Part I.

Getting Started

1.

Preface

1.1 Overview

This user manual is intended for the user who is configuring, managing and operating GOLDILOCKS. The purpose of this manual is to convey the basic concepts required for installation and management of GOL DILOCKS. This manual also describes cautions when using GOLDILOCKS system.

- The description which is presented in this document can be changed according to the intstallation en vironment and specific usage.
- This document is based on GOLDILOCKS 22c.1 version.
- This document is based on RedHat linux - based platform.

Target Reader

The target readers are as follows.

- Programmers who need basic knowledge about how to manage GOLDILOCKS database
- Administrators and performance managers of GOLDILOCKS database
- Administrators and performance managers of GOLDILOCKS cluster system

1.2 Summary

This chapter describes the basic structure and characteristics of GOLDILOCKS for the novice user. A user c an select either a standalone or a cluster system architecture to use GOLDILOCKS. Differences of each arc hitecture and their usages are described.

GOLDILOCKS Database Management System

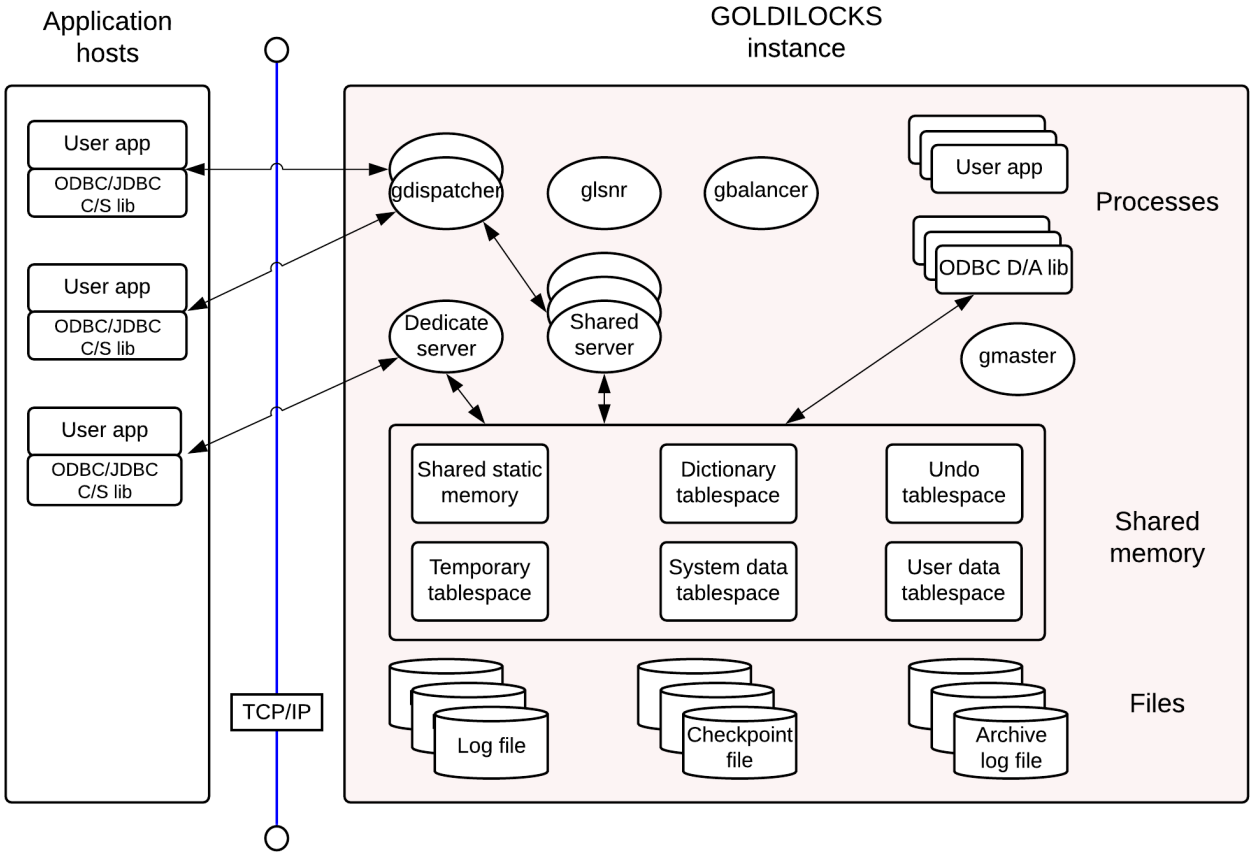
GOLDILOCKS database system consists of the following parts.

- User-installed GOLDILOCKS software binaries
- Database which is a set of tablespaces, implemented with one or more shared memory
- Various files for persistence support of database
  - The data files created with the same size as shared memory per shared memory
  - Redo log files which support the recovery of the database in the event of a failure
  - Configuration files for database settings
  - Trace log files which record information such as events during database operations
- gmaster processes which manage database, and many system threads within it

GOLDILOCKS Architecture

To prevent spreading the application process failure over the entire database system, GOLDILOCKS datab ase is a multi-process architecture based on shared memory, instead of a multi-thread architecture. The o verall architecture of GOLDILOCKS database is as shown in figure 1. Data are loaded onto a shared mem ory and gmaster process is a management daemon which manages database such as boot-up, log flush, aging. Also, it stores redo log files and data files on a disk file to ensure the permanence of data. Applicat ions using GOLDILOCKS database will use one of the following two accessing models.

Figure 1 GOLDILOCKS architecture



- Direct access (D/A) model
  - A user may use D/A model when user application is operated on the same equipment as GOLDIL OCKS database.
  - User applications should be used by linking with GOLDILOCKS ODBC/JDBC libraries for D/A.
  - GOLDILOCKS ODBC/JDBC libraries for D/A include query processing module and storage manage ment module inside and they process user request by directly attaching shared memory configuri ng that database.
  - It is suitable to implement a few works which require low-latency because the communication lo ad between application process and database process module is removed.
- Client/ Server (C/S) model
  - A user may use C/S model when user application is operated on the same equipment as GOLDIL OCKS database or on a different equipment.
  - User applications should be used by linking with GOLDILOCKS ODBC/JDBC libraries for C/S.
  - The GOLDILOCKS development library for C/S processes user's requests through TCP communica tion with the server (gserver) which serves the database specified in the connect string.
  - The response speed of single application of C/S is inferior to that of D/A. However, C/S does not depend on the location of the application, and the relatively stable operation is possible even wh en an error occurs in the application.
  - C/S model may be operated in shared mode or dedicated mode. In dedicated mode, a single serv er (gserver) process is performed on a single client. In shared mode, it responds to multiple client

s because dispatcher (gdispatcher) and shared-server (gserver) are always running.
- Dedicated mode is suitable for large amount of data, and shared mode is suitable for many client s, small amount of data.
- For more information about setting dedicated mode or shared mode, refer to **odbc.ini File** and **Lis tener Configuration**.

In D/A model, an application directly accesses to database and manipulates it, and thus the data base instance becomes unstable because many errors occur at an early development stages. The refore, it would be efficient to develop it in C/S model at an early development stage, and then, to switch it to D/A model at the final development stage.

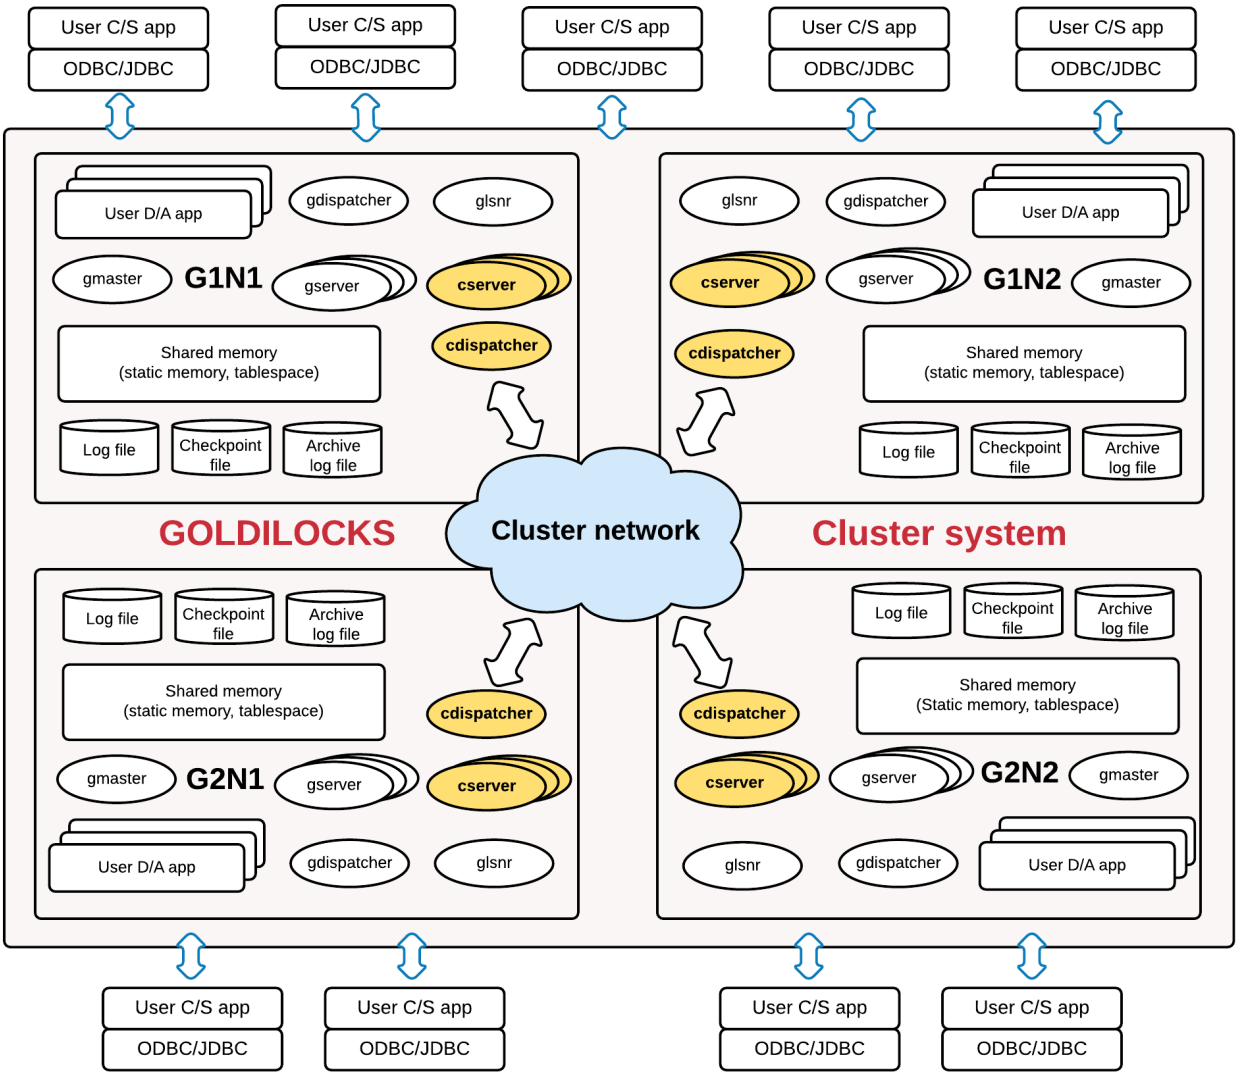
GOLDILOCKS Cluster System Architecture

GOLDILOCKS can be used by configuring a standalone database, or binding multiple databases into a sin gle cluster and managing the database in cluster unit. In other words, a user can distribute and store tabl e data into multiple nodes according to the desired sharding strategy. This guarantees high availability an d improves the throughput due to the parallel processing.

GOLDILOCKS cluster system guarantees ACID of transaction which is clister-widely performed. There fore, it provides the data reliability as same as that of the transaction performed on a standalone server when a ny node belonging to the cluster system is connected to perform the transaction.

Each database belonging to GOLDILOCKS cluster system has a structure for multi-process structure and d ata loading method, which is as same as the structure of the standalone database. However, cdispatcher process and cluster server (cserver) process are added. cdispatcher is a process for efficient communiation between member nodes in a cluster, and cluster server (cserver) process is for the data storage and mana gement on the cluster member node. Also, tablespaces and management areas for transaction managem ent of cluster system are added to the shared memory.

Figure 2 GOLDILOCKS cluster system architecture



1.3 Characteristics of GOLDILOCKS Cluster

Features of Cluster

GOLDILOCKS cluster is a cluster system of shared nothing structure and it overcomes limitations for trans action performance and storage of an existing standalone system.

- High throughput
  - GOLDILOCKS cluster does not limit creating groups, and the linear performance can be improved by creating groups.
  - It overcomes the limitation for the storage space of the existing memory-based standalone syste m.
- High availability
  - If a group consists of multiple members and at least one member is running in a group, it does n ot affect the availability.
  - Even when not every member in a group is available, other groups except for that group normall y provides service.
- Online expansion and online recovery
  - creating groups or members are possible even when the service is in progress, and it does not aff ect the service in progress.
  - Even the member of the suspended service due to an error can participate in a cluster online.
- Providing the perfect transaction
  - It perfectly provides the following properties of which a transaction should comply with.
    - Atomicity
    - Consistency
    - Isolation
    - Durability
- Providing the perfect MVCC (multi-version concurrency control)
  - GOLDILOCKS cluster provides a global statement level consistency as standalone system does.
  - The SQL starting at a specific point can access a desired version among the various versions when accessing to any node.
- Providing the standard SQL and the standard DBC
  - It provides SQL which is equivalent to SQL 92.
  - It provides standard DBCs such as JDBC, ODBC.
- Application compatibility
  - The application source or SQL developed in the existing standalone system can be used in GOLDI LOCKS cluster without modifying it.

Constraint of Cluster

All SQL statements in GOLDILOCKS cluster can be used same as those in standalone system except for th e following constraints.

PRIMARY KEY for the sharded table, UNIQUE constraint and the UNIQUE INDEX should include a sharding key.

The following is an example of a failure because the constraint of UNIQUE (name) does not include an id column which is a sharding key.

```
gSQL>
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    UNIQUE (name)
)
SHARDING BY HASH(id);
ERR-HYC00(16380): UNIQUE or PRIMARY KEY must include all sharding key columns for cluster
system
```

The constraint should be generated including sharding key as like UNIQUE (id, name) or UNIQUE (name, id) in the following example.

```
gSQL>
CREATE TABLE t1
(
    id   INTEGER PRIMARY KEY,
    name VARCHAR(128),
    UNIQUE( id, name )
)
SHARDING BY HASH (id);
Table created.
```

Non-deterministic statements should have the global secondary index to distinguish the same ro ws among the cluster members.

The following is an example of error which occurs when creating a table omitting the global secondary in

dex by force.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER ) WITHOUT GLOBAL SECONDARY INDEX;
Table created.
gSQL> INSERT INTO t1 VALUES (1), (2), (3), (4), (5);
5 rows created.
gSQL> COMMIT;
Commit complete.
```

The following is an example of deleting three rows and it does not guarantee that the cluster members d elete the same rows.

```
gSQL> DELETE FROM t1 FETCH 3;
ERR-42000(16423): does not support non-deterministic DML in the cluster system : global
secondary index expected
```

The following example does not guarantee that the cluster members update the same rows to the same value by using RANDOM(1, 100).

```
gSQL> UPDATE t1 SET c1 = RANDOM(1, 100);
ERR-42000(16423): does not support non-deterministic DML in the cluster system : global
secondary index expected
```

The following is an example of updating the row at the current position by using updatable cursor, and it requires the global secondary index to distinguish the same rows among cluster members.

```
gSQL> \var v1 INTEGER
gSQL> DECLARE cur1 CURSOR FOR SELECT c1 FROM t1 FOR UPDATE;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> FETCH cur1 INTO :v1;
V1
--
 1
1 row fetched.
gSQL> UPDATE t1 SET c1 = 1 WHERE CURRENT OF cur1;
ERR-42000(16423): does not support non-deterministic DML in the cluster system : global
secondary index expected
```

It does not support the deferrable constraint.

```
gSQL> ALTER TABLE t1 ADD CONSTRAINT t1_uk UNIQUE(id) DEFERRABLE;
ERR-HYC00(16388): does not support deferrable constraints in the cluster system :
ALTER TABLE t1 ADD CONSTRAINT t1_uk UNIQUE(id) DEFERRABLE
                                    *
ERROR at line 1:
```

It does not guarantee the sequence when using the same sequence in different servers.

- It is executed in g1n1 server.

```
gSQL> SELECT seq1.NEXTVAL FROM dual;
NEXTVAL
-------
      1
1 row selected.
gSQL> SELECT seq1.NEXTVAL FROM dual;
NEXTVAL
-------
      2
1 row selected.
```

- It is executed in g2n1 server.

```
gSQL> SELECT seq1.NEXTVAL FROM dual;
NEXTVAL
-------
     21
1 row selected.
```

- It is executed again in g1n1 server.

```
gSQL> SELECT seq1.NEXTVAL FROM dual;
NEXTVAL
-------
      3
1 row selected.
```

2.

Tutorial

2.1 Managing GOLDILOCKS Instance

This chapter describes the basic knowledge of managing the GOLDILOCKS instance.

Overview

GOLDILOCKS database system consists of database and instance. Database is a collection of various files which are necessary for driving database such as dictionary data on memory, user data, data file for dictio nary data and user data, online redo files.

Database instance consists of two parts. One is the memory portions containing the run-time information for operating GOLDILOCKS database, and the other is the background process which is used to operate a nd manage it. Each database instance is identified as shared memory key value and "GOLDILOCKS _DATA " environment variable value, both are used to configure shared memory.

Property Setting

GOLDILOCKS properties are listed in *$GOLDILOCKS _DATA/conf/goldilocks.properties.conf* file. A user m ay install GOLDILOCKS using the basic properties. This chapter describes the main properties such as TBS (Tablespace), LOG, CONTROL FILE.

The followings describe main property items of when installing GOLDILOCKS.

Table 2-1 Main property items

Property	Description	Default value
SYSTEM_TABLESPACE_DIR	It is the directory path of installing the following system TBS. • DICTIONARY_TBS • MEM_DATA_TBS • MEM_UNDO_TBS • MEM_TEMP_TBS • MEM_TRANS_TBS	'<GOLDILOCKS_DATA>/db'
SYSTEM_MEMORY_DICT_TABLESPACE_SIZE	It is the dictionary tablespace size.	128M
SYSTEM_MEMORY_DATA_TABLESPACE_SIZE	It is the memory data tablespace size.	200M
SYSTEM_DISK_DATA_TABLESPACE_SIZE	It is the disk data tablespace size.	200M
SYSTEM_MEMORY_UN	It is the undo tablespace size.	32M

Property	Description	Default value
DO_TABLESPACE_SIZE		
LOG_DIR	It is the default log directory path.	'<GOLDILOCKS_DATA>/wal'
SYSTEM_LOGGER_DIR	It is the system log directory path.	'<GOLDILOCKS_DATA>/trc'
CONTROL_FILE_COUNT	It is the number of control files.	2
CONTROL_FILE_0	It is the first control file path.	'<GOLDILOCKS_DATA>/wal/control_0.ctl'
CONTROL_FILE_1	It is the second control file path.	'<GOLDILOCKS_DATA>/wal/control_1.ctl'
BUFFER_CACHE_SIZE	It is the size of the buffer cache which is used to cache the table and the index page created in the disk tablespace.	64M

- DICTIONARY_TBS: It is the tablespace which stores dictionary tables of GOLDILOCKS.
- MEM_DATA_TBS: It is the memory tablespace in which the user table/index is generated.
- DISK_DATA_TBS: It is the disk tablespace in which the user table/index is generated.
- MEM_UNDO_TBS: It is the tablespace which contains the undo (rollback) information of the transaction.
- MEM_TRANS_TBS (Cluster only): It is the tablespace used for the global transaction recovery in cluster system. The size is automatically calculated based on the transaction table size and the number of cluster node.

A user can change the text property file ($GOLDILOCKS_DATA/conf/goldilocks.properties.conf), or define a new variable in the form of GOLDILOCKS_<property_name> to change the database settings or instance settings. In the priority, the property file takes precedence over the environment variable.

Background Process

GOLDILOCKS has a background process (gmaster) for managing instance. gmaster consists of multiple system thread internally, and the contents are as follows.

Table 2-2 System threads

Thread	Description
Main thread	It starts or ends gmaster process.
Log archiving thread	It copies the previous redo log file to a specified location when switching online redo file, and stores it.
Ager thread	It cleans up the resources being used by dropped schema objects.
Page flusher thread	It distributes the task to the IO slave and controls them in order to store the dirty pages in the disk at checkpoint.
Log flusher thread	It periodically collects the log records accumulated in the redo log buffer, and then stores them into online redo log file at run-time.
Checkpoint thread	It downloads dirty pages to the data file on the disk and the online redo log file when swi tching redo log file.
Cleanup thread	It cleans up resources used by abnormally terminated clients, and then rolls back the trans actions.
IO slave thread	It performs all disk IO related to data file such as checkpoint and data file loading.
Process monitor thread	It monitors after executing the processes such as balancer (gbalancer), dispatcher (gdispa tcher), shared-server (gserver), then reexecutes when abnormal termination is detected.
Cluster Recover Thread (Cluster only)	It recovers a global transaction in cluster system.
Failover Thread (Cluster only)	It deals with the failover through reselecting offiline and coordinator for the members wh en an error occurs on a specific node or in a network in cluster system.

Client Process

Client/ Server Model

The Client/ Server (C/S) model application is connected to listener (glsnr) which is waiting for access requ est. Then it creates a new database service process (gserver), in dedicated mode, and it handles user's req uest by using TCP communication. All these operations are carried out through inter process communicat ion, so any signal generated in the application process does not affect on the state of the database. More over, cleanup thread regularly checks and returns all the resources used by abnormally terminated applica tion.

Direct Access Model

GOLDILOCKS supports a direct access (D/A) model as well as Client/ Server (C/S) model. All applications u sing D/A model are linked to the server library supported by GOLDILOCKS, and then directly access datab ase and instance. Therefore, no other special service process exists but only the application processes doe s exist.

When D/A model application process is interrupted abnormally by the signal generated during operation, all resources in use will be cleaned up by the signal handler function which the library set during connecti on. The function cleans up the resources according to the two following steps.

1. The signal handler marks an abnormal termination on the session object and terminates the process.
2. The cleanup thread of gmaster return resources to the database in the same way as C/S model after a certain period of time.

Application processes directly access the database area in D/A model. Therefore, comply with the followi ng precautions.

- When the D/A model application process is terminated by a fatal signal such as SEGV, the signal han dler which was registered by the library at connection to the database should stop using shared resou rces. If a specific signal handler should be installed in the application it should be declared before con necting to the database.
- When forcibly shut down the application process, do not use SIGKILL (kill-9) because the process can not detect the generation of the signal. A user should use SIGTERM, SIGQUIT or SIGUSR2.

Memory Architecture of Instance

The memory size used by the database instance is determined by the relevant properties in the property fi le. Shared memory used by instance can be divided into static area and tablespace area. Static area includ es basic information about public instance, each session, statement, transaction, redo log buffer, dictiona ry cache and several other operation. Tablespace area includes page frame of each tablespace and Page Control Header (PCH) for controlling them.

The application process memory includes instance memory attached at connection. Additionally, it includ es process basis sharing ODBC environment, several ODBC handles, heap memory area with bind informa tion.

Startup and Shutdown Instance

To startup the GOLDILOCKS instance, set the SHARED_MEMORY_STATIC_KEY property differently from other instances. After that, a user can startup the GOLDILOCKS instance by using gsql. Execute it to take sysdba role as follows.

A user should run **listener** before startup or shutdown the GOLDILOCKS instance in dedicated mode of C/ S model.
A user can not startup or shutdown the GOLDILOCKS instance in shared mode of C/S model.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL>
```

Startup phrase in the GOLDILOCKS instance has several phases as follows.

