followings should be set in GOLDILOCKS before starting the replication using CYCLONE.

SUPPLEMENTAL LOGGING

SUPPLEMENTAL LOGGING stores additional information in the redo log file for the replication of CYCLONE. The database restart is required to change the settings of the database in operation, but the database restart is not required to set SUPPLEMENTAL LOGGING for a particular table.

Setting SUPPLEMENTAL LOGGING in Database

- If the GOLDILOCKS property is set as SUPPLEMENTAL LOGGING, SUPPLEMENTAL LOGGING is recorded for every table.
- GOLDILOCKS restart is required.
- The appropriate information is added or updated in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: SUPPLEMENTAL LOG_DATA_PRIMARY_KEY = YES

Setting SUPPLEMENTAL LOGGING in Specific Table Participating in Replication

```
<add table supplemental log statement> ::=
    ALTER TABLE table_name
        ADD SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS
    ;
```

ARCHIVE LOG

GOLDILOCKS reuses the redo log files recursively. When GOLDILOCKS reuses the redo log file being processed by CYCLONE, then CYCLONE does not proceed and is terminated. GOLDILOCKS should be operated in ARCHIVE LOG mode to ensure the continuous replication operation.

Changing Database in Operation to ARCHIVE LOG Mode

- Restart GOLDILOCKS.
- After database is shutdown, connect with sysdba and change it to ARCHIVE LOG mode in MOUNT p hase.

```
gSQL> \startup mount
Startup success
gSQL> alter database archivelog;
Database altered.
```

Setting ARCHIVE LOG Mode When Creating Database

- Update the property file before creating the database.
  - Property file: goldilocks.properties.conf
  - Property setting: ARCHIVELOG_MODE = 1

The path in which ARCHIVE LOG file is stored can be viewed and updated with 'ARCHIVELOG_ DIR'.

DATA_STORE_MODE

CYCLONE performs the replication by reading the redo log files of GOLDILOCKS. Therefore, GOLDILOCKS should be operated in Transactional Data Store (TDS) mode.

Changing DATA_STORE_MODE

- Restart the database.
- Add or update the corresponding information in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: DATA_STORE_MODE = 2

If the value of DATA_STORE_MODE is 1, it indicates Concurrent Data Store (CDS), and if it is 2, i t indicates Transactional Data Store (TDS).

Registering User and Setting Privileges

CYCLONE retrieves and manipulates the required information during the operation. The user operating CYCLONE and the proper privileges for the user are required.

Creating Database User

A specific user should be added to operate CYCLONE, and the corresponding user should be added for all GOLDILOCKS of which CYCLONE is operated in master, slave mode.

```
<user definition> ::=
    CREATE USER user_identifier IDENTIFIED BY password
    [ DEFAULT TABLESPACE tablespace_name ]
    [ TEMPORARY TABLESPACE tablespace_name ]
    [ INDEX TABLESPACE {tablespace_name¦NULL} ]
    [ <schema clause> ]
    ;
<schema clause> ::=
      WITH SCHEMA [schema_name]
    ¦ WITHOUT SCHEMA
```

The following is an example of creating the user cdc_user with the password cdc_password.

```
gSQL> CREATE USER cdc_user IDENTIFIED BY cdc_password;
```

Database Privileges

Granting User Access Privilege

The following is an example for granting the access privilege to cdc_user. It should be set on all GOLDILOCKS which is operated in both master/ slave mode.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO cdc_user;
```

Granting Privilege for Altering Table

The following is an example of granting the table updating privilege to cdc_user. It is set on GOLDILOCKS which is operated in slave mode.

```
gSQL> GRANT INSERT ANY TABLE, DELETE ANY TABLE, UPDATE ANY TABLE ON
DATABASE TO cdc_user;
```

Tablespace Privileges

The privileges on the data tablespace and temporary tablespace should be set. The following is an exampl e of granting the privilege for using the default tablespace to cdc_user. It is set on GOLDILOCKS which is operated in slave mode.

```
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_data_tbs TO cdc_user;
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_temp_tbs TO cdc_user;
```

Schema Privileges

The schema privileges for creating and managing meta managed in CYCLONE should be set. The followin g is an example granting the schema privilege to cdc_user. It is set on GOLDILOCKS which is operated in s lave mode.

```
gSQL> GRANT CREATE TABLE, CREATE INDEX, CREATE SEQUENCE, CREATE VIEW,
ADD CONSTRAINT ON SCHEMA cdc_user TO cdc_user;
```

51.3 Configuration

Configuration File

When performing CYCLONE, the information and options required for operating are set by using the con figuration file.

- When a specific configuration file is not set by using the --conf option, a specific file in the $GOLDILO CKS_DATA/conf directory is read. cyclone.master.conf file is read when it is operated in master mode and cyclone.slave.conf file is read when it is operated in slave mode.

Table 51-6 Configuration file options

Name	Description	Coverage
COMM_CHUNK_ COUNT	It sets the size of BUFFER for communication.	Master/ slave
DSN	It sets Data Source Name.	Master/ slave
GROUP_NAME	It sets the group name.	Master/ slave
HOST_IP	It sets the host IP address of which GOLDILOCKS operates.	Master/ slave
HOST_EXTERNAL _IP	It is used when slave GOLDILOCKS IP to which the cyclone master is to be co nnected is different from HOST_IP. (When master and slave are on wan sect ion.)	Slave
HOST_PORT	It sets the host port of which GOLDILOCKS operates.	Master/ slave
PORT	It sets the port for master/ slave communication.	Master/ slave
USER_ID	It sets the user name.	Master/ slave
USER_PW	It sets the user password.	Master/ slave
USER_ENCRYPT_ PW	It sets the encrypted password for DB user.	Master/ slave
CAPTURE_TABLE	It sets the table to be replicated.	Master
LOG_PATH	It is used when interworking with LOGMIRROR and it sets the location of th e redo log file.	Master
PROTOCOL	It sets the connection type which is to be connected to GOLDILOCKS. (DA o r TCP)	Master/ slave
READ_LOG_BLO CK_COUNT	It sets the amount of data to be read at a time when operating CAPTURE.	Master
TRANS_SORT_AR EA_SIZE	It sets the size of the BUFFER to be allocated to CAPTURE.	Master
TRANS_FILE_PAT H	It sets the location in which the temporarily generated file is to be stored wh en operating CAPTURE.	Master
SYNCHER_COUN T	It is applied when using SYNC feature, and it sets the number of SYNCHER s imultaneously performing the data insertion.	Master

Name	Description	Coverage
SYNC_ARRAY_SIZE	It is applied when using SYNC feature, and it sets the array size which insert data at a time.	Master
GIVEUP_INTERVAL	If the replication performance speed is lower than GOLDILOCKS performance, it is set to stop the replication.	Master
APPLIER_COUNT	It sets the number of APPLIER simultaneously performed during the replication.	Slave
APPLY_COMMIT_SIZE	It sets the maximum size for COMMIT during the replication.	Slave
APPLY_TABLE	It sets the table to which the replicated table is to be applied.	Slave
MASTER_IP	It sets the IP address of the equipment of which CYCLONE master is operated.	Slave
PROPAGATE_MODE	It sets whether to propagate the data applied by CYCLONE.	Slave
SEPARATE_CONFLICT_LOG	It sets whether to separate the conflict log from the trace log when storing it. (The default value is 0.) • 0: It is not separated. • 1: It is separated then stored. (The filename is cyclone_conflict_GROUPNAME.log.)	Slave
UPDATE_APPLY_MODE	It distinguishes the operation when updating. (The default value is 0.) • 0: It is updated only when the primary keys are same. • 1: It is updated only when the primary key and the value before the update are same. • 2: It is updated only when the primary keys are same. It compares the value before and after the update, then leaves a log if the values are different.	Slave
TCP_NODELAY	It sets TCP_NODELAY option of a socket. (The default value is 1.) • 0: TCP_NODELAY off • 1: TCP_NODELAY on	Master
HEARTBEAT_TIMEOUT	It sets the maximum time (second) maintaining connection if the connection is not smooth due to network disconnection or system error after replication connection.	Master/ slave
SKIP_COMMENT	It enters the text for transaction skip. If the same text is entered as commit comment in master, then it skips that transaction instead of replicating it.	Master
LOG_CAPTURE_INTERVAL_1	It sets the execution cycle of capture. If the value is not changed after executing 10 times with that value, then it is converted to the value of LOG_CAPTURE_INTERVAL_2 and performs capture. (The default value is 0.2 seconds.)	Master
LOG_CAPTURE_INTERVAL_2	It sets the execution cycle of capture. If the value is not changed after executing with the value of LOG_CAPTURE_INTERVAL_1, then it sets the execution cycle of capture. (The default value is 1 second.)	Master
CLUSTER	It specifies the connection information of a master when the master is in cluster environment. A master consists of the following three information. • ID: It is a delimiter and sets to 1 or more value.	Slave

Name	Description	Coverage
	• MASTER_IP • PORT	
ORACLE_DRIVER	It specifies the file location of the Oracle ODBC driver provided by Oracle.	Slave
MYSQL_DRIVER	It specifies the file location of the MySQL ODBC driver provided by MySQL.	Slave
MYSQL_DATABASE	It specifies the database name of MySQL to replicate.	Slave
PACKET_COMPRESSION_MODE	It sets whether to compress the data of communication of master and slave. (1: Enable, 0: Disable, Default: Enable)	Master
DB2_DRIVER	It specifies the file location of DB2 ODBC driver provided by DB2	Slave
DB2_DATABASE	It specifies the DB2 database name to replicate.	Slave

Configuration Option

COMM_CHUNK_COUNT

- It sets the number of buffers(chunk) used in data communication between master and slave of CYCLONE.
- It allocates the resource with 16M * N (the set value).
- The default value is 32, and the actual size is 16M * 32 = 512 M.
- The minimum value is 10.
- It can be set in master and slave.
    - If too small value is set so the buffer is not enough, the performance becomes poor.

- Settings applied to all groups

```
COMM_CHUNK_COUNT = 10
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    COMM_CHUNK_COUNT=20
    ....
    ....
}
```

DSN

- It sets the data source name which is required when connecting to GOLDILOCKS.
- It can be set in master and slave.
- The default value is GOLDILOCKS.

- Settings applied to all groups

```
DSN=GOLDILOCKS
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DSN=GOLDILOCKS
    ....
    ....
}
```

GROUP_NAME

- It is necessary for distinguishing the CYCLONE operation within the equipment and it is a unit of gen erating the operation process.
- It is the delimiter of when starting or terminating CYCLONE in group unit.
- After it is set, it should not be changed. If changed, it is regarded as a new group.
- It can be set in master and slave.
  - The connection between master and slave is separated not by GROUP_NAME but by PORT.
  - GROUP_NAME should be unique in the same equipment.
- The braces { } should be used.

```
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

HOST_IP

- It sets the IP address of GOLDILOCKS to be connected by CYCLONE.
- It can be set in master and slave.
  - It is valid only when PROTOCOL is set to TCP.

- Settings applied to all groups

```
HOST_IP = 127.0.0.1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_IP = 127.0.0.1
    ....
    ....
}
```

HOST_EXTERNAL_IP

- It can be set in slave.
- CYCLONE master access GOLDILOCKS of the slave's side when it is operated in sync, and it is used if s lave GOLDILOCKS IP to which the cyclone master is to be connected is different from HOST_IP.
  - It is used when IP on lan and IP on wan is different because master and slave are on wan section.
  - CYCLONE slave transfers this value to CYCLONE master, and it is used in CYCLONE master.

- Settings applied to all groups

```
HOST_EXTERNAL_IP = 192.168.0.120
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_EXTERNAL_IP = 192.168.0.120
    ....
    ....
}
```

HOST_PORT

- It sets the port of GOLDILOCKS to be connected by CYCLONE.
- It should be set together with HOST_IP.
- It can be set in master and slave.

- Settings applied to all groups

```
HOST_PORT = 22531
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_PORT = 22531
    ....
    ....
}
```

PORT

- It sets the PORT used in the communication between master and slave.
- The duplicated PORT should not be set between the groups, and the unique value should be used for each GROUP.
- It is mandatory be set and it can be set only within GROUP_NAME.

- It can be set only within a group.

```
GROUP_NAME = testGROUP
{
    PORT = 21102
    ....
    ....
}
```

USER_ID

- It sets the user ID required to access GOLDILOCKS.
- It can be set in master and slave.

- Settings applied to all groups

```
USER_ID = testID
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ID = testID
```

```
    ....
    ....
}
```

USER_PW

- It sets the user password required to access GOLDILOCKS.
- It can be set in master and slave.

- Settings applied to all groups

```
USER_PW = testPW
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_PW = testPW
    ....
    ....
}
```

USER_ENCRYPT_PW

- It sets the user password which is required for the access to GOLDILOCKS by encrypting.
- It is used instead of USER_PW.
- Encrypted user password is created by [cyclone --encrypt *user password* --key *the key to be encrypted*].
- If this value is used, then --key option should be used when executing cyclone. (In this case, the key v alue as same as that created with --encrypt should be used.

- Settings applied to all groups

```
USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
    ....
```

```
    ....
}
```

CAPTURE_TABLE

- It sets the table to be replicated.
  - It is set in *schema_name.table_name* format.
- It can set only in master.
- It can be set only within a group.
- When specifying several tables, the parentheses ( ) should be used.
- The table stored in the recycle bin can not be set to be replicated.

```
GROUP_NAME = testGROUP
{
    CAPTURE_TABLE =
    (
        testSchema1.testTable1,
        testSchema1.testTable2,
        testSchema2.testTable1
    )
}
```

LOG_PATH

- It is used when interworking with LOG MIRROR.
- It sets the path of the redo log files stored by LOGMIRROR.
  - The absolute path should be used.
  - The path should be specified by using single quote (').

- Settings applied to all groups

```
LOG_PATH = '/data/wal/'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_PATH = '/data/wal/'
    ....
    ....
}
```

PROTOCOL

- It sets the type to connect to GOLDILOCKS in operation.
- It can be set to DA or TCP.
- If PROTOCOL is set to DA, neither HOST_IP nor is HOST_PORT used when accessing to GOLDILOCKS.
  - However, in a slave, HOST_IP and HOST_PORT can be used for SYNC even when PROTOCOL is D A.
- The default value is DA.

- Settings applied to all groups

```
PROTOCOL = DA
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    PROTOCOL = DA
    ....
    ....
}
```

READ_LOG_BLOCK_COUNT

- It sets the number of the log blocks to be read at a time when capturing redo log file.
- It can be set only in master.
- The size of a log block is 512 bytes.
- The default value is 40960, and the actual read size is 20 MBytes.
  - The minimum value is 100.

- Settings applied to all groups

```
READ_LOG_BLOCK_COUNT = 1024
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    READ_LOG_BLOCK_COUNT = 1024
    ....
    ....
}
```

TRANS_SORT_AREA_SIZE

- It sets the memory space required for capturing the redo log files.
- It can be set only in master.
- The unit is MB (megabytes).
- The default value is 500 MB.
  - The minimum value is 10 MB.
- If the value is set too small, the performance becomes poor.

- Settings applied to all groups

```
TRANS_SORT_AREA_SIZE = 300
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_SORT_AREA_SIZE = 300
    ....
    ....
}
```

TRANS_FILE_PATH

- If a space bigger than TRANS_SORT_AREA_SIZE is required, the temporary file is created. It sets the p ath in which the temporary file is to be stored.
  - The absolute path should be used.
  - The path should be specified by using single quote (').
- It can be set only in master.

- Settings applied to all groups

```
TRANS_FILE_PATH = '/data/TmpTrans'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_FILE_PATH = '/data/TmpTrans'
    ....
    ....
}
```

SYNCHER_COUNT

- It is used for synchronization.
  - It sets the number of SYNCHERs participating in synchronization.
  - It is input in the number unit.
- It is set only in master.

- Settings applied to all groups

```
SYNCHER_COUNT = 8
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SYNCHER_COUNT = 8
    ....
    ....
}
```

SYNC_ARRAY_SIZE

- It is used for syncronization.
  - It sets the unit of record to be inserted at a time when performing synchronization.
  - It is input in the number unit.
- It can be set only in master.

- Settings applied to all groups

```
SYNC_ARRAY_SIZE = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SYNC_ARRAY_SIZE = 1000
    ....
    ....
}
```

GIVEUP_INTERVAL

- It gives up the replication and terminates CYCLONE if the INTERVAL between GOLDILOCKS and CYCL ONE is bigger than the set value.
  - It is input in the number of REDO LOG BLOCK unit.
- It can be set only in master.

- Settings applied to all groups

```
GIVEUP_INTERVAL = 10000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    GIVEUP_INTERVAL = 10000
    ....
    ....
}
```

APPLIER_COUNT

- It sets the number of APPLIER executing replication.
  - It indicates a parallel factor.
- The default value is 6, and 6 sessions are created.
  - The maximum value is not limited, but too high value can cause the contention between APPLIER s.
  - The set value significantly affects on performance.
  - The session is created according to the set value and the replication is simultaneously performed.
- It can be set only in slave.

- Settings applied to all groups

```
APPLIER_COUNT = 16
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    APPLIER_COUNT = 16
    ....
    ....
```

```
}
```

APPLY_COMMIT_COUNT

- It sets the number of transaction executing COMMIT when the replication is performed.
  - It executes COMMIT after performing the transaction once when replicating transactions commit ted in the original database to the remote database.
  - The set value indicates the maximum value.
- The set value affects on performance.
- It can be set only in slave.

- Settings applied to all groups

```
APPLY_COMMIT_COUNT = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    APPLY_COMMIT_COUNT = 1000
    ....
    ....
}
```

APPLY_TABLE

- It sets the table to which the replicated table is to be applied.
  - It is set in *replicating table name TO table name to which the replicated table is applied* format.
  - The table names are not necessary to be same.
- It can be set only in slave.
- It can be set only within a group.
- The parentheses ( ) should be used when specifying several tables.

```
GROUP_NAME = testGROUP
{
    APPLY_TABLE =
    (
        testSchema1.testTable1 TO testSchema1.testTable1,
        testSchema1.testTable2 TO testSchema2.testTable3,
        testSchema2.testTable3 TO testSchema2.testTable4
    )
```

```
}
```

MASTER_IP

- It sets the IP address of the device which CYCLONE master operates.
- It can be set only in slave.

- Settings applied to all groups

```
MASTER_IP = 192.168.0.100
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    MASTER_IP = 192.168.0.100
    ....
    ....
}
```

PROPAGATE_MODE

- If CYCLONE is circularly configured, it sets whether or not another CYCLONE applies the transactions of which a CYCLONE applied.
- It can be set only in slave.
  - The default value is '0' and it does not PROPAGATE.
  - If it is set to 1, it is PROPAGATEd. If it is set to 0, it is not PROPAGATEd.

- Settings applied to all groups

```
PROPAGATE_MODE = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    PROPAGATE_MODE = 1
    ....
    ....
}
```

SEPARATE_CONFLICT_LOG

- It sets whether to separate the conflict log from the trace log when storing it.
- It can be set only in slave.
  - Set it to 1 to separate it, or set it to 0 not to separate it.
    - The default value is 0.
    - If it is set to 1, then it is stored in cyclone_conflict_GROUPNAME.log file.
- It can not be set to apply to a specific group.

- Settings applied to all groups

```
SEPARATE_CONFLICT_LOG = 1
```

UPDATE_APPLY_MODE

- It is used for the update operation in slave.
  - 0: If only the primary keys are same, the update operation is performed. (The default value)
  - 1: If the primary key is same with the value of before updating, the update operation is performed.
  - 2: If only the primary keys are same, the update operation is performed. The values before and after updating are compared and if they are different, then it leaves the logs.
- If it is set to 0, the previous value is not checked and the update is performed.
- If it is set to 1 and the previous value is different, the update is failed and leaves the conflict log.
- If it is set to 2 and the previous value is different, the update is succeeded and leaves the conflict log.

- Settings applied to all groups

```
UPDATE_APPLY_MODE = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    UPDATE_APPLY_MODE = 1
    ....
    ....
}
```

For a column whose data type is long varchar or long varbinary, then only the lengths are compared for the performance reason.

TCP_NODELAY

- It is used only in master.
- It sets TCP_NODELAY option for the CDC transfer socket. (This option does not affect the sync. It is fixed to TCP_NODELAY on.)
  - 0: It offs the socket TCP_NODELAY option.
  - 1: It ons the socket TCP_NODELAY option. (Default)

- Settings applied to all groups

```
TCP_NODELAY = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TCP_NODELAY = 1
    ....
    ....
}
```

HEARTBEAT_TIMEOUT

- It can be set in master and slave.
- It sets the maximum time (second) maintaining connection if the connection is not smooth due to network disconnection or system error after replication connection between master and slave.
- The default value is 30 (seconds).
  - The minimum value is 10 (seconds).

- Settings applied to all groups

```
HEARTBEAT_TIMEOUT = 40
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HEARTBEAT_TIMEOUT = 40
    ....
    ....
}
```

SKIP_COMMENT

- It can be set in master.
- It is available when a specific transaction is not replicated.
- If the same value is input as a comment when executing transaction commit after setting the corresp onding value, then it skips that transaction instead of replicating it.

- Settings applied to all groups

```
SKIP_COMMENT = 'DO_SKIP'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SKIP_COMMENT = 'DO_SKIP'
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_1

- It can be set in master.
- It sets the execution cycle of capture operated in master. The execution cycle is set in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with that value, then it is converte d to the value of LOG_CAPTURE_INTERVAL_2 and performs capture.
- The default value is 200 (0.2 seconds), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_1 = 200
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_1 = 200
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_2

- It can be set in master.
- It sets the execution cycle of capture operated in master. The execution cycle is set in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with the value of LOG_CAPTURE_INTERVAL_1, then it is converted to the corresponding value and performs capture.
- The default value is 1000(1 second), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_2 = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_2 = 1000
    ....
    ....
}
```

CLUSTER

- It can be set in slave.
- It sets the connection information of N masters whih is operated in cluster environment. (It consists o f ID, MASTER_IP and PORT information.)
  - ID: It is an identifier of master in slave, and only number can be input. Once the value is set, it sho uld not be altered.
  - MASTER_IP: It sets IP in which master is being operated.
  - PORT:It sets port in which master is being operated.

- Cluster can be set only within a group.

```
GROUP_NAME = testGROUP
{
    CLUSTER = (ID=1, MASTER_IP=192.0.0.100, PORT=21102),
              (ID=2, MASTER_IP=192.0.0.101, PORT=21103)
    ....
    ....
}
```

ORACLE_DRIVER

- It can be set in slave.
- It specifies the location and name of ODBC driver file provided by Oracle.
  - Currently it supports Oracle 11g and 12c.