- NOMOUNT
  - It starts up gmaster process which is a managing daemon of the GOLDILOCKS instance.
- MOUNT
  - It loads properties and recovery control file by using $GOLDILOCKS _DATA environment variable.
- OPEN
  - After loading the tablespace contents from data file, it recovers by using redo log, rebuilds no-logging indexes, creates dictionary cache, and then waits for the user's service connection.

A user can start up the GOLDILOCKS instance by using gsql as follows.

```
gSQL> \startup nomount
Startup success
gSQL> alter system mount database;
System altered.
gSQL> alter system open database;
System altered.
```

To directly enter into OPEN phase, do as follows.

```
gSQL> \startup open
Startup success
```

If GOLDILOCKS instance is shut down, gmaster (the daemon process for management) would be terminated. Then, connection and database operation is no longer possible.

There are four ways to shutdown the GOLDILOCKS instance as follows.

- NORMAL
  - After blocking the access of a new session and waiting until the end of all connected sessions, a user perform a checkpoint and shuts down the instance.
- TRANSACTIONAL
  - After blocking the start of a new transaction and waiting until the end of all running transactions, a user performs a checkpoint and shuts down the instance.
- IMMEDIATE
  - After blocking the execution of a new unit operation (Connection unit with GOLDILOCKS database. e.g. FETCH or EXECUTE, etc.) and waiting until the end of all unit operations, a user rolls back all transactions, performs a checkpoint and shuts down the instance.

- ABORT
  - Regardless of any connected session's status, a user terminates gmaster and shuts down the inst ance.

To shutdown an instance, use gsql with sysdba role and perform `\shutdown`, as follows.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \shutdown normal
Shutdown success
gSQL>
```

Start and End of Listener

A user should run the listener to provide the service in the client/ server environment.

A user can start the listener as follows.

```
% glsnr --start

Listener is started successfully.
%
```

A user can end the listener as follows.

```
% glsnr --stop

Listener is stopped.
%
```

For more information about listener control, refer to **glsnr**.
For more information about how to start or end cluster system refer to **Start and End of Cluster System**.

2.2 Installing GOLDILOCKS and Creating Database

This chapter describes how to install the GOLDILOCKS software and create a database.

Overview

GOLDILOCKS software is a compressed file with the name such as *goldilocks-<version_no>-<os_type>-<cpu_type>.tar.gz*. After decompressing the file, software binaries, various samples, fundamental database directory structures are created at the corresponding location, and then installation is completed. After the installation, the directory is created, and the directory is named after the package. Then directories whose names are *goldilocks_home* and *goldilocks_data* are created under it.

- goldilocks_home directory
  - Binary home of GOLDILOCKS product
  - Defined as GOLDILOCKS _HOME environment variable
  - Operation binaries, libraries for the client, header files, licenses, etc. are located.
- goldilocks_data directory
  - Home of the user database (instance) which GOLDILOCKS creates.
  - Defined as GOLDILOCKS _DATA environment variable
  - A default location which has data files, log files, property files

After that, use a utility called gcreatedb in *$GOLDILOCKS_HOME/bin* directory to create a database in *$GOLDILOCKS _DATA* directory.

Release Platform

GOLDILOCKS is available in the following release platform.

Table 2-3 Release platform

Platform	Platform name	OS	CPU	Remarks
Server platform	linux-x86_64	linux	x86_64	>= linux kernel 2.6 >= glibc 2.1[1] >= gcc 4.1.2 >= java 1.6 <= java 1.8
				>= linux kernel 2.6 >= glibc 2.1[1]

Platform	Platform name	OS	CPU	Remarks
	linux-powerpc-64	linux	powerpc	>= gcc 4.1.2 >= java 1.6 <= java 1.8
	hpux11.31-itanium-64	HP-UX 11.31	itanium	>= java 1.6 <= java 1.8
	aix7-powerpc-64	AIX 6.1	powerpc	>= java 1.6 <= java 1.8
Client platform	linux-x86_64	linux	x86_64	>= linux kernel 2.6 >= glibc 2.1[1] >= gcc 4.1.2 >= java 1.6 <= java 1.8
	linux-x86_32	linux	x86_32	>= Linux kernel 2.6 >= glibc 2.1[1] >= gcc 4.1.2 >= java 1.6 <= java 1.8
	hpux11.31-itanium-64	HP-UX 11.31	itanium	>= java 1.6 <= java 1.8
	hpux11.31-itanium-32	HP-UX 11.31	itanium	>= java 1.6 <= java 1.8
	aix7-powerpc-64	AIX 7.2	powerpc	>= java 1.6 <= java 1.8
	linux-powerpc-64	linux	powerpc	>= Linux kernel 2.6 >= glibc 2.1[1] >= gcc 4.1.2 >= java 1.6 <= java 1.8
	windows-x86-64	Windows	PENTINUM x86	>= java 1.6 <= java 1.8
	windows-x86-32	Windows	PENTINUM x86	>= java 1.6 <= java 1.8

[1]The user should install libnsl separately in CentOS 8, RHEL 8 or higher.

System Requirements

Check the following requirements before installing GOLDILOCKS.

- At least 2 G should be secured at the physical memory and disk space.

- A sufficient amount of paging (swap) area is required.
- The correct package version which fits into the platform to be installed is required.

GOLDILOCKS Package Configuration

This chapter describes the directory configuration when installing GOLDILOCKS.

Package Directory Configuration

Table 2-4 Parent directory configuration

Directory	Server	Client	Description
GOLDILOCKS_HOME	O	O	Binaries and libraries are installed, overwriting-enabled group when updating
GOLDILOCKS_DATA	O	X	The data storing path, overwriting-unabled group

Table 2-5 Package directory configuration

Parent directory	Package directory	Description
GOLDILOCKS_HOME	admin	Required schema script to create database
	bin	Execution files
	lib	Library files
	include	Header files such as ODBC, XA, Embedded SQL, etc.
	license	License files
	sample	Sample files
	msg	Error message files
	script	Script file for ease of use (It will be supported in future)
	app_dev	Application development
GOLDILOCKS_DATA	conf	Configuration files
	db	Database files
	wal	Log files, control files
	archive_log	Archive log files
	backup	Back up files
	trc	Trace log files, warning message files
	journal	Journal file used at cluster rebalance
	data	Required TxFile to operate clustone

Package File List

The followings are description of files in a directory, and whether it is included in server package or client package.

Table 2-6 admin directory

File name	Server	Client	Description
README	O	X	Read me
DictionarySchema.sql	O	X	Dictionary schema creating script
InformationSchema.sql	O	X	Information schema creating script
PerformanceViewSchema.sql	O	X	Performanceview schema creating script

Table 2-7 admin/ cluster directory

File name	Server	Client	Description
README	O	X	read me
DictionarySchema.sql	O	X	Dictionary schema creating script
InformationSchema.sql	O	X	Information schema creating script
PerformanceViewSchema.sql	O	X	Performanceview schema creating script

The script created in admin/standalone directory is used when using GOLDILOCKS in standalone. On the other hand, the script created in admin/cluster directory is used when using GOLDILOCKS by configuring cluster system.

Table 2-8 bin directory (Unix)

File name	Server	Client	Description
README	O	O	Read me
gmaster	O	X	GOLDILOCKS master
gcreatedb	O	X	Database creating tool
glsnr	O	X	Listener control tool
gbalancer	O	X	Loads balancer for C/S shared
gdispatcher	O	X	Manages multiple connections for C/S shared
gserver	O	X	Instance manager for C/S
gsql	O	X	Interactive SQL tool
gsqlnet	O	O	Interactive SQL tool for C/S
gpec	O	O	Embedded SQL precompiler
logmirror	O	X	Redo log replication tool
cyclone	O	X	CDC replication tool
gloader	O	X	Import/ export tool
gloadernet	O	O	Import/ export tool for C/S
cymon	O	X	CDC monitoring Tool
gdump	O	X	Control/ log/ data/ binary property file viewer

File name	Server	Client	Description
gsyncher	O	X	Synchronization utility for shared memory log and disk log files
tablediff.jar	O	X	Table comparison tool
cdispatcher	O	X	Manages cluster connections and distributes protocols in cluster system
cserver	O	X	Instance manager for cluster system
gtrclogger	O	X	Trace log manager for cluster system
gmon	O	X	Process monitoring tool
galocator	O	X	Location management tool
gagent	O	X	Location provider tool
gloctl	O	O	Interactive location editing tool
cyfile	O	X	CDC exporting file tool
clustone	O	X	CDC replication tool for cluster
clustone_sender	O	X	CDC replication tool for cluster (sender tool)

Table 2-9 bin directory (Windows client)

File name	Server	Client	Description
README	X	O	read me
gloadernet.exe	X	O	Import/export tool for C/S
gpec.exe	X	O	Embedded SQL precompiler
gsqlnet.exe	X	O	Interactive SQL tool for C/S
gloctl.exe	X	O	-

Table 2-10 lib directory (Unix)

File name	Server	Client (64 bit)	Client (32 bit)	Description
README	O	O	O	Read me
libstib.so	O	X	X	Shared library for infiniband
libgoldilocks.a	O	X	X	D/A and C/S-inclusive static library for ODBC
libgoldilocksa.a	O	X	X	D/A-only static library for ODBC
libgoldilocksas.so	O	X	X	D/A-only shared library for ODBC
libgoldilocksc.a	O	O	O	C/S-only static library for ODBC
libgoldilockscs-ul32.so	O	O	X	64 bit-C/S-only shared library for ODBC (SQLLEN = 4 byte)
libgoldilockscs-ul64.so	O	O	X	64 bit-C/S-only shared library for ODBC (SQLLEN = 8 byte)
libgoldilockscs.so	X	X	O	32 bit-C/S-only shared library for ODBC
libgoldilockscvtGB18030_32.so	X	X	O	32 bit GB18030 character set conversion library
libgoldilockscvtGB18030				

File name	Server	Client (64 bit)	Client (32 bit)	Description
_64.so	O	O	X	64 bit GB18030 character set conversion library
libgoldilockscvtUHC_32.so	X	X	O	32 bit UHC character set conversion library
libgoldilockscvtUHC_64.so	O	O	X	64 bit UHC character set conversion library
libgoldilocksesql.a	O	O	O	Static library for embedded SQL
libgoldilocksesqls.so	O	O	O	Shared library for embedded SQL
libgoldilockss.so	O	X	X	D/A and C/S-inclusive shared library for ODBC

Installing GOLDILOCKS Software

This chapter describes the operating system and the environment setting before installing GOLDILOCKS.

Kernel Parameters

Shared Memory

Shared memory is a type of Inter Process Communication (IPC). It is a memory which is used for sharing data in multiple programs. GOLDILOCKS uses shared memory with user programs using gsql, gloader, ODBC for Client/ Server (C/S) environment. Because all tablespaces for operation are created in shared memory, the precise parameter setting is required.

The followings are parameters and the recommended values required for the shared memory which is used to install GOLDILOCKS.

Table 2-23 Kernal properties for shared memory

Parameter name	Description	Recommended value	Remarks
shmmax	The maximum size of single shared memory segment	The value should be bigger than the size of the biggest datafile.	The value should be set bigger than the size of the biggest datafile belonging to the desired tablespace.
shmmni	The maximum number of shared memory segment available in system	The value should be bigger than the value of which the number of all datafile + 1.	The value should be set bigger than the value of which the number of all datafile + 1 (shared memory segment for SSA).
shmall	The total sum of all shared memory segment (The number of pages)	The value should bebigger than the total sum of tablespace configuration.	It is the total sum of pages in shared memory available in system. Generally, it is used for 8 GB or bigger shared memory. If the total sum of tablespaces in GOLDILOCKS is 32 GB, shmall should be set bigger than it.

The following is an example to set shmall when the total size of tablespaces is 32 GB.

```
kernel.shmmax = 34359738368
kernel.shmmni=4096
kernel.shmall = 8388609
```

- It is assumed that the shmmax is 32 GB and PAGE_SIZE is 4096 bytes.

```
8388609 = (34359738368 / 4096) + 1
```

- In this case, the value of shmall should be bigger than 8388609.

Semaphore

Semaphore is a kind of IPC, like as shared memory, and it is a technology to control multiple processes' behavior using the resources from the operating system. Depending on semaphore setting, multiple processes can simultaneously refer to a relevant resource, and when any process is in use, the other process may wait until it stops using the resource.

GOLDILOCKS uses semaphore to control the access sequence to the shared memory. For example, if multiple GOLDILOCKS client programs request a change to the same data, it should be controlled properly. The semaphore parameter value should be set to an appropriate value according to semaphore operation of GOLDILOCKS. A general Linux value is recommended.

The followings are recommended semaphore values to install GOLDILOCKS.

Table 2-24 Recommended kernel parameter value for semaphore

Kernel parameter	Description	Recommended value
semmsl	The number of semaphores per single semaphore set	250
semmni	The number of semaphore sets	128
semmns	The total sum of semaphore sets (semmni * semmsl)	32000
semopm	The maximum number of semaphores per system call	100

In Linux based system such as Redhat, Ubuntu, if a user creating IPC resource logs out the session list managed by systemd, then the corresponding IPC resource is automatically deleted. Therefore, the system should be set as follows to prevent deleting the semaphore. (kernel 3.0.0 and higher)

```
# cp -i /etc/systemd/logind.conf /etc/systemd/logind.conf_prev
# cat /etc/systemd/logind.conf
[Login]
#NAutoVTs=6
#ReserveVT=6
```

```
...
RemoveIPC=no
```

- Modify it, then execute it.

```
# systemctl restart systemd-logind
```

Network

The backlog means the sockets' queue length waiting to be accepted during the TCP socket listen. Set gls nr's backlog in GOLDILOCKS as glsnr config file's BACKLOG. If the backlog's maximum value in system is bigger than somaxconn, then it sets to somaxconn. In this case, somaxconn should be extended.

GOLDILOCKS uses Unix Domain Socket (UDS) queue when it operates in C/S shared mode. The queue le ngth is set to max_dgram_qlen. If the value is small when clients access the network simultaneously, then it leads to bottleneck state of communication among glsnr, gbalancer and gdispatcher.

The followings are recommended network values to install GOLDILOCKS.

Table 2-25 Recommended kernel parameter value for network

Kernel parameter	Description	Recommended value
somaxconn	The maximum value of listen backlog	1024
max_dgram_qlen	Unix domain socket queue size	256

Applying Parameters

For a one-time execution, a user can do as follows. (It is required to reapply when the user restarts the sys tem).

```
[SHELL]> echo   34359738368   >  /proc/sys/kernel/shmmax
[SHELL]> echo   8388608 >   /proc/sys/kernel/shmall
[SHELL]> echo   4096   >  /proc/sys/kernel/shmmni
[SHELL]> echo   250 32000 100 128  /proc/sys/kernel/sem
[SHELL]> echo   1024   >  /proc/sys/net/core/somaxconn
[SHELL]> echo   256   >  /proc/sys/net/unix/max_dgram_qlen
```

If a user wants to apply it automatically even when the user restarts the system, the user can do as follow s in /etc/sysctl.conf.

```
# shared memory
kernel.shmmax = 34359738368
kernel.shmall = 8388608
kernel.shmmni = 4096
```

```
# semaphore
kernel.sem = 250 32000 100 128
# network
net.core.somaxconn = 1024
net.unix.max_dgram_qlen = 256
```

Use the following command to apply the changes given above.

```
[SHELL]> sysctl  -p
```

Checking Parameters

The described parameters can be checked by using the following commands.

```
[SHELL]> ipcs -l
------ Shared Memory Limits --------
max number of segments = 4096
max seg size (kbytes) = 33554432
max total shared memory (kbytes) = 33554432
min seg size (bytes) = 1
------ Semaphore Limits --------
max number of arrays = 128
max semaphores per array = 250
max semaphores system wide = 32000
max ops per semop call = 100
semaphore max value = 32767
```

Decompressing GOLDILOCKS

GOLDILOCKS package is supplied in a compressed form. The basic installation completes by decompressi on.

The followings are simple examples of how to install the GOLDILOCKS package.

```
##  $GOLDILOCKS_HOME=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
[SHELL]> gzip  - d goldilocks-mercury.2.1.0-linux-x86_64.tar.gz
[SHELL]> tar -xvf goldilocks-server-mercury.2.1.0-linux-x86_64.tar
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/sqlext.h
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/goldilocks.h
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/sqlca.h
...
```

When the decompression completes, a user can change the directory name <package_file_name> on the user's taste, and accordingly the user should change the environment variables of $GOLDILOCKS _HOME and $GOLDILOCKS _DATA.

For more information about directory created by decompression, refer to **GOLDILOCKS Package Configuration**

Setting Enviromment Variables

After decompression of GOLDILOCKS package, bin and lib path will be created under $GOLDILOCKS _HOME directory. Then as given below, a user should add bin and lib path under PATH and LD__LIBRARY_PATH to execute GOLDILOCKS software and develop applications. (When developing GOLDILOCKS client application, a user should always insert $GOLDILOCKS_HOME/include to include file directory of compile option.)

```
export PATH=$GOLDILOCKS _HOME/bin:$PATH
export LD_LIBRARY_PATH=$GOLDILOCKS _HOME/lib:$LD_LIBRARY_PATH
```

Environment variables are required to use GOLDILOCKS. A user should set them prior to installation because some variables are referenced to even during installation.

Table 2-26 OS environment variables for GOLDILOCKS installation

Environment variables	Description	Remarks
GOLDILOCKS_HOME	Directory path to install GOLDILOCKS binaries	This variable is referenced during GOLDILOCKS operation, and the directory to install GOLDILOCKS should be set as an environment variable in advance.
GOLDILOCKS_DATA	The location to create GOLDILOCKS database instance	This variable is referenced during GOLDILOCKS database creation and operation.
PATH	Directory path of GOLDILOCKS executable file	This variable should be set to execute various GOLDILOCKS binaries without an absolute path.
LANG	Character set of terminal	• If the character set is different from the original character set which is created during GOLDILOCKS database creation, characters (Except alphabets, numbers and special characters) may not be displayed properly. Or the string related functions may not be executed correctly. • A user should set locale corresponding to GB18030, SQL_ASCII, UHC, UTF8. • e.g. export LANG=ko_KR.utf8

```
##  $GOLDILOCKS_HOME=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
[SHELL]> gzip  -d goldilocks-mercury.2.1.0-linux-x86_64.tar.gz
```

```
[SHELL]> tar -xvf goldilocks-server-mercury.2.1.0-linux-x86_64.tar
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/sqlext.h
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/goldilocks.h
goldilocks-server-mercury.2.1.0-linux-x86_64/goldilocks_home/include/sqlca.h
...
```

Deleting Database

Delete datafile, control file, redo log file and archive log file (when using the archive log file) should be de leted when deleting the existing database to recreate the GOLDILOCKS DATABASE.

The following is an example of deleting GOLDILOCKS DATABASE.

```
## $GOLDILOCKS_BASE=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
## $GOLDILOCKS_DATA=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_data/
## $GOLDILOCKS_HOME=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_home/
[SHELL]> rm -rf $GOLDILOCKS_DATA/db/*.dbf
[SHELL]> rm -rf $GOLDILOCKS_DATA/wal/*.ctl
[SHELL]> rm -rf $GOLDILOCKS_DATA/wal/*.log
[SHELL]> rm -rf $GOLDILOCKS_DATA/archive_log/*.log
```

The location of the data file and archive file may vary depending on the settings by a user.

Deletion

GOLDILOCKS package is not provided in compressed file format, so a specific deletion rule is not required. Delete the installed directory after terminating DATABASE.

The following is an example of deleting GOLDILOCKS package.

```
## $GOLDILOCKS_BASE=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
## $GOLDILOCKS_DATA=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_data/
## $GOLDILOCKS_HOME=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_home/
[SHELL]> rm -rf $GOLDILOCKS_DATA
[SHELL]> rm -rf $GOLDILOCKS_HOME
[SHELL]> rm -rf $GOLDILOCKS_BASE
## ~/.bash_profile
$GOLDILOCKS_BASE=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/ ❶ Delete
```

```
$GOLDILOCKS_DATA=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_data/ ❷ Delete
$GOLDILOCKS_HOME=/home/GOLDILOCKS/goldilocks-mercury.2.1.0-linux-x86_64/
                    goldilocks_home/ ❸ Delete
```

Creating Database

Create database after the completion of property creation. A user can create database by using $GOLDILOCKS_HOME/bin/gcreatedb. The followings are how to use the gcreatedb commands.

```
[SHELL]> gcreatedb --help
Usage
    gcreatedb [options]
Options:
    --cluster        cluster system (if not specified, stand-alone system)
    --db_name        database name
    --db_comment     database comment
    --timezone       timezone ( {+/-}{TZH:TZM} )
    --character_set  character set
                       SQL_ASCII
                       UTF8
                       UHC
                       GB18030
    --char_length_units  char length units
                          OCTETS
                          CHARACTERS
    --member         local cluster member name
    --host           cluster ip address or host name
    --port           cluster port number
    --silent         suppresses the display of the result message
    --help           print help message
examples:
    gcreatedb --db_name="goldilocks" --db_comment="goldilocks database" --timezone="+09:00"
--character_set="UTF8" --char_length_units="OCTETS" --silent
```

$GOLDILOCKS_HOME/conf/goldilocks.properties.conf is referenced when creating database. Then, table space files are created in *SYSTEM_TABLESPACE_DIR* path in *goldilocks.properties.conf* with the value of ****_TABLESPACE_SIZE*.

--cluster option should be specified when creating the database which is to participate in cluster system.

The followings are execution arguments of gcreatedb.

Table 2-27 Execution arguments of gcreatedb

Argument	Description
--cluster	It is the database to be used in cluster system. If it is omitted, standalone database is created.
--db_name	It is the database name. If it is omitted, it is set as goldilocks.
--db_comment	It is the database description. If it is omitted, it is set as goldilocks database.
--timezone	It is the timezone. If it is omitted, it is set as TIMEZONE property.
--character_set	It is the database character set. GOLDILOCKS supports four types of character sets. • GB18030: Simplified Chinese • SQL_ASCII: Character set supporting ASCII • UHC: Unified Hangul Code • UTF8: Unicode Transformation Format - 8 If it is omitted, it is set as CHARACTER_SET property.
--char_length_units	It is the unit of character length. • OCTETS: It identifies 1 byte as 1 character • CHARACTERS: It identifies 1 character (n byte) as 1 character. If it is omitted, it is set as CHAR_LENGTH_UNITS property.
--member	It is the member name local database to be used in cluster system. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER property.
--host	It is the host name or the IP address of local member to be used for communication between cluster system members. If the host name is used, then it uses the first IPv4 address of the system. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_HOST property.
--port	It is the TCP listen port of local member to be used for communication between cluster system members. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_PORT property.
--silent	It hides display messages.
--help	It displays help messages.

A user should consider the followings when creating database.

- Setting kernel parameter shared memory
  - If the size specified in shared memory setting is smaller than the size described in $GOLDILOCKS_HOME/conf/goldilocks.properties.conf, a user can not create the database.
- Tablespace size
  - Tablespace files are created when the database is created, and the tablespace is used after being allocated to the memory as big as the tablespace size when driving GOLDILOCKS. Therefore, it us

es memory even when the actual user data does not exist in the data tablespace. Therefore, a user should create database with the sufficient memory considering the actually available memory as well as shared memory on GOLDILOCKS startup machine when writing goldilocks.properties.conf.

- Whether to use cluster system
  - It should be specified that whether the database will participatte as a member of cluster system when creating the database. In other words, --cluster option should be omitted when executing gcreatedb using the database as standalone, but --cluster option should be specified when using the database as cluster system.

When database is created successfully, a user can check the following tablespace file in the path described in SYSTEM_TABLESPACE_DIR of goldilocks.properties.conf.

```
[SHELL]> gcreatedb
Database created
[SHELL]> gcreatedb --db_name="TEST_DB"                   \
                   --db_commnet="test database comment"  \
                   --timezone="+09:00"                   \
                   --character_set="UHC"                 \
                   --char_length_units="OCTETS"
Database created
[SHELL]> ls $GOLDILOCKS_DATA/db
system_data.dbf  system_dict.dbf  system_undo.dbf
```

The following is an example of creating database to be used in cluster system.

```
[SHELL]> gcreatedb --cluster
Database created
[SHELL]> gcreatedb --cluster --member=G1N1
Database created
[SHELL]> gcreatedb --cluster --member=G1N1 --host=127.0.0.1 --port 10101
Database created
[SHELL]> gcreatedb --cluster                          \
                   --db_name="TEST_DB"                \
                   --home=$GOLDILOCKS_DATA            \
                   --host=127.0.0.1                   \
                   --port=10101                       \
                   --db_comment="g1n1 db comment"     \
                   --timezone="+09:00"                \
                   --character_set="UHC"              \
                   --char_length_units="OCTETS"
Database created
```

```
[SHELL]> ls $GOLDILOCKS_DATA/db
system_data.dbf  system_dict.dbf  system_trans.dbf system_undo.dbf
```

Building Dictionary Schema Information

Create the following schema to get the system and object information.

A user should build the following schema after database creation. Otherwise, there is a possibility of malfunction in Catalog API of ODBC, JDBC for obtaining the object's structure information (for example, SQLTables() function). If so, it will not interlock with third party tools.

- DICTIONARY_SCHEMA: It consists of views and tables to get object information such as DBA_*, ALL_*, USER_* .
- INFORMATION_SCHEMA: It consists of views and tables included in the SQL standard INFORMATION_SCHEMA.
- PERFORMANCE_VIEW_SCHEMA: It consists of views to get system information by combining the fixed tables' information.

Views and tables included in each schemas provides convenience to get system information.

After driving GOLDILOCKS instance on OPEN phase, a user should execute the sql files as follows. It should be done at least once after the first database creation.

The scripts to build dictionary schema information are divided into the script for standalone system and the script for cluster system. Therefore, a user should use the appropriate script for the purpose to build the information.

The following describes how to build the information by using the script for standalone database.

```
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/standalone/DictionarySchema.sql
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/standalone/InformationSchema.sql
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/standalone/PerformanceViewSchema.sql
```

The following describes how to build the information by using the script for cluster system.

```
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/DictionarySchema.sql
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/InformationSchema.sql
% gsql --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/PerformanceViewSchema.sql
```

2.3 Managing Database Memory Structure

This chapter describes the database components which compose GOLDILOCKS instance.

Database Memory Structure

GOLDILOCKS database is divided into memory area and disk area. Memory area is a collection of tablespa ce consisting of one or more shared memories. GOLDILOCKS database never goes down to the disk by re place operation.

Disk area consists of data files, control file, property file, online redo log files. Data file exists one per shar ed memory of each tablespace, and control file contains instance configuration information. property file stores instance environment settings, and online redo log file is used to recover database.

Control File

Control file records the physically stored information on the disk of database, and determines the status o f database by firstly reading at the beginning of Instance startup. The control file records the following inf ormation.

- Instance state at the time of the previous checkpoint
- Transaction durability mode (CDS/TDS) at the time of the previous startup
- Online redo log file information
- Data file information of each tablespace

Online Redo Log File

Online redo log files store all changes made to the database by transactions in instances. It is used to reco ver unwritten changes on the data file when restarting instance after database's abnormal termination. F our online redo log files are generated by default in the size specified in LOG_FILE_SIZE property when cr eating database. A user can add more if the user need. The redo log files are reused in circulation manner.

Checkpoint are generated when online redo log file switches to the next file, and then some dirty pages move down to an appropriate data file. If the checkpoint operation is delayed and the updated page doe s not move down (ACTIVE state), all transactions will be suspended until checkpoint completion. Therefor e, creating a suitable size online redo log file according to the application's characteristic is helpful to imp rove the database system performance.

Undo Segment

Undo segments records images in advance of changing operation to use when transactions partially or to tally rollback. A single undo segment is assigned to a single transaction during update operation. Undo se gments are stored in MEM_UNDO_TBS tablespace. It is recommended to secure enough undo tablespace, in preparation for multiple update transactions or a single transaction with large amount of update opera tion (bulk delete).

Data File

Data file includes the contents of tables/indexes stored in tablespace.

Data file consists of the followings.

- Page
  - The minimum unit of database I/O. The current size is 8 Kbytes.
- Extent
  - A certain number of continuous pages' collection. The minimum unit of which the segment is all ocated space from the tablespace.
  - Extent size of each tablespace could be different.
- Segment
  - A specific type of data structure's collection. A segment consists of extent sets.

Exceptionally, a temporary tablespace, such as MEM_TEMP_TBS tablespace, does not execute redo loggi ng, nor does data file create.

Tablespace

Database is divided into tablespaces which is a logical structure containing tables and indexes. GOLDILOC KS tablespace is classified into the memory tablespace and the disk tablespace. In the memory tablespace, a separate disk I/O does not occur when the shared memory is created per each data file in the tablespac e and accesses to the page. However, in the disk tablespace, the buffer cache of the system is used to acc ess the page. The information about the tablespace existing in the current database can be output by retr ieving V$TABLESPACE table.

GOLDILOCKS supports the following tablespaces by default.

Table 2-28 Tablespaces of GOLDILOCKS

Owner	Name	Description
	DICTIONARY_TBS	Default dictionary tables are stored in this tabespace to operate database.
	MEM_UNDO_TBS	Undo segments and transaction information are stored in this table space.
	MEM_DATA_TBS	If a user does not specify a tablespace when creating schema object, the data ta ble is stored in this tablespace by default.

Owner	Name	Description
SYSTEM	DISK_DATA_TBS	It is the disk tablespace which the user uses by default.
	MEM_TEMP_TBS	Indexes which does not specified tablespace name, and temporary tables which are used by queries are created in the tablespace. Indexes are rebuilt when restarting instance because logging does not occur.
	MEM_TRANS_TBS	It is used to recover global transaction in cluster system. It is created only when it is configured as cluster system.
USER	User-defined	User defines this tablespace to collect specific tables to a specific tablespace and manage them.

Tablespace Types

There are five types of tablespace as follows.

- DICT
  - Tablespace type for storing dictionary tables and indexes.
- DATA
  - Tablespace type for storing general schema objects such as tables and indexes.
  - It becomes the subject of redo logging and page flushing.
- UNDO
  - Tablespace type for storing undo segments.
  - It becomes the subject of redo logging and page flushing.
- TEMPORARY
  - Tablespace type for storing the temporary tables and no-logging indexes which are created during SELECT query.
  - It is not the subject of redo logging and page flushing.
- TRANSACTION (Cluster only)
  - Tablespace type which is used to recover global transaction in cluster system

Checking Information of Database Storage Structure

This chapter describes a method to check the information about multiple database storage structure which are mentioned above.

Control File Information

Use gdump utility to check the contents because control file is stored in binary format.

```
[SHELL]> gdump CONTROL control_0.ctl
```

Online Redo Log File Information

Retrieve the control file by using gdump tool, then the name and current state of each online redo file wil l be displayed.

Data File Information

Retrieve the control file by using gdump tool, then the data files in each tablespaces and its states will be displayed. Also, viewing the V$DATAFILE table, their current states will be displayed.

Tablespace Information

Retrieve the control file by using gdump tool, then the name and state of each tablespace in the current database will be displayed. Also, a user can enquire the V$TABLESPACE table by using SQL.

Property Information

Open the text file $GOLDILOCKS_Data/conf/goldilocks.properties.conf, then the property information wil l be displayed. When working online, retrieve V$PROPERTY, V$DB_PROPERTY tables, then the informatio n about currently applied property values will be displayed.

General Operation of Data Storage

A tablespace stores data, and its operation is as follows.

Creating Tablespace

The memory and the disk USER DATA tablespaces are created as follows.

```
gSQL> CREATE TABLESPACE TEST_TBS DATAFILE 'TEST_TBS.dbf' SIZE 10M;
Tablespace created.
gSQL> CREATE MEMORY TABLESPACE TEST_TBS DATAFILE 'TEST_MEM_TBS.dbf' SIZE 10M;
Tablespace created.
gSQL> CREATE DISK TABLESPACE TEST_TBS DATAFILE 'TEST_DISK_TBS.dbf' SIZE 10M;
Tablespace altered.
gSQL> CREATE DISK TABLESPACE DISK_TBS DATAFILE 'TEST_DISK_TBS.dbf' SIZE 10M AUTOEXTEND OFF;
Tablespace altered.
```

TEMPORARY tablespace does not include data file, so it is created as follows.

```
gSQL> CREATE TEMPORARY TABLESPACE TEST_TEMP_TBS MEMORY 'TEST_TEMP_TBS' SIZE 10M;
Tablespace created.
```

Retrieving Tablespace Usage State

A tablespaces space is allocated or deallocated in the unit of one extent consisting of one or more consec utive pages. A user can retrieve the size of one extent (BYTE) in a specific tablespace as follows.

```
gSQL> SELECT EXTENT_SIZE FROM V$TABLESPACE WHERE TBS_NAME = 'TEST_TBS';
EXTENT_SIZE
-----------
     262144
1 row selected.
```

A user can view the state of all extents in tablespaces by using D$TABLESPACE_EXTENT table. When an e xtent is in use, the STATE column is 'U'. When an extent is in free state, the STATE column is 'F'. Therefor e, the remaining size of space in the current tablespace (the number of extents) can be calculated as follo ws.

```
gSQL> SELECT COUNT(*) FROM D$TABLESPACE_EXTENT('TEST_TBS') WHERE STATE = 'F';
COUNT(*)
--------
      38
1 row selected.
```

Seeing the result above, the empty space in TEST_TBS is 38 * 262144 = 9437184 Byte.

Altering Tablespace

A user can alter the tablespaces by using Add/Remove Data File (Memory in case of temporary tablespace s), and Online/Offline.

Add/ Drop Data File (or Memory)

If a user wants to add spaces to tablespaces while operating the database, the DATA tablespaces allocate the additional space by using the following syntax.

```
gSQL> ALTER TABLESPACE TEST_TBS ADD DATAFILE 'TEST_TBS2.dbf' SIZE 10M;
Tablespace altered.
```

TEMPORARY tablespace adds spaces as follows. Unlike DATA tablespace, a name should be given, and th e name should be a unique memory name in database.

```
gSQL> ALTER TABLESPACE TEST_TEMP_TBS ADD MEMORY 'TEST_TEMP_TBS2' SIZE 10M;
Tablespace altered.
```

A user can drop the space in DATA tablespace by using the following syntax. However, if any part of the area is used, the user can not drop it.

```
gSQL> ALTER TABLESPACE TEST_TBS DROP DATAFILE 'TEST_TBS2.dbf';
Tablespace altered.
```

Similarly, a user can withdraw the space in TEMPORARY tablespace by using the following syntax.

```
gSQL> ALTER TABLESPACE TEST_TEMP_TBS DROP MEMORY 'TEST_TEMP_TBS2';
Tablespace altered.
```

Offline Tablespace

Switch the tablespace to offline mode if a user wants to move the location of data file in the tablespace. Use the following syntax.

```
gSQL> ALTER TABLESPACE TEST_TBS OFFLINE;
Tablespace altered.
```

A user can switch the tablespace to online mode again by using the following syntax.

```
gSQL> ALTER TABLESPACE TEST_TBS ONLINE;
Tablespace altered.
```

Altering Automatic Data File Expand Property in Disk Tablespace

The data file in the disk tablespace is created in the initial size, and it is automatically extended to the max imum size when it is needed. The automatic expand property can be on or off as follows. The automatic expand size and the maximum size of the data file can be altered when altering the automatic expand pr operty.

```
gSQL> ALTER DATABASE DATAFILE 'TEST_DISK_TBS.dbf' AUTOEXTEND ON;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'TEST_DISK_TBS.dbf' AUTOEXTEND OFF;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'TEST_DISK_TBS.dbf' AUTOEXTEND ON NEXT 10M MAXSIZE 20M;
Database altered.
```

Rename

Rename the tablespace by using the following syntax.

```
gSQL> ALTER TABLESPACE TEST_TBS RENAME TO TEST_TBS2;
Tablespace altered.
```

Switch the tablespace to offiline mode, if a user wants to change the location of data file in the tablespac e. Then, move the data file by using OS command, rename it by using ALTER TABLESPACE statement, the n switch the tablespace to online state.

```
gSQL> ALTER TABLESPACE TEST_TBS OFFLINE;
Tablespace altered.
gSQL> ALTER TABLESPACE TEST_TBS RENAME DATAFILE 'TEST_TBS.dbf' TO 'TEST_TBS_1.dbf';
ERR-42000(16164): file does not exist :
ALTER TABLESPACE TEST_TBS RENAME DATAFILE 'TEST_TBS.dbf' TO 'TEST_TBS_1.dbf'
                                                                        *
ERROR at line 1:
```

- The following procedure describes how to rename the file by using OS command.

```
gSQL> ALTER TABLESPACE TEST_TBS RENAME DATAFILE 'TEST_TBS.dbf' TO 'TEST_TBS_1.dbf';
Tablespace altered.
gSQL> ALTER TABLESPACE TEST_TBS ONLINE;
Tablespace altered.
```

Dropping Tablespace

Drop an unnecessary tablespace by using the following syntax. The statement after INCLUDING is optiona l, but if the statement is given then it will delete all the content (schema object) and data file in the tables paces.

```
gSQL> DROP TABLESPACE TEST_TBS INCLUDING CONTENTS AND DATAFILES;
Tablespace dropped.
```

Store Mode

GOLDILOCKS uses the store mode as an instance unit to maximize performance under certain circumstan ce. Store mode defines which part of ACID property to give up to improve the operation performance in t he transaction.

GOLDILOCKS supports two types of store modes.

- Transactional Data Store (TDS) mode
  - TDS mode is default store mode of GOLDILOCKS database.
  - Transactional Data Store (TDS) mode is general DBMS store mode. In this mode, all transactions i n the instance write both undo log and redo log. Therefore, a user can rollback the transactions a nd recover using data file and online redo log file even when an instance is terminated abnormall y, because periodical checkpoint are performed.
- Concurrent Data Store (CDS) mode
  - All running transactions in the instance write undo logs, but do not write redo logs. Therefore, th e transactions can deal with all run-time errors, and can rollback. But if an instance is terminated abnormally or terminated using shutdown abort statement, all updated data would be lost. (It do es not provide recover facility). It is because checkpoint action does not occur. CDS Mode control s concurrency among transactions, so it ensures normal operations of transactions even when dif ferent transactions access the same object at the same time.
  - CDC Mode is mainly used in run-time information oriented database in which query/update oper ations are frequently performed but does not require durability such as cache server.

Store mode is set through the property setting when a user starts up the instance. Transactions can not b e executed in different store modes. The user should carefully set the store mode when the user starts up the instance because the user can not change the instance in online mode.

2.4 Managing Schema Object

Schema Object

Schema object is a set of logical structure created by a user. GOLDILOCKS supports the following schema objects, which are table, index, synonym, view, sequence, constraint and stored procedure.

Schema Object Management Privileges

Currently, GOLDILOCKS supports user and his privilege. Therefore, not all the users share all the created o bjects, so the privilege should be given to a user.

Managing Table

This chapter describes table overview, methods of retrieving the table information, creating/ altering tabl e and loading/ dropping data.

Table

A table is the most basic unit of storage containing user data. A table consists of columns and rows.

Table Type

Currently, GOLDILOCKS supports general heap table whose data saving order is irrelevant to sort order of a particular column. However, GOLDILOCKS does not support clustered table, partitioned table.

- It supports basic heap table only.
- It supports primary key/unique/not null constraint.
- It supports the datatypes as follows.
  - BOOLEAN
  - SMALLINT, INTEGER, BIGINT, REAL, DOUBLE, NUERMIC, FLOAT
  - CHAR (MAX 2000), VARCHAR (MAX 4000), BINARY, VARBINARY, LONG VARCHAR, LONG VA RBINARY
  - DATE, TIME, TIMESTAMP, INTERVAL (It supports WITH/WITHOUT TIMEZONE of TIME/TIMEST AMP.)
  - It does not support BLOB type.

- The number of columns, indexes and constraints are not limited.
- A user can retrieve the entire table information using a query *SELECT * FROM TABLES;*.

If a huge number of rows are stored in a particular table, and then the table size becomes big, even bulk delete operation does not return the table's empty space to the tablespace. But TRUNCATE operation can return all existing space to the tablespace.

Table data can be stored and retrieved being distributed to multiple nodes according to the user's desirin g distribution policy when using GOLDILOCKS configuring it as cluster system. For more information, refe r to **Managing Table**

Managing Index

This chapter describes index overview and creating/deleting index.

Overview

Index is a subsidiary schema object which is linked to tables. A user can easily find the location of specific ally conditioned row using the index. A user can also retrieve the row's column value if the column is the key column of the index.

GOLDILOCKS can create as many indexes in need to tables. However, too many indexes burden the exec ution of inserting/ changing/ deleting operation of the table, then it may lower the performance.

Primary key or unique constraint automatically creates an index on that column.

Index Property

- It supports B-link tree form index.
  - GOLDILOCKS provides B-link tree form index by default.
- The size of a single index node is 8 Kbytes.
- The maximum number of key columns is 32, and the maximum key length is 2000 bytes.
- It supports unique index.
- It supports Ascending/Descending, NULLS FIRST and NULLS LAST.
  - A user can define whether to sort index key columns in ascending order (ASC) or in descending (DESC) order.
  - A user can define whether to list NULL value of the index key column at first (NULLS FIRST) or at last (NULLS LAST).
- A user can retrieve the whole index information by using the query *SELECT * FROM INDEXES;*.
- A user can calculate the index size in the similar way of calculating table because index is implemente d by segment in the same way of implementing table.

Sequence

Sequence is a schema object which generates a unique number.

A user can generate the sequence as follows.

```
gSQL> CREATE SEQUENCE customers_seq START WITH 1000 INCREMENT BY 1 NOCACHE NOCYCLE;
Sequence created.
```

A user can use the sequence by using NEXTVAL.

```
gSQL> SELECT customers_seq.NEXTVAL FROM dual;
```

A user can drop the sequence as follows.