- It can be set in any group.

```
ORACLE_DRIVER = '/app/oracle/product/11.2.0/db_1/lib/libsqora.so.11.1'
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

MYSQL_DRIVER

- It can be set in slave.
- It specifies the location and name of ODBC driver file provided by MySQL.

- It can be set in any group.

```
MYSQL_DRIVER = '/usr/lib64/libmaodbc.so'
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

MYSQL_DATABASE

- It can be set in slave.
- It specifies the DATABASE name of MySQL to replicate.
- The DATABASE name of MySQL has the same meaning as the SCHEMA name.

- It can be set in any group.

```
MYSQL_DATABASE = mysql
GROUP_NAME = testGROUP
{
    ....
```

```
    ....
}
```

PACKET_COMPRESSION_MODE

- It can be set in master.
- It sets whether to compress the data which is transferred from master to slave.
  - 1: Enable (Default)
  - 0: Disable

- It can be set in a specific group.

```
GROUP_NAME = testGROUP
{
    PACKET_COMPRESSION_MODE = 1
    ....
    ....
}
```

DB2_DRIVER

- It can be set in slave.
- It specifies the location and name of ODBC driver file provided by DB2.

- It can be set in any group.

```
DB2_DRIVER = '/usr/lib64/libdb2o.so'
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

DB2_DATABASE

- It can be set in slave.
- It specifies the DATABASE name of DB2 to replicate.

- It can be set in any group.

```
DB2_DATABASE = db2
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

51.4 Operating

CYCLONE can be operated in D/A or C/S environment of GOLDILOCKS.

CONFIG file or PROTOCOL configuration of ODBC.INI should be used according to the environments as f ollows. CONFIG configuration takes precedence over ODBC.INI configuration.

Table 51-7 CONFIG, ODBC.INI

Configuration	Description
PROTOCOL=DA	It is used in D/A environment. (Default)
PROTOCOL=TCP	It is used in C/S environment.

The running contents during the operation can be viewed through trace log.

Item	File
Cyclone master	$GOLDILOCKS_DATA/trc/cyclone_master.trc
Cyclone slave	$GOLDILOCKS_DATA/trc/cyclone_slave.trc

For more information about error message and its handling method stored in trace log, refer to **Troubleshooting of CYCLONE**.

GOLDILOCKS Connection Policy

It is the policy for CYCLONE to connect to GOLDILOCKS.

There are two ways to connect to GOLDILOCKS. One is that CYCLONE connects to local GOLDILOCKS, a nd the other is that CYCLONE master remotely connects to slave side GOLDILOCKS on the slave's side wh en performing SYNC. Both use CYCLONE config value is preferentially used, then use odbc.ini. However, when performing SYNC, PROTOCOL value is ignored and it is set to TCP no matter what.

The config properties relating to GOLDILOCKS connection are DSN, PROTOCOL, HOST_IP, HOST_EXTERN AL_IP, HOST_PORT, USER_ID, USER_PW.
(USER_ENCRYPT_PW is listed as USER_PW because it replaces USER_PW.)

Correct Examples

- It is available just with USER_ID and USER_PW because it is connected as D/A.

Item	File
CONFIG	USER_ID=test, USER_PW=test
GOLDILOCKS configuration of odbc.ini	-

- The information should exist either in CONFIG or in odbc.ini. HOST_IP and HOST_PORT are ignored b ecause it is operated in D/A.

Item	File
CONFIG	HOST_IP=127.0.0.1, HOST_PORT=22581,USER_ID=test
GOLDILOCKS configuration of odbc.ini	USER_PW=test

- USER_ID is operated with the test account because it is connected with TCP and CONFIG takes prece dence.

Item	File
CONFIG	PROTOCOL=TCP, USER_ID=test, USER_PW=test
GOLDILOCKS configuration of odbc.ini	HOST_IP=127.0.0.1, HOST_PORT=22581, USER_ID=test2, USER_PW=test2

- HOST_EXTERANL_IP can not be set in slave even though it is connected as D/A.

Item	File
CONFIG	PROTOCOL=DA, HOST_EXTERNAL_IP=192.168.0.10, USER_ID=test
GOLDILOCKS configuration of odbc.ini	HOST_IP=127.0.0.1, HOST_PORT=22581,USER_PW=test

Wrong Examples

- It is connected as D/A, but USER_PW does not exist.

Item	File
CONFIG	HOST_EXTERNAL_IP=192.168.0.10
GOLDILOCKS configuration of odbc.ini	PROTOCOL=DA,USER_ID=test

- It is connected as TCP, but HOST_IP does not exist.

Item	File
CONFIG	HOST_EXTERNAL_IP=192.168.0.10, USER_ID=test
GOLDILOCKS configuration of odbc.ini	PROTOCOL=TCP, HOST_PORT=22581,USER_PW=test

Executing Option

CYCLONE should be used with the following options at run-time.

Table 51-8 Executing options

Option	Description	Remarks
--start | -s	It starts CYCLONE.	It should be used together with --master | --slave.
--stop | -t	It terminates CYCLONE.	It should be used together with --master | --slave.
--master | -m	It is performed in master mode.	It should be used together with --start | --stop.
--slave | -l	It is performed in slave mode.	It should be used together with --start | --stop.
--status | -u	It displays the operating status of CYCLONE.	It should be used together with --master | --slave.
--conf | -c	It sets the path of configuration file which is required when executing CYCLONE.	It is input in --conf CONFIG_FILE format. It should be used together with --start. If it is not explicitly set, master uses $GOLDILOCKS_DATA/cyclone.master.conf, and slave uses $GOLDILOCKS_DATA/cyclone.slave.conf.
--silent | -i	It sets not to output messages.	-
--reset | -r	It resets operational information of the replication.	It is input in --reset TABLE_NAME or --reset all format. It should be described within a single quote (') when resetting multiple tables.
--group | -g	It sets a specific group.	It is input in --group GROUP_NAME format.
--help | -h	It outputs the help message.	
--sync | -n	It performs data synchronization.	It should be used together with --master | --slave.
--encrypt | -e	It encrypts the user password with the given key.	-
--key | -k	It sets the encryption key when performing the --encrypt option. If USER_ENCRYPT_PW is used in the config, it sets the decryption key.	-
--info | -o	It displays the status of the table which is currently being replicated.	It should be used together with --master, --group.
--recovery | -v	It is used when passing the replication being performed in a standalone mode of cluster environment to another cluster member.	It is used in --recovery GROUP_NAME form, and GROUP_NAME describes CYCLONE GROUP_NAME of a slave which was previously performed.

Option	Description	Remarks
--stand-alone | -S	It is operated in a standalone mode of cluster environment. (It is operated in a cluster mode in cluster environment.)	It is valid only in master. (It is set in the configuration file in slave.)
--local | -a	It is used when synchronizing the table sharded in cluster environment. It synchronizes only the data in the corresponding cluster group.	It should be used together with --sync.

- It executes all groups in master mode by using the default environment file.

```
prompt> cyclone --master --start
```

- It terminates all groups in master mode.

```
prompt> cyclone --master --stop
```

- It executes all groups in slave mode by using the default environment file.

```
prompt> cyclone --slave --start
```

- It terminates all groups in slave mode.

```
prompt> cyclone --slave --stop
```

- It executes only the TEST_GROUP group in master mode.

```
prompt> cyclone --master --start --group TEST_GROUP
```

- It terminates only TEST_GROUP group among the groups operated in master mode.

```
prompt> cyclone --master --stop --group TEST_GROUP
```

- It sets the TEST_CONFIG file in slave mode and executes it.

```
prompt> cyclone --slave --start --conf TEST_CONFIG
```

- It encrypts GOLDILOCKS user password.

```
prompt> cyclone --encrypt test --key 1234
Cyclone Encrypted Passwd : 'YFH+bpBPNvk='
```

- USER_ENCRYPT_PW is set in the config.

```
prompt> cyclone --master --start --key 1234
```

- It deletes the existing replications of master and slave, and newly starts it.

```
prompt> cyclone --master --start --reset all
prompt> cyclone --slave --start --reset all
```

- It deletes the existing replications of only the tables T1, T2 in master, and starts it newly from the curr ent point.

```
prompt> cyclone --master --start --reset 'T1, T2'
prompt> cyclone --slave --start
```

- It displays the current replication status per each table on master side.

```
prompt> cyclone --master --info --group GROUP1
================================================
 GROUP NAME = GROUP1
================================================

```

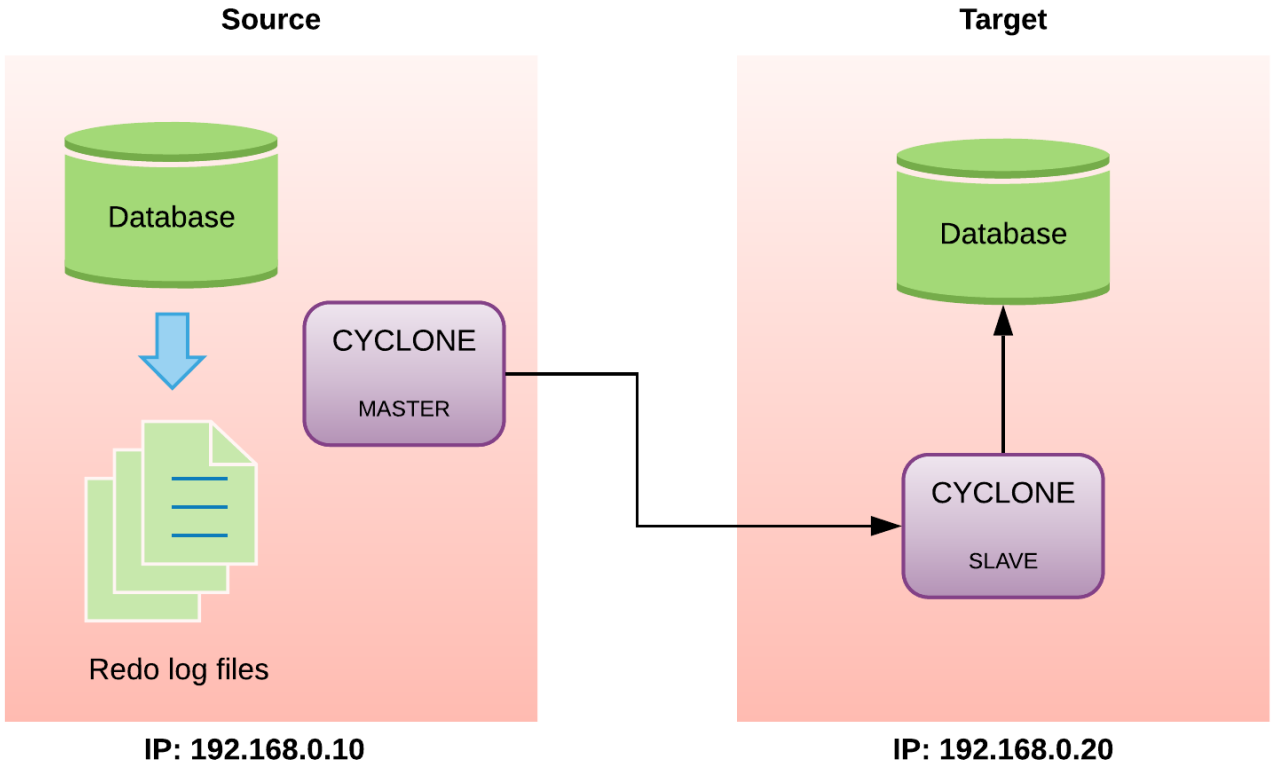
For more information about examples of adding/deleting node or group, refer to **Adding and D eleting Nodes**.

> For more information about examples of initializing replication, refer to **Initializing Replication**.

51.5 Operating Examples

The structure of operating CYCLONE is as follows.

Figure 1 The structure of operating CYCLONE



- Device structure
  - The source device which is the original data
    - GOLDILOCKS IP: 192.168.0.10
    - GOLDILOCKS port: 22581
    - The table to be replicated: T1, T2
  - The remote target device for replication
    - GOLDILOCKS IP: 192.168.0.20
    - GOLDILOCKS port: 22581

Operating Order

1. Set the original GOLDILOCKS environment.
2. Set the remote GOLDILOCKS environment.
3. Set the CYCLONE MASTER environment.
4. Set the CYCLONE SLAVE environment.

5. Execute and operate it.

Original GOLDILOCKS Configuration

Execute all described **Requirements**.
Create tables T1, T2 for testing.

```
gSQL > CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > CREATE TABLE T2( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > COMMIT;
```

Remote GOLDILOCKS Configuration

Execute **Registering User and Setting Privileges**.

CYCLONE MASTER Configuration

- CYCLONE MASTER configuration file
  - Storing path: $GOLDILOCKS_DATA/conf/cyclone.master.conf
  - It is the source device.

- It is connected with D/A of the same device, so HOST information does not exist.

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = GROUP1
{
    PORT = 21102
    CAPTURE_TABLE =
    (
        T1,
        T2
    )
}
```

CYCLONE SLAVE Configuration

- CYCLONE SLAVE configuration file
  - Storing path: $GOLDILOCKS_DATA/conf/cyclone.slave.conf
  - It is the target device.

- It is connected with D/A of the same device, but HOST_IP and HOST_PORT are used for SYNC.

```
USER_ID = cdc_user
USER_PW = cdc_password
HOST_IP = 192.168.0.20
HOST_PORT = 22581
GROUP_NAME = GROUP1
{
    PORT = 21102
    APPLY_TABLE =
    (
        T1 TO T1,
        T2 TO T2
    )
}
```

Executing and Operating

- Execute CYCLONE master.
  - It should be executed in the source device.

```
cyclone --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf
```

- Execute CYCLONE SLAVE.
  - It should be executed in the target device.

```
cyclone --slave --start --conf $GOLDILOCKS_DATA/conf/cyclone.slave.conf
```

Synchronizing Data

- Synchronizing data
  - It copies all data from the master to the slave, and it performs the replication.
  - It copies the table data in the master to be replicated to the table in the slave when performing d ata synchronization.
- It should be performed after giving --sync option to both master and slave when starting the operatio n.
  - *--sync all* is used to sync all tables, and *--sync TABLE_NAME* is used to sync a specific table.
    - The table name of master is described in TABLE_NAME. (The table name of master should be described in TABLE_NAME even when it is operated in slave.)
- HOST_IP (or HOST_EXTERNAL_IP) and HOST_PORT should be set in CONFIG or odbc.ini of slave thou gh it is D/A.

- If there is data in the slave table participating in the replication, data synchronization may n ot be properly performed due to duplicated PK. Therefore, the user should manually delete the data from the slave table before data synchronization.
- When data synchronization is performed by using the --sync option, the previous informatio n of replication is deleted. In other words, the --reset option is internally forced to be set wh en using the --sync option.
- Cyclone which is operated as master directly connects to GOLDILOCKS which is operated as slave and it performs the data synchronization.

If the target DB of the slave is Oracle or MySQL, then SYNC feature is not operable.

- Execute CYCLONE master
  - It should be executed in the source device.

```
cyclone --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf --sync all
```

- Execute CYCLONE SLAVE
  - It should be executed in the target device.

```
cyclone --slave --start --conf $GOLDILOCKS_DATA/conf/cyclone.slave.conf --sync --all
```

- The following is an example of a sync error.
  - It is recommended to delete the data from tables od slave to prevent an error.

  - Execute MASTER.

```
gSQL> CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL> INSERT INTO T1 VALUES( 1, 'HELLO' );
```

- Execute SLAVE.

```
gSQL> CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL> INSERT INTO T1 VALUES( 1, 'BYE' );
```

- Execute MASTER.

```
cyclone --master --start --sync all
```

- Execute SLAVE.

```
cyclone --slave  --start --sync all
SLAVE cyclone log
[RECEIVER] start the data synchronization.
[RECEIVER] Error Occurred.
STOP Done.
```

An error occurs and the sync does not operate due to an attempt to using the same value in the primary key.

Initializing Replication Information

- Initializing replication information
  - It restarts the replication from current point for the entire table or a specific table participating in the replication.
  - It is performed by using the --reset TABLE_NAME option or the --reset ALL option.
- Differences of between master and slave when performing the --reset option
  - Master stores table information and column information participating in the replication as meta. If RESET is performed in master by using the --Reset ALL option or the Reset Table_name option, it removes the meta in the table and configures meta again by using the information at the current point.
    - The --reset option should be performed in master to replicate again the table which is given up during the replication performing DDL.
  - The slave stores the information for recovery when restating the replication. *--reset All* or *--reset TABLE_NAME* should be described when executing slave as same as when executing master.

- Add the --reset ALL option to initialize all tables participating in the replication when perfor ming master/ slave.
  prompt> cyclone --master --start --reset ALL
  prompt> cyclone --slave --start --reset ALL

- Add the --reset TABLE_NAME option when performing master to initialize the replication in formation of a specific table.
  - The table name of when performing slave should be as same as that of when performin g master.

  prompt> cyclone --master --start --reset T1
  prompt> cyclone --slave --start

- A single quote (') should be used to initialize two or more tables.
  prompt> cyclone --master --start --reset 'T1 T2'
  prompt> cyclone --master --start --reset 'T1, T2'

Recovery

- When using recovery,
  - It is used when handing over the replication to another cluster member in the same group and pr oceeding it, due to an error of master while the replication is being processed by using a standalo ne option in cluster environment.
  - It is performed with --recovery GROUP_NAME in master, and GROUP_NAME describes the group name of slave which previously performed the replication.

The process of resetting the replication information

1. Replicate with G1N1 member (standalone) in cluster environment.
prompt> cyclone --master --start --reset ALL --group g1n1_master --stand-alone
prompt> cyclone --slave --start --reset ALL --group g1n1_slave

2. Stop operating the existing cyclone to stop the cluster member or to hand over the service.
prompt> cyclone --master --stop
prompt> cyclone --slave --stop

3. Service the new replication (G1N2) by using the information of the existing replication. (G1N 1)

```
prompt> cyclone --master --start --reset all --group g1n2_master --stand-alone --recovery g1n1_
slave
prompt> cyclone --master --start --reset all --group g1n2_slave
```

51.6 Operating CYCLONE in Cluster

Requirements

- It provides a method to replicate members in the same cluster group in cluster environment.
  - Master and slave are operated in a relationship of 1 : 1 in standalone environment.
  - Master and slave are operated in a relationship of N: 1 in cluster environment.
- Available environment
  - Master should be cluster environment. (It is automatically detected.)
  - Slave can be either standalone or cluster environment.
- The status of master connected to slave is called as a node.

1. Master connecting to a slave should be a member in the same cluster group.
   - If it is a member of another cluster group, it should be operated in another slave.
2. If master is cluster environment, CYCLONE is basically operated in cluster mode, and --stand-alone option should be used to operate CYCLONE in standalone mode.
   - --stand-alone option is used only when performing master.
   - If the cluster information of master is described by adding CLUSTER option to configuration file, then slave is operated in cluster mode.

Operating

Starting and Terminating

- The time of terminating master and slave are different each in standalone environment and in cluster environment.
  - Standalone environment
    - If master is terminated, then slave is automatically terminated.
    - If slave is terminated, master is switched to an idle state but it is not terminated.
  - Cluster environment
    - Even when master is terminated, slave is not terminated. If another master is already connected, then the replication proceeds. If any master is not connected, slave is switched to an idle state.
    - If slave is terminated, all connected masters are automatically terminated.

If master is running in cluster environment, then slave should use CLUSTER_LIST option.
If standalone option is used to run master in cluster environment, then slave should not use CLU STER_LIST option.

Node Type

In cluster environment, CYCLONE classifies master connecting to slave into a trust node and a non-trust n ode.

Table 51-9 Node in cluster environment

Node	Description	Replication
Trust node	It is a node all of whose tables participating in replication are online.	O
Non-trust node	It is a node one or more of whose tables participating in replication are offli ne.	X

Operation According to Node Status

- Switching from a non-trust node to a trust node
  - It is executed when all tables are switched to online by rebalancing the cluster member while an offline table exists.
  - The node is automatically switched from a non-trust node to a trust node, and participates in repl ication.
- Switching from a trust node to a non-trust node
  - It is executed when a table being replicated in another cluster member in operation is altered whi le the cluster member is terminated and is not operated.
  - A non-trust node is automatically altered when a cluster member joins, and it is excluded from re plication.

- The replication is maintained when one or more trust nodes exist among masters participati ng in the replication.
- A trust node is not restricted to a specific node, and any node is allowed regardless of node types.
- If all masters participating in replication becomes non-trust nodes, the replication does not proceed any more, and the replication does not start again even when they become trust n odes.
- At least one or more trust nodes are required to proceeds the replication in cluster environ ment.

Executing

Configuration File

The configuration file of master is as same as that of standalone.
The following is an example of configuring G1N1 master environment, and IP of that device is assumed a s 192.168.0.10.

- There is nothing to alter for master even in cluster environment.

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = G1N1_Master
{
    PORT = 21011
    CAPTURE_TABLE =
    (
        T1,
        T2
    )
}
```

The following is an example of configuring G1N2 master environment, and IP of that device is assumed a s 192.168.0.20.

- There is nothing to alter for master even in cluster environment.

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = G1N2_Master
{
    PORT = 21012
    CAPTURE_TABLE =
    (
        T1,
        T2
    )
}
```

CLUSTER is added to the configuration file of slave to describe the information of master.

- CLUSTER consists of ID, MASTER_IP, and PORT. (The sequence does not matter.)
  - ID is input in numbers, and it is used as an internal delimiter to distinguish master in slave. Once i t is set, it can not be altered. (If it is altered, it is recognized as a different master.)
  - MASTER_IP is IP in which CYCLONE MASTER is operated in CLUSTER member.
  - PORT is a PORT in which CYCLONE MASTER is operated in CLUSTER member.
- The information of a CLUSTER is described in parentheses, and it is distinguished by a comma (,) bet ween parentheses.

MASTER_IP, PORT which are the master information of CLUSTER are described in CLUSTER configuration.

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = G1_Slave
{
    CLUSTER = ( ID = 1, MASTER_IP = 192.168.0.10, PORT = 21011 ),
              ( ID = 2, MASTER_IP = 192.168.0.20, PORT = 21012 )
    APPLY_TABLE =
    (
        T1 TO T1,
        T2 TO T2
    )
}
```

Executing Method

Executing in Master

- It is executed in G1N1.

```
cyclone --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf --group G1N1_Master
```

- It is executed in G1N2.

```
cyclone --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf --group G1N2_Master
```

Executing in Slave

```
cyclone --slave --start --conf $GOLDILOCKS_DATA/conf/cyclone.slave.conf --group G1_Slave
```

SYNC Method

Executing Master

It is executed in G1N1. (It is master of which SYNC is to be executed, and it uses --sync option.)

```
cyclone --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf --sync all
```

Executing Slave

```
cyclone --slave --start --conf $GOLDILOCKS_DATA/conf/cyclone.slave.conf --sync all
```

--local option should be used when syncing if a sharded table participates in the replication. It is because the data of a sharded table exists only in each cluster group, and data in other cluster groups are synchronized when executing sync without --local option. However, if all tables participating in the replication in cluster environment are cloned tables, then --local option does not need to be used.