```
gSQL> DROP SEQUENCE customers_seq;
```

Global sequence object is automatically created when user creates sequence by using GOLDILOCKS confi guring cluster system. This object manages the global pool of the sequence value which is used being sha red by all member nodes in cluster system. Each member node is allocated the sequence value as many as specified from the global object when calling NEXTVAL and uses them.
For more information, refer to **Global Sequence**.

2.5 Managing User

Creating User

Only the SYS user and the user with the CREATE USER ON DATABASE privilege can create a user for GOL DILOCKS database. The CREATE SESSION ON DATABASE privilege is required to connect to the newly cre ated user.

The followings are the syntax to create a user.

```
<user definition> ::=
    CREATE USER user_identifier IDENTIFIED BY password
    [ DEFAULT TABLESPACE tablespace_name ]
    [ TEMPORARY TABLESPACE tablespace_name ]
```

The followings are the syntax rules and parameters to create a user.

- user_identifier
  - It is a username to be created.
  - The username and the role name should be unique.
  - The length of a user_identifier should be smaller than 128 bytes.
- password
  - The password is stored encrypted.
  - The length of a password should be smaller than 128 bytes.
  - Password is case-sensitive.
- DEFAULT TABLESPACE tablespace_name
  - It specifies the default tablespace which stores the objects such as tables, indexes (LOGGING) cre ated by a user which is to be created.
  - If DEFAULT TABLESPACE clause is omitted, it specifies as the default data tablespace (MEM_D ATA_TBS) which is defined when creating DATABASE (<database definition>).
- TEMPORARY TABLESPACE tablespace_name
  - It specifies the TABLESPACE to store user-created temporary tables, index (NO LOGGING), and q uery processing-generated intermediate results.
  - If TEMPORARY TABLESPACE clause is omitted, it is specified as the default temporary tablespace (MEM_TEMP_TBS) which is defined when creating DATABASE (<database definition>).
- INDEX TABLESPACE tablespace_name
  - It specifies the default tablespaces to store an index object created by a user to be created.
  - If INDEX TABLESPACE clause is omitted, the default value is INDEX TABLESPACE NULL.

Dropping User

It drops the created user of GOLDILOCKS database. An access privilege and user range for dropping user are as same as those for creating user.

The following is the syntax to drop a user.

```
<drop user statement> ::=
    DROP USER [ IF EXISTS ] user_identifier [ <drop behavior> ]
    ;
<drop behavior> ::=
      RESTRICT
    | CASCADE
```

The followings are the syntax rules and parameters for dropping a user.

- IF EXISTS
  - Even when the user does not exist, an error does not occur.
- user_identifier
  - It is a database username to be dropped.
  - A user can not drop a user, such as SYS, which is automatically generated when the database is created.
  - It does not drop objects, such as tablespace, which is not the owner but created by user_identifier.
- drop behavior
  - If drop behavior is omitted, the default value is RESTRICT.

Altering User

It alters the definition of the GOLDILOCKS database user. ALTER USER privilege is required for an ordinary user. However, if a user is the user_identifier user, then the user can alter the definition without the privilege.

The followings are the syntax to alter the user definition.

```
<alter user statement> ::=
      ALTER USER user_identifier <alter user action>
    | ALTER USER PUBLIC <alter schema path>
    ;
<alter user action> ::=
```

```
      <alter password>
    ¦ <alter profile>
    ¦ <alter default tablespace>
    ¦ <alter temporary tablespace>
    ¦ <alter index tablespace>
    ¦ <alter schema path>
<alter password> ::=
    IDENTIFIED BY new_password [ REPLACE old_password ]
<alter profile> ::=
    PROFILE { profile_name ¦ DEFAULT ¦ NULL }
<password expire> ::=
    PASSWORD EXPIRE
<account lock> ::=
    ACCOUNT { LOCK ¦ UNLOCK }
<alter default tablespace> ::=
    DEFAULT TABLESPACE tablespace_name
<alter temporary tablespace> ::=
    TEMPORARY TABLESPACE tablespace_name
<alter index tablespace> ::=
    INDEX TABLESPACE { tablespace_name ¦ NULL }
<alter schema path> ::=
    SCHEMA PATH ( { schema_name ¦ CURRENT PATH } [, ...] )
```

The followings are the syntax rule and parameters for altering user.

- user_identifier
  - It is a username to be altered.
- <alter password>
  - It alters user password.
  - IDENTIFIED BY new_password
    - It changes the current password, and the new password is stored encrypted.
    - The length of a password should be smaller than 128 bytes.
    - Password is case-sensitive.
  - REPLACE old_password
    - If a user have ALTER USER ON DATABASE privilege, the user can omit it.
    - If a user do not have ALTER USER ON DATABASE privilege, the user can not omit it.
    - The user and user_identifier should be same.
- <alter profile>
  - It alters the profile for password management policies.
  - PROFILE profile_name
    - It allocates profile_name created by a user.

    - PROFILE DEFAULT
        - It allocates "DEFAULT" which is the default profile.
    - PROFILE NULL
        - It does not allocate the profile.
- 〈password expire〉
    - It expires the user password.
- 〈account lock〉
    - ACCOUNT LOCK
        - It locks the user account.
    - ACCOUNT UNLOCK
        - It unlocks the account lock.
- 〈alter default tablespace〉
    - It alters user's default tablespace.
    - tablespace_name should be data tablespace.
- 〈alter temporary tablespace〉
    - It alters user's temporary tablespace.
    - tablespace_name should be temporary tablespace.
- 〈alter index tablespace〉
    - It alters the index tablespace of a user.
    - It assigns INDEX TABLESPACE tablespace_name
        - When assigning the data tablespace, it becomes the LOGGING index.
        - When assigning the temporary tablespace, it becomes the NOLOGGING index.
    - INDEX TABLESPACE NULL
        - It does not assign the index tablespace.

2.6 GOLDILOCKS Property

GOLDILOCKS property is classified as the property which is applied when creating database and the property which can be updated at online/offline. A user can change the tablespace path and the redo log file only at MOUNT phase of startup.

Properties When Creating Database

Table 2-29 Properties when creating database

Name	Description
SYSTEM_MEMORY_DICT_TABLESPACE_SIZE	Initial size of dictionary tablespace
SYSTEM_MEMORY_DATA_TABLESPACE_SIZE	Initial size of system data tablespace
SYSTEM_MEMORY_UNDO_TABLESPACE_SIZE	Initial size of system undo tablespace
SYSTEM_MEMORY_TEMP_TABLESPACE_SIZE	Initial size of system temporary tablespace
LOG_BLOCK_SIZE	Block size of redo log file
LOG_FILE_SIZE	Initial size of redo log file
LOG_GROUP_COUNT	The number of redo log files
CHARACTER_SET	Character set
TIMEZONE	Time zone
CHAR_LENGTH_UNITS	Character length unit

Properties When Driving Database

There are more than 100 properties in GOLDILOCKS database. The followings are frequently used properties among them.

Table 2-30 Frequently used properties when driving database

Name	Description
SHARED_MEMORY_STATIC_KEY	Key value to create the shared memory
SHARED_MEMORY_STATIC_SIZE	Size of the shared memory
DATA_STORE_MODE	Storage mode of GOLDILOCKS instance
LOG_BUFFER_SIZE	Log buffer size
LOG_DIR	Directory path of redo log
PRIVATE_STATIC_AREA_SIZE	Static area size per session
CLIENT_MAX_COUNT	The maximum number of accessible session
PROCESS_MAX_COUNT	The maximum number of process

Name	Description
NET_BUFFER_SIZE	Network buffer size per session

2.7 GOLDILOCKS Utility

gcreatedb

The gcreatedb utility initializes GOLDILOCKS database and gets ready for the service. The gcreatedb gene rates data files and log files in the GOLDILOCKS_DATA environment variable location according to given properties. The following is a syntax.

```
[SHELL]> gcreatedb --help
Usage
    gcreatedb [options]
Options:
    --cluster               cluster system (if not specified, stand-alone system)
    --db_name               database name
    --db_comment            database comment
    --timezone              timezone ( {+/-}{TZH:TZM} )
    --character_set         character set
                              SQL_ASCII
                              UTF8
                              UHC
                              GB18030
    --char_length_units     char length units
                              OCTETS
                              CHARACTERS
    --member                local cluster member name
    --host                  cluster ip address or host name
    --port                  cluster port number
    --silent                suppresses the display of the result message
    --help                  print help message
examples:
    gcreatedb --db_name="goldilocks" --db_comment="goldilocks database" --timezone="+09:00"
--character_set="UTF8" --char_length_units="OCTETS" --silent
```

Tablespace files are created in *SYSTEM_TABLESPACE_DIR* of goldilocks.properties.conf as each value of * **_TABLESPACE_SIZE by referring to $GOLDILOCKS_HOME/conf/goldilocks.properties.conf when creati ng the database.

The followings are execution arguments of gcreatedb command.

Table 2-31 Execution arguments of gcreatedb

Argument	Description
--cluster	It is the database to be used in cluster system. If it is omitted, standalone database is created.
--db_name	It is the database name. If it is omitted, it is set as *goldilocks*.
--db_comment	It is the database description. If it is omitted, it is set as *goldilocks database*.
--timezone	It is the timezone. If it is omitted, it is set as TIMEZONE property.
--character_set	It is the database character set. GOLDILOCKS supports four types of character sets. • GB18030: Simplified Chinese • SQL_ASCII: Character set supporting ASCII • UHC: Unified Hangul Code • UTF8: Unicode Transformation Format - 8 If it is omitted, it is set as CHARACTER_SET property.
--char_length_units	It is the unit of character length. • OCTETS: It identifies 1 byte as 1 character. • CHARACTERS: It identifies 1 character (n byte) as 1 character. If it is omitted, it is set as CHAR_LENGTH_UNITS property.
--home	It is the database home directory. It searches for a property file, and is referenced to as a location of creating and storing various DB files. If it is omitted, it uses the value set in GOLDILOCKS_DATA environment variable.
--member	It is the member name of local database to be used in cluster system. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER property.
--host	It is the host name or the IP address of local member to be used for communication between cluster system members. If the host name is used, then it uses the first IPv4 address of the system. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_HOST property.
--port	It is the TCP listen port of local member to be used for communication between cluster system members. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_PORT property.
--silent	It hides display messages.
--help	It displays help messages.

gsql (GOLDILOCKS Interactive SQL Tool)

gsql is an interactive command line utility to execute SQL statements for managing GOLDILOCKS databas e. DBA creates initial table schema by using gsql, or checks the current database state.

The following is the gsql syntax.

```
[SHELL]> gsql <userid> <passwd>
gSQL> CREATE TABLE T1 ( COL1 INTEGER );
create success
gSQL> \q
[SHELL]>
```

gloader (GOLDILOCKS Data Upload/download Tool)

The gloader utility downloads existing data in database to a file in text format, or it uploads an existing d ata in text format to a new database. The text data file format of gloader is Comma-Separated Value (CS V).

The following is how to use gloader.

```
gloader [export¦import] userid/passwd control='control_file_name' \
data='data_file_name' log='log_file_name' bad='bad_file_name'
```

Table 2-32 Arguments of gloader

Argument	Description
export	import	It declares whether to downlad the contents of existing table to data_file_name, or to upload existing data in data_file_name to a specified tabe in control_file_name.
userid	It specifies user ID.
passwd	It specifies the password of the userid.
control	It specifies the file path in which detailed settings are written during export/import op eration.
data	It specifies target data file to export, or data file to import.
log	It specifies log file path in which the progress and the elapsed time of import/export o peration.
bad	It specifies bad file path which records data records failed in insertion at importing du e to various errors.

The following is an example of a control file.

```
TABLE  TEST_TBL
FIELDS TERMINATED BY ','
OPTIONALLY ENCLOSED BY '"'
```

3.

Cluster Tutorial

3.1 Managing GOLDILOCKS Cluster System

This chapter describes the basic information for configuring and managing the cluster system by using multiple GOLDILOCKS databases. Only the parts added to the cluster system or distinguishing the cluster system comparing to the standalone database are described in this chapter, so it is prerequisite to read the standalone database tutorial before read this chapter.

Overview

GOLDILOCKS can be used by configuring a standalone database as described in the previous chapter. Or, a user can also bind multiple databases into a single cluster, then select an appropriate solution for data distribution. In other words, a user can customize how to distribute massive data to multiple servers when using GOLDILOCKS cluster system. This guarantees high availability and improves the throughput due to the parallel processing.

GOLDILOCKS cluster system consists of one or more cluster groups, and a cluster group consists of one or more cluster members. It does not require an extra application server or a meta server. Applications are operated accessing to cluster members corresponding to the data server. Cluster members belonging to the same cluster group keeps the same data replication.

A user should determine whether to use GOLDILOCKS database as standalone system or as cluster system, when creating database of each node. To use it as cluster system, a user should add options related to cluster when creating database of each node.

Property Setting

Properties to build cluster system are described in *$GOLDILOCKS_DATA/conf/goldilocks.property.conf* file of each server as like when using standalone database. Main properties for TBS (tablespace), LOG, CONTROL FILE can be set as same as setting in standalone system even when using cluster system. However, there should not be the same path or port of files among cluster members when creating multiple databases to configure cluster system in a single server.

The followings describe main property items of when configuring cluster system.

Table 3-1 Main property items

Property	Description	Default value
	It is the directory path of installing the following system TBS.	

Property	Description	Default value
SYSTEM_TABLESPACE_DIR	• DICTIONARY_TBS • MEM_DATA_TBS • MEM_UNDO_TBS • MEM_TEMP_TBS • MEM_TRANS_TBS	'<GOLDILOCKS_DATA>/db'
SYSTEM_MEMORY_DICT_TABLESPACE_SIZE	It is the dictionary tablespace size.	256M
SYSTEM_MEMORY_DATA_TABLESPACE_SIZE	It is the data tablespace size.	200M
SYSTEM_MEMORY_UNDO_TABLESPACE_SIZE	It is the undo tablespace size.	32M
LOG_DIR	It is the default log directory path.	'<GOLDILOCKS_DATA>/wal'
SYSTEM_LOGGER_DIR	It is the system log directory path.	'<GOLDILOCKS_DATA>/trc'
CONTROL_FILE_COUNT	It is the number of control files.	2
CONTROL_FILE_0	It is the first control file path.	'<GOLDILOCKS_DATA>/wal/control_0.ctl'
CONTROL_FILE_1	It is the second control file path.	'<GOLDILOCKS_DATA>/wal/control_1.ctl'
LOCAL_CLUSTER_MEMBER	It is the name of cluster member of which local server uses in cluster system.	'G1N1'
LOCAL_CLUSTER_MEMBER_HOST	It is the host name of local server.	'127.0.0.1'
LOCAL_CLUSTER_MEMBER_PORT	It is TCP listen port of which local server uses for the communication in cluster system.	10101

The name of cluster member and host-port combination should be unique in cluster system. To omit the property setting above, provide information by using *--member, --host, --port* options when creating database using gcreatedb. The member information provided by property or gcreatedb option is stored and managed in *$GOLDILOCKS_DATA/wal/location.ctl* file.

To modify the properties, update the text property file (*$GOLDILOCKS_DATA/conf/goldilocks.properties.conf*), or define a new variable in a form of *GOLDILOCKS_<property_name>* in an environment variable. The property file is prior to the environment variable.

Background Process

GOLDILOCKS cluster system has the background process (gmaster) to manage instances per each member node. gmaster of each node consists of multiple system threads internally. Most of them are as same as those in standalone system, but the following system threads are added to manage cluster system.

The following threads are performed only when starting the database created as cluster mode.

- Cluster recover thread: It recovers global transaction in cluster system.
- Failover thread: It deals with the failover through reselecting offiline and coordinator for the member s when an error occurs on a specific node or in a network in cluster system.

Two following processes are additionally driven when using GOLDILOCKS as cluster system.

- cdispatcher: It transmit/receive cluster packet and manages sessions.
- cserver: It performs operation of modifying and querying for the database to which the member nod e belongs.

GOLDILOCKS cluster system requires complex cluster protocol communication among member nodes, an d cluster dispatcher (cdispatcher) is a process to efficiently perform the management of network commu nication context and packet distribution mechanism. In addition, it performs monitoring continuously the validity of cluster session through heartbeat.

In cluster system, SQL performing in a specific node (driver node) needs to store data on the remote mem ber node by referring to the sharding strategy of the target table or enquires the data stored in the corres ponding node. In this case, a process is required to process this request and return the result in each me mber node, and that process is cserver.

Client Process

A user can use both client server (C/S) model and direct access (D/A) model in cluster system as like stand alone system. However, each member node of cluster system has its own listener, so the client program s hould know the listen port of the cluster member to access beforehand (in C/S mode). A user can process various transactions when accessing to any node of cluster system as like standalone database.

Signal handling, cleanup for connection, releasing shared resources in cluster system are processes as sa me as those in standalone system.

Memory Structure of Instance

GOLDILOCKS cluster system is used to bind multiple shared-nothing databases to a management unit wh ich is a single cluster system. Therefore, a method of using memory of cluster member nodes is similar to that of standalone. The memory size of which each member node uses are determined by properties set i n its own property. Static area contains instance basic information for database management, informatio n for each session, statement, transaction, redo log buffer, dictionary cache, and other operational infor mation as like standalone system. Additionally, information for management of cluster session such as inf

ormation for location and cluster session are also stored.

Tablespace area consists of page frames and page control header (PCH). The page frame contains the co ntents of each tablespace and PCH controls those page frames.

The application process memory contains instance memories attached when connecting, ODBC environm ent shared in process unit, various ODBC handles and heap memory area containing other information su ch as bind information.

Start and End of Cluster System

To start GOLDILOCKS system, create instance on each member node beforehand (gcreatedb), and then r egister cluster group and cluster member. Later, a user can start or end the system by using sysdba role th rough gsql and gsqlnet.

listener should be in operation if a user wants to start or end GOLDILOCKS cluster system in dedicated m ode of C/S model(to use gsqlnet).

GOLDILOCKS cluster system can not be started or ended in the shared mode of C/S model.

```
% gsql --as sysdba
Enter user-name: sys
Enter password:
Connected to an idle instance.
gSQL>
```

GOLDILOCKS cluster system has the following startup phases. OPEN phase is subdivided into LOCAL OPE N and GLOBAL OPEN unlike the standalone system.

- NOMOUNT
  - It launches gmaster which is a demon to manage GOLDILOCKS instance.
- MOUNT
  - It reads properties, and the control file for the recovery by using $GOLDILOCKS_DATA environme nt variable.
- LOCAL OPEN
  - It loads tablespace content from data files, then performs recovery by using the redo log files, an d recovers in-doubt global transaction, newly build no-logging indexes, and creates dictionary ca ches.
- OPEN (GLOBAL OPEN)
  - It connects cluster sessions of each cluster member, arranges shard map, selects a global manage r (global coordinator) and a group manager (group coordinator), then waits for the user to acces s the service.

To start or end the GOLDILOCKS cluster system the cluster system environment should be configured perf orming the following preliminary works. If the member name, host address, port number are uniquely giv en when creating each member database by using gcreatedb, the property setting process for each node can be omitted.

- Setting property: Update property files to be used on each member node.
- Creating database: Create the database through gcreatedb on each member node.
- Creating cluster group and adding a member: Create a group and a member configuring cluster syste m.
- Driving listener: The listner on each node should be driven beforehand to use gsqlnet.

Use the following syntaxes to create a cluster group or a member.

- **ALTER CLUSTER GROUP name ADD MEMBER**
- **CREATE CLUSTER GROUP**

• Creating database: It is performed on each node.

```
% gcreatedb --cluster --db_name='goldilocks' --member='g1n1' \
    --host='192.168.0.11' --port 10110
% gcreatedb --cluster --db_name='goldilocks' --member='g1n2' \
    --host='192.168.0.12' --port 10120
```

• Creating a cluster group and a member: It is performed on a single node. The startup phase of the clus ter member to be created or added should be GLOBAL OPEN.

```
gSQL> create cluster group g1 cluster member g1n1
        host '192.168.0.11' port 10110;
gSQL> alter cluster group g1 add cluster member g1n2
        host '192.168.0.12' port 10120;
```

If the configuration of GOLDILOCKS cluster system is completed as above, the entire cluster system can b e started or ended by using the following two methods.

- Accessing to each member node to start or end nodes one by one
  - Use \startup and \shutdown commands.
- Start or end the entire member node at once in a single member node
  - Connect through gsqlnet, and then use \cstartup and \cshutdown commands.

The following describes the first method above which is how to access each member node then drive clus ter system. \startup command is used to directly enter into LOCAL OPEN phase without the intermediate phase. This can be operated being subdividing into three phases, which are \startup nomount, alter syste m mount database, and alter system open local database.

Drive up to LOCAL OPEN phase on each node through \startup, and then access a single node and drive up to GLOBAL OPEN phase.

- Startup up to LOCAL OPEN: It is performed on each member node.

```
% gsql sys gliese --as sysdba
  gSQL> \startup
  Startup success.
```

- Startup up to OPEN: It is performed on a single node.

```
% gsql sys gliese --as sysdba
  gSQL> alter system open global database;
  System altered.
```

Starting up with the first method can be a burden to an operator if many nodes are included in cluster system. It is because the entire process from end of cluster system to LOCAL OPEN should be performed everytime on every member node. The following is a simple method to startup the entire member for the ease of operation.

- Startup to GLOBAL OPEN: It is performed on a single node.