Others

--reset option can be used as same as it is used in standalone environment.

51.7 Monitoring (CYMON)

CYMON (CYclone MONitor) is a tool for monitoring CYCLONE and CLUSTONE which are CDC replication tools. It periodically updates the monitoring information of CDC replication to GOLDILOCKS operated as master.

Table 51-10 Execution files

File name	Description
cymon	Monitoring cyclone and clustone

Configuration File

The configuration file of cymon uses the configuration file used when running cyclone as master. If a specific configuration file is not set by using the --conf option, the $GOLDILOCKS_DATA/conf/cyclone.master.conf file is read as the default when cyclone is run as master.

CYMON should be run on the device which is as same as the device of which CYCLONE runs as master.

Monitoring Contents

CYMON

CYMON periodically updates the operating information of CYCLONE to the CYCLONE_MONITOR_INFO table of GOLDILOCKS. The monitoring information is as follows.

Table 51-11 CYCLONE_MONITOR_INFO

Column	Description
GROUP_NAME	It is the name of a group in which CYCLONE was executed.
TIME	It is the information of time at which the information was updated. (YYYY-MM-DD HH24:MI:SS)
MASTER_STATE	It is the state of CYCLONE which is operated as MASTER. • N/A: The state is unknown. • READY: It is waiting for connection of SLAVE • RUNNING: SLAVE is connected and the replication is running.

Column	Description
SLAVE_STATE	It is the state of CYCLONE which is operated as SLAVE. • N/A: The state is unknown. • RUNNING: The replication is running.
MASTER_PORT	It is the information of PORT on which CYCLONE operated in MASTER is waiting for slave.
SLAVE_IP	It is an IP address of the device connected with CYCLONE SLAVE.
REDO_LOG_FILESEQ	It is the sequence number of the redo log file of the running GOLDILOCKS.
REDO_LOG_BLOCKSEQ	It is the block sequence number of the redo log file of the running GOLDILOCKS.
CAPTURE_FILESEQ	It is the sequence number of the redo log file being captured by CYCLONE master.
CAPTURE_BLOCKSEQ	It is the block sequence number of the redo log file being captured by CYCLONE master.
APPLY_FILESEQ	It is the sequence number of the redo log file being processed by CYCLONE slave.
APPLY_BLOCKSEQ	It is the block sequence number of the redo log file being processed by CYCLONE slave.
CAPTURE_INTERVAL	It is the number of the remaining redo log blocks to be processed by CYCLONE master • 1 block = 512 bytes (Redo log block size = 512 bytes)
CAPTURE_INTERVAL_SIZE	It is the size of the remaining redo log files to be processed by CYCLONE master.
TOTAL_TX_COUNT	It is the number of all transactions captured by CYCLONE master.
CAPTURE_TX_COUNT	It is the number of all transactions in which the replication targets are included among the transactions captured by CYCLONE master.
CAPTURE_COMMIT_LSN	It is the commit log number of the last transaction which was captured in CYCLONE master. It is not updated if there is not a transaction to be captured any more.
APPLY_COMMIT_LSN	It is the commit log number of the transaction being processed in CYCLONE slave. It is not updated if there is not a transaction to be processed any more.

INTERVAL information is the CAPTURE information for analyzing the redo log file of CYCLONE operated as master, and it is not the information reflected by APPLIER in CYCLONE SLAVE.

Executing and Monitoring

Executing Option

Table 51-12 Executing option

Option	Description	Remarks
--conf | -c	It sets the configuration file path.	It is input in --conf CONFIG FILE format. • It should set the file as same as the configuration

Option	Description	Remarks
		file used when running CYCLONE as master.
--start | -s	It executes CYMON.	-
--stop | -t	It terminates CYMON.	-
--status | -u	It displays the operating status of CY MON.	-
--cycle | -y	It sets the update cycle of monitoring i nformation.	It is input in --cycle X format. • It should be entered in seconds.
--key | -k	It sets the decryption key when USER_ ENCRYPT_PW is used in config.	-
--trace | -r	It simultaneously records the monitori ng information of capture on the trac e log.	The trace log is recorded in $GOLDILOCKS_DATA/trc/c ymon.trc.
--silent | -i	It sets not to output the message.	-
--help | -h	It outputs the help message.	-

Examples

- Execute CYMON (Update the monitoring information of cyclone_monitor_info table.)
  - Executes CYMON to update the monitoring information per second. It continuously updates the i nformation until terminating CYMON.

```
cymon --start --cycle 1
```

- View the monitoring information

```
gSQL> \set vertical on
gSQL> select * from cyclone_monitor_info;
               GROUP_NAME # GROUP1
                     TIME # 2015-01-13 17:34:53
             MASTER_STATE # READY
              SLAVE_STATE # N/A
              MASTER_PORT # 21102
                 SLAVE_IP # null
         REDO_LOG_FILESEQ # 0
        REDO_LOG_BLOCKSEQ # 52392
          CAPTURE_FILESEQ # 0
         CAPTURE_BLOCKSEQ # 0
            APPLY_FILESEQ # 0
           APPLY_BLOCKSEQ # 0
         CAPTURE_INTERVAL # 0
```

```
   CAPTURE_INTERVAL_SIZE # 0
      CAPTURE_COMMIT_LSN # 0
        APPLY_COMMIT_LSN # 0
```

    - The information above describes that only CYCLONE MASTER is being operated and SLAVE is wa iting.

```
gSQL> \set vertical on
gSQL> select * from cyclone_monitor_info;
              GROUP_NAME # GROUP1
                    TIME # 2015-01-13 17:36:17
            MASTER_STATE # RUNNING
             SLAVE_STATE # RUNNING
             MASTER_PORT # 21102
                SLAVE_IP # 127.0.0.1
        REDO_LOG_FILESEQ # 0
       REDO_LOG_BLOCKSEQ # 52811
         CAPTURE_FILESEQ # 0
        CAPTURE_BLOCKSEQ # 52811
           APPLY_FILESEQ # 0
          APPLY_BLOCKSEQ # 52811
        CAPTURE_INTERVAL # 0
   CAPTURE_INTERVAL_SIZE # 0
      CAPTURE_COMMIT_LSN # 1023
        APPLY_COMMIT_LSN # 1023
```

    - The information above describes that CYCLONE MASTER and SLAVE are being operated.

- Execute CYMON (Store the monitoring information in trace log)
    - The monitoring information is stored not only in amonitoring table but also in a trace log since w hen CYMON is normally executed with master.
    - Generally, it is used when unable to view cyclone_monitor_info table due to an error of the mast er DB. In this case, the information of master DB such as information of REDO_LOG_FILESEQ and REDO_LOG_BLOCKSEQ are not included.
    - Trace log is in $GOLDILOCKS_DATA/trc/cymon.trc.

```
cymon --start --trace
```

- View the monitoring information (When using --trace option)
    - It stores the monitoring information since when the cyclone master is normally executed.

```

52.

CLUSTONE

52.1 CLUSTONE

CLUSTONE is a replication tool which uses the Change Data Capture (CDC) method.

Overview

Database records the data changes which occur during the operation in the redo log file for the recovery. CDC performs the replication by analyzing the information of the recorded redo log file.

CLUSTONE is driven being divided into master and slave. Master recognizes the changes of the redo log file in the original database and analyzes it, then transfers it to the slave. Slave analyzes the received data and performs the replication by using ODBC.

Differences between CLUSTONE and CYCLONE

Both CLUSTONE and CYCLONE are replication tools which use the Change Data Capture (CDC) method, but there are differences as follows.

Table 52-1 Differences between CLUSTONE and CYCLONE

Item	CLUSTONE	CYCLONE
Operating master : slave	It is operated 1 : N in standalone environment, and it is operated N : N in cluster environment.	It is operated 1 : 1 in standalone environment, and it is operated N : 1 in cluster environment.
Replication information	It creates TxData file by processing the redo log file, then extracts the replication data from this file.	It extracts the replication data by directly reading the redo log file.
Whether to support DDL	It does not support DDL replication.	It partially supports DDL replication based on the procedure.
Structure	Multi-process structure	Multi-thread structure
Interwork with other vendor DB	It is not supported.	It is supported.
SYNC feature	It is not supported.	It is supported.

- The biggest difference between CLUSTONE and CYCLONE is the number of targets to replicate.
  - If CYCLONE replicates two targets, then two masters and two slaves should be operated.
  - However, if CLUSTONE replicates two targets, then only one master and two slaves should be operated.

- CLUSTONE creates and stores TxData file by processing the redo log file, so it requires an extra space in HDD.
- If CYCLONE replicates multiple targets, then the performance of the original database may be degrad ed because redo log file I/O increases during the capture operation.
- Recommended environment for CYCLONE and CLUSTONE
  - If replicating in standalone environment or replicating between clusters, then it is recommended to use cyclone.
  - If replicating two or more cluster, then it is recommended to use clustone.

Figure 1 The structure of operating CYCLONE (master : slave = 1 : 2)

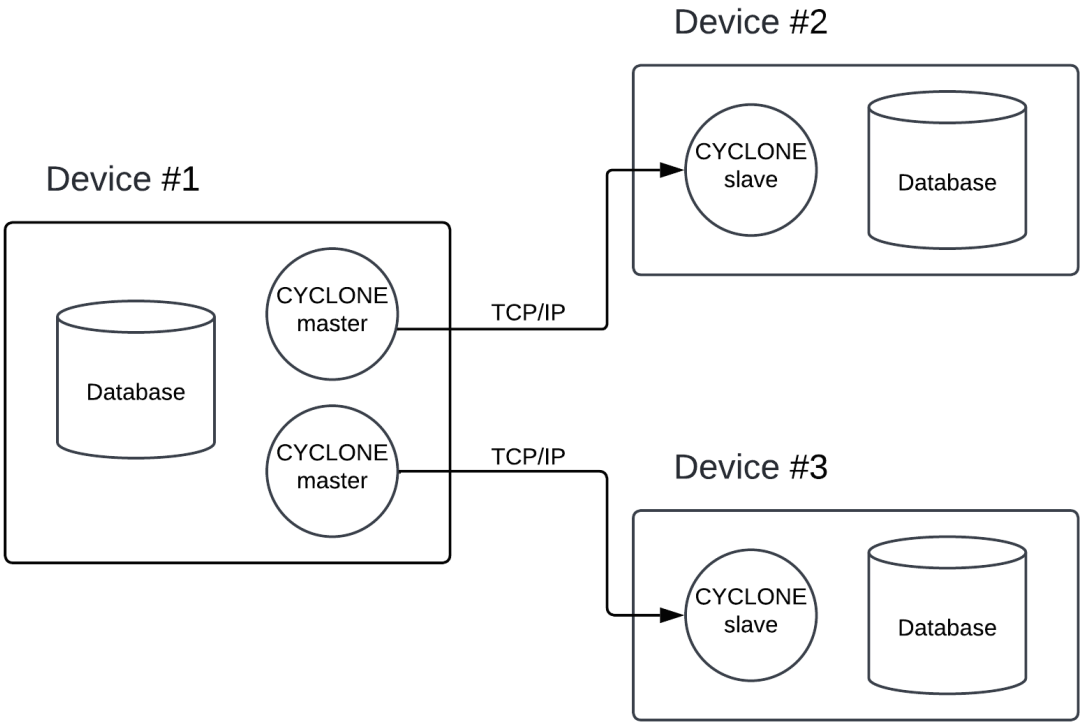

Figure 2 The structure of operating CLUSTONE (master : slave = 1 : 2)

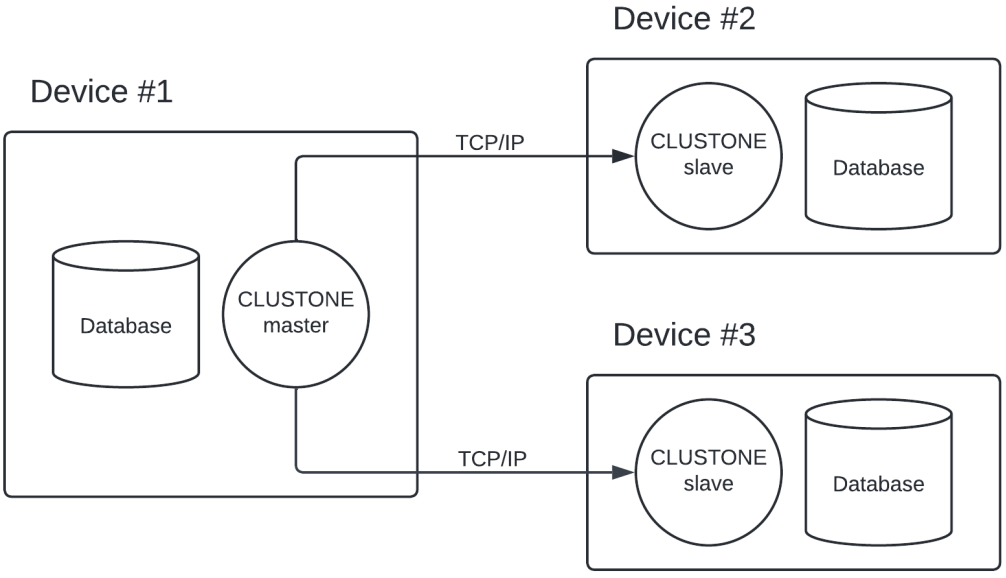

Operational Features

- It replicates GOLDILOCKS which is operated in standalone or cluster.
- It is divided into master and slave and is operated as master/slave in group unit.
  - It can replicate one master and N slaves, so it can be used to replicate clusters. (master : slave = 1 : N)
  - The master which is operated in N members of the same cluster group can be connected to one s lave. (master : slave = N : 1)
- TxDataFile is created and stored during operating clustone.
  - This file can execute/ terminate the transaction which replicates the redo log file in group unit.
  - Replicating transaction is executed in table unit, and a group may include one or more tables.
- Master and slave of clustone uses TCP/ IP communication.
- A single table may be operated being included in several groups.
- The original database should have the redo log files, so DATA_STORE_MODE should be operated in T DS.
- The original database should have SUPPLEMENTAL LOGGING.
  - SUPPLEMENTAL LOGGING adds an additional information to the redo log files for the replication of clustone.
- The original database should be operated in ARCHIVE LOG mode.
  - GOLDILOCKS recursively reuses the redo log files. When the redo log files are reused before the r eplication is completed, the replication becomes aborted and the existing replication from the cu rrent point is canceled then restarted. Therefore, the redo log files should be operated in ARCHIV E LOG mode to be archived.
- It does not affect GOLDILOCKS even when it fails to replicate because it is operated as an independe nt process.

Operational Restrictions

- The table participated in the replication should have a PRIMARY KEY.
- Only the committed transaction is allowed to be replicated. Therefore, the content is unknown to the slave before committing the transaction.
- The primary key update is not supported.
  - When the primary key is updated, the table is given up and it is not replicated any more.
- The table participated in the replication can not use the column which has Generated Always As Iden tity property.
- When Data Definition Language (DDL) is performed on the table in which the replication is being ope rated, it could be given up.
  - It is same in case of the truncated table.
- The given-up table can be reset only when it was given up with --reset TABLE_NAME
- The columns configuring the table participating in the replication should have the same structure.(da

ta type, order)
- The database performing the replication should have the same character encoding.
- The table stored in the recycle bin is not a replication target.
- When replicating one slave and N masters, the environment settings for the masters should be same.
  - e.g. capture table list

TxData File

- If clustone is operated as master, then it reads the redo log file, filters the information related to the r eplication only, reforms it to the appropriate form for the replication, then stores it as a file. This file i s called as TxData file.
  - TxData file is stored in $GOLDILOCKS_DATA/data.
  - The file name format is clustone.GROUP_NAME_FILENO.dat, and the extension is dat.
  - The file should be periodically deleted and managed. (It is manually deleted and managed so far, but the option for automatic deletion/management will be provided soon.)
- TxData file is stored together with the control file which manages the storage information.
  - The file name format of the control file is clustone.GROUP_NAME_FILENO.ctl.
  - The control file is stored together with the backup file whose extension is ctl_0 in case for losing the original data.
- The user is not allowed to modify TxData file and the control file.

52.2 Requirements

Original GOLDILOCKS: It is required to perform GOLDILOCKS preparations, user registration and privilege setting all.
Remote GOLDILOCKS: It is required to perform user registration and privilege setting only.

GOLDILOCKS Requirements

The followings should be set in GOLDILOCKS before starting the replication using CLUSTONE.

SUPPLEMENTAL LOGGING

SUPPLEMENTAL LOGGING stores additional information in the redo log file for the replication of CLUSTONE. The database restart is required to change the settings of the database in operation, but the database restart is not required to set SUPPLEMENTAL LOGGING for a particular table.

Setting SUPPLEMENTAL LOGGING in Database

- If the GOLDILOCKS property is set as SUPPLEMENTAL LOGGING, SUPPLEMENTAL LOGGING is recorded for every table.
- GOLDILOCKS restart is required.
- The appropriate information is added or updated in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: SUPPLEMENTAL LOG_DATA_PRIMARY_KEY = YES

Setting SUPPLEMENTAL LOGGING in Specific Table Participating in Replication

```
<add table supplemental log statement> ::=
    ALTER TABLE table_name
        ADD SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS
    ;
```

ARCHIVE LOG

GOLDILOCKS reuses the redo log files recursively. When GOLDILOCKS reuses the redo log file being processed by CLUSTONE, then CLUSTONE does not proceed and is terminated. GOLDILOCKS should be operated in ARCHIVE LOG mode to ensure the continuous replication operation.

Changing Database in Operation to ARCHIVE LOG Mode

- Restart GOLDILOCKS.
- After database is shutdown, connect with sysdba and change it to ARCHIVE LOG mode in MOUNT p hase.

```
gSQL> \startup mount
Startup success
gSQL> alter database archivelog;
Database altered.
```

Setting ARCHIVE LOG Mode When Creating Database

- Update the property file before creating the database.
  - Property file: goldilocks.properties.conf
  - Property setting: ARCHIVELOG_MODE = 1

The path in which ARCHIVE LOG file is stored can be viewed and updated with 'ARCHIVELOG_ DIR'.

DATA_STORE_MODE

CLUSTONE performs the replication by reading the redo log files of GOLDILOCKS. Therefore, GOLDILOCK S should be operated in Transactional Data Store (TDS) mode.

Changing DATA_STORE_MODE

- Restart the database.
- Add or update the corresponding information in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: DATA_STORE_MODE = 2

If the value of DATA_STORE_MODE is 1, it indicates Concurrent Data Store (CDS), and if it is 2, i t indicates Transactional Data Store (TDS).

Registering User and Setting Privileges

CLUSTONE retrieves and manipulates the required information during the operation. The user operating CLUSTONE and the proper privileges for the user are required.

Creating Database User

A specific user should be added to operate CLUSTONE, and the corresponding user should be added for all GOLDILOCKS of which CLUSTONE is operated in master, slave mode.

```
<user definition> ::=
    CREATE USER user_identifier IDENTIFIED BY password
    [ DEFAULT TABLESPACE tablespace_name ]
    [ TEMPORARY TABLESPACE tablespace_name ]
    [ INDEX TABLESPACE {tablespace_name¦NULL} ]
    [ <schema clause> ]
    ;
<schema clause> ::=
      WITH SCHEMA [schema_name]
    ¦ WITHOUT SCHEMA
```

The following is an example of creating the user cdc_user with the password cdc_password.

```
gSQL> CREATE USER cdc_user IDENTIFIED BY cdc_password;
```

Database Privileges

Granting User Access Privilege

The following is an example for granting the access privilege to cdc_user. It should be set on all GOLDILOCKS which is operated in both master/ slave mode.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO cdc_user;
```

Granting Privilege for Altering Table

The following is an example of granting the table updating privilege to cdc_user. It is set on GOLDILOCKS which is operated in slave mode.

```
gSQL> GRANT INSERT ANY TABLE, DELETE ANY TABLE, UPDATE ANY TABLE ON
DATABASE TO cdc_user;
```

Tablespace Privileges

The privileges on the data tablespace and temporary tablespace should be set. The following is an exampl e of granting the privilege for using the default tablespace to cdc_user. It is set on GOLDILOCKS which is operated in slave mode.

```
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_data_tbs TO cdc_user;
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_temp_tbs TO cdc_user;
```

Schema Privileges

The schema privileges for creating and managing meta managed in CLUSTONE should be set. The followi ng is an example granting the schema privilege to cdc_user. It is set on GOLDILOCKS which is operated in slave mode.

```
gSQL> GRANT CREATE TABLE, CREATE INDEX, CREATE SEQUENCE, CREATE VIEW,
ADD CONSTRAINT ON SCHEMA cdc_user TO cdc_user;
```

52.3 Configuration

Configuration File

When performing CLUSTONE, the information and options required for operating are set by using the configuration file.

- When a specific configuration file is not set by using the --conf option, a specific file in the $GOLDILOCKS_DATA/conf directory is read. clustone.master.conf file is read when it is operated in master mode and clustone.slave.conf file is read when it is operated in slave mode.