```
% gsqlnet sys gliese --as sysdba
gSQL> \cstartup
Startup success.
```

- \cstartup and \cshutdown commands can be performed only in gsqlnet, and it is not supported in gsql. Also, listener should be driven beforehand on every member node to be driven.

- To build GOLDILOCKS cluster system containing multiple members on a single physical node, home directory name, member name and the cluster port information should not be duplicated when creating each database.

When GOLDILOCKS system ends, gmaster, the management daemon process, ends on each member node, so it does not allow any more connection or other database operations.

ABORT is the only shutdown mode available when terminating only the single node in GOLDILOCKS cluster system. ABORT mode immediately terminates gmaster regardless of the state of connected sessions, and unloads the instance.

If \shutdown command is performed by using gsql as follows, only the connected member node is termin ated.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \shutdown abort
Shutdown success
gSQL>
```

To terminate the entire member belonging to cluster system at once, use \cshutdown command of gsqln et as follows. The normal option can be omitted.

```
% gsqlnet sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \cshutdown normal
Shutdown success
gSQL>
```

Using abort option when performing \cshutdown, it terminates the entire member node by forc e. Therefore, some member nodes may fail to join cluster system when restarting it by using \cs tartup. Although the failed nodes can join through the following join commands and rebalance process, it is recommended to terminate it by using \cshutdown normal which is a safe method.

To terminate and start a member node or some member nodes belonging to cluster system, follow the pr ocess below. The following describes how to restart only the G1N2 node among cluster member nodes t hen make it join cluster system.

```
% gsql sys gliese --as sysdba --dsn=g1n2
Connected to GOLDILOCKS Database.
gSQL> \shutdown abort
Shutdown success
gSQL> \startup
Startup success
gSQL> alter system join database;
System altered.
```

To restart a member node and make it rejoin cluster system, rebalancing operation for the altered table may be required if the corresponding node is terminated when a transaction occurs. It the rebalancing op eration is not performed, the transaction performing on a driver node may fail to alter the table on which the rebalaning is not performed.

A rebalancing operation is a process which synchronizes data distribution policy and property information of table among member nodes, and dividedly stores table data again in each member nodes according to the data distribution policy.

```
% gsql sys gliese --as sysdba
Connected to GOLDILOCKS Database.
gSQL> \shutdown abort
Shutdown success
gSQL> \startup
Startup success
gSQL> alter system join database;
ERR-42000(16405): some tables in the database need to be rebalanced
System altered.
gSQL> alter database rebalance;
Database altered.
```

3.2 Installing GOLDILOCKS and Creating Database

Installing and creating member database which is to be included in GOLDILOCKS cluster system is almost as same as those in standalone system. This chapter describes only the unique feature and method used f or installing and creating database of cluster system comparing to standalone system.

Configuring GOLDILOCKS Package

The package used to configure GOLDILOCKS cluster system is as same as those of standalone database. However, the scripts to build dictionary and performance view are divided into the script for standalone s ystem and the script for cluster system. Therefore, a user should use the appropriate script for the purpos e to build the information after creating the database.

The script for standalone database is located below the *$GOLDILOCKS_HOME/admin/standalone* director y and the script for cluster system is located below the *$GOLDILOCKS_HOME/admin/cluster* directory.

Table 3-2 admin/ standalone directory

File name	Description
README	Read me
DictionarySchema.sql	It is the dictionary schema creation script.
InformationSchema.sql	It is the information schema creation script.
PerformanceViewSchema.sql	It is the PerformanceView schema creation script.

Table 3-3 admin/ cluster directory

File name	Description
README	Read me
DictionarySchema.sql	It is the dictionary schema creation script.
InformationSchema.sql	It is the information schema creation script.
PerformanceViewSchema.sql	It is the PerformanceView schema creation script.

Installing GOLDILOCKS Software

GOLDILOCKS software should be installed on every member node belonging to cluster system, and the in stalling method is as same as that of standalone system. The method for setting and checking kernel para meter, setting environment variable are as same as those of standalone system, so refer to the correspon ding tutorial.

In this case, be cautious that setting properties for each cluster member node, database name, database version, character set, time zone should be same for the normal operation of cluster system.

Creating Database

Use gcreatedb utility to create database on each member node configuring cluster system as like standalone system.

The following options of gcreatedb are used only when creating cluster database. Other options are as same as standalone system.

Table 3-4 Execution arguments of gcreatedb

Argument	Description
--cluster	It represents that it is cluster database. When it is omitted, standalone database is created.
--member	The member name of local database to be used in cluster system. When it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER property.
--host	IP address of local member to be used for communication between cluster system members. If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_HOST property.
--port	TCP listen port of local member to be used for communication between cluster system members If it is omitted, it uses the value set in LOCAL_CLUSTER_MEMBER_PORT property.

The following is an example of creating database to be used in cluster system.

```
[SHELL]> gcreatedb --cluster
Database created
[SHELL]> gcreatedb --cluster --member=G1N1
Database created
[SHELL]> gcreatedb --cluster --member=G1N1 --host=127.0.0.1 --port 10101
Database created
[SHELL]> gcreatedb --cluster                        \
                   --db_name="TEST_DB"              \
                   --home=$GOLDILOCKS_DATA          \
                   --host=127.0.0.1                 \
                   --port=10101                     \
                   --db_comment="g1n1 db comment"   \
                   --timezone="+09:00"              \
                   --character_set="UHC"            \
                   --char_length_units="OCTETS"
```

```
Database created
[SHELL]> ls $GOLDILOCKS_DATA/db
system_data.dbf  system_dict.dbf  system_trans.dbf system_undo.dbf
```

Building Dictionary Schema Information

To normally use cluster system, the dictionary schema information should be built as like standalone syste m. If the following schema is not built, the catalog API (e.g. SQLTables() function) of ODBC, JDBC obtaini ng object's structure information malfunctions, then it can not interwork with the third party tools. In con clusion, it should be built after creating database.

It is recommended to build schema in cluster system after completing the operation of creating a cluster group and a member. It is because GOLDILOCKS automatically creates schema on every member node w hen performing creation script by connecting to a member node after completing cluster system configur ation.

- DICTIONARY_SCHEMA: It consists of tables and views inquiring object information such as DBA_*, A LL_*, USER_*.
- INFORMATION_SCHEMA: It consists of tables and views included in the SQL standard INFORMATION _SCHEMA.
- PERFORMANCE_VIEW_SCHEMA: It consists of views inquiring system information combining inform ation of fixed tables.

The followings describe how to build schema by using the script for cluster system. Perform the operation by accessing to a single member node in GLOBAL OPEN phase as described above.

```
% gsql sys gliese --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/DictionarySchema.sql
% gsql sys gliese --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/InformationSchema.sql
% gsql sys gliese --as sysdba --import
$GOLDILOCKS_HOME/admin/cluster/PerformanceViewSchema.sql
```

Various structure information can be viewed by using the schema information built above. What is differe nt from standalone system is that a user can extract only the desired node information by giving group na me and member node after the object when inquiring the information.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL> select origin_member_name, stat_name, stat_value
    2   from gv$system_mem_stat
    3  where stat_name = 'PLAN_CACHE_TOTAL_SIZE';
ORIGIN_MEMBER_NAME STAT_NAME             STAT_VALUE
```

```
------------------ ---------------------- ----------
G1N1               PLAN_CACHE_TOTAL_SIZE   17844952
G2N2               PLAN_CACHE_TOTAL_SIZE   16796288
G2N1               PLAN_CACHE_TOTAL_SIZE   16796288
G1N2               PLAN_CACHE_TOTAL_SIZE   16796288
G3N1               PLAN_CACHE_TOTAL_SIZE   16796288
G3N2               PLAN_CACHE_TOTAL_SIZE   16796288
6 rows selected.
gSQL> select origin_member_name, stat_name, stat_value
    2   from gv$system_mem_stat@g1n2
    3  where stat_name = 'PLAN_CACHE_TOTAL_SIZE';
ORIGIN_MEMBER_NAME STAT_NAME             STAT_VALUE
------------------ ---------------------- ----------
G1N2               PLAN_CACHE_TOTAL_SIZE   16796288
1 row selected.
gSQL> select origin_member_name, stat_name, stat_value
    2   from gv$system_mem_stat@g1
    3  where stat_name = 'PLAN_CACHE_TOTAL_SIZE';
ORIGIN_MEMBER_NAME STAT_NAME             STAT_VALUE
------------------ ---------------------- ----------
G1N1               PLAN_CACHE_TOTAL_SIZE   17844952
G1N2               PLAN_CACHE_TOTAL_SIZE   16796288
2 row selected.
```

3.3 Managing Schema Object

The schema object is a logical structure created by a user. GOLDILOCKS cluster system supports the schema objects such as table, index and global sequence. This chapter describes features of each schema object in cluster system comparing to standalone system. How to efficiently manage them is also described.

Managing Table

A user can specifies one of four following sharding strategies as an option when creating a table in GOLDILOCKS cluster system. Sharding strategy is how to distribute and store table data to each cluster group in cluster system. This option can be specified only in cluster system, and it can not be used when database is created as standalone.

- Cloned strategy
  - It equally copies entire table data.
- Hash sharding strategy
  - It distributes table data based on the hash value of sharding key.
- Range sharding strategy
  - It distributes table data based on the range value of sharding key.
- List sharding strategy
  - It distributes table data based on the list value of sharding key.

For more information about creating table, refer to **CREATE TABLE** and **Cluster Table and Shard**.

When omitting the sharding strategy option, it is defined by **DEFAULT_SHARDING** property. The default value of DEFAULT_SHARDING is 0, and it creates cloned table.

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
);
```

If a table is created without giving the sharding strategy by as user as above, then GOLDILOCKS cluster system internally creates a table by using the following syntax.

```
CREATE TABLE t1
(
    id   INTEGER,
```

```
    name VARCHAR(128)
)
    CLONED
    AT CLUSTER WIDE
;
```

Hash/Range/List sharded table should comply with the followings when creating constraints.
- PRIMARY KEY, UNIQUE constraint should include the sharding key.

Cloned Strategy

It does not distribute the table data based on a specific condition, but it copies all data. The target of cop ying data can be all nodes in cluster system, or it can be a specific cluster group. In other words, it arrang es clones in cluster members of a defined cluster group.

- AT CLUSTER WIDE
  - It arranges clones in all cluster members of all cluster group in cluster system.
  - When adding a cluster group or cluster member, a user can rearranges clones by using **ALTER TA BLE name REBALANCE** statement.
- AT CLUSTER GROUP group_list
  - It arranges clones in all cluster members of a defines cluster group.
  - When adding a cluster member to a defined cluster group, a user can rearranges clones by using **ALTER TABLE name REBALANCE** statement.
  - Adding cluster group does not affect the rearrangement of clones.

When the option is omitted, the default value is automatically set to *AT CLUSTER WIDE*.

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
)
CLONED
AT CLUSTER WIDE;
```

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
)
CLONED
```

```
AT CLUSTER GROUP G1, G2;
```

Hash Sharding Strategy

It distributes the table data based on the hash value of a column defined as a sharding key.

To use hash sharding strategy, sharing key should be defined complying with the following conditions.

- Up to 32 columns can be listed.
- The duplicated column can not be used.
- The column of LONG VARCHAR or LONG VARBINARY type can not be used.

```
CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) )
    SHARDING BY HASH(id);
```

When hash sharding related options are omitted as above, GOLDILOCKS system interprets it as follows.

```
CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) )
    SHARDING BY HASH(id)
    SHARD COUNT 24
    AT CLUSTER WIDE;
```

Table rows are distributes to one of 24 shards based on hash value of id column, and 24 shards are equall y arranged over the entire cluster system. For more information, refer to **Cluster Table and Shard**.

Range Sharding Strategy

It distributes the table data based on the range value of the column defined as a sharding key. The shards are classified based on each range value, and they can be arranged by defining a specific group, or arrang ed as CLUSTER WIDE.

The following is a syntax of defining six range shards based on the range value of the sharding key colum n, and creating a table to distribute them as CLUSTER WIDE. If a cluster group is created after creating a t able, the rearrangement of shard containing the created group can be performed by using REBALANCE f eature.

- Create a range sharded table.
- Arrange six shards in existing cluster groups (g1, g2, g3).

```
CREATE TABLE t1
(
   id   INTEGER,
   name VARCHAR(32)
```

```
)
SHARDING BY RANGE (id)
    AT CLUSTER WIDE
    SHARD s1 VALUES LESS THAN ( 200000 ),
    SHARD s2 VALUES LESS THAN ( 400000 ),
    SHARD s3 VALUES LESS THAN ( 500000 ),
    SHARD s4 VALUES LESS THAN ( 600000 ),
    SHARD s5 VALUES LESS THAN ( 800000 ),
    SHARD s6 VALUES LESS THAN ( MAXVALUE )
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Rearrange the range shard.
- Rearrange six shards in cluster groups (g1, g2, g3, g4) in which the added group is included.

```
ALTER TABLE t1 REBALANCE;
```

The following is a syntax of defining range shards, which are defined based on the range of sharding key column value, only to be arranged in a specific cluster group. In other words, the shard s1 whose range v alue is smaller than 200000 is allocated in cluster group g1, s2 is allocated in cluster group g2, and shard s3 is allocated in g3. Like as shards can not be rearranged by using REBALANCE feature even when a clus ter group is added later in a table created by defining cluster group.

- Create a range sharded table.
- Allocate each range shards to defined cluster groups.

```
CREATE TABLE t1
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY RANGE (id)
    SHARD s1 VALUES LESS THAN ( 200000 )   AT CLUSTER GROUP g1,
    SHARD s2 VALUES LESS THAN ( 400000 )   AT CLUSTER GROUP g2,
    SHARD s3 VALUES LESS THAN ( 500000 )   AT CLUSTER GROUP g3,
    SHARD s4 VALUES LESS THAN ( 600000 )   AT CLUSTER GROUP g2,
    SHARD s5 VALUES LESS THAN ( 800000 )   AT CLUSTER GROUP g3,
```

```
    SHARD s6 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP g1
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Rearrange the range shard.
- A shard is not allocated to the newly created cluster group (g4).

```
ALTER TABLE t1 REBALANCE;
```

The following conditions should be considered to specify the range sharding key.

- Up to 32 columns can be listed.
- The duplicated column can not be used.
- The column of LONG VARCHAR or LONG VARBINARY type can not be used.

List Sharding Strategy

It distributes the table data based on the list value of the column defined as a sharding key. Like as the ra nge sharding strategy, each shard can be arranged by defining a specific group, or arranged as CLUSTER WIDE.

The followings are conditions to define the shard key in list sharding strategy.

- Only a single column can be used.
- The column of LONG VARCHAR or LONG VARBINARY type can not be used.

The following is a syntax of creating a table of which created list shards are arranged as CLUSTER WIDE. Use REBALANCE feature to rearrange shards including a cluster group created after creating a table.

- Create a list sharded table.
- Arrange five shards in existing cluster groups (g1, g2, g3).

```
CREATE TABLE city
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY LIST (name)
```

```
    AT CLUSTER WIDE
    SHARD s1 VALUES IN ( 'SEOUL' ),
    SHARD s2 VALUES IN ( 'PUSAN', 'ULSAN', 'DAEGU' ),
    SHARD s3 VALUES IN ( 'DAEJEON', 'GWANGJU' ),
    SHARD s4 VALUES IN ( 'ANSAN', 'GOYANG' ),
    SHARD s5 VALUES IN ( DEFAULT )
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Rearrange the list shard.
- Rearrange five shards in cluster groups (g1, g2, g3, g4) in which the created group is included.

```
ALTER TABLE city REBALANCE;
```

The following is a syntax of defining list shards, which are defined based on the list value of sharding key column value, only to be arranged in a specific cluster group. Shards can not be rearranged by using REB ALANCE feature even when a cluster group is created.

- Create a list sharded table.
- Allocate each range shards to defined cluster groups.

```
CREATE TABLE city
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY LIST (name)
    SHARD s1 VALUES IN ( 'SEOUL' )                  AT CLUSTER GROUP g1,
    SHARD s2 VALUES IN ( 'PUSAN', 'ULSAN', 'DAEGU' ) AT CLUSTER GROUP g2,
    SHARD s3 VALUES IN ( 'DAEJEON', 'GWANGJU' )     AT CLUSTER GROUP g3,
    SHARD s4 VALUES IN ( 'ANSAN', 'GOYANG' )        AT CLUSTER GROUP g2,
    SHARD s5 VALUES IN ( DEFAULT )                  AT CLUSTER GROUP g1
;
```

- Create a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Rearrange the list shard.
- A shard is not allocated to the newly created cluster group (g4).

```
ALTER TABLE city REBALANCE;
```

Managing Index

Global Secondary Index

In cluster system, multiple member nodes exist, and table records are dividedly stored or duplicated based on the shard strategy. Standalone system guarantees the uniqueness of a record by storing unique value (Row Identifier: RID) in the database when the record is stored. However, in cluster system, each node ca n have the duplicated value, so the uniqueness can not be guaranteed.

Therefore, it is required to guarantee the uniqueness of a record in cluster system. This is a reason why gl obal RID(GRID) is added. The GRID value of a record is not updated even when the record is updated, the n it guarantees the uniqueness of a specific record in cluster system.

Global secondary index is a B-tree index which consists of keys to search the GRID value of the records qu ickly in cluster system.

A use can select whether to create global secondary index through the following properties when creatin g a table. The user also can delete or recreate the global secondary index after table creation is complete d. Only one global secondary index can be created per table.
For more information, refer to **DEFAULT_GLOBAL_SECONDARY_INDEX_CREATION**.

A global secondary index is necessary to perform the non-deterministic query for a table. If a global secon dary index does not exist in a table, then a non-deterministic query fails as follows.

```
gSQL> DELETE FROM T1 LIMIT 1;
ERR-42000(16423): does not support non-deterministic DML in the cluster system : global
secondary index expected
```

Enquire USER_GSI_PLACE DICTIONARY, or use ALL_GSI_PLACE and DBA_GSI_PLACE dictionary to check if the global secondary index of a table is created.

```
gSQL> CREATE TABLE T1( I1 INTEGER );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT *
    2   FROM USER_GSI_PLACE@LOCAL
    3  WHERE TABLE_NAME = 'T1';
TABLE_SCHEMA TABLE_NAME GROUP_ID GROUP_NAME MEMBER_ID MEMBER_NAME MEMBER_OFFLINE
------------ ---------- -------- ---------- --------- ----------- --------------
BLOCKS
------
PUBLIC       T1                1 G1                 1 G1N1        FALSE
    64
PUBLIC       T1                1 G1                 2 G1N2        FALSE
  null
2 rows selected.
gSQL> DROP TABLE T1;
Table dropped.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT *
    2   FROM USER_GSI_PLACE@LOCAL
    3  WHERE TABLE_NAME = 'T1';
no rows selected.
```

Global Sequence

GOLDILOCKS cluster system provides global sequence object which are an expansion of the existing sequence for multiple member nodes to share and use the set of sequence value fitting into user defined conditions. In other words, the global sequence object is internally and automatically created when a user creates a sequence in cluster system, then the sequence values in a specific range are allocated and used when calling NEXTVAL on each member node. The following is a syntax of creating and using the global sequence, which are as same as those of sequence in standalone.

```
gSQL> CREATE SEQUENCE global_user_seq START WITH 1000 INCREMENT BY 1 NOCACHE NOCYCLE;
Sequence created.
gSQL> SELECT global_user_seq.NEXTVAL FROM dual;
NEXTVAL
-------
```

```
      1
1 row selected.
gSQL> DROP SEQUENCE global_user_seq;
Sequence dropped.
```

Like as the sequence used in standalone, the global sequence object can define a cache size as a creating option, and this means acquiring several sequence value from the global sequence object and loading at l ocal cache. The followings are local cache status of each member node and return values of when calling NEXTVAL, this is when creating the global sequence object by setting cache size to 5.