Table 52-2 Configuration file options

Name	Description	Coverage
COMM_CHUNK_COUNT	It sets the size of BUFFER for communication.	Master/ slave
DSN	It sets Data Source Name.	Master/ slave
GROUP_NAME	It sets the group name.	Master/ slave
HOST_IP	It sets the host IP address of which GOLDILOCKS operates.	Master/ slave
HOST_PORT	It sets the host port of which GOLDILOCKS operates.	Master/ slave
PORT	It sets the port for master/ slave communication.	Master/ slave
USER_ID	It sets the user name.	Master/ slave
USER_PW	It sets the user password.	Master/ slave
USER_ENCRYPT_PW	It sets the encrypted password for DB user.	Master/ slave
CAPTURE_TABLE	It sets the table to be replicated.	Master
LOG_PATH	It is used when interworking with LOGMIRROR and it sets the location of the redo log file.	Master
PROTOCOL	It sets the connection type which is to be connected to GOLDILOCKS. (DA or TCP)	Master/ slave
READ_LOG_BLOCK_COUNT	It sets the amount of data to be read at a time when operating CAPTURE.	Master
TRANS_SORT_AREA_SIZE	It sets the size of the BUFFER to be allocated to CAPTURE.	Master
TRANS_FILE_PATH	It sets the location in which the temporarily generated file is to be stored when operating CAPTURE.	Master
APPLIER_COUNT	It sets the number of APPLIER simultaneously performed during the replication.	Slave
APPLY_COMMIT_SIZE	It sets the maximum size for COMMIT during the replication.	Slave
APPLY_TABLE	It sets the table to which the replicated table is to be applied.	Slave

Name	Description	Coverage
MASTER_IP	It sets the IP address of the equipment of which CLUSTONE master is operated.	Slave
PROPAGATE_MODE	It sets whether to propagate the data applied by CLUSTONE.	Slave
UPDATE_APPLY_MODE	It distinguishes the operation when updating. (The default value is 0.) • 0: It is updated only when the primary keys are same. • 1: It is updated only when the primary key and the value before the update are same. • 2: It is updated only when the primary keys are same. It compares the value before and after the update, then leaves a log if the values are different.	Slave
TCP_NODELAY	It sets TCP_NODELAY option of a socket. (The default value is 1.) • 0: TCP_NODELAY off • 1: TCP_NODELAY on	Master
HEARTBEAT_TIMEOUT	It sets the maximum time (second) maintaining connection if the connection is not smooth due to network disconnection or system error after replication connection.	Master/ slave
SKIP_COMMENT	It enters the text for transaction skip. If the same text is entered as commit comment in master, then it skips that transaction instead of replicating it.	Master
LOG_CAPTURE_INTERVAL_1	It sets the execution cycle of capture. If the value is not changed after executing 10 times with that value, then it is converted to the value of LOG_CAPTURE_INTERVAL_2 and performs capture. (The default value is 0.2 seconds.)	Master
LOG_CAPTURE_INTERVAL_2	It sets the execution cycle of capture. If the value is not changed after executing with the value of LOG_CAPTURE_INTERVAL_1, then it sets the execution cycle of capture. (The default value is 1 second.)	Master
CLUSTER	It specifies the connection information of a master when the master is in cluster environment. A master consists of the following three information. • ID: It is a delimiter and sets to 1 or more value. • MASTER_IP • PORT	Slave
TXDATA_FILE_SIZE	It specifies the maximum size of TXDATA file which was created by processing the redo log file.	Master
TXDATA_FILE_PATH	It sets the path in which the TxData file is to be stored.	Master
PACKET_COMPRESSION_MODE	It sets whether to compress the data of communication of master and slave. (1: Enable, 0: Disable, Default: Enable)	Master
SHARED_MEMORY_NAME	It specifies the name of the shared memory which is used during running the master. The name should be unique so that the redundant names do not exist within the clustone group in the same equipment.	Master
SHARED_MEMORY_KEY	It specifies the shared memory key which is used during running the master. It should be unique so that the redundant values do not exist within the clus	Master

Name	Description	Coverage
	tone group in the same equipment.	

Configuration Option

COMM_CHUNK_COUNT

- It sets the number of buffers(chunk) used in data communication between master and slave of CLUS TONE.
- It allocates the resource with 16M * N (the set value).
- The default value is 32, and the actual size is 16M * 32 = 512 M.
- The minimum value is 10.
- It can be set in master and slave.
  - If too small value is set so the buffer is not enough, the performance becomes poor.

- Settings applied to all groups

```
COMM_CHUNK_COUNT = 10
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    COMM_CHUNK_COUNT=20
    ....
    ....
}
```

DSN

- It sets the data source name which is required when connecting to GOLDILOCKS.
- It can be set in master and slave.
- The default value is GOLDILOCKS.

- Settings applied to all groups

```
DSN=GOLDILOCKS
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DSN=GOLDILOCKS
    ....
    ....
}
```

GROUP_NAME

- It is necessary for distinguishing the CLUSTONE operation within the equipment and it is a unit of gen erating the operation process.
- It is the delimiter of when starting or terminating CLUSTONE in group unit.
- After it is set, it should not be changed. If changed, it is regarded as a new group.
- It can be set in master and slave.
  - The connection between master and slave is separated not by GROUP_NAME but by PORT.
  - GROUP_NAME should be unique in the same equipment.
- The braces { } should be used.

```
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

HOST_IP

- It sets the IP address of GOLDILOCKS to be connected by CLUSTONE.
- It can be set in master and slave.
  - It is valid only when PROTOCOL is set to TCP.

- Settings applied to all groups

```
HOST_IP = 127.0.0.1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_IP = 127.0.0.1
    ....
    ....
```

```
}
```

HOST_PORT

- It sets the port of GOLDILOCKS to be connected by CLUSTONE.
- It should be set together with HOST_IP.
- It can be set in master and slave.

- Settings applied to all groups

```
HOST_PORT = 22531
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_PORT = 22531
    ....
    ....
}
```

PORT

- It sets the PORT used in the communication between master and slave.
- The duplicated PORT should not be set between the groups, and the unique value should be used for each GROUP.
- It is mandatory be set and it can be set only within GROUP_NAME.

- It can be set only within a group.

```
GROUP_NAME = testGROUP
{
    PORT = 21102
    ....
    ....
}
```

USER_ID

- It sets the user ID required to access GOLDILOCKS.
- It can be set in master and slave.

- Settings applied to all groups

```
USER_ID = testID
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ID = testID
    ....
    ....
}
```

USER_PW

- It sets the user password required to access GOLDILOCKS.
- It can be set in master and slave.

- Settings applied to all groups

```
USER_PW = testPW
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_PW = testPW
    ....
    ....
}
```

USER_ENCRYPT_PW

- It sets the user password which is required for the access to GOLDILOCKS by encrypting.
- It is used instead of USER_PW.
- Encrypted user password is created by [clustone --encrypt *user password* --key *the key to be encrypte*

d].

- If this value is used, then --key option should be used when executing clustone. (In this case, the key value as same as that created with --encrypt should be used.

- Settings applied to all groups

```
USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
    ....
    ....
}
```

CAPTURE_TABLE

- It sets the table to be replicated.
  - It is set in *schema name.table name* format.
- It can set only in master.
- It can be set only within a group.
- When specifying several tables, the parentheses ( ) should be used.
- The table stored in the recycle bin can not be set to be replicated.

```
GROUP_NAME = testGROUP
{
    CAPTURE_TABLE =
    (
        testSchema1.testTable1,
        testSchema1.testTable2,
        testSchema2.testTable1
    )
}
```

LOG_PATH

- It is used when interworking with LOG MIRROR.
- It sets the path of the redo log files stored by LOGMIRROR.
  - The absolute path should be used.

    - The path should be specified by using single quote (').

- Settings applied to all groups

```
LOG_PATH = '/data/wal/'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_PATH = '/data/wal/'
    ....
    ....
}
```

PROTOCOL

- It sets the type to connect to GOLDILOCKS in operation.
- It can be set to DA or TCP.
- If PROTOCOL is set to DA, neither HOST_IP nor is HOST_PORT used when accessing to GOLDILOCKS.
- The default value is DA.

- Settings applied to all groups

```
PROTOCOL = DA
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    PROTOCOL = DA
    ....
    ....
}
```

READ_LOG_BLOCK_COUNT

- It sets the number of the log blocks to be read at a time when capturing redo log file.
- It can be set only in master.
- The size of a log block is 512 bytes.
- The default value is 40960, and the actual read size is 20 MBytes.

    - The minimum value is 100.

- Settings applied to all groups

```
READ_LOG_BLOCK_COUNT = 1024
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    READ_LOG_BLOCK_COUNT = 1024
    ....
    ....
}
```

TRANS_SORT_AREA_SIZE

- It sets the memory space required for capturing the redo log files.
- It can be set only in master.
- The unit is MB (megabytes).
- The default value is 500 MB.
    - The minimum value is 10 MB.
- If the value is set too small, the performance becomes poor.

- Settings applied to all groups

```
TRANS_SORT_AREA_SIZE = 300
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_SORT_AREA_SIZE = 300
    ....
    ....
}
```

TRANS_FILE_PATH

- If a space bigger than TRANS_SORT_AREA_SIZE is required, the temporary file is created. It sets the p ath in which the temporary file is to be stored.

    - The absolute path should be used.
    - The path should be specified by using single quote (').
- It can be set only in master.

- Settings applied to all groups

```
TRANS_FILE_PATH = '/data/TmpTrans'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_FILE_PATH = '/data/TmpTrans'
    ....
    ....
}
```

APPLIER_COUNT

- It sets the number of APPLIER executing replication.
    - It indicates a parallel factor.
- The default value is 6, and 6 sessions are created.
    - The maximum value is not limited, but too high value can cause the contention between APPLIER s.
    - The set value significantly affects on performance.
    - The session is created according to the set value and the replication is simultaneously performed.
- It can be set only in slave.

- Settings applied to all groups

```
APPLIER_COUNT = 16
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    APPLIER_COUNT = 16
    ....
    ....
}
```

APPLY_COMMIT_COUNT

- It sets the number of transaction executing COMMIT when the replication is performed.
  - It executes COMMIT after performing the transaction once when replicating transactions commit ted in the original database to the remote database.
  - The set value indicates the maximum value.
- The set value affects on performance.
- It can be set only in slave.

- Settings applied to all groups

```
APPLY_COMMIT_COUNT = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    APPLY_COMMIT_COUNT = 1000
    ....
    ....
}
```

APPLY_TABLE

- It sets the table to which the replicated table is to be applied.
  - It is set in *replicating table name TO table name to which the replicated table is applied* format.
  - The table names are not necessary to be same.
- It can be set only in slave.
- It can be set only within a group.
- The parentheses ( ) should be used when specifying several tables.

```
GROUP_NAME = testGROUP
{
    APPLY_TABLE =
    (
        testSchema1.testTable1 TO testSchema1.testTable1,
        testSchema1.testTable2 TO testSchema2.testTable3,
        testSchema2.testTable3 TO testSchema2.testTable4
    )
}
```

MASTER_IP

- It sets the IP address of the device which CLUSTONE master operates.
- It can be set only in slave.

- Settings applied to all groups

```
MASTER_IP = 192.168.0.100
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    MASTER_IP = 192.168.0.100
    ....
    ....
}
```

PROPAGATE_MODE

- If CLUSTONE is circularly configured, it sets whether or not another CLUSTONE applies the transactio ns of which a CLUSTONE applied.
- It can be set only in slave.
  - The default value is '0' and it does not PROPAGATE.
  - If it is set to 1, it is PROPAGATEd. If it is set to 0, it is not PROPAGATEd.

- Settings applied to all groups

```
PROPAGATE_MODE = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    PROPAGATE_MODE = 1
    ....
    ....
}
```

UPDATE_APPLY_MODE

- It is used for the update operation in slave.
  - 0: If only the primary keys are same, the update operation is performed. (The default value)
  - 1: If the primary key is same with the value of before updating, the update operation is performe d.
  - 2: If only the primary keys are same, the update operation is performed. The values before and af ter updating are compared and if they are different, then it leaves the logs.
- If it is set to 0, the previous value is not checked and the update is performed.
- If it is set to 1 and the previous value is different, the update is failed and leaves the conflict log.
- If it is set to 2 and the previous value is different, the update is succeeded and leaves the conflict log.

- Settings applied to all groups

```
UPDATE_APPLY_MODE = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    UPDATE_APPLY_MODE = 1
    ....
    ....
}
```

For a column whose data type is long varchar or long varbinary, then only the lengths are comp ared for the performance reason.

TCP_NODELAY

- It is used only in master.
- It sets TCP_NODELAY option for the CDC transfer socket. (This option does not affect the sync. It is fi xed to TCP_NODELAY on.)
  - 0: It offs the socket TCP_NODELAY option.
  - 1: It ons the socket TCP_NODELAY option. (Default)

- Settings applied to all groups

```
TCP_NODELAY = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TCP_NODELAY = 1
    ....
    ....
}
```

HEARTBEAT_TIMEOUT

- It can be set in master and slave.
- It sets the maximum time (second) maintaining connection if the connection is not smooth due to ne twork disconnection or system error after replication connection between master and slave.
- The default value is 30 (seconds).
  - The minimum value is 10 (seconds).

- Settings applied to all groups

```
HEARTBEAT_TIMEOUT = 40
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HEARTBEAT_TIMEOUT = 40
    ....
    ....
}
```

SKIP_COMMENT

- It can be set in master.
- It is available when a specific transaction is not replicated.
- If the same value is input as a comment when executing transaction commit after setting the corresp onding value, then it skips that transaction instead of replicating it.

- Settings applied to all groups

```
SKIP_COMMENT = 'DO_SKIP'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SKIP_COMMENT = 'DO_SKIP'
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_1

- It can be set in master.
- It sets the execution cycle of capture operated in master. The execution cycle is set in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with that value, then it is converte d to the value of LOG_CAPTURE_INTERVAL_2 and performs capture.
- The default value is 200 (0.2 seconds), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_1 = 200
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_1 = 200
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_2

- It can be set in master.
- It sets the execution cycle of capture operated in master. The execution cycle is set in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with the value of LOG_CAPTURE_ INTERVAL_1, then it is converted to the corresponding value and performs capture.
- The default value is 1000(1 second), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_2 = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_2 = 1000
    ....
    ....
}
```

CLUSTER

- It can be set in slave.
- It sets the connection information of N masters whih is operated in cluster environment. (It consists o f ID, MASTER_IP and PORT information.)
  - ID: It is an identifier of master in slave, and only number can be input. Once the value is set, it sho uld not be altered.
  - MASTER_IP: It sets IP in which master is being operated.
  - PORT:It sets port in which master is being operated.

- Cluster can be set only within a group.

```
GROUP_NAME = testGROUP
{
    CLUSTER = (ID=1, MASTER_IP=192.0.0.100, PORT=21102),
              (ID=2, MASTER_IP=192.0.0.101, PORT=21103)
    ....
    ....
}
```

TXDATA_FILE_SIZE

- It sets the maximum size of TxData file.
- It can be set in master.
- The unit is MB (megabytes).
- The default value is 500 MB.
  - The minimum value is 100 MB.
  - The maximum value is 4 GB (4096).

- Settings applied to all groups

```
TXDATA_FILE_SIZE = 1024
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TXDATA_FILE_SIZE = 1024
    ....
    ....
}
```

TXDATA_FILE_PATH

- It sets the path in which the TxData file is to be stored.
  - The absolute path should be used.
  - The path should be specified by using single quote (').
- It can be set only in master.

- Settings applied to all groups

```
TXDATA_FILE_PATH = '/data/TxData'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TXDATA_FILE_PATH = '/data/TxData'
    ....
    ....
}
```

PACKET_COMPRESSION_MODE

- It can be set in master.
- It sets whether to compress the data which is transferred from master to slave.
  - 1: Enable (Default)
  - 0: Disable

- It can be set in a specific group.

```
GROUP_NAME = testGROUP
{
    PACKET_COMPRESSION_MODE = 1
    ....
    ....
}
```

SHARED_MEMORY_NAME

- It specifies the name of the shared memory which is used during running CLUSTONE.
  - The name should be unique so that the redundant names do not exist within the clustone group in the same equipment.
- Maximum seven characters are allowed to input.
- It can be set only in master.

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SHARED_MEMORY_NAME = '_CLUON'
    ....
    ....
}
```

SHARED_MEMORY_KEY

- It specifies the shared memory key which is used during running CLUSTONE.
  - It should be unique so that the redundant values do not exist within the clustone group in the same equipment.
- It can be set only in master.

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    SHARED_MEMORY_KEY = 4321102
    ....
    ....
}
```

52.4 Operating

CLUSTONE can be operated in D/A or C/S environment of GOLDILOCKS.

CONFIG file or PROTOCOL configuration of ODBC.INI should be used according to the environments as f ollows. CONFIG configuration takes precedence over ODBC.INI configuration.

Table 52-3 CONFIG, ODBC.INI

Configuration	Description
PROTOCOL=DA	It is used in D/A environment. (Default)
PROTOCOL=TCP	It is used in C/S environment.

The running contents during the operation can be viewed through trace log.

Item	File
Clustone master	$GOLDILOCKS_DATA/trc/clustone_master.trc
Clustone slave	$GOLDILOCKS_DATA/trc/clustone_slave.trc

GOLDILOCKS Connection Policy

It is the policy for CLUSTONE to connect to GOLDILOCKS.

The config properties relating to GOLDILOCKS connection are DSN, PROTOCOL, HOST_IP, HOST_EXTERN AL_IP, HOST_PORT, USER_ID, USER_PW.
(USER_ENCRYPT_PW is listed as USER_PW because it replaces USER_PW.)

Correct Examples

- It is available just with USER_ID and USER_PW because it is connected as D/A.

Item	File
CONFIG	USER_ID=test, USER_PW=test
GOLDILOCKS configuration of odbc.ini	-

- The information should exist either in CONFIG or in odbc.ini. HOST_IP and HOST_PORT are ignored b ecause it is operated in D/A.

Item	File
CONFIG	HOST_IP=127.0.0.1, HOST_PORT=22581,USER_ID=test
GOLDILOCKS configuration of odbc.ini	USER_PW=test

- USER_ID is operated with the test account because it is connected with TCP and CONFIG takes prece dence.

Item	File
CONFIG	PROTOCOL=TCP, USER_ID=test, USER_PW=test
GOLDILOCKS configuration of odbc.ini	HOST_IP=127.0.0.1, HOST_PORT=22581, USER_ID=test2, USER_PW=test2

- HOST_EXTERANL_IP can not be set in slave even though it is connected as D/A.

Item	File
CONFIG	PROTOCOL=DA, HOST_EXTERNAL_IP=192.168.0.10, USER_ID=test
GOLDILOCKS configuration of odbc.ini	HOST_IP=127.0.0.1, HOST_PORT=22581,USER_PW=test

Wrong Examples

- It is connected as TCP, but HOST_IP does not exist.

Item	File
CONFIG	HOST_EXTERNAL_IP=192.168.0.10, USER_ID=test
GOLDILOCKS configuration of odbc.ini	PROTOCOL=TCP, HOST_PORT=22581,USER_PW=test

Executing Option

CLUSTONE should be used with the following options at run-time.

Table 52-4 Executing options

Option	Description	Remarks
--start | -s	It starts CLUSTONE.	It should be used together with --master | --slave.
--stop | -t	It terminates CLUSTONE.	It should be used together with --master | --slave.
--master | -m	It is performed in master mode.	It should be used together with --start | --stop.

Option	Description	Remarks
--slave | -l	It is performed in slave mode.	It should be used together with --start | --stop.
--status | -u	It displays the operating status of CLUSTONE.	It should be used together with --master | --slave .
--conf | -c	It sets the path of configuration file which is required when executing CLUSTONE.	It is input in --conf CONFIG_FILE format. It should be used together with --start. If it is not explicitly set, master uses $GOLDILOCKS_DATA/clustone.master.conf, and slave uses $GOLDILOCKS_DATA/clustone.slave.conf.
--silent | -i	It sets not to output messages.	-
--reset | -r	It resets operational information of the replication.	It is input in --reset TABLE_NAME or --reset all format. It should be described within a single quote (') when resetting multiple tables.
--group | -g	It sets a specific group.	It is input in --group GROUP_NAME format.
--help | -h	It outputs the help message.	
--encrypt | -e	It encrypts the user password with the given key.	-
--key | -k	It sets the encryption key when performing the --encrypt option. If USER_ENCRYPT_PW is used in the config, it sets the decryption key.	-
--info | -o	It displays the status of the table which is currently being replicated.	It should be used together with --master, --group.
--stand-alone | -S	It is operated in a standalone mode of cluster environment. (It is operated in a cluster mode in cluster environment.)	It is valid only in master. (It is set in the configuration file in slave.)
--dump | -d	It dumps txData file.	It should be input in --dump txdatafile format.

- It executes all groups in master mode by using the default environment file.

```
prompt> clustone --master --start
```

- It terminates all groups in master mode.

```
prompt> clustone --master --stop
```

- It executes all groups in slave mode by using the default environment file.

```
prompt> clustone --slave --start
```

- It terminates all groups in slave mode.

```
prompt> clustone --slave --stop
```

- It executes only the TEST_GROUP group in master mode.

```
prompt> clustone --master --start --group TEST_GROUP
```

- It terminates only TEST_GROUP group among the groups operated in master mode.

```
prompt> clustone --master --stop --group TEST_GROUP
```

- It sets the TEST_CONFIG file in slave mode and executes it.

```
prompt> clustone --slave --start --conf TEST_CONFIG
```

- It encrypts GOLDILOCKS user password.

```
prompt> clustone --encrypt test --key 1234
clustone Encrypted Passwd : 'YFH+bpBPNvk='
```

- USER_ENCRYPT_PW is set in the config.

```
prompt> clustone --master --start --key 1234
```

- It deletes the existing replications of master and slave, and newly starts it.

```
prompt> clustone --master --start --reset all
prompt> clustone --slave --start --reset all
```

- It deletes the existing replications of only the tables T1, T2 in master, and starts it newly from the curr ent point.

```
prompt> clustone --master --start --reset 'T1, T2'
prompt> clustone --slave --start
```

- It displays the current replication status per each table on master side.

```
prompt> clustone --master --info --group GROUP1
================================================

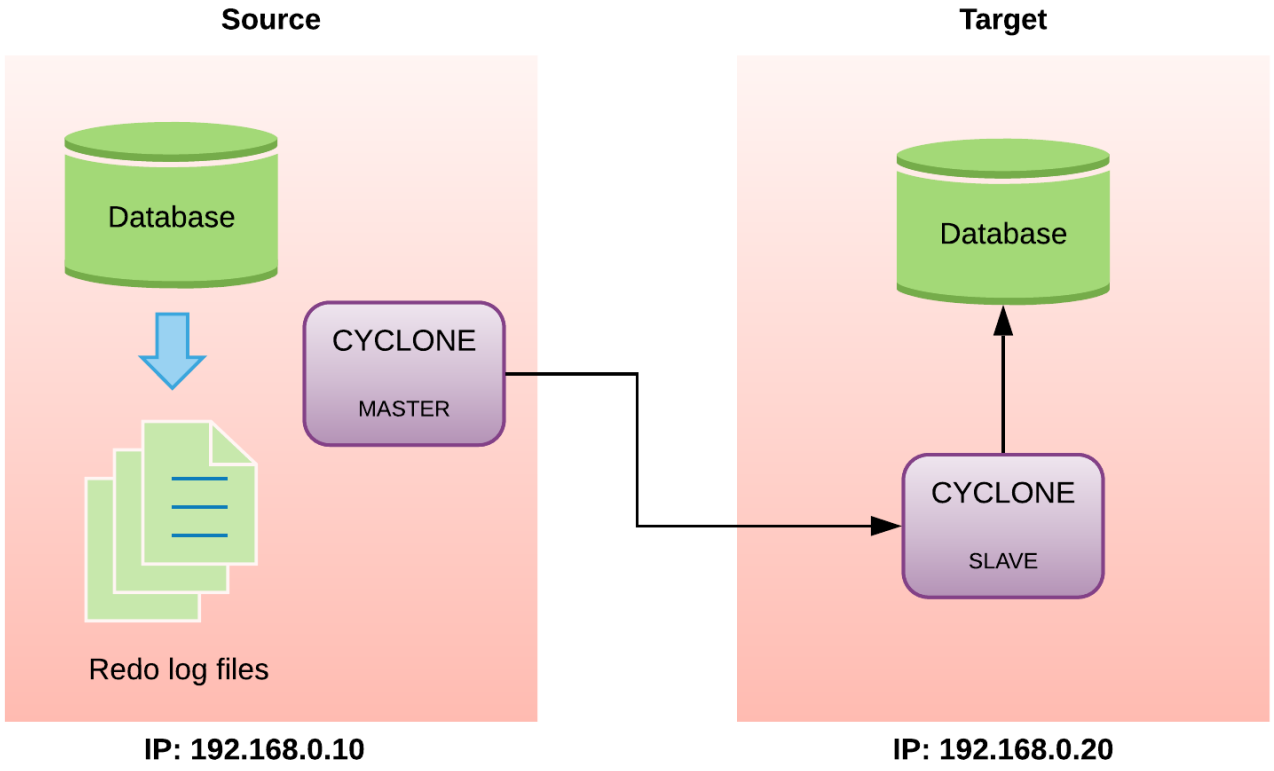
52.5 Operating Examples

The structure of operating CLUSTONE is as follows.

Figure 3 The structure of operating CLUSTONE



- Device structure
  - The source device which is the original data
    - GOLDILOCKS IP: 192.168.0.10
    - GOLDILOCKS port: 22581
    - The table to be replicated: T1, T2
  - The remote target device 1 for replication
    - GOLDILOCKS IP: 192.168.0.20
    - GOLDILOCKS port: 22581
  - The remote target device 2 for replication
    - GOLDILOCKS IP: 192.168.0.21
    - GOLDILOCKS port: 22581

Requirements

- It provides a method to replicate members in the same cluster group in cluster environment.
- Available environment
  - Master should be cluster environment. (It is automatically detected.)
  - Slave can be either standalone or cluster environment.
- The status of master connected to slave is called as a node.

Node Type

In cluster environment, CLUSTONE classifies master connecting to slave into a trust node and a non-trust node.

Table 52-5 Node in cluster environment

Node	Description	Replication
Trust node	It is a node all of whose tables participating in replication are online.	O
Non-trust node	It is a node one or more of whose tables participating in replication are offline.	X

Operation According to Node Status

- Switching from a non-trust node to a trust node
  - It is executed when all tables are switched to online by rebalancing the cluster member while an offline table exists.
  - The node is automatically switched from a non-trust node to a trust node, and participates in replication.
- Switching from a trust node to a non-trust node
  - It is executed when a table being replicated in another cluster member in operation is altered while the cluster member is terminated and is not operated.
  - A non-trust node is automatically altered when a cluster member joins, and it is excluded from replication.

- The replication is maintained when one or more trust nodes exist among masters participating in the replication.
- A trust node is not restricted to a specific node, and any node is allowed regardless of node types.
- If all masters participating in replication becomes non-trust nodes, the replication does not proceed any more, and the replication does not start again even when they become trust nodes.
- At least one or more trust nodes are required to proceeds the replication in cluster environ

> ment.

Operating Order

1. Set the original GOLDILOCKS environment.
2. Set the remote GOLDILOCKS environment.
3. Set the CLUSTONE MASTER environment.
4. Set the CLUSTONE SLAVE environment.
5. Execute and operate it.

Original GOLDILOCKS Configuration

Execute all described **Requirements**.

Create tables T1, T2 for testing.

```
gSQL > CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > CREATE TABLE T2( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > COMMIT;
```

Remote GOLDILOCKS Configuration

Execute **Registering User and Setting Privileges**.

CLUSTONE MASTER Configuration

- CLUSTONE MASTER configuration file
  - Storing path: $GOLDILOCKS_DATA/conf/clustone.master.conf
  - It is the source device.

- It is connected with D/A of the same device, so HOST information does not exist.

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = GROUP1
```

```
{
    PORT = 21102
    CAPTURE_TABLE =
    (
        T1,
        T2
    )
}
```

CLUSTONE SLAVE Configuration

- CLUSTONE SLAVE configuration file
  - Storing path: $GOLDILOCKS_DATA/conf/clustone.slave.conf
  - It is the target device.
- The following is an example of operating two slaves, so it describes two information.

- The connection information of the first slave and the information about the original cluster's member.
  - The following example describes the connection information of two masters in cluster, but actual ly it is connected by using ID 1 information only.

```
USER_ID = cdc_user
USER_PW = cdc_password
HOST_IP = 192.168.0.20
HOST_PORT = 22581
GROUP_NAME = GROUP1
{
    PORT = 21102
    CLUSTER = ( ID=1, MASTER_IP = 192.168.0.10, PORT=21102 ),
              ( ID=2, MASTER_IP = 192.168.0.10, PORT=21103 )
    APPLY_TABLE =
    (
        T1 TO T1,
        T2 TO T2
    )
}
```

- The connection information of the second slave and the information about the original cluster's mem ber.
  - The following example describes the connection information of two masters in cluster, but actual ly it is connected by using ID 1 information only.

```
USER_ID = cdc_user
USER_PW = cdc_password
HOST_IP = 192.168.0.21
HOST_PORT = 22581
GROUP_NAME = GROUP2
{
    PORT = 21102
    CLUSTER = ( ID=1, MASTER_IP = 192.168.0.10, PORT=21102 ),
              ( ID=2, MASTER_IP = 192.168.0.10, PORT=21103 )
    APPLY_TABLE =
    (
        T1 TO T1,
        T2 TO T2
    )
}
```

Executing and Operating

- Execute CLUSTONE master.
  - It should be executed in the source device.

```
clustone --master --start --conf $GOLDILOCKS_DATA/conf/clustone.master.conf
```

- Execute CLUSTONE SLAVE.
  - It should be executed in the target device.
  - It is executed in both devices.

```
clustone --slave --start --conf $GOLDILOCKS_DATA/conf/clustone.slave.conf
```

Initializing Replication Information

- Initializing replication information
  - It restarts the replication from current point for the entire table or a specific table participating in the replication.
  - It is performed by using the --reset TABLE_NAME option or the --reset ALL option.
- Differences of between master and slave when performing the --reset option
  - Master stores table information and column information participating in the replication as meta. I f RESET is performed in master by using the --Reset ALL option or the Reset Table_name option, i

t removes the meta in the table and configures meta again by using the information at the curre nt point.

- The --reset option should be performed in master to replicate again the table which is given up during the replication performing DDL.

◦ The slave stores the information for recovery when restating the replication. *--reset All* or *--reset TABLE_NAME* should be described when executing slave as same as when executing master.

- Add the --reset ALL option to initialize all tables participating in the replication when perfor ming master/ slave.

  prompt> clustone --master --start --reset ALL

  prompt> clustone --slave --start --reset ALL

- Add the --reset TABLE_NAME option when performing master to initialize the replication in formation of a specific table.
  - The table name of when performing slave should be as same as that of when performin g master.

  prompt> clustone --master --start --reset T1

  prompt> clustone --slave --start

- A single quote (') should be used to initialize two or more tables.

  prompt> clustone --master --start --reset 'T1 T2'

  prompt> clustone --master --start --reset 'T1, T2'

52.6 Monitoring (CYMON)

CYMON (CYclone MONitor) is a tool for monitoring CYCLONE and CLUSTONE which are CDC replication tools. It periodically updates the monitoring information of CDC replication to GOLDILOCKS operated in master.

Table 52-6 Execution files

File name	Description
cymon	Monitoring cyclone and clustone

Configuration File

The configuration file of cymon uses the configuration file used when running clustone as master. If a specific configuration file is not set by using the --conf option, the $GOLDILOCKS_DATA/conf/clustone.master.conf file is read as the default when clustone is run as master.

CYMON should be run on the device which is as same as the device of which CLUSTONE runs as master.

Monitoring Contents

CYMON

CYMON periodically updates the operating information of CLUSTONE to the CLUSTONE_MONITOR_INFO table of GOLDILOCKS. The monitoring information is as follows.

Table 52-7 CLUSTONE_MONITOR_INFO

Column	Description
ID	It is the identifier of the connected SLAVE.
MASTER_GROUP_NAME	It is the CLUSTONE group name which is operated as master.
SLAVE_GROUP_NAME	It is the slave group name of CLUSTONE which is connected to the master.
TIME	It is the information of time at which the information was updated. (YYYY-MM-DD HH24:MI:SS)
MASTER_STATE	It is the state of CLUSTONE which is operated as MASTER. • N/A: The state is unknown.

Column	Description
	• READY: It is waiting for connection of SLAVE • RUNNING: SLAVE is connected and the replication is running.
SLAVE_STATE	It is the state of CLUSTONE which is operated as SLAVE. • N/A: The state is unknown. • RUNNING: The replication is running.
MASTER_PORT	It is the information of PORT on which CLUSTONE operated in MASTER is waiting for slave.
SLAVE_IP	It is an IP address of the device connected with CLUSTONE SLAVE.
REDO_LOG_FILESEQ	It is the sequence number of the redo log file of the running GOLDILOCKS.
REDO_LOG_BLOCKSEQ	It is the block sequence number of the redo log file of the running GOLDILOCKS.
CAPTURE_FILESEQ	It is the sequence number of the redo log file captured by CLUSTONE master.
CAPTURE_BLOCKSEQ	It is the block sequence number of the redo log file captured by CLUSTONE master.
CAPTURE_COMMIT_LSN	It is the commit log number of the last transaction which was captured in CLUSTONE master. It is not updated if there is not a transaction to be captured any more.
CAPTURE_COMMIT_SCN	It is the commit scn number of the last transaction which was captured in CLUSTONE master. It is not updated if there is not a transaction to be captured any more.
CAPTURE_INTERVAL	It is the number of the remaining redo log blocks to be processed by CLUSTONE master • 1 block = 512 bytes (Redo log block size = 512 bytes)
CAPTURE_INTERVAL_SIZE	It is the size of the remaining redo log files to be processed by CLUSTONE master.
TOTAL_TX_COUNT	It is the number of all transactions captured by CLUSTONE master.
CAPTURE_TX_COUNT	It is the number of all transactions in which the replication targets are included among the transactions captured by CLUSTONE master.

INTERVAL information is the CAPTURE information for analyzing the redo log file of CLUSTONE operated as master, and it is not the information reflected by APPLIER in CLUSTONE SLAVE.

Executing and Monitoring

Executing Option

Table 52-8 Executing option

Option	Description	Remarks
--conf | -c	It sets the configuration file path.	It is input in --conf CONFIG FILE format. • It should set the file as same as the configuration file used when running CLUSTONE as master.
--start | -s	It executes CYMON.	-

Option	Description	Remarks
--stop | -t	It terminates CYMON.	-
--status | -u	It displays the operating status of CY MON.	-
--cycle | -y	It sets the update cycle of monitoring information.	It is input in --cycle X format. • It should be entered in seconds.
--key | -k	It sets the decryption key when USER_ ENCRYPT_PW is used in config.	-
--trace | -r	It simultaneously records the monitori ng information of capture on the trac e log.	The trace log is recorded in $GOLDILOCKS_DATA/trc/cy mon.trc.
--silent | -i	It sets not to output the message.	-
--help | -h	It outputs the help message.	-

53.

LOGMIRROR

53.1 LOGMIRROR

LOGMIRROR is a replication tool which copies the redo logs generated by GOLDILOCKS to the remote loc ation for the configuration of the same redo log file.

Overview

CYCLONE, using the CDC method, analyzes and replicates the redo log file generated during the operatio n of GOLDILOCKS. Therefore, if the operating server is failed when analysis of the redo log file is not com pleted, then unanalyzed redo log file is not replicated and the data is lost.

However, if the redo logs are sent to a remote location without data loss and the redo log file is configur ed by using LOGMIRROR, then this problem of CYCLONE can be solved.

LOGMIRROR is a tool for eliminating the data loss which is caused because CYCLONE uses the ASYNC m ethod, and it should work together with CYCLONE.

Operational Features

- It is performed being divided into master and slave. Only one LOGMIRROR per GOLDILOCKS is allowe d to be operated.
- Master and slave can use the TCP/ IP and infiniband communication.
  - Network speed significantly affects the GOLDILOCKS operation speed.
- The replication target is the redo log file of GOLDILOCKS.
- The original database should be operated in Transactional Data Store (TDS) mode.
  - LOGMIRROR has the same operational characteristics of CYCLONE because it should be operated together with CYCLONE.

Performance Degradation Factors of GOLDILOCKS When Ope rating LOGMIRROR

LOGMIRROR sends the redo logs generated by GOLDILOCKS to the remote location before storing them i n the file, then processes the next after it is normally processed. Therefore, the network speed between t he replication devices is an important factor of the performance, and it can cause performance degradati on than GOLDILOCKS operated without LOGMIRROR. However, the high speed infiniband is supported t

o minimize the performance degradation.

53.2 Requirements

GOLDILOCKS Requirement

The followings should be set in GOLDILOCKS before performing LOG MIRROR.

LOG_MIRROR_MODE

The LOG_MIRROR_MODE property is set to use LOGMIRROR in GOLDILOCKS. When it is activated, the re sources which temporarily store the redo logs generated by GOLDILOCKS before LOGMIRROR sends the m to a remote location are allocated.

- If the LOG_MIRROR_MODE property is changed, it is applied after restarting GOLDILOCKS.
- The changes are added or reflected in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: LOG_MIRROR_MODE = 1

Or, the following statement is executed in gSQL.

```
gSQL> ALTER SYSTEM SET LOG_MIRROR_MODE=1 SCOPE=FILE;
System altered.
```

LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE

LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE sets the temporary storage space used by LOGMIRROR.

- It is a temporary storage space used before storing redo log file from redo log buffer.
  - The set value is related to MAXIMUM_FLUSH_LOG_BLOCK_COUNT used when storing the redo l og file.
- The default value is 100 M.
  - The minimum value is 10 M, and the maximum value is 1 G.
  - Too small set value can affect the performance.

- If LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE property is changed, then it is applied after the G OLDILOCKS is restarted.
- The changes are added or reflected in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE = the set value

Or, the following statement is executed in gSQL.

```
gSQL> ALTER SYSTEM SET LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE = 200M SCOPE=FILE;
System altered.
```

LOG_MIRROR_TIMEOUT

When interworking with LOGMIRROR, GOLDILOCKS includes the step of waiting for the response from LOG MIRROR. Too slow response causes the degradation of GOLDILOCKS performance. LOG_MIRROR_TIMEOUT sets the response time so when there is not any response after the time is over, LOGMIRROR stops the service, but only the GOLDILOCKS continues the service.

When restarting LOGMIRROR to perform LOGMIRROR again, it is normally operated after the recovery process.

- The default value is '0'.
  - 0 refers to an infinite waiting.
  - It can be set in seconds.
- If LOG_MIRROR_TIMEOUT property is changed, it is immediately reflected.
- The changes are added or reflected in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: LOG_MIRROR_TIMEOUT = the set value

Or, the following statement is executed in gSQL.

```
gSQL> ALTER SYSTEM SET LOG_MIRROR_TIMEOUT = 20;
System altered.
```

The GOLDILOCKS requirements for operating CYCLONE should also be applied.

53.3 Configuration

Configuration File

The information and options required for the operation can be set by using the configuration file when executing LOGMIRROR.

- If a specific configuration file is not set by using the --conf option, a specific file is read at $ GOLDILOCKS_DATA / conf directory. The logmirror.master.conf file is read when operating as master and the logmirror.slave.conf file is read when operating as slave.

Table 53-1 Configuration contents

Name	Description	Coverage
PORT	It sets the port to be used for the communication between master and slave.	Master/ slave
DSN	It sets Data Source Name.	Master
HOST_IP	It sets the host IP address which is operated by GOLDILOCKS.	Master
HOST_PORT	It sets the host port which is operated by GOLDILOCKS.	Master
USER_ID	It sets the user name.	Master
USER_PW	It sets the user password.	Master
USER_ENCRYPT_PW	It sets encrypted user password.	Master/ slave
LOG_PATH	It sets the path in which the replicated redo log file is to be stored.	Slave
MASTER_IP	It sets the IP address of the device which is being operated by the log mirror master.	Slave
HEARTBEAT_TIMEOUT	It sets the maximum time (second) maintaining connection if the connection is not smooth due to network disconnection or system error after replication connection.	Master/ slave
TCP_NODELAY	It sets TCP_NODELAY option of a socket. (The default value is 1.) • 0: TCP_NODELAY off • 1: TCP_NODELAY on	Master

Configuration Options

PORT

- It sets the port used for the communication between master and slave.
- It can be set in master and slave.

```
PORT=21106
```

DSN

- It sets the data source name required for the access to GOLDILOCKS.
- It can be set in master.

```
DSN = GOLDILOCKS
```

HOST_IP

- It sets the IP address of GOLDILOCKS in which LOGMIRROR is to be operated.
- It should be set together with HOST_PORT.
- It can be set in master.

```
HOST_IP = 127.0.0.1
```

HOST_PORT

- It sets the port of GOLDILOCKS on which LOGMIRROR is to be operated.
- It should be set together with HOST_IP.
- It can be set in master.

```
HOST_PORT = 22531
```

USER_ID

- It sets the user ID required for the access to GOLDILOCKS.
- It can be set in master.

```
USER_ID = testID
```

USER_PW

- It sets the user password required for the access to GOLDILOCKS.
- It can be set in master.

```
USER_PW = testPW
```

USER_ENCRYPT_PW

- It sets the user password which is required for the access to GOLDILOCKS by encrypting.
- It is used instead of USER_PW.
- Encrypted user password is created by [logmirror --encrypt *user password* --key *the key to be encrypted*].
- If this value is used, then --key option should be used when executing logmirror. (In this case, the key value as same as that created with --encrypt should be used.

```
USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
```

LOG_PATH

- It sets the path in which the replicated redo log file is to be stored.
  - The set path should be an absolute path.
  - The path is set by using a single quote (') .
- It can be set in slave.

```
LOG_PATH = '/data/wal'
```

MASTER_IP

- It sets the IP address of the device of which LOGMIRROR master is operating.
- It can be set in slave.

```
MASTER_IP = 192.168.0.100
```

HEARTBEAT_TIMEOUT

- It can be set in master and slave.
- It sets the maximum time (second) maintaining connection if the connection is not smooth due to network disconnection or system error after replication connection between master and slave.
- The default value is 30 (seconds).
  - The minimum value is 10 (seconds).

```
HEARTBEAT_TIMEOUT = 40
```

TCP_NODELAY

- It is used only in master.
- It sets TCP_NODELAY option for the LogMirror transfer socket.
  - 0: It offs the socket TCP_NODELAY option.
  - 1: It ons the socket TCP_NODELAY option. (Default)

```
TCP_NODELAY = 1
```

53.4 Operating

The executing environment of master/ slave of LOGMIRROR is as follows.

Table 53-2 Executing environment

Item	Whether to operate GOLDILOCKS	Description
Master	O	When operating as master, LOGMIRROR should be operated at the device in which GOLDILOCKS is operated.
Slave	X	When operating as slave, GOLDILOCKS is not required to be operated and the storage space in the disk is required to store the redo log file.

The operating contents during the execution can be viewed through a trace log.

Item	File
Master	$GOLDILOCKS_DATA/trc/LogMirror_master.trc
Slave	$GOLDILOCKS_DATA/trc/LogMirror_slave.trc

For more information about the error messages and handlings stored in the trace log, refer to **Troubleshooting of LOGMIRROR**.

Operating LOGMIRROR

LOGMIRROR can normally replicates the redo log file only when the following procedures should be completed even after the GOLDILOCKS configuration, initializing and operating master/ slave.

SWITCH of the redo log file should occur to start the replication. LOGMIRROR starts the normal operation after generating the new log file. Therefore, the following step should be performed.

```
gSQL> ALTER SYSTEM SWITCH LOGFILE;
System altered.
```

The redo log file replicated by LOGMIRROR is continuously stored, and it is not automatically deleted. Therefore, the file management such as deleting or moving is regularly required according to the environment of the operating device.

Executing Option

Table 53-3 Execution options

Option	Description	Remarks
--start | -s	It executes LOGMIRROR.	It should be used together with --master | --slave.
--stop | -t	It terminates LOGMIRROR.	It should be used together with --master | --slave.
--master | -m	It is performed in master mode.	It should be used together with --start | --stop.
--slave | -l	It is performed in slave mode.	It should be used together with --start | --stop.
--conf | -c	It sets the configuration file path.	It is input in --conf CONFIG_FILE format.
--infiniband | -f	It uses infiniband network environment.	It is not input when using TCP/IP environment.
--silent | -i	It sets not to output the message.	-
--help | -h	It sets to output the help message.	-

- Execute it in master mode by using the default configuration file.

```
prompt> logmirror --master --start
```

- Terminate the LOGMIRROR which is being operated in master mode.

```
prompt> logmirror --master --stop
```

- Execute it in slave mode by using the default configuration file.

```
prompt> logmirror --slave --start
```

- Terminate the LOGMIRROR which is being operated in slave mode.

```
prompt> logmirror --slave --stop
```

- Execute it in master mode by using TEST_CONFIG file and infiniband network.

```
prompt> logmirror --master --start --conf TEST_CONFIG --infiniband
```

- Execute it in slave mode by using TEST_CONFIG file and infiniband network.