```
gSQL> CREATE SEQUENCE seq START WITH 1 CACHE 5;
Sequence created.
```

Member name	NEXTVAL result	The number of remaining local cache sequence		Description
		G1N1	G1N2	
G1N1	1	4	0	From Global Object (Alloc 1 ~ 5)
G1N1	2	3	0	From Local Cache
G1N1	3	2	0	From Local Cache
G1N2	6	3	4	From Global Object (Alloc 6 ~ 10)
G1N2	7	3	3	From Local Cache
G1N2	8	3	2	From Local Cache
G1N2	9	3	1	From Local Cache
G1N2	10	3	0	From Local Cache
G1N2	11	3	4	From Global Object (Alloc 11 ~ 15)
G1N2	12	3	3	From Local Cache
G1N1	4	1	3	From Local Cache
G1N1	5	0	3	From Local Cache
G1N1	16	4	3	From Global Object (Alloc 16 ~ 20)

In the table above, The sequence values are allocated to G1N1 and G1N2 two times each (four times in t otal) from the global sequence object. The cache option value is set to 5 when creating a sequence, so fiv e sequence values are allocated each from the global object. Those five sequences allocated to a member node is stored in its own local cache, then it is returned one by one whenever calling NEXTVAL.

- G1N1
  - The values of five sequences (1~5) are allocated from the global sequence object when calling th e first NEXTVAL.

    - A single sequence is returned as a result of NEXTVAL and the values of other four sequences are l oaded in its own local cache.
    - NEXTVAL called later returns in turn the values of the sequences loaded in the local cache.
- G1N2
    - The values of sequences (6~10) which are after the sequences allocated on G1N1 are allocated when calling the first NEXTVAL.
    - 6 is returned as a result of NEXTVAL, and the values of other four sequences (7~10) are loaded i n its own local cache.
    - NEXTVAL called later returns the sequence values loaded in the local cache.
    - Local cache is run out, so values of other five sequences (11~15) are allocated again from the glo bal sequence object.
- G1N1
    - Local cache is run out, so the values of five sequences (16~20) after the sequences allocated last on G1N2 are allocated.

The sequence as big as the CACHE size are allocated to all member nodes when NEXTVAL has never bee n called on its own node or when all allocated nodes are run out. Therefore, if a system needs to acquire the sequence value quickly, it is required to set the appropriate cache size when creating a sequence to pr event too much frequent allocation. It is because, unlike standalone database, allocating sequence from t he global sequence object is accompanied by the network communication cost.

The sequence values loaded in local cache can not be reused when database restarts due to a system erro r or operational work. The sequence values are allocated again from the global sequence object when cal ling NEXTVAL for the first time since the restart. Therefore, the CACHE size allocated when creating the s equence also means the range value of sequence which is possible to be lost when an error occurs, so th e size should be set appropriately considering not only the corresponding feature but also loss range.

The result value of calling NEXTVAL from a specific node may not be sequential in cluster system. In the e xample above, the return value is not sequential when G1N1 node calls NEXTVAL. After the first allocate d value(1~5) is run out, 16~20 is allocated second, so 16 is returned to a user as the next sequence value of 5. It is because a single global sequence pool is allocated competitively to multiple nodes.

The followings are features and constraints of global sequence object, comparing to the sequence for exi sting standalone database.

- The sign can not be modified by using INCREMENT BY option in ALTER SEQUENCE statement. (The si ze can be modified.)
- The duplicated value among member nodes can be returned depending on the pool size of entire seq uence when using CYCLE option. Therefore, create the sequence pool big enough, considering INCR EMENT BY, CACHE SIZE, and the number of cluster member nodes when CYCLE option is in need.
- The return value from a specific node may not be sequential even when an error does not occur. Of c ourse, if only one member node calls NEXTVAL, then sequential sequence value is obtained.
- The CACHE SIZE is 1 for NOCACHE, so the additional sequence values are not loaded in local cache. I n this case, only one sequence is allocated from the global sequence object whenever calling NEXTV

AL, and it increases the network cost and degrades the performance.

- Creating, updating and deleting sequences are operated as AUTO COMMIT.
- All sequence values loaded in local cache of all nodes are reset when the size of CACHE and INCREM ENT are updated by ALTER statement. In other words, a new sequence set should be allocated from t he global sequence object when calling NEXTVAL afterwards.

3.4 GOLDILOCKS Property

The followings are main properties used in GOLDILOCKS cluster system.

Table 3-5 Main properties of GOLDILOCKS

Name	Description
LOCAL_CLUSTER_MEMBER	Member name
LOCAL_CLUSTER_MEMBER_HOST	Host address for connecting to cluster session
LOCAL_CLUSTER_MEMBER_PORT	Port for connecting to cluster session
CDISPATCHER_THREADS	The number of cluster dispatcher threads
CSERVERS	The number of cluster server process
CLUSTER_DATA_SYNC_SERVERS	The number of cluster server process to synchronize replica data

Each property has the following two alterable scopes in GOLDILOCKS cluster system.

- LOCAL: It can alter property values not only for entire member but also for a specific member only.
- GLOBAL: It can not alter the property value only for a specific member, but it should alter the propert y value for all members.

For example, PRIVATE_STATIC_AREA_SIZE properties can be altered up to the LOCAL range (IS_GLOBAL column = FALSE) as follows, so the property value can be altered by using *alter system set* statement not only for entire member but also for a specific member only. If AT clause is not added to after *alter system set* statement, the altered properties are applied to all members of cluster system.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL> select origin_member_name, property_name, property_value, is_global
    2   from gv$property
    3  where property_name = 'PRIVATE_STATIC_AREA_SIZE';
ORIGIN_MEMBER_NAME PROPERTY_NAME            PROPERTY_VALUE IS_GLOBAL
------------------ ------------------------ -------------- ---------
G1N1               PRIVATE_STATIC_AREA_SIZE 104857600      FALSE
G1N2               PRIVATE_STATIC_AREA_SIZE 104857600      FALSE
2 rows selected.
gSQL> alter system set private_static_area_size = 200000000 at g1n2;
System altered.
gSQL> select origin_member_name, property_name, property_value, is_global
    2   from gv$property
    3  where property_name = 'PRIVATE_STATIC_AREA_SIZE';
ORIGIN_MEMBER_NAME PROPERTY_NAME            PROPERTY_VALUE IS_GLOBAL
```

```
------------------ ------------------------ -------------- ---------
G1N1               PRIVATE_STATIC_AREA_SIZE 104857600      FALSE
G1N2               PRIVATE_STATIC_AREA_SIZE 200000000      FALSE
2 rows selected.
gSQL> alter system set private_static_area_size = 300000000;
System altered.
gSQL> select origin_member_name, property_name, property_value, is_global
    2   from gv$property
    3  where property_name = 'PRIVATE_STATIC_AREA_SIZE';
ORIGIN_MEMBER_NAME PROPERTY_NAME            PROPERTY_VALUE IS_GLOBAL
------------------ ------------------------ -------------- ---------
G1N1               PRIVATE_STATIC_AREA_SIZE 300000000      FALSE
G1N2               PRIVATE_STATIC_AREA_SIZE 300000000      FALSE
2 rows selected.
```

However, DDL_AUTOCOMMIT can be altered up to GLOBAL as follows. Therefore, an error occurs when specifying a member by using AT clause in *alter system set* statement.

```
% gsql test test
Connected to GOLDILOCKS Database.
gSQL> select origin_member_name, property_name, property_value, is_global
    2   from gv$property
    3  where property_name = 'DDL_AUTOCOMMIT';
ORIGIN_MEMBER_NAME PROPERTY_NAME  PROPERTY_VALUE IS_GLOBAL
------------------ -------------- -------------- ---------
G1N1               DDL_AUTOCOMMIT NO             TRUE
G1N2               DDL_AUTOCOMMIT NO             TRUE
2 rows selected.
gSQL> alter system set ddl_autocommit = false at g1n2;
ERR-42000(16398): the domain of property does not match with domain 'G1N2' :
alter system set ddl_autocommit = false at g1n2
                                          *
ERROR at line 1:
gSQL> alter system set ddl_autocommit = false;
System altered.
gSQL> select origin_member_name, property_name, property_value, is_global
    2   from gv$property
    3  where property_name = 'DDL_AUTOCOMMIT';
ORIGIN_MEMBER_NAME PROPERTY_NAME  PROPERTY_VALUE IS_GLOBAL
------------------ -------------- -------------- ---------
G1N1               DDL_AUTOCOMMIT NO             TRUE
```

```
G1N2                DDL_AUTOCOMMIT NO             TRUE
2 rows selected.
```

4.

What's New

4.1 Feature Matrix

This chapter briefly describes the features added to each major version.

Architecture

System Architecture

The following is a feature matrix for system architecture.

Table 4-1 Feature matrix for system architecture

Feature	2.x	3.x	20c.1	21c.1	22c.1
Shared Nothing Cluster	X	O	O	O	O
DA (Direct Attach)	O	O	O	O	O
JDBC DA (Direct Attach)	X	O	O	O	O
C/S (Client/Server) Dedicated	O	O	O	O	O
C/S (Client/Server) Shared	O	O	O	O	O
multi-process applications	O	O	O	O	O
multi-threaded applications	O	O	O	O	O
Linux platform	O	O	O	O	O
HP platform	O	O	O	O	O
AIX platform	O	O	O	O	O
Windows Client Platform	O	O	O	O	O
CDC(Change Data Capture) replication	O	O	O	O	O
CDC replication with log mirror	O	O	O	O	O
multi-level start up	O	O	O	O	O
parallel database loading	O	O	O	O	O
parallel index build	O	O	O	O	O
SQL plan cache	O	O	O	O	O
IPC	X	X	X	O	O

Storage Internal

The following is a feature matrix for storage internal.

Table 4-2 Feature matrix for storage internal

Feature	2.x	3.x	20c.1	21c.1	22c.1
memory dictionary tablespace	O	O	O	O	O
memory data tablespace	O	O	O	O	O
memory undo tablespace	O	O	O	O	O
memory temporary tablespace	O	O	O	O	O
memory bitmap data segment	O	O	O	O	O
memory bitmap undo segment	O	O	O	O	O
memory bitmap instant segment	O	O	O	O	O
memory heap table	O	O	O	O	O
memory instant table	O	O	O	O	O
memory B-tree index	O	O	O	O	O
memory instant B-tree	O	O	O	O	O
memory instant hash	O	O	O	O	O
global secondary index	X	O	O	O	O
disk data tablespace	X	X	O	O	O
disk bitmap data segment	X	X	O	O	O
disk B-tree index	X	X	O	O	O
disk global secondary index	X	X	O	O	O

Transaction Control

The following is a feature matrix for transaction control.

Table 4-3 Feature matrix for transaction control

Feature	2.x	3.x	20c.1	21c.1	22c.1
CDS(Concurrency Data Store) database mode	O	O	O	O	O
TDS(Transactional Data Store) database mode	O	O	O	O	O
read-only database	O	O	O	O	O
read/write database	O	O	O	O	O
flat transaction	O	O	O	O	O
distributed transaction	O	O	O	O	O
read-only transaction	O	O	O	O	O
read/write transaction	O	O	O	O	O
READ COMMITTED isolation level	O	O	O	O	O
SERIALIZABLE isolation level with SELECT FOR UPDATE	O	O	O	O	O
MVCC(Multi Version Concurrency Control)	O	O	O	O	O
multi-version read consistency	O	O	O	O	O
multi-statement consistent read	O	O	O	O	O
implicit lock for DML	O	O	O	O	O
writer don't blocks readers	O	O	O	O	O
row-level locking	O	O	O	O	O
deadlock detection	O	O	O	O	O
deadlock resolution	O	O	O	O	O

INTERVAL MINUTE	O	O	O	O	O
INTERVAL SECOND	O	O	O	O	O
INTERVAL YEAR TO MONTH	O	O	O	O	O
INTERVAL DAY TO HOUR	O	O	O	O	O
INTERVAL DAY TO MINUTE	O	O	O	O	O
INTERVAL DAY TO SECOND	O	O	O	O	O
INTERVAL HOUR TO MINUTE	O	O	O	O	O
INTERVAL HOUR TO SECOND	O	O	O	O	O
INTERVAL MINUTE TO SECOND	O	O	O	O	O

Dynamic SQL

The following is a feature matrix for dynamic SQL.

Table 4-24 Feature matrix for dynamic SQL

Feature	2.x	3.x	20c.1	21c.1	22c.1
SELECT .. INTO	O	O	O	O	O
EXECUTE IMMEDIATE sql	O	O	O	O	O
PREPARE stmt	O	O	O	O	O
EXECUTE stmt	O	O	O	O	O
DECLARE cursor FOR sql	O	O	O	O	O
DECLARE cursor FOR stmt	O	O	O	O	O
OPEN cursor	O	O	O	O	O
OPEN cursor USING	O	O	O	O	O
FETCH cursor INTO	O	O	O	O	O
CLOSE cursor	O	O	O	O	O
DELETE .. WHERE CURRENT OF cursor	O	O	O	O	O
UPDATE .. WHERE CURRENT OF cursor	O	O	O	O	O

PyDBC

Module

The following is a method feature matrix for pygoldilocks provided by PyDBC.

Table 4-25 Feature matrix for pygoldilock method

Feature	2.x	3.x	20c.1	21c.1	22c.1
connect	X	O	O	O	O
Date	X	O	O	O	O
Time	X	O	O	O	O
Timestamp	X	O	O	O	O
DateFromTicks	X	O	O	O	O
TimeFromTicks	X	O	O	O	O
TimestampFromTicks	X	O	O	O	O
Binary	X	O	O	O	O
STRING	X	O	O	O	O
BINARY	X	O	O	O	O
NUMBER	X	O	O	O	O
DATETIME	X	O	O	O	O
ROWID	X	O	O	O	O
getDecimalSeparator	X	O	O	O	O
setDecimalSeparator	X	O	O	O	O

The following is an attribute feature matrix for pygoldilocks module.

Table 4-26 Feature matrix for pygoldilock attribute

Feature	2.x	3.x	20c.1	21c.1	22c.1
apilevel	X	O	O	O	O
threadsafety	X	O	O	O	O
paramstyle	X	O	O	O	O
version	X	O	O	O	O
lowercase	X	O	O	O	O

Connection

The following is a method feature matrix for connection object.

Table 4-27 Feature matrix for connection method

Feature	2.x	3.x	20c.1	21c.1	22c.1
cursor	X	O	O	O	O
commit	X	O	O	O	O

Feature	2.x	3.x	20c.1	21c.1	22c.1
rollback	X	O	O	O	O
close	X	O	O	O	O
getinfo	X	O	O	O	O
execute	X	O	O	O	O
set_attr	X	O	O	O	O

The following is an attribute feature matrix for connection object.

Table 4-28 Feature matrix for connection attribute

Feature	2.x	3.x	20c.1	21c.1	22c.1
autocommit	X	O	O	O	O
searchescape	X	O	O	O	O
timeout	X	O	O	O	O

Cursor

The following is a method feature matrix for cursor object.

Table 4-29 Feature matrix for cursor method

Feature	2.x	3.x	20c.1	21c.1	22c.1
excute	X	O	O	O	O
executemany	X	O	O	O	O
fetchone	X	O	O	O	O

4.2 What's New in GOLDILOCKS 22c.1

This chapter briefly describes the features added to GOLDILOCKS 22c.1.

Architecture

System Architecture

It has not been changed.

Storage Internal

It has not been changed.

Transaction Control

It has not been changed.

Backup & Recovery

It has not been changed.

Database Information

DICTIONARY_SCHEMA

It has not been changed.

INFORMATION_SCHEMA

It has not been changed.

PERFORMANCE_VIEW_SCHEMA

V$OPEN_CURSOR has been added.

V$PROPERTY_ALIAS has been added.

V$DB_PROPERTY has been added.

V$LICENSE has been added.

Server Property

REBALANCE_SHARD_DIVISOR has been added.

SESSION_MEMORY_INIT_SIZE has been added.

SESSION_POOL_NEXT_SIZE has been added.

ADMIN_SESSION_POOL_INIT_SIZE has been added.

ADMIN_SESSION_POOL_NEXT_SIZE has been added.

The default value of **DEFAULT_INDEX_PCTFREE** has been changed to 10.

The default value of **DEFAULT_MAXTRANS** has been changed to 32.

The name of the property INCREMENTAL_CHECKPOINT_CRITERIA which sets the criteria to perform the i ncremental checkpoint of system, has been changed to **BUFFER_DIRTY_PAGE_LIMIT**. Its default value als o has been changed to 0.

BUFFER_LRU_SCAN_PERCENT property has been added to improve the buffer management algorithm fo r the disk tablespace.

CLUSTER_CM_BUFFER_COUNT property, which specifies the number of communication buffers in a clust er environment, has been deprecated. Instead, **LOCKABLE_DISPATCHER_CM_BUFFER_COUNT**, **LOCKLES S_DISPATCHER_CM_BUFFER_COUNT**, and **SYNC_DISPATCHER_CM_BUFFER_COUNT** properties that spe cify the number of communication buffers for lockable, lockless, and synchronization dispatchers have be en added.

The threshold of the table size determines whether to cache the tables created in the disk tablespace to b uffer cache when performing a full scan. **FULL_TABLE_SCAN_CACHING_THRESHOLD** property, which set s this threshold value, has been added.

INST_HASH_TABLE_BUCKET_MAX_COUNT property has been added to set the maximum expected buck et counts of the hash instant table.

The maximum number of SQL to be cached in the plan cache used to be controlled by two properties. M AXIMUM_FLANGE_COUNT property was deprecated, so only **PLAN_CACHE_SIZE** controls the maximum number of SQL.

SQL

SQL Element

Data Type

It has not been changed.

Function

DISTINCT Condition has been added.

SESSIONTIMEZONE has been added.

Window Function has been added.

Object

SQL Object

It has not been changed.

Cluster Object

ALTER DATABASE DROP OFFLINE SEGMENTS has been added.

ALTER DATABASE SYNCHRONIZE has been added.

ALTER TABLE name DROP OFFLINE SEGMENTS has been added.

ALTER TABLE name SYNCHRONIZE has been added.

SHARD DIVISOR and PARALLEL options have been added to **ALTER DATABASE MOVE SHARD**, **ALTER DATABASE REBALANCE**, **ALTER DATABASE REBALANCE EXCLUDE CLUSTER GROUP**, **ALTER TABLE name MOVE SHARD**, **ALTER TABLE name REBALANCE**, **ALTER TABLE name REBALANCE EXCLUDE CLUSTER GROUP cluster_group_list**.

ALTER TABLE REBUILD GLOBAL SECONDARY INDEX statement has been changed to **ALTER TABLE name ALTER GLOBAL SECONDARY INDEX REBUILD**.

SQL Language

DML

It has not been changed.

Query

Lateral Inline View

Lateral inline view has been added to **from clause**.

Table Function Derived Table

Table function derived table has been added to **from clause**.

WINDOW Clause

WINDOW clause has been added, which defines the execution range of the window function.
For more information, refer to **window clause**.

Control Language

It has not been changed.

PSM Language

Table Function

TABLE (table function column list) statement has been added to **return clause**.
The table function can be created by defining the table type when performing function DDL.
For more information, refer to **CREATE FUNCTION**.

RETURN TABLE Statement

RETURN TABLE Statement has been added to the PSM statement.

Performance Improvement of PSM statement

The performance of PSM syntax has been improved as follows.

	BLOCK	CALL	RETURN	ASSIGN	IF	Simple_CASE	Search_CASE	LOOP	FOR_LOOP	WHILE_LOOP	EXIT	CONTINUE	GOTO	RAISE
21c	2,925,516	722,741	660,597	3,746,721	2,177,984	2,139,449	2,127,885	2,446,004	1,710,805	1,201,359	1,888,324	2,932,121	2,952,465	490,236
22c	9,575,792	3,133,519	3,165,458	11,855,36	7,637,085	7,589,556	7,617,886	8,480,325	6,366,182	5,251,825	6,973,500	10,051,26	10,097,95	1,616,736

API

ODBC

TRACE_POLICY has been added to **Data Source Configuration**.

JDBC

It has been modified to prevent missing microsecond when outputting time type and timestamp type in s tring.

It supports the auto-generated key.

GoldilocksTypes.REF_CURSOR has been added.

GoldilocksPreparedStatement.setFixedCHAR(), a JDBC non standard function, has been added.

Embedded SQL

gpec supports **Declaring Function Argument**.

PDO

It has not been changed.

PyDBC

It has not been changed.

Ruby

It has not been changed.

Hibernate

It has not been changed.

Utility

gcreatedb

It has not been changed.

glsnr

cyfile

It has not been changed.

4.3 Patch Notes

22c.1.4 Patch Notes

ISSUE-6381 The conversion rule from the numeric type to the character type is different from other DBMS.

Description

1. If converting the numeric type to the varchar type, it is converted to an exponential type or to a real number type according to the varchar precision. In this case, it is converted by rounding off so that it can be expressed appropriately for the space used as much as possible.
   Therefore, the precision of the valid number representation for the original number decreases.

2. The result of the numeric type → CHAR type conversion and the numeric type → VARCHAR type con version are different.
   I. NUMBER / NUMERIC
      i. Conversion to CHAR: It is converted only to a real number type. (If it can not be expressed within the precision, then an error occurs.)
      ii. Conversion to VARCHAR: It is converted to an exponential type or to a real number type ac cording to precision by rounding off.
   II. NATIVE_REAL / NATIVE_DOUBLE
      i. CHAR: It is converted to an exponential type so that all of the valid numbers are expressed. (If it is truncated, then an error occurs.)
      ii. VARCHAR: It is converted to an exponential type according to precision by rounding off.

Troubleshooting

- If all valid numbers of the numeric type can be expressed, then modify it as follows.
  - NUMBER/ NUMERIC: Convert it to an exponential type or to a real number type according to the precision of the character type.
  - NATIVE_REAL/ NATIVE_DOUBLE: Convert it to an exponential type.
- The result of the numeric type → CHAR type conversion and the numeric type → VARCHAR type conv ersion are same.

Symptom

It is converted by rounding off so that it can be expressed appropriately for the space used as much as po ssible, so the precision of the valid number representation for the original number decreases.

```
gSQL> create table t1 ( c1 varchar(2) );
Table created.
gSQL> insert into t1 values ( 2.4 );
1 row created.
gSQL> insert into t1 values ( 2.5 ) ;
1 row created.
gSQL> commit;
Commit complete.
gSQL> select * from t1;
C1
--
2
3
2 rows selected.
```

Workaround

Specify the appropriate character type precision to express all valid numbers for the original number.

```
gSQL> create table t1 ( c1 varchar(10) );
Table created.
gSQL> insert into t1 values ( 2.4 );
1 row created.
gSQL> insert into t1 values ( 2.5 ) ;
1 row created.
gSQL> commit;
Commit complete.
gSQL> select * from t1;
C1
---
2.4
2.5
2 rows selected.
```

ISSUE-6255 [CDC] PWD was exposed in the connection string recorded in the trace log, so it is replaced with '*' when it is recorded.

Description

PWD was exposed in the connection string recorded in the trace log of cyclone, clustone, cymon and cyfile, and this error has been fixed by replacing it with '*' when it is recorded.

Symptom

PWD was exposed in the connection string of cyclone, clustone, cymon and cyfile when it was recorded i n the trace log.

```
connection string [PROTOCOL=DA;DSN=goldilocks_jinsil;PORT=11100;UID=test;PWD=test]
```

Workaround

The patch is required.

ISSUE-6030 An error occurred in cyclone when rebalancing members i n the Cluster environments, and this error has been fixed.

Description

When rebalancing cluster members while cyclone was in operation in a cluster environment, cyclone coul d not process it, and this error has been fixed.

Symptom

The followings were recorded in cyclone operated in the cluster member where rebalancing was execute d, and no further operation was executed.

```
[2023-12-08 16:33:58.782398 THREAD(3292,140620625983232)]
Ready to Rebalance-Tx commit. (Waiting for slave response)
```

Workaround

The patch is required.

ISSUE-6116 The performance of long procedure's direct execution has been improved.

Description

The direct execution performance of the procedure which consists of massive PL stmt and expression has been improved.

Symptom

proc1 is the procedure which consists of 2000 BEGIN .. END blocks, 12000 PL stmt, and 230,000 expressi ons in the following example.

If proc1() was called as follows, it used to take 150 ms or more.

```
gSQL> call proc1(200,439);
Procedure Call complete.
Elapsed time: 157.09300 ms
```

The performance has been improved as follows by widely improving the plan size of procedure execution and the optimization process.

```
gSQL> call proc1(200,439);
Procedure Call complete.
Elapsed time: 12.35000 ms
```

Workaround

Call the procedure with a prepare-execution.

```
--# prepare
gSQL> \prepare sql call proc1(200,439);
SQL prepared.
--# 1st execution
--# data optimize - execute
gSQL> \exec
Procedure Call complete.
Elapsed time: 158.82600 ms
--# 2nd execution
--# execute
gSQL> \exec
Procedure Call complete.
Elapsed time: 2.79600 ms
```

ISSUE-6231 An error occurs when entering GLOBAL OPEN with an invalid IP.