```
prompt> logmirror --slave --start --conf TEST_CONFIG --infiniband
```

For examples of initializing LOGMIRROR, refer to **LOGMIRROR**.

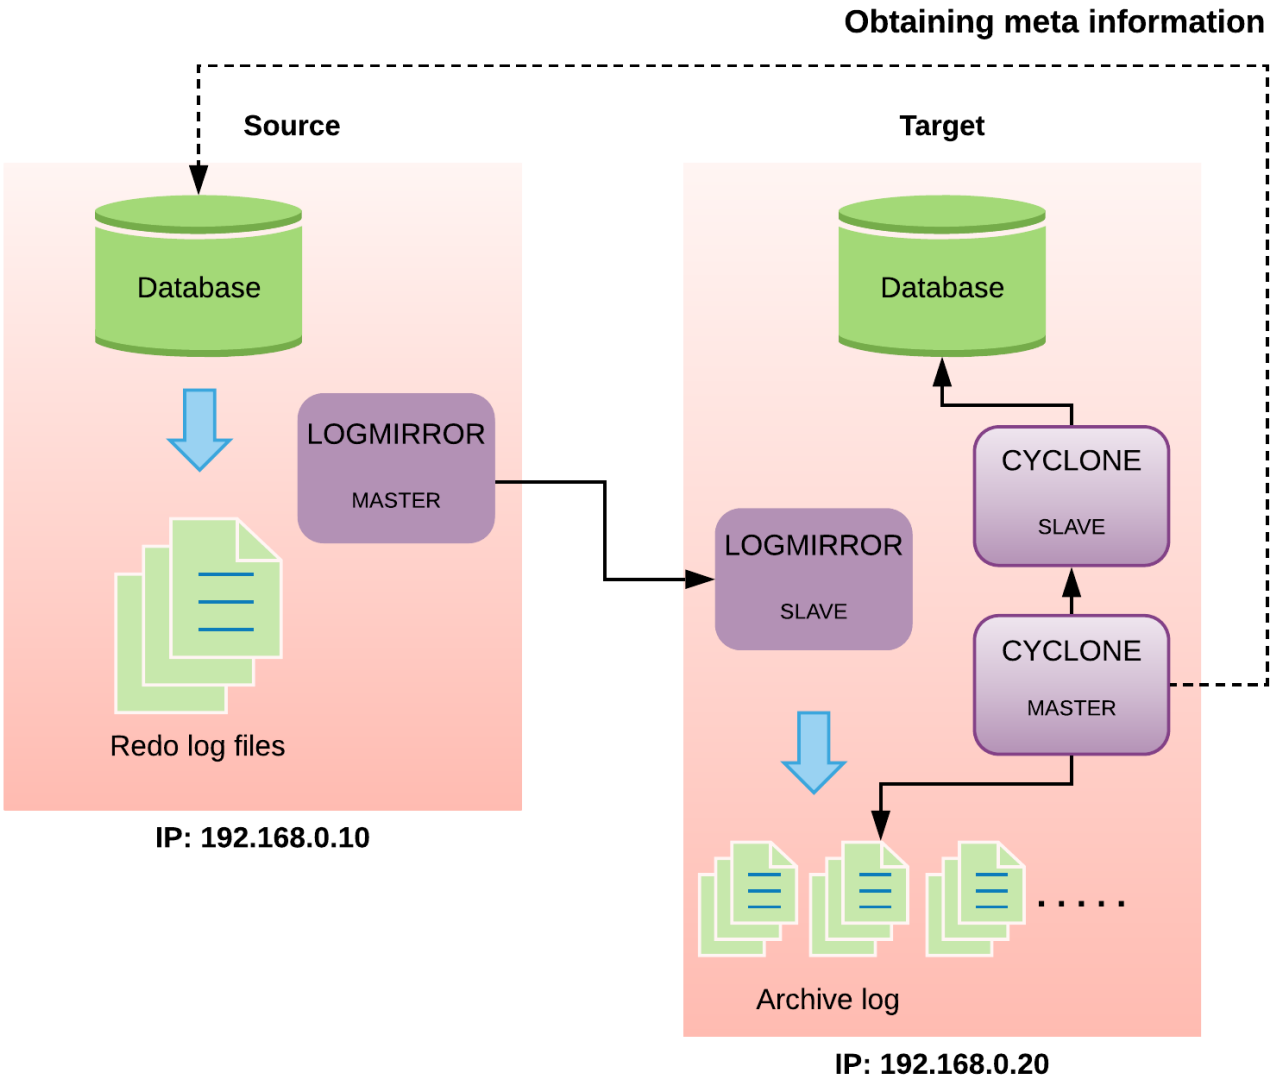
53.5 Examples of Interworking with CYCLONE

Interworking of CYCLONE, the CDC replication tool, with LOGMIRROR, the replication tool of the redolo g file, eliminates the risk of data loss.

Tool	Function	Interworking
CYCLONE	Replication of CDC	If it is independently operated it may cause the data loss.
LOGMIRROR	Replication of REDO LOG FILE	If it is operated together it does not cause the data loss.

The following describes the examples of interworked operation, and its structure.

Figure 1 Example of operating structure



- Device structure
  - The source device which is the original data
    - IP: 192.168.0.10

        - GOLDILOCKS listen port: 22581
        - The table to be replicated: T1, T2
- The remote target device for replication
    - IP: 192.168.0.20
- Two devices executes interworking between LOGMIRROR and CYCLONE for the replication without data loss.
    - Source device: LOGMIRROR (master)
    - Target device: LOGMIRROR (slave) + CYCLONE (master, slave)

Operating Order

1. Set the configuration of CYCLONE and LOGMIRROR in the original GOLDILOCKS.
2. Set the configuration of LOGMIRROR MASTER/SLAVE.
3. Execute LOGMIRROR MASTER/SLAVE.
4. Perform LOG FILE SWITCH of the original GOLDILOCKS for the normal operation of LOGMIRROR.
5. Set the remote GOLDILOCKS configuration.
6. Set the CYCLONE MASTER/SLAVE configuration.
7. Execute CYCLONE MASTER/SLAVE.

Configuring CYCLONE and LOGMIRROR in Original GOLDILOCKS

Refer to the followings.

- CYCLONE configuration: **Requirements**
- LOGMIRROR configuration: **Requirements**

Create the tables T1, T2 for a test after the configuration.

```
gSQL > CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > CREATE TABLE T2( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > COMMIT;
```

Configuring LOGMIRROR MASTER/SLAVE

- LOGMIRROR MASTER configuration file
    - Storage location: $GOLDILOCKS_DATA/conf/logmirror.master.conf
    - It is the source device.

LOG MIRROR MASTER should be operated on the device in which the original GOLDILOCKS is operated.

- Enter DSN or HOST information. HOST information is entered in the following example.

```
HOST_IP   = 192.168.0.10
HOST_PORT = 22581
```

- Use CYCLONE USER created in the previous step.

```
USER_ID = cdc_user
USER_PW = cdc_password
```

- Set the PORT to be used for LOGMIRROR communication.

```
PORT = 21106
```

- LOGMIRROR SLAVE configuration file
  - Storage path: $GOLDILOCKS_DATA/conf/logmirror.slave.conf
  - It is the target device.

- Enter the IP address of the device in which LOG MIRROR MASTER is being operated.

```
MASTER_IP = 192.168.0.10
```

- The PORT which is as same as LOGMIRROR MASTER should be entered.

```
PORT = 21106
```

- Enter the absolute path in which the replicated redo log file is to be stored.

```
LOG_PATH = '/data/LogMirrorWAL'
```

Executing LOGMIRROR MASTER/ SLAVE

- Execute LOGMIRROR MASTER.
  - It should be executed in the source device.

```
logmirror --master --start --conf $GOLDILOCKS_DATA/conf/logmirror.master.conf
```

- Execute LOGMIRROR SLAVE.

- It should be executed in the target device.

```
logmirror --slave --start --conf $GOLDILOCKS_DATA/conf/logmirror.slave.conf
```

Executing LOGFILE SWITCH of Original GOLDILOCKS for Normal Operation of LOGMIRROR

- LOGFILE SWITCH for starting to record LOGMIRROR file.
  - It should be executed in the source device.

```
gSQL> ALTER SYSTEM SWITCH LOGFILE;
```

When it is executed as above, the redo log file is generated in the path set in the SLAVE device. If the redo log file is not generated, a user should check the directory privilege or check whether the directory is created.

Configuring Remote GOLDILOCKS

It is required to check the table configuration for the normal operation and replication of GOLDILOCKS operated on the target device, and check the schema information.

The tables T1, T2 are created for test as follows.

```
gSQL > CREATE TABLE T1( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > CREATE TABLE T2( COL1 INTEGER PRIMARY KEY, COL2 VARCHAR(20) );
gSQL > COMMIT;
```

Configuring CYCLONE MASTER/ SLAVE

- CYCLONE MASTER configuration file
  - Storage path: $GOLDILOCKS_DATA/conf/cyclone.master.conf
  - It is the target device.

- Enter DSN or HOST information of the source device. HOST information is entered in the following example.

```
HOST_IP   = 192.168.0.10
HOST_PORT = 22581
```

- Use CYCLONE USER

```
USER_ID = cdc_user
USER_PW = cdc_password
GROUP_NAME = GROUP1
{
    PORT = 21102
    CAPTURE_TABLE =
    (
        T1,
        T2
    )
}
```

- CYCLONE SLAVE configuration file
  - Storage path: $GOLDILOCKS_DATA/conf/cyclone.slave.conf
  - It is the target device.

- Connect to GOLDILOCKS which is operated in the target device with D/A. (Therefore, DSN and HOST information does not exist.)

```
USER_ID = cdc_user
USER_PW = cdc_password
```

- CYCLONE master is being operated on the same device.

```
MASTER_IP = 192.168.0.20
GROUP_NAME = GROUP1
{
```

- Enter the path set by LogMirror slave.

```
LOG_PATH = '/data/LogMirrorWAL'
    PORT = 21102
    APPLY_TABLE =
    (
        T1 TO T1,
        T2 TO T2
    }
}
```

Executing CYCLONE MASTER/ SLAVE

- Execute CYCLONE MASTER.
  - It should be executed in the target device when it is connected with D/A.

```
cyclonet --master --start --conf $GOLDILOCKS_DATA/conf/cyclone.master.conf
```

- Execute CYCLONE SLAVE.
  - It should be executed in the target device when it is connected with D/A.

```
cyclone --slave --start --conf $GOLDILOCKS_DATA/conf/cyclone.slave.conf
```

54.

CYFILE

54.1 CYFILE

CYFILE is a tool which uses Change Data Capture (CDC) method to store the altered data in Comma-Separated Values (CSV) format file.

Overview

It analyzes the redo log file in real time and stores the transaction executed in the database in CSV format file. It can replicate the transaction file which is recorded in an async way and in near real time to database by using the 3rd party tool, or converts it to another format.

Operational Features

- It should be operated in the device in which the database is being operated.
- A single file is stored per a group.
- It can be started or terminated in groups.
- Storing CSV file can be set in a unit of table, and one or more tables can be included in a group.
- A table can be included in multiple groups.
- The redo log file should exist in the original database. In other words, DATA_STORE_MODE should be operated in TDS.
- SUPPLEMENTAL LOGGING should exist in the original database.
  - SUPPLEMENTAL LOGGING adds an additional information to the redo log file.
- The database should be operated in ARCHIVE LOG mode.
- Its process is independent from that of GOLDILOCKS, so terminating the tool does not affect GOLDILOCKS.

Operational Restrictions

- The table to capture should have PRIMARY KEY.
- It captures the committed transaction only. Therefore, it is unable to see the contents in CSV file before commitment
- It does not support the primary key update.
  - When the primary key value is updated, then the table is given up and is not captured any more.
- The table to capture can not use a column which has Generated Always As Identity property.
- When Data Definition Language (DDL) was performed on the table to capture, then it is given up.

    - It does not affect the replication of another table.
    - It is same for the truncate table.
- Only the table which was given up with --reset TABLE_NAME among give up tables can be reset.
- The table stored in the trash bin can not be a target to capture.
- It does not support long varchar, long varbinary.

The server property **DISABLE_DDL_CDC_GIVEUP** can disable the DDL statement which causes th e replication give up to avoid user created errors. Also, the server property **DISABLE_UPDATE_P K_CDC_GIVEUP** can disable primary key update.

Others

It stores the file at the following moment.

- It stores the file from the moment when TX occurs at the first running.
- It stores the file in succession from the terminated moment even when run it again after it is terminat ed during the operation.
- Use --reset option to give up the old file and restart from the current time.

54.2 Requirements

It is required to perform GOLDILOCKS preparations, user registration and privilege settings.

GOLDILOCKS Requirements

The followings should be set in GOLDILOCKS before starting CYFILE.

SUPPLEMENTAL LOGGING

SUPPLEMENTAL LOGGING stores an additional information together in the redo log file. The database sh ould be restarted to change the settings of operating database, but restarting is not needed when setting SUPPLEMENTAL LOGGING only in the specific table.

Setting SUPPLEMENTAL LOGGING in Database

- When setting SUPPLEMENTAL LOGGING as GOLDILOCKS property, SUPPLEMENTAL LOGGING is rec orded for all tables.
- Restart GOLDILOCKS.
- Add or update the contents in the property file.
  - Property file: goldilocks.properties.conf
  - Property setting: SUPPLEMENTAL LOG_DATA_PRIMARY_KEY = YES

Setting SUPPLEMENTAL LOGGING in Specific Table Participating in the Replicatio n

```
<add table supplemental log statement> ::=
    ALTER TABLE table_name
        ADD SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS
    ;
```

ARCHIVE LOG

GOLDILOCKS reuses the redo log files recursively. When GOLDILOCKS reuses the redo log file being proc essed by CYFILE, then CYFILE does not proceed and is terminated. GOLDILOCKS should be operated in A RCHIVE LOG mode to ensure the continuous replication operation.

Changing Database in Operation to ARCHIVE LOG Mode

- Restart GOLDILOCKS.
- After database is shutdown, connect with sysdba and change it to ARCHIVE LOG mode in MOUNT p hase.

```
gSQL> \startup mount
Startup success
gSQL> alter database archivelog;
Database altered.
```

Setting ARCHIVE LOG Mode When Creating Database

- Update the property file before creating the database.
  - Property file: goldilocks.properties.conf
  - Property setting: ARCHIVELOG_MODE = 1

The path in which ARCHIVE LOG file is stored can be viewed and updated with 'ARCHIVELOG_ DIR'.

DATA_STORE_MODE

CYFILE performs the replication by reading the redo log files of GOLDILOCKS. Therefore, GOLDILOCKS sh ould be operated in Transactional Data Store (TDS) mode.

Changing DATA_STORE_MODE

- Restart the database.
- Add or update the corresponding information in the property file.
  - Property file: goldilocks.properies.conf
  - Property setting: DATA_STORE_MODE = 2

If the value of DATA_STORE_MODE is 1, it indicates Concurrent Data Store (CDS), and if it is 2, i t indicates Transactional Data Store (TDS).

Registering User and Setting Privileges

CYFILE retrieves and manipulates the required information during the operation. The user operating CYFILE and the proper privileges for the user are required.

Creating Database User

A specific user should be added to operate CYFILE.

```
<user definition> ::=
    CREATE USER user_identifier IDENTIFIED BY password
    [ DEFAULT TABLESPACE tablespace_name ]
    [ TEMPORARY TABLESPACE tablespace_name ]
    [ INDEX TABLESPACE {tablespace_name¦NULL} ]
    [ <schema clause> ]
    ;
<schema clause> ::=
      WITH SCHEMA [schema_name]
    ¦ WITHOUT SCHEMA
```

The following is an example of creating the user cyfile_user and the password cyfile_password.

```
gSQL> CREATE USER cyfile_user IDENTIFIED BY cyfile_password;
```

Database Privileges

Granting User Access Privilege

The following is an example for granting the access privilege to cyfile_user.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO cyfile_user;
```

54.3 Configuration

Configuration File

When performing CYFILE, the information and options required for operating are set by using the configuration file.

- When a specific configuration file is not set by using the --conf option, *$GOLDILOCKS_DATA/conf/ cyfile.conf* file is read.

Table 54-1 Configuration file options

Name	Description
DSN	It sets Data Source Name.
GROUP_NAME	It sets the group name.
HOST_IP	It sets the host IP address of which GOLDILOCKS operates.
HOST_PORT	It sets the host port of which GOLDILOCKS operates.
USER_ID	It sets the user name.
USER_PW	It sets the user password.
USER_ENCRYPT_PW	It sets the encrypted password for a user.
CAPTURE_TABLE	It sets the table to be replicated.
PROTOCOL	It sets the connection type which is to be connected to GOLDILOCKS. (DA or TCP)
READ_LOG_BLOCK_COUNT	It sets the amount of data to be read at a time when operating CAPTURE.
TRANS_SORT_AREA_SIZE	It sets the size of the BUFFER to be allocated to CAPTURE.
TRANS_FILE_PATH	It sets the location in which the temporarily generated file is to be stored when operating CAPTURE.
LOG_CAPTURE_INTERVAL_1	It sets the execution cycle of capture. If the value is not changed after executing 10 times with that value, then it is converted to the value of LOG_CAPTURE_INTERVAL_2 and performs capture. (The default value is 0.2 seconds.)
LOG_CAPTURE_INTERVAL_2	It sets the execution cycle of capture. If the value is not changed after executing with the value of LOG_CAPTURE_INTERVAL_1, then it sets the execution cycle of capture. (The default value is 1 second.)
DATA_FILE_PATH	It sets the path to store CSV file. (It should be an absolute path.)
DATA_FILE_PREFIX	It sets the prefix of CSV file name.
DATA_FILE_SIZE	It sets the maximum size of CSV file. (It is an approximate size and it is not always set to the specified value.)
UPDATE_BEFORE_VALUE	It sets whether to store the value before the update in CSV when processing update SQL. (The default value is 0.)

Configuration Options

DSN

- It sets the data source name required for the access to GOLDILOCKS.
- It can be set in master and slave.
- The default value is GOLDILOCKS.

- Settings applied to all groups

```
DSN=GOLDILOCKS
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DSN=GOLDILOCKS
    ....
    ....
}
```

GROUP_NAME

- It is necessary for distinguishing the CYFILE operation within the equipment and it is a unit of generating the operation process.
- It is the delimiter of when starting or terminating CYFILE in group unit.
- After it is set, it should not be changed. If changed, it is regarded as a new group.
- GROUP_NAME should be unique in the same equipment.
- The braces { } should be used.

```
GROUP_NAME = testGROUP
{
    ....
    ....
}
```

HOST_IP

- It sets the IP address of GOLDILOCKS in which CYFILE accesses to.
- It is valid only when PROTOCOL is set to TCP.

- Settings applied to all groups

```
HOST_IP = 127.0.0.1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_IP = 127.0.0.1
    ....
    ....
}
```

HOST_PORT

- It sets port of GOLDILOCKS in which CYFILE accesses to.
- It should be set together with HOST_IP.

- Settings applied to all groups

```
HOST_PORT = 22531
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    HOST_PORT = 22531
    ....
    ....
}
```

USER_ID

It sets the user ID required for the access to GOLDILOCKS.

- Settings applied to all groups

```
USER_ID = testID
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ID = testID
    ....
    ....
}
```

USER_PW

It sets the user password required for the access to GOLDILOCKS.

- Settings applied to all groups

```
USER_PW = testPW
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_PW = testPW
    ....
    ....
}
```

USER_ENCRYPT_PW

- It sets the user password which is required for the access to GOLDILOCKS by encrypting.
- It is used instead of USER_PW.
- Encrypted user password is created by [cyfile --encrypt *user password* --key *the key to be encrypted*].
- If this value is used, then --key option should be used when executing cyfile. (In this case, the key valu e as same as that created with --encrypt should be used.

- Settings applied to all groups

```
USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    USER_ENCRYPT_PW = 't33KImiqvhqNyfN+uZmFrw=='
    ....
```

```
    ....
}
```

CAPTURE_TABLE

- It sets the table to capture.
  - It is set in *schema name.table name* format.
- It can be set only within a group.
- When specifying several tables, the parentheses ( ) should be used.
- The table stored in the recycle bin can not be set to be replicated.

```
GROUP_NAME = testGROUP
{
    CAPTURE_TABLE =
    (
        testSchema1.testTable1,
        testSchema1.testTable2,
        testSchema2.testTable1
    )
}
```

PROTOCOL

- It sets the type to connect to GOLDILOCKS in operation.
- It can be set to DA or TCP.
- If PROTOCOL is set to DA, neither HOST_IP nor is HOST_PORT used when accessing to GOLDILOCKS.
- The default value is DA.

• Settings applied to all groups

```
PROTOCOL = DA
```

• Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    PROTOCOL = DA
    ....
    ....
}
```

READ_LOG_BLOCK_COUNT

- It sets the number of the log blocks to be read at a time when capturing redo log file.
- The size of a log block is 512 bytes.
- The default value is 40960, and the actual read size is 20 MBytes.
  - The minimum value is 100.

- Settings applied to all groups

```
READ_LOG_BLOCK_COUNT = 1024
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    READ_LOG_BLOCK_COUNT = 1024
    ....
    ....
}
```

TRANS_SORT_AREA_SIZE

- It sets the memory space required for capturing the redo log files.
- The unit is MB (megabytes).
- The default value is 500 MB.
  - The minimum value is 10 MB.
- If the value is set too small, the performance becomes poor.

- Settings applied to all groups

```
TRANS_SORT_AREA_SIZE = 300
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_SORT_AREA_SIZE = 300
    ....
    ....
}
```

TRANS_FILE_PATH

- If a space bigger than TRANS_SORT_AREA_SIZE is required, the temporary file is created. It sets the path in which the temporary file is to be stored.
  - The absolute path should be used.
  - The path should be specified by using single quote (').

- Settings applied to all groups

```
TRANS_FILE_PATH = '/data/TmpTrans'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    TRANS_FILE_PATH = '/data/TmpTrans'
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_1

- It sets the execution cycle of capture in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with that value, then it is converted to the value of LOG_CAPTURE_INTERVAL_2 and performs capture.
- The default value is 200 (0.2 seconds), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_1 = 200
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_1 = 200
    ....
    ....
}
```

LOG_CAPTURE_INTERVAL_2

- It sets the execution cycle of capture in millisecond.
- It is used to quickly detect the changes of the redo log file.
- If the value of redo log file is not changed after executing 10 times with the value of LOG_CAPTURE_INTERVAL_1, then it is converted to the corresponding value and performs capture.
- The default value is 1000(1 second), and the unit is millisecond.

- Settings applied to all groups

```
LOG_CAPTURE_INTERVAL_2 = 1000
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    LOG_CAPTURE_INTERVAL_2 = 1000
    ....
    ....
}
```

DATA_FILE_PATH

- It sets the path to store CSV file.
  - The absolute path should be used.
  - The path should be specified by using single quote (').
- If it is not set, then the location in which cyfile is run becomes the default path.
- The following files are stored.
  - Data file (.dat)
  - Control file (.ctl)
  - Control mirror file (.ctl_0)

- Settings applied to all groups

```
DATA_FILE_PATH = '/home/goldilocks/dat'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DATA_FILE_PATH = '/home/goldilocks/dat'
    ....
```

```
    ....
}
```

DATA_FILE_PREFIX

- It sets the prefix of the name to be used when storing CSV file.
- If it is not set, then the prefix is 'cyfile'.

- Settings applied to all groups

```
DATA_FILE_PREFIX = 'SET_PREFIX'
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DATA_FILE_PREFIX = 'SET_PREFIX'
    ....
    ....
}
```

DATA_FILE_SIZE

- It sets the approximate maximum size of CSV file.
  - The size can be maximum 16 M bigger than the input size.
- The input value is in megabytes.
  - Input 1024 for 1 giga.
- The default value is 100 M.
  - The minimum value is 30 M and the maximum value is 4096 M (4G).

- Settings applied to all groups

```
DATA_FILE_SIZE = 200
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    DATA_FILE_SIZE = 200
    ....
    ....
```

```
}
```

UPDATE_BEFORE_VALUE

- It sets whether to store the value before the update in CSV when processing UPDATE SQL.
  - Set it to 1 to preserve the previous value.
  - Set it to 0 not to preserve the previous value.
- The default value is 0 which does not preserve the previous value.

- Settings applied to all groups

```
UPDATE_BEFORE_VALUE = 1
```

- Settings applied to a specific group

```
GROUP_NAME = testGROUP
{
    UPDATE_BEFORE_VALUE = 1
    ....
    ....
}
```

54.4 Operating

CYFILE can be operated in D/A or C/S environment of GOLDILOCKS.

CONFIG file or PROTOCOL configuration of ODBC.INI should be used according to the environments as f ollows. CONFIG configuration takes precedence over ODBC.INI configuration.

Table 54-2 CONFIG, ODBC.INI

Configuration	Description
PROTOCOL=DA	It is used in D/A environment. (Default)
PROTOCOL=TCP	It is used in C/S environment.

The running contents during the operation can be viewed through trace log.

Item	File
Cyfile	$GOLDILOCKS_DATA/trc/cyfile_(groupName).trc

Executing Option

CYFILE should be used with the following options at run-time.

Table 54-3 Executing options

Option	Description	Remarks
--start | -s	It starts CYFILE.	-
--stop | -t	It stops CYFILE.	-
--status | -u	It displays the status of CYFILE.	-
--conf | -c	It sets the path of configuration file which is req uired when executing CYFILE.	It is input in --conf CONFIG_FILE format. It should be used together with --start. If it is not explicitly set, $GOLDILOCKS_DATA/conf/cyfile.conf is used.
--silent | -i	It sets not to output messages.	-
--reset | -r	It resets the information about capture.	It is input in --reset TABLE_NAME or --reset all f ormat. It should be described within a single quote (') when resetting multiple tables.
--group | -g	It sets a specific group.	It is input in --group GROUP_NAME format.
--help | -h	It outputs the help message.	-
--encrypt | -e	It encrypts the user password with the given ke y.	-

Option	Description	Remarks
--key | -k	It sets the encryption key when performing the --encrypt option. If USER_ENCRYPT_PW is used in the config, it sets the decryption key.	-
--info | -o	It displays the status of currently running table.	It should be used together with --group.

- It executes all groups by using the default environment file.

```
prompt> cyfile --start
```

- It stops all groups.

```
prompt> cyfile --stop
```

- It executes TEST_GROUP group only.

```
prompt> cyfile --start --group TEST_GROUP
```

- It stops only TEST_GROUP group among operating groups.

```
prompt> cyfile --stop --group TEST_GROUP
```

- The encrypts GOLDILOCKS user password.

```
prompt> cyfile --encrypt test --key 1234
Cyfile Encrypted Passwd : '73LsLxss6lk='
```

- USER_ENCRYPT_PW is set in the config.

```
prompt> cyfile --start --key 1234
```

- It deletes the existing operational information and newly starts it.

```
prompt> cyfile --start --reset all
```

- It deletes the existing operational information of the tables T1, T2, and starts it newly from the current point.

```
prompt> cyfile --start --reset 'T1, T2'
```

- It displays the current operational information per each table.

```
prompt> cyfile --info --group GROUP1
================================================
 GROUP NAME = GROUP1

```

54.5 Files

CYFILE stores the information about insert/ update/ delete and capture table in CSV format. It uses async method but it is operated in near real-time.

There are two types of file for storage when operating CYFILE, which are the data file and the control file. The data file stores the transaction in CSV format and the control file stores the storage information about the data file. The control file creates and operates the mirror file in preparation for data loss or damage.

Table 54-4 CYFILE

File	Name information
Data file	It is stored in CSV format, and the extension is dat.
Control file	The extension is ctl. The extension of mirror file is ctl_0.

Data File

It records I/D/U information which is performed in transaction unit and in CSV format, the information about the column of the table participating in capture and give up table information. Those files are not automatically deleted unless a user deletes them.

File Name

The location and name of the stored file is determined by DATA_FILE_PREFIX, DATA_FILE_PATH. The extension is .dat and it is created according to the following rules.

- Data file format
  - (DATA_FILE_PREFIX).(GROUP_NAME)_(FILE_SEQUENCE).dat
    - e.g. CYFILE.GROUP1_1.dat, CYFILE.GROUP1_2.dat

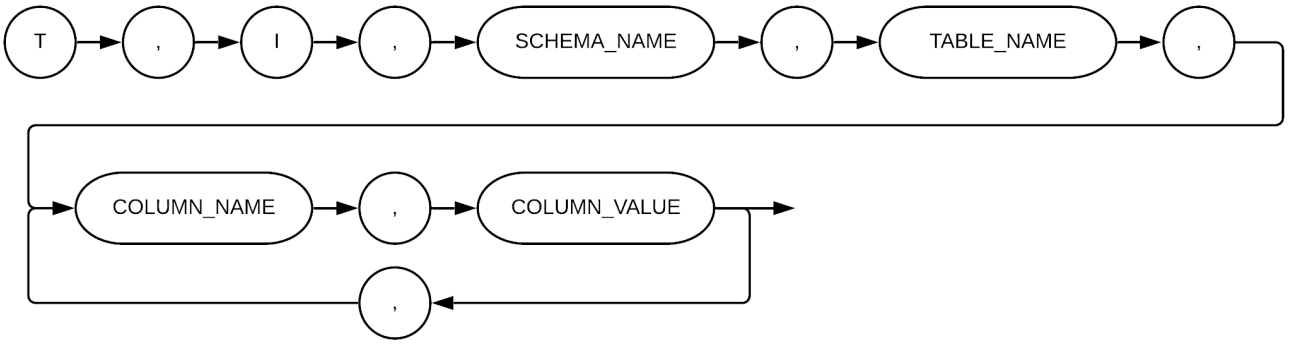
When a new file is created because the data file size becomes bigger than DATA_FILE_SIZE, then the value is determined by adding 1 to FILE_SEQUENCE.

DATA_FILE_PATH, DATA_FILE_PREFIX should not be changed after it starts the operation.

INSERT Storage Format

- In case of INSERT, T standing for table and I standing for insert are described as delimiters, and the sc hema name and the table name of the table in which the insert is performed are described.
- The actual data is a pair of the column name and the column value, and the information about the e ntire column is described in it.

Figure 1 INSERT expression



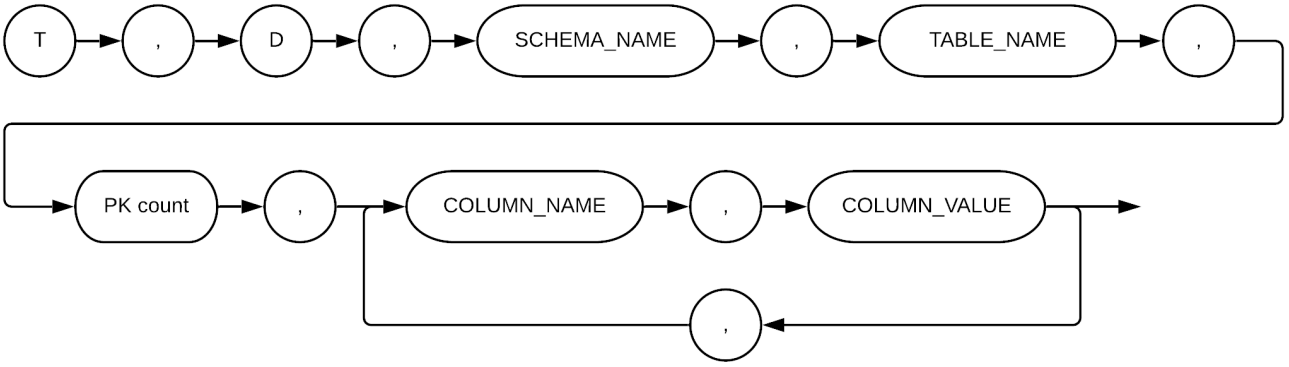
```
Query: INSERT INTO PUBLIC.TEST(C1, C2, C3) VALUES( 1, 2, 'ABC' );
CSV storage: T, I, "PUBLIC", "TEST", "C1", "1", "C2", "2", "C3", "ABC"
```

```
Query: INSERT INTO PUBLIC.TEST(C1, C3) VALUES( 1, ABC );
CSV storage: T, I, "PUBLIC", "TEST", "C1", "1", "C2", NULL, "C3", "ABC"
```

DELETE Storage Format

- In case of DELETE, T standing for table and D standing for delete are described as delimiters, and the schema name and the table name of the table in which the delete is performed are described.
- The primary key information of the deleted data is described, and if it is a composite key, then the pri mary key count becomes 2 or bigger and repeatedly described as many times as the count.

Figure 2 DELETE expression



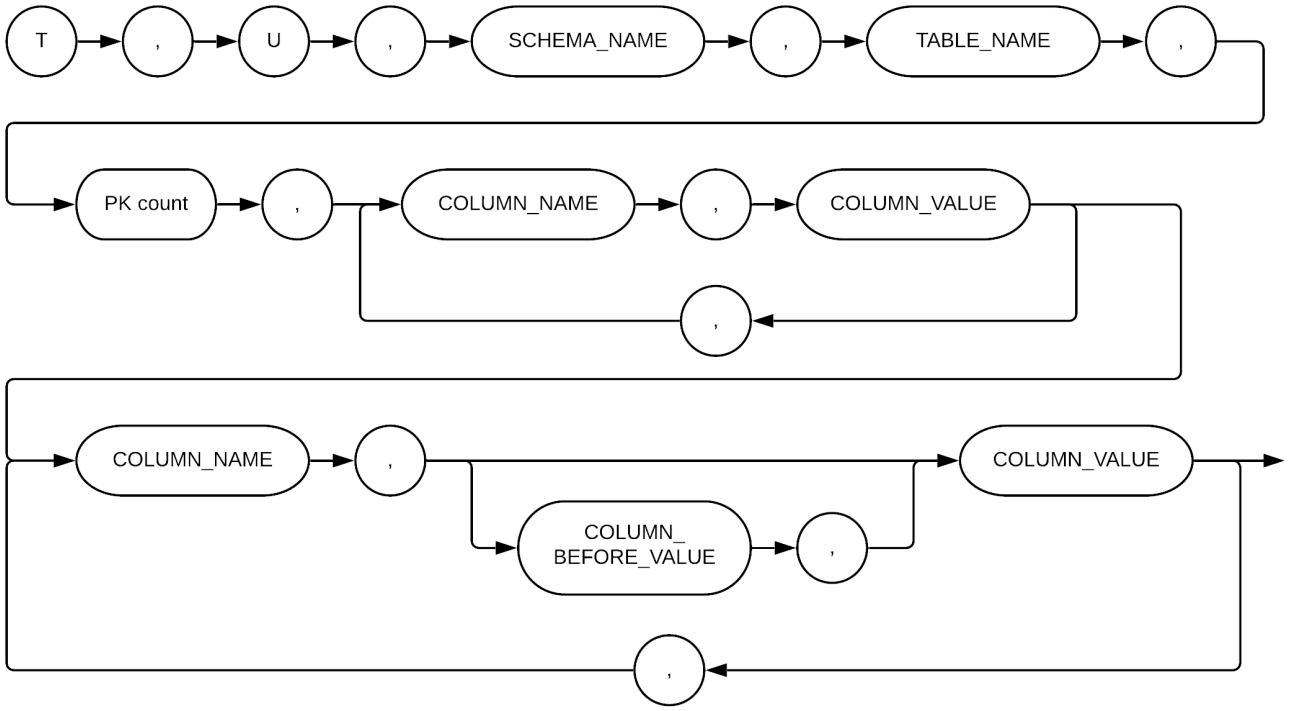
```
Sample: When there is one primary key
Query: DELETE FROM PUBLIC.TEST WHERE C1=1;
CSV storage: T, D, "PUBLIC", "TEST", 1, "C1", "1"
```

```
Sample: When there are two or more primary keys
Query: DELETE FROM PUBLIC.TEST WHERE C1=1 AND C2=2;
CSV storage: T, D, "PUBLIC", "TEST", 2, "C1", "1", "C2", "2"
```

UPDATE Storage Format

- In case of UPDATE, T standing for table and U standing for update are described as delimiters, and th e schema name and the table name of the table in which the update is performed are described.
- The primary key information of the updated data is described, and if it is a composite key, then the pr imary key count becomes 2 or bigger and repeatedly described as many times as the count.
- The information of actually updated column is repeatedly described.
  - When UPDATE_BEFORE_VALUE is set to 1, the value before the update is described together.

Figure 3 UPDATE expression



```
Sample: C2 value in the record whose primary key is only c1 is changed from 1 to 2.
Query: UPDATE PUBLIC.TEST SET C2=2 WHERE C1=1;
* When UPDATE_BEFORE_VALUE is not set
CSV storage: T, U, "PUBLIC", "TEST", 1, "C1", "1", "C2", "2"
* When UPDATE_BEFORE_VALUE is set
CSV storage: T, U, "PUBLIC", "TEST", 1, "C1", "1", "C2", "1", "2"
```

```
Sample: Change C3 value from 'ABC' to 'BCD', and C4 value from 3 to 4 in the record whose primary keys are C1, C2.
Query: UPDATE PUBLIC.TEST SET C3='BCD', C4=4 WHERE C1=1 AND C2=2;
* When UPDATE_BEFORE_VALUE is not set
CSV storage: T, U, "PUBLIC", "TEST", 2, "C1", "1", "C2", "2", "C3", "BCD", "C4", "4"
* When UPDATE_BEFORE_VALUE is set
CSV storage: T, U, "PUBLIC", "TEST", 2, "C1", "1", "C2", "2", "C3", "ABC", "BCD", "C4", "3", "4"
```

Transaction Information

- begin stands for the beginning of the transaction.
  - Additional information: Transaction ID
    - For cluster environment (Global transaction ID)
- Transaction commit
  - Additional information: Commit SCN (System Change Number)
    - For cluster environment (Global SCN)

Figure 4 Transaction begin expression

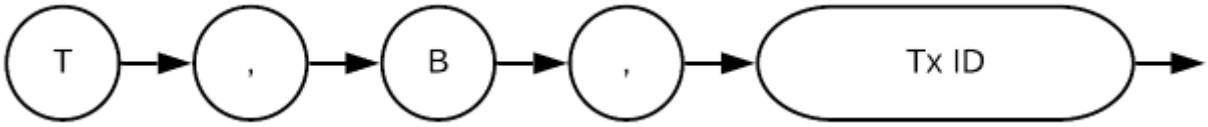


Figure 5 Transaction commit expression

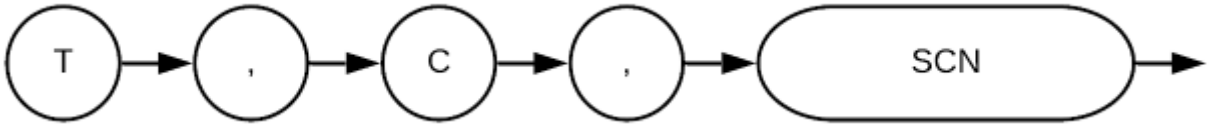

Table Information

- It records the information about the table and column to replicate.
  - The information about N columns per one table information are consecutively recorded.
  - It is repeatedly recorded as may times as the number of tables to replicate.
- It is recorded only once.
  - It is recorded for the first time when starting the program.
  - It is not recorded when restarting the program.
- When resetting or the table is added, then the information is recorded again.
- It records the information about the give up table.
  - The give up table is not captured any more.

- It can make the table to participate in the replication again by using reset option.

Figure 6 Table expression

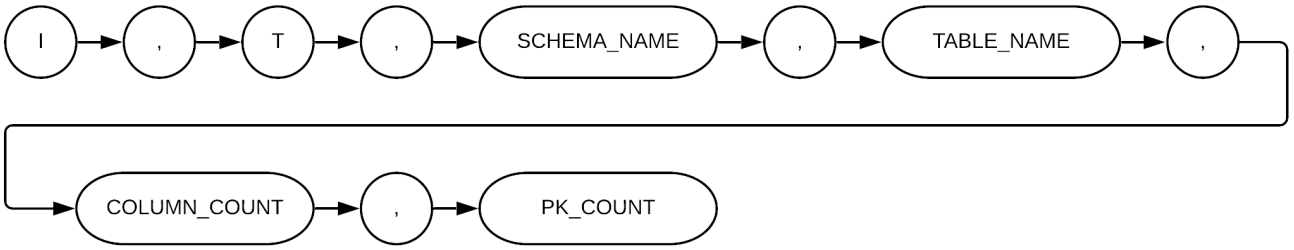

Figure 7 COLUMN expression

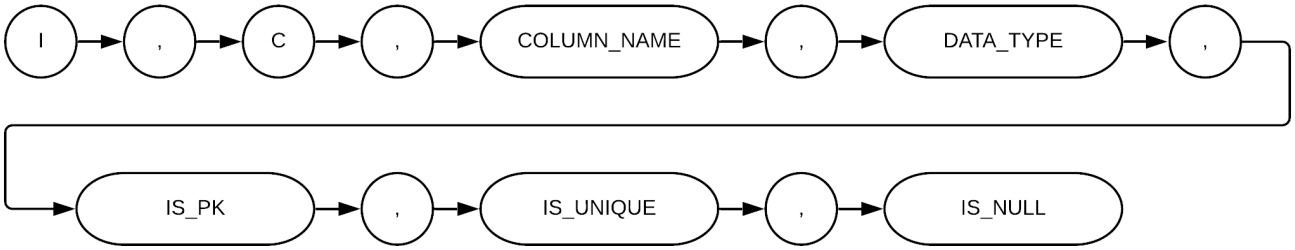

- Information about table TEST, TEST2

```
I,T,"PUBLIC","TEST",3,1
I,C,"C1","NUMBER(10,0)",1,0,0
I,C,"C2","VARCHAR(20)",0,0,1
I,C,"C3","VARCHAR(10)",0,0,1
I,T,"PUBLIC","TEST2",2,1
I,C,"C1","NUMBER(10,0)",1,0,0
I,C,"C2","VARCHAR(20)",0,0,1
```

Meta Information

- The following information is recorded at the front line when creating the data file.
  - Version information
    - 8 byte version information
    - It is used to check the compatibility of the data file.
  - Date information
    - The point of when the file is created is recorded.
  - Control file path
    - It records the path of the control file in which the information of the data file is recorded.

Figure 8 Version expression

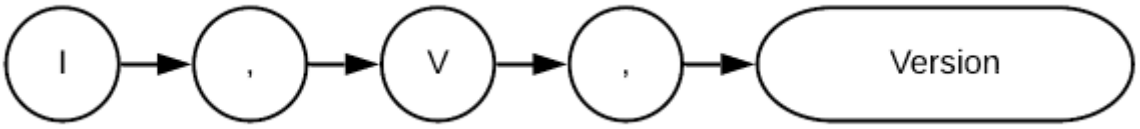

Figure 9 Date information expression

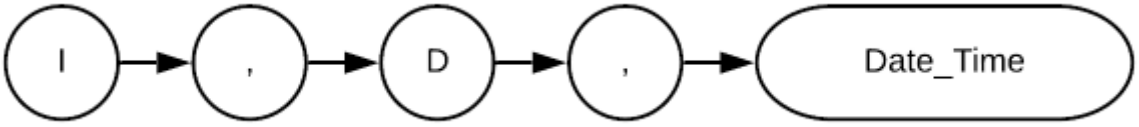

Figure 10 Control file information expression

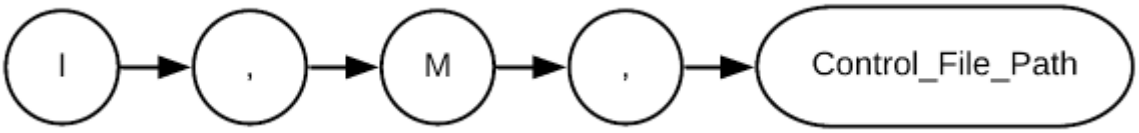
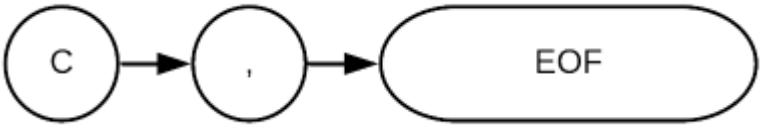


```
I,V, 00000000
I,D,"2022-12-24 00:01:00.000000"
I,M,"/home/cyfile/ctrl_file/cyfile.GROUP1.ctl"
```

Command Information

- EOF is recorded at the end of the existing file when the data file is stored in a new file because its size exceeds the maximum size.
  - Process it by reading the following file when that information is recorded.

Figure 11 EOF expression



Control File

- It records the valid information about the data file.
  - The data file is restarted and restored, so the stored value is not always valid.
  - If the information in the control file is used, then the value is always valid even when it is restarte d and restored.

- The control file size is 512 Bytes.
  - It should be used by offsetting the data or defining the structure.