Description

It failed when trying to go up to GLOBAL OPEN with an invalid remote IP, and this error has been fixed.

Symptom

When trying to go up to GLOBAL OPEN with an invalid remote IP, it should have gone up to GLOBAL OPEN excluding the failed node, but it fails as follows.

```
gSQL> alter system open global database;
ERR-HY000(11047): MEMBER(G1N2): invalid network address : invalid address()
```

Workaround

Alter the IP of the failed node to the valid IP by using ALTER CLUSTER LOCATION statement.

```
gSQL> alter cluster location g1n2 host '127.0.0.1' port 12150;
altered.
```

ISSUE-6358 Cache coherency error in weak memory ordering device

Description

The server was abnormally terminated due to a discrepancy between the sequence of memory access and the program order, and this error has been fixed.

Symptom

The server may experience abnormal behavior or termination because outdated data in the CPU cache is used instead of the most recent data.

Workaround

The patch is required.

22c.1.3 Patch Notes

ISSUE-5799 An error did not occur even though the default expression was not valid when performing CREATE TABLE/ ALTER TABLE.

Description

If defining the default clause when performing CREATE TABLE/ ALTER TABLE, it checks whether the default expression is valid.

Symptom

An error did not occur even though the default expression was not valid.

```
CREATE TABLE t1 ( c1 INTEGER DEFAULT 1 / 0 );
Table created.
```

It has been fixed now, so the error occurs as follows.

```
CREATE TABLE t1 ( c1 INTEGER DEFAULT 1 / 0 );
ERR-22012(12122): divisor is equal to zero
```

Workaround

The patch is required.

ISSUE-5828 The join query including ROWNUM should not be sent to t he remote node, but sometimes it is sent.

Description

The join query including ROWNUM should not be sent to the remote node. If each node stores data in a different order then the result may be wrong even though it is a clone table.

Symptom

```
\explain plan
SELECT COUNT(*)
  FROM ( SELECT c1
           FROM t_clone
          WHERE ROWNUM <= 1000
       ) X
     , t_shard Y
 WHERE X.c1 = Y.c1
;

"_A3"."C1" FROM "PUBLIC"."T_CLONE"@LOCAL AS "_A3" WHERE ROWNUM <= :_V0 ) AS "_A2"("C1") INNER
JOIN "PUBLIC"."T_SHARD"@LOCAL AS "_A1" ON "_A1"."C1" = "_A2"."C1") ALIAS "_A4"
           TARGET DOMAIN : G1(G1N1) 1 rows, G2(G2N1) 1 rows, G3(G3N1) 1 rows
           RE-AGGREGATION
             AGGREGATION : SUM( COUNT(*) )
     4  -  TARGET : COUNT(*)
     5  -  AGGREGATION : COUNT(*)
     6  -  JOINED COLUMN : NOTHING
     7  -  COLUMN : _A3.C1 AS C1
     8  -  TARGET : _A3.C1
     9  -  STOP KEY FILTER : ROWNUM <= :_V0
    10  -  CLONED
           READ COLUMN : _A3.C1
    11  -  HASH KEY : _A1.C1
           READ KEY COLUMN : _A1.C1
             HASH FILTER : _A1.C1 = _A2.C1
           FETCH ONE ROW
    12  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : _A1.C1
<<<  end print plan
```

The join query including ROWNUM should not be sent to the remote node, but ROWNUM filter is sent to the remote query node in the query above.

Workaround

Use */*+ LOCAL_JOIN(Y) */* hint.

ISSUE-5810 [CYCLONE] If a record does not exists in the table containing a long varchar column, then it fails to SYNC.

Description

The error occurs because the null check for a long varchar column is incorrectly performed while checking the existence of a record in the table of the master during SYNC. It determines that there is a record even though a record does not exist. Then, it tries to INSERT the null data to the slave, and it outputs the error message "cannot insert NULL into" and it fails to SYNC.

Symptom

If a record does not exist in the table containing a long varchar column while transferring the data of the master to the slave by using SYNC feature during the replication using CYCLONE, then "cannot insert NULL into" error occurs, and it fails to SYNC.

Workaround

The patch is required.

ISSUE-5665 If the join including three or more tables is performed by using the instant nested loop join method, then the result may be wrong.

Description

If the join including three or more tables is performed by using the instant nested loop join method, then the result may be wrong.

Symptom

```
--# result : 27
\EXPLAIN PLAN
SELECT COUNT(t2.col1)
  FROM t2, t3, t4, t1
 WHERE t2.col1 + t1.col1 = t4.col1
   AND t3.col1 + t1.col1 = t4.col1;
```

```

|    7  |              NESTED JOIN (INNER JOIN)                                 |
|    8  |                INDEX ACCESS ("T2", "T2_COL1")                         |
|    9  |                INDEX ACCESS ("T3", "T3_COL1")                         |
|   10  |              INDEX ACCESS ("T4", "T4_COL1")                           |
================================================================================
     1  -  TARGET : COUNT( T2.COL1 )
     2  -  AGGREGATION : COUNT( T2.COL1 )
     3  -  JOINED COLUMN : T2.COL1
     4  -  READ COLUMN : T1.COL1
     5  -  SORT KEY : "T4.COL1 ASC NULLS LAST"
           RECORD COLUMN : T2.COL1
           READ KEY COLUMN : T4.COL1
           READ RECORD COLUMN : T2.COL1
             MIN RANGE : T4.COL1 = T2.COL1 + {T1.COL1} AND T4.COL1 = T3.COL1 + {T1.COL1}
             MAX RANGE : T4.COL1 = T2.COL1 + {T1.COL1} AND T4.COL1 = T3.COL1 + {T1.COL1}
     6  -  JOINED COLUMN : T4.COL1, T2.COL1, T3.COL1
     7  -  JOINED COLUMN : T2.COL1, T3.COL1
     8  -  READ INDEX COLUMN : T2.COL1
     9  -  READ INDEX COLUMN : T3.COL1
    10  -  READ INDEX COLUMN : T4.COL1
<<<  end print plan
```

The result from the query above should be '27', but actually '0' is output.

The WHERE clause condition 'T4.COL1 = T2.COL1 + T1.COL1 AND T4.COL1 = T3.COL1 + T1.COL1' can n ot be used as an index range condition, but actually it is used.

However, if the query is modified, then the correct result is output as follows.

```
\EXPLAIN PLAN
SELECT COUNT(t2.col1)
  FROM t2, t3, t4, t1
 WHERE t2.col1 + t1.col1 = t4.col1
   AND t3.col1 + t1.col1 = t4.col1;

```

Workaround

Use a hint other than USE_INL(t1). For example, use USE_NL(t1), USE_HASH(t1) or USE_MERGE(t1).

ISSUE-5710 If a view exists inside a view and group by exists in the innermost view, then the complex view merging occurs in succession, causing an error.

Description

If a view exists inside a view and group by exists in the innermost view, then the complex view merging occurs in succession, causing an error. In this case, the error occurs in an aggregation expression of SELECT list.

Even though the conditions above are satisfied, if an aggregation does not exist in SELECT list, then an error does not occur.

Symptom

```
\EXPLAIN PLAN
SELECT sum(case_sum )
  FROM (
         SELECT
                v1.col1, v1.col2, ( case when v1.sum > 0 then 2
                                    else 1
                                    end
                                  )as case_sum
          FROM ( SELECT col1, col2, sum(col3) as sum
                   FROM t1
                  WHERE col3 > 0
                  GROUP BY col1, col2
                ) v1
       ) v2
      , t2
 WHERE v2.col1 = t2.col1;
ERR-42000(12119): comparison is not applicable: ROWID and NUMBER :
```

If v1 is merged first, and then v2 is merged, then it can not find v1.sum in 'case when then' statement.

Workaround

If either one of two views fails to merge, then an error does not occur. Therefore, use /*+ NO_MERGE(v 1) */ hint or /*+ NO_MERGE(v2)*/ hint.

ISSUE-5667 When a subquery refers to the outer query, if the subquery refers to both a materialized view and an ordinary table, then the serv er is abnormally terminated.

Description

If all of the following conditions are satisfied, then the server is abnormally terminated.

1. When tables are listed in <from clause>, the materialized view specified by <with clause> is listed ahe ad, followed by the ordinary table.
2. A subquery exists and the subquery refers to both a materialized view and an ordinary table.

Symptom

```
DROP TABLE IF EXISTS r;
DROP TABLE IF EXISTS s;
DROP TABLE IF EXISTS t;
CREATE TABLE r ( c1 INTEGER, c2 INTEGER );
INSERT INTO r VALUES(1,1);
CREATE TABLE s ( c1 INTEGER, c2 INTEGER, c3 INTEGER );
INSERT INTO s VALUES(1,1,1);
CREATE TABLE t ( c1 INTEGER, c2 INTEGER );
INSERT INTO t VALUES(1,1);
COMMIT;
--# result : 1 row
\EXPLAIN PLAN
WITH w AS ( SELECT /*+ MATERIALIZE */
                   c1
              FROM r
             WHERE c1 > 0 )
SELECT *
  FROM w, s
 WHERE s.c1 IN ( SELECT t.c1
                   FROM t
                  WHERE s.c1 = t.c1
                    AND w.c1 = t.c2
```

```
                    ) ;
```

In the query above, w and s are listed in an order of w,s in FROM clause, and the subquery refers to both s.c1 and w.c1. In this case, the server is abnormally terminated.

Workaround

List the materialized view last in FROM clause.

ISSUE-5634 V$LICENSE has been added.

Description

The view has been added to view the license information of the currently running server.

Symptom

N/A

Workaround

The patch is required.

ISSUE-5442 [CYCLONE] If replicating the column with a unique attribute, then the transaction may fail.

Description

If a column has a unique attribute in the table to replicate, then it is normally processed in an source database, but unique violation or NO_ROWS error may occur in a remote database. Therefore, to solve this problem, the feature to control concurrency of the column has been added when replicating the column with the unique attribute.

Symptom

```
[APPLIER #1(SID:100)-INSERT] ERR-23000(16057) : unique constraint (PUBLIC.TEST1) violated
[APPLIER #2(SID:101)-UPDATE] Conflict.
[APPLIER #3(SID:102)-DELETE] Conflict.
```

If a column has a unique attribute in the replicating table, then logs are frequently recorded on the trace log of the slave as given above.

Workaround

The patch is required.

ISSUE-5568 [CYCLONE] If replicating recovery spans two redo log files, then the starting point of the recovery is incorrectly set.

Description

When restarting after terminating the replication, cyclone finds the starting point of the recovery by using the information applied to the existing applier, then restarts the replication.

When recovering, it finds the optimal starting point by comparing the information between multiple appli ers. If the redo log file information between appliers is different, then it discards the information of the ol d redo log file, and determines the starting point of the recovery by using only the new redo log file infor mation, and this error has been fixed.

Symptom

When restarting after terminating the replication, a transaction may not be replicated.

Workaround

The patch is required.

ISSUE-5511 [CYCLONE] The internal transaction ID is set incorrectly in t he distributor.

Description

It is guaranteed that the transaction IDs are not duplicated among simultaneously performed transactions in an original database. However, the completed transaction ID can be reused later.

When transferring the transaction to the slave after extracting the original transaction for the replication, the execution time of the transaction ID may be different from the original due to the parallel apply. In thi s case, the slave changes the separate transaction ID into the internally distinguishable ID to prevent ident ity duplication by reusing the transaction ID.

This internal transaction ID is allocated by the distributor, but it uses the original value instead of the inter nal value while analyzing specific logs, so the problem occurs, which a single transaction has two transact ion IDs.

Two transaction ID values used as a delimiter value of concurrency control in distributor are allocated to a single transaction, so self dead-lock may occur in a specific situation.

Symptom

```
CREATE TABLE T1 ( C1 INTEGER PRIMARY KEY, C2 LONG VARCHAR );
INSERT INTO T1 VALUES( 1, 'AAA' );
DELETE FROM T1 WHERE C1=1;
INSERT INTO T1 VALUES( 1,'AAAAAAA .......' );  ❶ INSERT the data over 8K
COMMIT;
```

As above, if performing the query processing the same key value and INSERT which inserts the record ove r 8K in a single transaction, then the dead-lock occurs.

Workaround

The patch is required.

ISSUE-5499 If the argument of the window function is a scalar subquer y expression, then the value is not evaluated.

Description

If the scalar subquery expression which can become a constant is used as the argument of the window fu nction in the cluster environment, then the expression is not evaluated when executing the query, so the result is NULL.

Symptom

```
--# BUGBUG
--# result : 1
SELECT SUM( ( SELECT 1 FROM dual ) ) OVER() AS C_NAME
  FROM dual@G2;
C_NAME
------
  null
```

In the cluster environment, all expressions which can become constants are evaluated on the driver node and the result value is transferred to the generated query.

When using the subquery expression as an argument of the window function, then it did not determine whether to configure the constant, so it did not become a constant. If it is required to transfer the result v alue of the subquery expression through the generated query, then a result error occurs.

If the query is performed only on the local node in the standalone or the cluster environment, then the ex pression in the window function is evaluated even when it is not become a constant, so an error does not

occur.

Workaround

The patch is required.

ISSUE-5505 If the access method for leftmost table in the join is the unique index access, and only part of key columns in the group by belong to the unique index, then the result may be wrong.

Description

If the access method for leftmost table in the join is the unique index access, and only part of key columns in the group by belong to the unique index, then the result may be wrong.

Symptom

```
DROP TABLE IF EXISTS r;
DROP TABLE IF EXISTS s;
DROP TABLE IF EXISTS t;
CREATE TABLE r( c1 INTEGER, c2 INTEGER, c3 INTEGER, c4 INTEGER, c5 INTEGER );
INSERT INTO r VALUES(1, 1, 1, 1, 1);
INSERT INTO r VALUES(1, 2, 1, 1, 1);
INSERT INTO r VALUES(1, 2, 1, 1, 1);
INSERT INTO r VALUES(2, 1, 2, 1, 1);
INSERT INTO r VALUES(2, 1, 2, 2, 1);
INSERT INTO r VALUES(3, 1, 2, 2, 1);
INSERT INTO r VALUES(3, 2, 3, 2, 1);
INSERT INTO r VALUES(4, 1, 3, 3, 1);
INSERT INTO r VALUES(5, 1, 3, 3, 1);
INSERT INTO r VALUES(1, 3, 2, 1, 1);
INSERT INTO r VALUES(1, 1, 1, 1, 1);
COMMIT;
CREATE TABLE s( c1 INTEGER PRIMARY KEY, c2 INTEGER, c3 INTEGER, c4 INTEGER, c5 INTEGER );
INSERT INTO s VALUES(1, 1, 1, 1, 1);
INSERT INTO s VALUES(2, 3, 1, 1, 1);
INSERT INTO s VALUES(3, 3, 1, 1, 1);
INSERT INTO s VALUES(4, 2, 2, 1, 1);
INSERT INTO s VALUES(5, 2, 2, 2, 1);
INSERT INTO s VALUES(6, 1, 2, 2, 1);
INSERT INTO s VALUES(7, 1, 3, 2, 1);
```

```
INSERT INTO s VALUES(8, 3, 3, 3, 1);
INSERT INTO s VALUES(9, 3, 3, 3, 1);
COMMIT;
CREATE TABLE t( c1 INTEGER, c2 INTEGER, c3 INTEGER, c4 INTEGER, c5 INTEGER );
INSERT INTO t VALUES(1, 1, 1, 1, 1);
INSERT INTO t VALUES(1, 3, 3, 1, 1);
INSERT INTO t VALUES(1, 3, 3, 1, 1);
INSERT INTO t VALUES(1, 2, 2, 1, 1);
INSERT INTO t VALUES(1, 2, 2, 1, 1);
INSERT INTO t VALUES(2, 3, 1, 1, 1);
INSERT INTO t VALUES(3, 3, 1, 1, 1);
INSERT INTO t VALUES(4, 2, 2, 1, 1);
INSERT INTO t VALUES(5, 2, 2, 2, 1);
COMMIT;
--# result : 6 rows
\EXPLAIN PLAN
SELECT s.c1, s.c2, t.c3
  FROM s, r, t

< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                     ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                    ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                       ¦
¦    2  ¦      GROUP                                                         ¦
¦    3  ¦        HASH JOIN (INNER JOIN)                                      ¦
```

```
|    4  |          MERGE JOIN (INNER JOIN)                              |
|    5  |            INDEX ACCESS ("S", "S_PRIMARY_KEY_INDEX")          |
|    6  |            INDEX ACCESS ("R", "R_IDX")                        |
|    7  |          HASH JOIN INSTANT                                    |
|    8  |            TABLE ACCESS ("T")                                 |
=====================================================================
```

The result from the query above should be 6 rows, but actually 18 rows are output. The leftmost table s u ses 'S_PRIMARY_KEY_INDEX', so the join result is sorted for s.c1. In the plan above, group by performs t he grouping by using the sorted result of the join. However, the sorted records are not sorted for all grou p key columns, so it may lead to the wrong result.

Workaround

Use */*+ USE_GROUP_HASH */* hint.

ISSUE-5500 GoldilocksPreparedStatement.setFixedCHAR(), a JDBC non standard function, has been added.

Description

GoldilocksPreparedStatement.setFixedCHAR(), a JDBC non standard function, has been added.

Symptom

If binding a CHAR column to the WHERE clause in a SELECT statement by using PreparedStatement.setSr ting(), then the result is not found.

```
create table x (c char(4));
insert into x (c) values ('a');  -- inserts 'a   '
```

```
PreparedStatement stmt =
  conn.prepareStatement("select * from x where c = ?");
stmt.setString(1, "a");    // This won't return any records
stmt.executeQuery();
```

Workaround

Change the CHAR column to a VARCHAR column.

ISSUE-5482 If the logs are insufficient during the incomplete recovery, then the recovery fails.

Description

The recovery fails during the incomplete recovery even though it could be completed, and this error has b
een fixed.

Symptom

If performing the incomplete recovery by using the backup redo logs because the redo log is lost, and the backup redo log is earlier than the archive log, then it can not find the log later than the archive log, so th
e error occurs.

```
gSQL> ALTER DATABASE RECOVER UNTIL TIME '2023-04-05 19:05:01.559752';
ERR-HY000(14068): logfile does not exist -
'/goldilocks/goldilocks_data/archive_log/archive_4.log'
```

Workaround

If the redo log later than the archive log does not exist, then perform an interactive incomplete recovery which performs the recovery by using undefected log only as follows.

```
gSQL> ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_0.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 139992)
Database altered.
gSQL> ALTER DATABASE RECOVER AUTOMATICALLY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_4.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 144143)
Database altered.
gSQL> ALTER DATABASE END INCOMPLETE RECOVERY;
Database altered.
```

ISSUE-5445 Even if LOGFILE GROUP size is set sufficiently it fails to add LOGFILE GROUP when performing ADD LOGFILE GROUP.

Description

Even if LOGFILE GROUP size is set sufficiently it fails to add LOGFILE GROUP with a error message saying the logfile is smaller than the minimum size.
It is because the minimum size of the logfile should be calculated based on the number of log buffers and pending log buffers which were revised during the startup, but actually it is calculated based on the property value when performing ADD LOGFILE GROUP.

Symptom

If attempting to add a logfile group after starting up to mount phase with PROPERTY set as follows, then it fails.

```
LOG_BUFFER_SIZE=1G
PENDING_LOG_BUFFER_COUNT=32
```

```
gSQL> STARTUP MOUNT
Startup success
gSQL> ALTER DATABASE ADD LOGFILE GROUP 4 ('redo_4_0.log') SIZE 512M;
ERR-42000(16198): size of log file is smaller than minimum size of log file(1107296256 bytes).
```

Workaround

Create a logfile group by revising LOG_BUFFER_SIZE property and PENDING_LOG_BUFFER_COUNT property.

ISSUE-5424 If executing SELECT statement of an embedded SQL without INTO clause, then an error occurs even when the data exists, and this error has been fixed.

Description

If repeatedly executing SELECT statement of an embedded SQL without INTO clause, then an error occurs, and this error has been fixed.

Symptom

```
EXEC SQL SELECT 1 FROM DUAL;
EXEC SQL SELECT 1 FROM DUAL;
```

If repeatedly executing the same SELECT statement as given above, then the following error occurs.

```
Invalid cursor state : A cursor was open on the StatementHandle.
```

Workaround

Add INTO clause to the SELECT statement, then execute it.

ISSUE-5411 It throws NullPointerException when using getBinaryStream method of ResultSet class in JDBC, and this error has been fixed.

Description

It throws NullPoinerException when using getBinaryStream method of ResultSet class to get null data of long varbinary type, and this error has been fixed.

Symptom

C_BLOB of LONG VARBINARY type in table TEST_LOB has NULL data.

```
CREATE TABLE PUBLIC.TEST_LOB
(
   ID NUMBER( 10, 0 ),
   C_BLOB LONG VARBINARY
);
INSERT INTO TEST_LOB VALUES(1,UNHEX(HEX('XXXXXXXX')));
INSERT INTO TEST_LOB VALUES(2,null);
COMMIT;
```

The following is a code which uses getBinaryStream method to get the data of LONG VARBINARY type.

```
Statement stmt = con.createStatement();
ResultSet rs = stmt.executeQuery("SELECT ID, C_BLOB FROM TEST_LOB");
while (rs.next()) {
    try{
        InputStream is = rs.getBinaryStream("c_blob");
        byte[] bytes = new byte[0];
        bytes = new byte[is.available()];
        is.read(bytes);
    } catch( Exception e){
        System.out.println(e);
    }
}
```

When executing the code above, it throws java.lang.NullPointerException.

Workaround

The patch is required.

ISSUE-5398 The data is lost when gloader uploads the data in the text mode, and this error has been fixed.