```
typedef struct ctrlFileStr
{
    char           mVersion[8];
    unsigned int   mFileInfoCrc;   //mFileSeq + mFileOffset CRC
    unsigned int   mDummy;         //Not Used.

    signed long    mFileSeq;
    signed long    mFileOffset;    //Valid Offset
} ctrlFileStr;
```

- mVersion: Checking the compatibility
- mFileInfoCRC: CRC information of mFileSeq and mFileOffset
- mDummy: It is not used.
- mFileSeq: The current data file number
- mFileSeq: The valid location in the data file number including mFileSeq (Offset)

Appendix A.

Error Codes

GOLDILOCKS provides user error codes as follows. The error messages can be viewed with **V$ERROR_CODE**.

A.1 OS Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-1 OS related error

Error code	SQLSTATE	Message
11000	HY000	Invalid argument
11001	HY000	The operation was incomplete although some processing was performed and the results are partially valid
11002	HY000	Permission denied '%s'
11003	HY000	Standard Layer has encountered the end of the file
11004	HY000	Unable to duplicate a file
11005	HY000	File Lock Error
11006	HY000	File Unlock Error
11007	HY000	Unable to open the file '%s'
11008	HY000	Unable to close the file
11009	HY000	Unable to remove the file
11010	HY000	Unable to link the file
11011	HY000	Unable to read the file
11012	HY000	Unable to write the file
11013	HY000	Unable to sync the file
11014	HY000	Unable to seek the file
11015	HY000	Unable to truncate the file
11016	HY000	Unable to get the status of the file
11017	HY000	Unable to create a pipe
11018	HY000	Unable to wait for the given process
11019	HY000	Insufficient resource
11020	HY000	Unable to send signal to given process
11021	HY000	Unable to set a signal handler
11022	HY000	Unable to block a signal
11023	HY000	Unable to set thread attribute
11024	HY000	Unable to create a thread
11025	HY000	Unable to join with a terminated thread
11026	HY000	Unable to set thread once code
11027	HY000	Truncation occurred on I/O operation
11028	HY000	The given name(%s) is too long
11029	HY000	shared memory segment exists
11030	HY000	Unable to allocate a shared memory segment

Error code	SQLSTATE	Message
11031	HY000	Unable to attach the shared memory segment
11032	HY000	Unable to detach the shared memory segment
11033	HY000	Unable to destroy the shared memory segment
11034	HY000	Unable to create a semaphore
11035	HY000	Unable to acquire the given semaphore
11036	HY000	Unable to release the given semaphore
11037	HY000	Unable to destory the given semaphore
11038	HY000	The given object was busy
11039	HY000	Operation timed out
11040	HY000	No such object (%s)
11041	HY000	Two objects do not match
11042	HY000	Not enough memory
11043	HY000	File system is full
11044	HY000	Unable to execute the program

Table A-29 gbalancer related error

Error code	SQLSTATE	Message
51000	HY000	overflow fd

A.23 gsyncher Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-30 gsyncher related error

Error code	SQLSTATE	Message
53000	HY000	invalid phase(%s): executable phase is %s
53001	HY000	GOLDILOCKS_DATA system environment is invalid
53002	HY000	gmaster is active
53003	HY000	gsyncher is already running
53004	HY000	Shared memory is cleared

A.24 Cluster Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-31 Cluster related error

Error code	SQLSTATE	Message
56000	HY000	location information of member '%s' already exists
56001	HY000	location information of member '%s' does not exist
56002	HY000	location information of member '%s' is modified by concurrent execution
56003	HY000	has inactive member (%s)
56004	HY000	location file is corrupted - '%s'
56005	HY000	connections of some cluster members are broken
56006	40000	transaction rollback: failed to prepare global transaction
56007	HY000	must be accessible to at least one of replicas
56008	40000	transaction rollback: failed to synchronize replicas
56009	HY000	remote server (member ID: %ld) is abnormally terminated
56010	40000	transaction rollback: remote session is abnormally terminated
56011	HY000	a shared session cannot modify NUMA property
56012	HY000	no connection was established to recover in-doubt transactions
56013	HY000	cannot resolve in-doubt transaction
56014	HY000	MAX_NODE_COUNT property value '%d' must be equal to or less than '%d'
56015	HY000	'%s' property value must be greater than or equal to '%s' property value '%d'
56016	HY000	all members affected by the transaction are inactive - cannot guarantee durability of the transaction
56017	40000	transaction rollback: failed to open remote session
56018	HY000	protocol payload size(%ld) exceed maximum packet size(%ld)
56019	HY000	failover busy
56020	HY000	internal error (%s, %d)
56021	HY000	exceeded maximum response timeout
56022	HY000	failed to connect to an host
56023	HY000	invalid cluster communication protocol
56024	HY000	sequence '%s' is offline
56025	HY000	cannot synchronize because some members were disconnected
56026	HY000	identity column '%s' of table '%s' is offline
56027	HY000	cannot resolve in-doubt transaction '%d.%d.%ld' because the transaction remains unfinished
56028	HY000	the property '%s' is not compatible with the cluster system
56029	HY000	unable to open a remote session for read only statement

Error code	SQLSTATE	Message
56030	HY000	total cdispatcher threads '%d' must be equal to or less than '%d'

A.25 cserver Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-32 cserver related error

Error code	SQLSTATE	Message
57000	HY000	sample error

A.26 cdispatcher Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-33 cdispatcher related error

Error code	SQLSTATE	Message
58000	HY000	the sender failed to connect to the member(%d)
58001	HY000	the socket of target member '%s' is already disconnected
58002	HY000	the location information for member '%s' is not found
58003	HY000	the connection information is invalid; %s %d is either equal to or greater than %d
58004	HY000	the connection timeout from remote(%d)
58005	HY000	the disconnection timeout from remote(%d)
58006	HY000	invalid connection state transition
58007	HY000	dispatcher thread counts of two hosts do not match
58008	HY000	failed to start '%s' thread of cluster dispatcher
58009	HY000	internal error (%s, %d)
58010	HY000	broken socket
58011	HY000	old cluster connection is still alive
58012	HY000	failover event is in progress
58013	HY000	the connection can be established at LOCAL OPEN or OPEN phase
58014	HY000	old cluster sessions are still alive
58015	HY000	Timeout expired - %s
58016	HY000	cancel dequeue operation - database is going shutdown
58017	HY000	join database is in progress
58018	HY000	connection request from old cluster
58019	HY000	member position is out of range(0 to %d) - local(%d), remote(%d)
58020	HY000	the cluster protocol version '%d.%d' of cluster member '%d' is not compatible with the cluster protocol version '%d.%d' of cluster member '%d'

A.27 gtrclogger Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-34 gtrclogger related error

Error code	SQLSTATE	Message
59000	HY000	exceeded port cnt
59001	HY000	gtrclogger is already running
59002	HY000	gtrclogger is not running
59003	HY000	Operation timed out
59004	22000	Invalid GOLDILOCKS_DATA directory

A.28 glocator Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-35 glocator related error

Error code	SQLSTATE	Message
60000	HY000	syntax error
60001	HY000	file does not exist - '%s'
60002	HY000	GOLDILOCKS_DATA system environment is invalid
60003	HY000	Invalid value - %s(%s)
60004	HY000	file name is too long - '%s'
60005	HY000	glocator is already started.
60006	HY000	Location file is corrupted - '%s'
60007	HY000	Property value is out of length - '%s'
60008	HY000	Invalid property value [YES | NO | 1 | 0] - '%s'
60009	HY000	Invalid property value [%ld ~ %ld] - '%s'
60010	HY000	Invalid property value [%ld ~ %ld] - '%s'
60011	HY000	File already exists - '%s'
60012	HY000	Location file exceeded max size(%ld) - over size(%ld)
60013	HY000	Not exist node information - '%s'
60014	HY000	Exceeded response time for failover.
60015	HY000	Node is on failover - '%s'
60016	HY000	Need more alternate locator host information.
60017	HY000	Invalid configure file specification - property:[%s]
60018	HY000	Failed to propagate - '%s:%d'
60019	HY000	Not exist service information - '%s'
60020	HY000	'%s' node is already connected.
60021	HY000	overflow fd.

A.29 gloctl Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-36 gloctl related error

Error code	SQLSTATE	Message
61000	HY000	Syntax error
61001	HY000	File does not exist - '%s'
61002	HY000	Can not find any ini object in file - '%s'
61003	HY000	Dsn does not exist - '%s'
61004	HY000	ADD MEMBER keyword syntax is error - '%s'
61005	HY000	ADD SERVICE keyword syntax is error - '%s'
61006	HY000	Invalid property value [YES | NO | 1 | 0] - '%s'
61007	HY000	Invalid property value [%ld ~ %ld] - '%s'
61008	HY000	Invalid property value [%ld ~ %ld] - '%s'
61009	HY000	STL_ENV_DB_DATA system environment is invalid
61010	HY000	Keyword syntax is invalid - '%s'
61011	HY000	Data value is invalid - '%s'

A.30 gmon Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-37 gmon related error

Error code	SQLSTATE	Message
62000	HY000	gmon is already running
62001	HY000	process(%ld) did not respond signal
62002	HY000	GOLDILOCKS_DATA system environment is invalid

A.31 gagent Related Error

- Error code: GOLDILOCKS-specific error code
- SQLSTATE: SQL standard state code
- Message: Error message

Table A-38 gagent related error

Error code	SQLSTATE	Message
63000	HY000	GOLDILOCKS_DATA system environment is invalid
63001	HY000	Property value is out of length - '%s'
63002	HY000	Invalid property value [YES | NO | 1 | 0] - '%s'
63003	HY000	Invalid property value [%ld ~ %ld] - '%s'
63004	HY000	Invalid property value [%ld ~ %ld] - '%s'
63005	HY000	gagent is already started.
63006	HY000	file name is too long - '%s'
63007	HY000	file does not exist - '%s'
63008	HY000	Database is not cluster.
63009	HY000	Invalid configure file specification - property:[%s]
63010	HY000	Invalid phase(%s): executable phase is between %s and %s
63011	HY000	Property PORT of dsn(%s) is not set in file 'odbc.ini'
63012	08000	Timeout expired.
63013	HYT00	Unable to establish connection.

Appendix B.

Wait Event

B.1 Wait Event

Performance views which is related to the wait event is as follows.

- v$system_event **V$SYSTEM_EVENT**
- v$session_event **V$SESSION_EVENT**
- v$session_wait **V$SESSION_WAIT**
- v$wait_event_name **V$WAIT_EVENT_NAME**
- v$wait_event_class_name **V$WAIT_EVENT_CLASS_NAME**

B.2 Class of Wait Event

- Administrative: Waits resulting from DBA commands that cause users to wait (for example, an index rebuild)
- Application: Waits resulting from user application code (for example, lock waits caused by row level l ocking or explicit lock commands)
- Cluster: Waits related to cluster resources (for example, global cache resources)
- Commit: This wait class only comprises one wait event - wait for redo log write confirmation after a c ommit (that is, 'log file sync')
- Concurrency: Waits for internal database resources (for example, latches)
- Configuration: Waits caused by inadequate configuration of database or instance resources (for exa mple, undersized log file sizes, shared pool size)
- Idle: Waits that signify the session is inactive, waiting for work (for example, 'gsql message from clien t')
- Network: Waits related to network messaging
- Other: Waits which should not typically occur on a system
- Scheduler: Resource manager related waits
- System IO: Waits for background process IO
- User IO: Waits for user IO

B.3 Item of Wait Event

ENQUEUE: GDISPATCHER REQUEST

It is the time of which GDISPATCHER enqueues a request in a shared mode.
Parameter: None

ENQUEUE: SHARED-SERVER RESPONSE

It is the time of which a shared server enqueues a response in a shared mode.
Parameter: None

DEQUEUE: SHARED-SERVER REQUEST

It is the time of which a shared server dequeues a request in a shared mode.
Parameter: None

DEQUEUE: GDISPATCHER RESPONSE

It is the time of which GDISPATCHER dequeues a response in a shared mode.
Parameter: None

SEND: DEDICATE-SERVER SPOOLED RESPONSE

It is the time of which a dedicate server sends the spooled response to the client in a dedicate mode.

Parameter	Description
send data size	Bytes of the data to be sent

SEND: DEDICATE-SERVER RESPONSE

It is the time of which a dedicate server sends a response to the client in a dedicate mode.

Parameter	Description
send data size	Bytes of the data to be sent

RECV: DEDICATE-SERVER REQUEST

It is the time of which a dedicate server receives a request from the client in a dedicate mode.
Parameter: None

SEND: GDISPATCHER RESPONSE

It is the time of which GDISPATCHER sends a response to a client in a shared mode.

Parameter	Description
send data size	Bytes of the data to be sent

RECV: GDISPATCHER REQUEST

It is the time of which GDISPATCHER receives a request from a client in a shared mode.
Parameter: None

ENQUEUE: CLUSTER REQUEST

It is the time of enqueuing a request of cluster.
Parameter: None

ENQUEUE: CLUSTER BROADCAST REQUEST

It is the time of enqueuing a broadcast request of cluster.
Parameter: None

DEQUEUE: CLUSTER RESPONSE

It is the time of dequeuing a response of cluster.
Parameter: None

SEND: CDISPATCHER

It is the time of sending in cluster CDISPATCHER.
Parameter: None

RECV: CDISPATCHER

It is the time of receiving in cluster CDISPATCHER.
Parameter: None

GMASTER: ARCHIVE LOG

It is the time of processing archive logs in gmaster.
Parameter: None

GMASTER: CHECKPOINT

It is the time of processing checkpoints in gmaster.
Parameter: None

GMASTER: IO SLAVE

It is the time of processing IO slave in gmaster.
Parameter: None

GMASTER: LOG FLUSH

It is the time of processing archive logs in gmaster.
Parameter: None

GMASTER: PAGE FLUSH

It is the time of processing page flush in gmaster.
Parameter: None

WRITE: TRACE LOG

It is the time of writing trace logs.
Parameter: None

WRITE: COPY ARCHIVING LOG

It is the time of copying archiving logs.
Parameter: None

WRITE: BACKUP CTRL FILE

It is the time of backing up control files.
Parameter: None

WRITE: RESTORE CTRL FILE

It is the time of restoring the control file.
Parameter: None

READ: ARCHIVE LOG

It is the time of reading archive log files.
Parameter: None

READ: CTRL FILE

It is the time of reading the control file.
Parameter: None

WRITE: LOG FILE

It is the time of writing log files.
Parameter: None

WRITE: PAGE FILE

It is the time of writing page files.
Parameter: None

WRITE: CTRL FILE

It is the time of writing the control file.
Parameter: None

WRITE: REMOVE DATA FILE

It is the time of removing the data file.
Parameter: None

WRITE: JOURNAL BUFFER

It is the time of writing journal buffers.
Parameter: None

READ: JOURNAL BUFFER

It is the time of reading journal buffers.
Parameter: None

WAIT TRANSACTION

It is the time of waiting for transactions.

Parameter	Description
wait transaction id	Transaction id for which to wait

WAIT OTHER TRANSACTION

It is the time of waiting for other transactions to be terminated.

Parameter	Description
wait transaction id	ID of the waiting transaction
target transaction id	ID of the transaction to be terminated

WAIT ENABLE LOGGING

It is the time of waiting until when the logging is available.
Parameter: None

WAIT LOG FLUSHER

It is the time of waiting for the log flusher.

Parameter	Description
send data size	Bytes of the data to be sent

WAIT PAGE FLUSHER

It is the time of waiting for the page flusher.

Parameter	Description
send data size	Bytes of the data to be sent

WAIT XA CONTEXT

It is the time of waiting for the XA context.
Parameter: None

LATCH: LOG BUFFER

It is the time of waiting for the log buffer latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PROCESS MANAGER

It is the time of waiting for the process manager latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: ENV MGR

It is the time of waiting for the env manager latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SESSION ENV MGR

It is the time of waiting for the session env manager latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PCH

It is the time of waiting for the Page Control Header (PCH) latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PAGE

It is the time of waiting for the page latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PENDING LOG

It is the time of waiting for the pending log latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: ALLOC TRANS

It is the time of waiting for the allocate transaction latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: UNDO SEGMENT

It is the time of waiting for the undo segment latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: CLUSTER LOCATION

It is the time of waiting for the cluster location latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: DICT HASH ELEMENT AGING

It is the time of waiting for the dict hash element aging latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: DICT HASH RELATED AGING

It is the time of waiting for the dict hash related aging latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: FILE MANAGER

It is the time of waiting for the file manager latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: TRACE LOG

It is the time of waiting for the trace log latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: STATIC HASH

It is the time of waiting for the static hash latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: STATIC HASH BUCKET

It is the time of waiting for the static hash bucket latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SQL HANDLE

It is the time of waiting for SQL handle latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: XA CONTEXT HASH

It is the time of waiting for XA context hash latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PLAN CLOCK

It is the time of waiting for the plan clock latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: XA CONTEXT

It is the time of waiting for XA context latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: MEM CONTROLLER

It is the time of waiting for the memory controller latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: DYNAMIC MEM

It is the time of waiting for the dynamic memory latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: PROPERTY

It is the time of waiting for the property latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: ATTACH SHM

It is the time of waiting for the attack shared memory latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: BACKUP TBS

It is the time of waiting for the backup tablespace latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: DATABASE COMPONENT

It is the time of waiting for the database component latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: TABLESPACE

It is the time of waiting for the tablespace latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: BACKUP DATABASE

It is the time of waiting for the backup database latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: JOURNAL BUFFER

It is the time of waiting for the journal buffer latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: JOURNAL BUFFER ENTRY

It is the time of waiting for the journal buffer entry latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: JOURNAL WRITE BUFFER

It is the time of waiting for the journal write buffer latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: LOCK ITEM

It is the time of waiting for the lock item latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: RECORD HASH

It is the time of waiting for the record hash latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: DEADLOCK

It is the time of waiting for the deadlock latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SEQUENCE

It is the time of waiting for the sequence latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: LOG STREAM

It is the time of waiting for the log stream latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: BUILD AGABLE SCN

It is the time of waiting for the build agable SCN latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: TRANSACTION TABLE

It is the time of waiting for the transaction table latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SESSION LINK HASH

It is the time of waiting for the session link hash latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: ALLOC XA CONTEXT

It is the time of waiting for the allocate XA context latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SEQUENCE GLOBALX

It is the time of waiting for the sequence global latch X.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: SEQUENCE GLOBALY

It is the time of waiting for the sequence global latch Y.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: TRANSACTION LOG FILE

It is the time of waiting for the transaction logfile latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

ASYNC RESPONSE

It is the time of waiting for the response from the remote node in the cluster environment.
Parameter: None

ASYNC TRANSACTION

It is the time of waiting for the response for the ASYNC TRANSACTION's COMMIT from the remote node in the cluster environment.
Parameter: None

ASYNC COMMIT

N/A

GMASTER: BUFFER FLUSH

It is the time of executing the buffer flush by the io slave of gmaster.
Parameter: None

LATCH: BUFFER HASH BUCKET

It is the time of waiting for the buffer hash bucket's latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

READ: PAGE FILE

It is the time of reading pages from the disk to read the disk tablespace's pages.
Parameter: None

LATCH: BUFFER CHECKPOINT LIST

N/A

WRITE: CHANGE TRACKING FILE

It is the time of writing the disk tablespace's change tracking file.
Parameter: None

WAIT FREE BUFFER

It is the time of waiting for the free buffer, to read the pages in the disk tablespace.
Parameter: None

GLOBAL SEQUENCE: LOCK AND QUERY

It is the time of waiting for the global latch by all members to synchronize the global sequence in cluster, and the time of waiting to get the latest information of the global sequence.
Parameter: None

GLOBAL SEQUENCE: SYNC

It is the time of synchronizing the global sequence in cluster.
Parameter: None

LATCH: SEQUENCE GLOBAL NEXT

It is the time of waiting for the sequence global next latch in cluster.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

LATCH: BUFFER LRU LIST

It is the time of waiting for the buffer lru list latch.

Parameter	Description
address	The address of the latch for which the process is waiting
tries	A count of the number of times the process tried to get the latch

WAIT DIRTY PAGE LIMIT

It is the time of waiting until the number of dirty pages in the system becomes smaller than **BUFFER_DIRTY_PAGE_LIMIT** to access the pages cached in the buffer.
Parameter: None

WAIT BUFFER READ COMPLETE

It is the time of waiting for the disk read to be completed to access the page of the disk tablespace.
Parameter: None

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sectio ns 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting th e License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled b y, or are under common control with that entity. For the purposes of this definition, "control" means (i) t he power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial o wnership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to softw are source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source fo rm, including but not limited to compiled object code, generated documentation, and conversions to oth er media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the L icense, as indicated by a copyright notice that is included in or attached to the work (an example is provid ed in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived fr om) the Work and for which the editorial revisions, annotations, elaborations, or other modifications repr esent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any mo difications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licens or for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to subm it on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of el ectronic, verbal, or written communication sent to the Licensor or its representatives, including but not li

mited to communication on electronic mailing lists, source code control systems, and issue tracking syste ms that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the W ork, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution ha s been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, w orldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Deriv ative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License.

Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, w orldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent licen se to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such licens e applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contributio n(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counter claim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes dire ct or contributory patent infringement, then any patent licenses granted to You under this License for tha t Work shall terminate as of the date such litigation is filed.

4. Redistribution.

You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with o r without modifications, and in Source or Object form, provided that You meet the following conditions:

1. You must give any other recipients of the Work or Derivative Works a copy of this License; and

2. You must cause any modified files to carry prominent notices stating that You changed the files; and

3. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, paten t, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

4. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that Yo u distribute must include a readable copy of the attribution notices contained within such NOTICE fil e, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of t he following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display gen

erated by the Derivative Works, if and wherever such third-party notices normally appear. The conte nts of the NOTICE file are for informational purposes only and do not modify the License. You may a dd Your own attribution notices within Derivative Works that You distribute, alongside or as an adde ndum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or differe nt license terms and conditions for use, reproduction, or distribution of Your modifications, or for any suc h Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions.

Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work b y You to the Licensor shall be under the terms and conditions of this License, without any additional term s or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any se parate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks.

This License does not grant permission to use the trade names, trademarks, service marks, or product na mes of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty.

Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contribut or provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIN D, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INF RINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible f or determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability.

In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unl ess required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or conseq uential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malf unction, or any and all other commercial damages or losses), even if such Contributor has been advised o f the possibility of such damages.

9. Accepting Warranty or Additional Liability.

While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with thi s License. However, in accepting such obligations, You may act only on Your own behalf and on Your sol e responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor b y reason of your accepting any such warranty or additional liability.