Description

gloader uses the field delimiter and the line delimiter which start with the same character when uploadin g the data in the text mode. If the data includes the first character of these delimiter, then the data is tru ncated and uploaded in an invalid form, and this error has been fixed.

Symptom

The following is an example of a data file.

```
data 1^^^Cc__Cc^data 2^Rr__Rr
```

The following is an example of a control file.

```
TABLE TEST
FIELD TERMINATED BY '^Cc__Cc^'
LINE TERMINATED BY '^Rr__Rr\n'
```

If uploading the data by using the control file and the data file above, then the data is truncated.

```
gloader test test -i --control test.ctl --data test.dat --array 1 --no-copyright
COMPLETED IN IMPORTING TABLE: PUBLIC.TEST, TOTAL 3 RECORDS, SUCCEEDED 3 RECORDS
gSQL> SELECT * FROM TEST;
C1      C2
------- -------------
data 1^ null
^       null
null    data 2^Rr__Rr
```

Workaround

Use the the field delimiter and the line delimiter which start with the different character each other.

ISSUE-5407 Cluster peer which is waiting for the lock to be release can not recognize that driver node is killed.

Description

If the driver member is abnormally terminated while waiting for the lock to be released on the remote, th en the remotely created session remains alive.

Symptom

The following is an example of an environment that the cluster group G1 has G1N1, G1N2 as members, and the table T1 is created.

The record of table T1 is updated on G1N1.

```
gSQL> UPDATE T1 SET A = A + 1 WHERE A = 1;
1 row updated.
```

If the same record is updated on G1N2, then it will wait.

```
gSQL> UPDATE T1 SET A = 10 WHERE A = 1;
```

When checking the session on G1N1, then it is seen that the cluster session is waiting for the update sent from G1N2.

```
gSQL> SELECT SESSION_STATUS FROM V$SESSION@G1N1
       WHERE PROGRAM_NAME = 'cluster peer';
SESSION_STATUS
--------------
CONNECTED
```

Even when gsql waiting for the update sent from G1N2 is killed, the session still remains alive on G1N1 a s follows.

```
gSQL> SELECT SESSION_STATUS FROM V$SESSION@G1N1
       WHERE PROGRAM_NAME = 'cluster peer';
SESSION_STATUS
--------------
CONNECTED
```

Workaround

The patch is required.

22c.1.2 Patch Notes

ISSUE-5174 gpec supports declaring function arguments.

Description

gpec supports declaring function arguments. For more information, refer to **Declaring Function Argument**.

Symptom

N/A

Workaround

The patch is required.

ISSUE-5353 When connecting and disconnecting by using the window ODBC, then the number of program handles increase and this error has been fixed.

Description

When repeatedly connecting and disconnecting by using the window ODBC, then the number of entire program handles increase and this error has been fixed.

Symptom

When repeatedly connecting and disconnecting by using the window ODBC, then the number of entire program handles increase.

Workaround

The patch is required.

ISSUE-5344 When performing view projection pruning it deletes the column used in the upper block.

Description

If the following conditions are satisfied, the server may be abnormally terminated due to improperly performed view projection pruning.

- *group by* or *order by* exists within a view.
- expr to be deleted from the view's select list is an argument of another function expression.

Symptom

The following is a sample query which can cause an error.

```
SELECT sum_col1
  FROM ( SELECT sum(col1) as sum_col1
              , DECODE( sum(col1), NULL, 0 ) as decode_sum_col1
           FROM t1
          GROUP BY col2
       ) v1;
```

decode_sum_col1 is not used in the upper block in v1, so it is pruned. Moreover, sum(col1) which is an argument of DECODE is also pruned. However, sum(col1) is already specified in select list and it is used in the view's upper block, so it should not be deleted.

Workaround

The patch is required.

ISSUE-5336 When using SUBQUERY in SELECT INTO statement of gpec, then it is not processed as a SELECT INTO statement.

Description

If gpec parses the SQL which has SUBQUERY after a SELECT INTO statement, then it is not processed as a SELECT INTO statement.

Symptom

The following is an example of using SUBQUERY after using the host variable array in a SELECT INTO statement.

```
EXEC SQL BEGIN DECLARE SECTION;
int no[10];
int count[10];
EXEC SQL END DECLARE SECTION;
EXEC SQL SELECT empno, B.COUNT
    INTO :no, :count,
    FROM emp, (SELECT count(*) as COUNT FROM emp);
```

When performing the example above, then the following error occurs.

```
SQLCODE :-16289
SQLSTATE: 42000
ERROR MSG : into clause can have only one row
```

Workaround

Fetch the cursor instead of using the host variable array in a SELECT INTO statement.

ISSUE-5277 A hang occurs because buffers cannot be reused after deleting a disk tablespace.

Description

If the disk tablespace is deleted, then the ager thread moves the buffer cache which cached the the deleted tablesapace to the free list. In this case, it only displays that the dirty pages should be discarded. However, if the checkpoint does not occur, then the discarded pages can not be reused, so the hang occurs in the session looking for the free buffer, and this error has been fixed.

Symptom

If the buffers which cached pages of the deleted disk tablespace become the dirty page, then the session accessing the disk tablespace can not get the free buffer, so the hang occurs.

Workaround

Clear the dirty pages of the deleted disk tablespace by performing the checkpoint.

ISSUE-4945 Use SQLTables to check the existence of the table while creating a table to operate CYCLONE, CLUSTONE, CYMON.

Description

It has been modified to create the table after checking the existence of the table required to operate CYCLONE, CLUSTONE, CYMON by using SQLTables.

Symptom

N/A

Workaround

Validate the table existence when preparing, then use the result to determine whether the table exist.

ISSUE-5218 Using async commit leads to an excessive use of transaction by a single session.

Description

Async commit in the cluster environment can use a new transaction while the transaction is not terminated, so a single session may use two ore more transactions.

Symptom

An excessive use of transactions may cause the lack of transactions.

Workaround

The patch is required.

ISSUE-5029 Even when the master rejoins with reset all option while operating Cyclone in the cluster environment, but the existing replication information is not initialized.

Description

When restarting the previously operated master with reset all option while Cyclone is operating in the cluster environment, then it should not use the existing replication information, and the replication should be resumed from the current time.

Symptom

Even when restarting the master with reset all option, the recovery process uses the existing replication o perating information.

Workaround

The patch is required.

22c.1.1 Patch Notes

ISSUE-5132 It supports DML execution for the single domain table with out the global secondary index in the cluster environment.

Description

If the global secondary index is not configured when executing DML for the single domain table in cluster environment, then it may fail. DML query requires the global secondary index to guarantee the data consi stency between servers. Therefore, if the data is stored in a single server, and it is not required to guarant ee the data consistency between server, then it supports DML without the global secondary index.

It is recommended to configure the global secondary index to manage a single table in multiple servers in cluster environment.

Symptom

```
--# G4 group has G4N1 only.
CREATE TABLE r ( c1 INTEGER )
   CLONED
   AT CLUSTER GROUP g4
   WITHOUT GLOBAL SECONDARY INDEX;
--# result: success
INSERT INTO r VALUES (1), (2), (3);
--# Improvement
--# result: success
DELETE FROM r WHERE c1 = 2;
ERR-42000(16519): global secondary index expected in cluster DML
```

Workaround

The patch is required.

ISSUE-5193 When executing a query including index backward scan in cluster environment, then the result is wrong.

Description

When executing the user query in cluster environment, if it is required to access the remote server and th e user query includes index backward scan by ORDER BY statement or by a hint, then the query result ma y be in an order of index forward scan.

Symptom

If it is required to access the remote server when executing the user query in cluster environment, then th e generated query is configured and transferred to the remote server. However, the remote server perfor ms the index forward scan because the access path hint information is wrong when configuring the gene rated query including the index backward scan.

```
CREATE TABLE t1
(
    c1 INTEGER
)
    SHARDING BY RANGE ( c1 )
    SHARD s1 VALUES LESS THAN ( 10 )       AT CLUSTER GROUP g1,
    SHARD s2 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP g2;
INSERT INTO t1 VALUES ( 12 );
INSERT INTO t1 VALUES ( 11 );
INSERT INTO t1 VALUES ( NULL );
CREATE INDEX t1_idx1 ON t1( c1 ASC NULLS LAST );
--# BUGBUG
--# result: 3 rows
--#         null
--#           12
--#           11
\EXPLAIN PLAN
SELECT c1 FROM t1@g2 ORDER BY c1 DESC NULLS FIRST;
  C1
----
  11
  12
```

```
null
3 rows selected.
```

Workaround

The patch is required.

ISSUE-5109 Cyclone malfunctions after shard rebalancing and split brai n, and this error has been fixed.

Description

When recovering after shard rebalancing and split brain, Cyclone is terminated with "internal error occurr ed (Not Need Rebalance)" error.

Symptom

Even when cyclone determines rebalancing is not required, but it is rebalanced in a specific situation. This may happen in shard rebalancing and split brain situation.

Workaround

Restart Cyclone with --reset.

ISSUE-5162 Even when SQL_ATTR_CONNECTION_TIMEOUT is set in O DBC, it may wait longer than the settings, and this error has been fixe d.

Description

Even when SQL_ATTR_CONNECTION_TIMEOUT is set in ODBC to detect the network disconnection, it m ay wait longer than the given timeout setting, and this error has been fixed.

Symptom

Even when SQL_ATTR_CONNECTION_TIMEOUT is set in ODBC, it can not detect the network disconnecti on in a specific situation, so it keeps waiting for the server's response in ODBC.

Workaround

Add the following attributes to odbc.ini, so that it can quickly detect the network disconnection.

- KEEPALIVE_IDLE_TIME

- KEEPALIVE_INTERVAL
- KEEPALIVE_COUNT

Or, alter the following kernel attributes, so that it can quickly detect the network disconnection.

- net.ipv4.tcp_keepalive_intvl
- net.ipv4.tcp_keepalive_probes
- net.ipv4.tcp_keepalive_time
- net.ipv4.tcp_retries2

ISSUE-5160 When LONGVARCHAR, LONGVARBINARY parameters exist in ODBC global connection environment, the client's memory increases, and this error has been fixed.

Description

When repeatedly performing the statement including LONGVARCHAR, LONGVARBINARY parameters in ODBC global connection environment, the client's memory increases, and this error has been fixed.

Symptom

When repeatedly performing the SQL including LONGVARCHAR, LONGVARBINARY parameters with the same statement in ODBC global connection environment, the client's memory increased.

Workaround

The patch is required.

ISSUE-5156 SQLSTATEs of some errors have been changed.

Description

SQLSTATEs of some errors have been changed.

Symptom

SQLSTATEs of some errors have been changed as follows.

Error number	Old SQLSTATE	Modified SQLSTATE	Message
13034	RD000	08S01	Service is not available
16351	08000	HY000	failed to connect to the cluster member '%s'
16523	HY000	08S01	the database system is shutting down

Error number	Old SQLSTATE	Modified SQLSTATE	Message
25001	HY000	08001	Server is not running

Workaround

The patch is required.

ISSUE-5147 Even when it was set as PROTOCOL=TCP in the configuration of CYMON, it was connected by using DA, and this error has been fixed.

Description

Even when it was set as PROTOCOL=TCP in the configuration of CYMON, it was connected by using DA. However, this error has been fixed, so it is connected by using TCP now.

Symptom

If it is set as PROTOCOL=TCP in the configuration of CYMON, it should be connected by using TCP, but, in reality, it is connected by using DA.

Workaround

The patch is required.

ISSUE-5004 A deadlock occurs on the slave's pre-process phase during the replication with CYCLONE in the cluster environment.

Description

A deadlock intermittently occurs during the replication with CYCLONE in the cluster environment.

Symptom

The replication is not proceeding and it seems to be stop. It is because a deadlock occurs during the pre-process for the replication in the cluster environment. The replication is not proceeding any more even when monitoring with CYMON.

Workaround

Reset the master and the slave of CYCLONE.

ISSUE-4985 The progressing information in slave has been added to the CYCLONE's monitoring information.

Description

The information being processed in slave (Apply_FileSeq, Apply_BlockSeq, Apply_Commit_Lsn) has been added to the CYCLONE's monitoring information.

Symptom

N/A

Workaround

The patch is required.

ISSUE-4882 It is modified to report the detatiled error message when an error occurs while processing CYCLONE SYNC.

개요

It is modified to record the detailed error message together with *ERROR OCCURRED* on the trace log when an error occurs while processing CYCLONE SYNC.

Symptom

N/A

Workaround

The patch is required.

Part II.

Administration Manual

5.

Basic Management of GOLDILOCKS Database

5.1 Creating and Configuring GOLDILOCKS Database

Creating Database

Create database using gcreatedb which is included in GOLDILOCKS package. Before creating database, the followings should be considered.

Table 5-1 Considerations when creating database

Considerations	For more information, refer to
Consider the space size of tables and indexes to be used in database.	• **Structure and Storage Structure of GOLDILOCKS Database**
Consider the location to create database files. It is because the database performance will be improved by properly distributing the files and dispersing the disk IO. For example, a user can allocate redo log file to a separate disk or stripe it, and then disperse data file into a number of disks, to execute a parallel disk IO operation.	• **Managing Redo Log File**
Be aware of each property's concepts and its operation which are set in server property file, then constantly manage them.	• **Specifying Initial Property** • **Managing Initial Property Using GOLDILOCKS Configuration File** • **Server Property**

In addition to the above considerations, refer to **Creating Database** in **Getting Started** for more options to be considered when creating database.

A user should set environment variables to use GOLDILOCKS, and the variables are $GOLDILOCKS_HOME and $GOLDILOCKS_DATA. The property file, *goldilock.properties.conf*, for creating and managing GOLDILOCKS database is in *$GOLDILOCKS_DATA/conf*.

- GOLDILOCKS_HOME: Binaries which are included in GOLDILOCKS package are installed here, and it can be overwritten during software version upgrading (The license backup is required.)
- GOLDILOCKS_DATA: Log file, data file, control file which are used by GOLDILOCKS database are installed here, and it can not be overwritten.

Specifying Initial Property

A user can use properties to control the information for operation and management in GOLDILOCKS.

Initial Property

Set the properties of when creating or starting the database as follows.

1. Setting system environment variable
    I. Change it by typing in the command window in which GOLDILOCKS is installed and database is created or operated.
    II. It is necessary to add the prefix before the property name, and the prefix is *GOLDILOCKS_*.

- The following is an example of changing SHARED_MEMORY_STATIC_SIZE to 100M.

```
export GOLDILOCKS_SHARED_MEMORY_STATIC_SIZE=100M
```

2. Property file: The prefix is not required, so change it directly in the property file.

- The following is an example of changing SHARED_MEMORY_STATIC_SIZE to 200M.
- Shared memory static size (100 M ~ 32 G)

```
SHARED_MEMORY_STATIC_SIZE = 200M
```

If the same property is set to system environment variable and property file, then the value of th e property file will be applied. For example, if SHARED_MEMORY_STATIC_SIZE is set to 100 M as the system environment variable, and SHARED_MEMORY_STATIC_SIZE is set to 200 M as the property file, then SHARED_MEMORY_STATIC_SIZE will be applied to 200 M when operating d atabase.

Managing Initial Property Using GOLDILOCKS Configuration F ile

Property file is in *$GOLDILOCKS_DATA/conf*, and is divided into two according to the file format.

- Text property file
    - File name: goldilocks.properties.conf
    - It is "property name = value" format file, and a user can directly edit it.

    - If a binary property file exists, it does not read text property file.

- Binary property file
    - It is created by the system, and a user can not edit it directly.
    - File name: goldilocks.properties.binary
    - Use gdump tool to retrieve the binary file's contents.

If a text property file and a binary property file exist together, it reads the binary property file only. The text property file is not processed. This binary property file is managed by user SQL (ALTER SYSTEM SET), and can be edited using SQL only.

For information, refer to **ALTER SYSTEM SET property_name**, **ALTER SYSTEM RESET property_name**.

- Editing text property file
    - Use "PROPERTY_NAME = VALUE" format.
    - Use '#' for annotation.
    - Property has one of the following three data types.
        - Character data type: Use a single quote (') to set the character value. Use *<GOLDILOCKS_DATA>* if the character value includes $GOLDILOCKS_DATA link.
        - Numeric data type: Do not use calculation for numeric data. For example, LOG_BUFFER_SIZE =1024 * 1024 is not allowed to use. Its size is selectable accordingly such as K (kilobyte), M (megabyte), G (gigabyte), T (terabyte), and P (petabyte)
        - Boolean data type: Allowed to use ON/OFF, ENABLE/DISABLE, 1/0 and TRUE/FALSE, YES/NO.

5.2 Starting up and Shutting down GOLDILOCKS Instance

This chapter describes starting up and shutting down of GOLDILOCKS instance.

Starting up Instance

GOLDILOCKS instance can be started only by a user with SYSDBA privilege.
GOLDILOCKS instance can be started by using Direct Attach (D/A) method and dedicated method of Client/Server (C/S). However, it can not be started by using shared method of C/S.

Multi-level Startup

GOLDILOCKS has multi-level startup procedure. Multi-level startup procedure enables to change the database's state by the intervention of administrator in each phase.

The phases are idle, nomount, mount, open, and each phase has the following features.

Idle Phase

The idle phase is a state in which an instance is not started up.

If connecting to gsql when an instance is not started, then it will be connected to idle instance as follows. In this phase, any sever command can not be executed except for \startup.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> select * from dual;
ERR-08003(40044): connection does not exist
gSQL>
```

- Administrator operations in idle phase
  - Adjusting the property required to start up the instance
  - Transition to nomount using `\startup` in gsql

- Operation in an instance at the nomount transition
  - Starting up gmaster which is a daemon managing GOLDILOCKS instance
  - Starting up timer thread and cleanup thread in gmaster
  - Allocating and initializing Shared memory Static Area (SSA).

Table 5-2 Applied properties at the transition to nomount

Property name	Description
CLIENT_MAX_COUNT	Maximum number of connectable sessions
CONTROL_FILE_0 ~ 7	Path of control file
CONTROL_FILE_COUNT	The number of valid path among the path of control file
DATA_STORE_MODE	Store mode of GOLDILOCKS instance
PLAN_CACHE_SIZE	Maximum size of shared memory for plan cache
PROCESS_MAX_COUNT	Maximum number of connectable process
SHARED_MEMORY_ADDRESS	Address of shared memory
SHARED_MEMORY_STATIC_NAME	Name of shared memory
SHARED_MEMORY_STATIC_KEY	Key value for creating shared memory
SHARED_MEMORY_STATIC_SIZE	Size of shared memory to be created
SYSTEM_LOGGER_DIR	Path of system logger

Properties can not be changed in idle phase. An administrator changes the properties as follows.

To use an environment variable, then set GOLDILOCKS_[property_name] to a desired value and transit it t o nomount. Then, the properties will be applied.

```
% export GOLDILOCKS_CLIENT_MAX_COUNT=1000
```

To use 'SCOPE = FILE', record the property value to be changed in the file. The recorded property will be applied at nomount transition.

```
gSQL> alter system set client_max_count = 1000 scope = file;
System altered.
gSQL> \shutdown
Shutdown success
gSQL> \startup
Startup success
gSQL>
```

Nomount Phase

The nomount phase is a state in which it is not mounted to database, and only the gmaster process has b een started. A gmaster is a daemon which manages GOLDILOCKS instance.

The following describes how to transit idle phase to nomount phase.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup nomount
Startup success
```

```
gSQL>
```

- Administrator operations in nomount phase
  - Adjusting nomount property
  - For more information, refer to **ALTER SYSTEM {MOUNT | OPEN} DATABASE**, **ALTER DATABASE R ESTORE**.

- Operation in an instance at the mount transition
  - Loading the control file to database
  - Preparing for database recovery
  - Starting up threads in gmaster such as checkpoint, log flusher, page flusher, IO slave, archive log

Table 5-3 Updatable properties in nomount phase

Property name	Description
LOG_BUFFER_SIZE	Redo log buffer size
PARALLEL_LOAD_FACTOR	The number of threads for parallel operations after loading database
PARALLEL_IO_FACTOR	The number of parallel threads for loading database
PARALLEL_IO_GROUP_1 ~ 16	Datafile group at parallel loading
PENDING_LOG_BUFFER_COUNT	The number of delayed log buffers
TRANSACTION_TABLE_SIZE	Transaction table size
UNDO_RELATION_COUNT	The number of undo relations

Mount Phase

The mount phase is a state in which it is mounted to database, and the database recognizes the control fi le. All sections in the control file is controllable in this phase.

The following describes how to transit nomount phase to mount phase.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup nomount
Startup success
gSQL> alter system mount database;
System altered.
gSQL>
```

- Administrator operations in mount phase
  - Adjusting mount properties
  - **ALTER SYSTEM {MOUNT | OPEN} DATABASE**
  - **ALTER DATABASE ADD LOGFILE**
  - **ALTER DATABASE DROP LOGFILE**
  - **ALTER DATABASE RENAME GLOBAL TRANSACTION LOGFILE**

  - **ALTER DATABASE RENAME LOGFILE**
  - **ALTER DATABASE { ARCHIVELOG | NOARCHIVELOG }**
  - **ALTER DATABASE DELETE BACKUP**
  - **ALTER DATABASE REGISTER**
  - **ALTER DATABASE RECOVER**
  - **ALTER DATABASE RESTORE**
  - **ALTER SESSION SET property_name**
  - **ALTER SYSTEM RESET property_name**
  - **ALTER SYSTEM SWITCH LOGFILE**
  - **ALTER SYSTEM [KILL | DISCONNECT] SESSION**
  - **ALTER TABLESPACE name ADD [DATAFILE|MEMORY]**
  - **ALTER TABLESPACE name RENAME DATAFILE**
  - **ALTER TABLESPACE name [ONLINE|OFFLINE]**

- Operation in an instance at the open transition
  - Loading all data file used in an instance to shared memory
  - Performing instance recovery
  - Creating NOLOGGING index
  - Deleting objects or files which are not deleted by ager thread
  - Creating cache for dictionary objects
  - If "SHARED_SESSION" property is set to *YES*, process monitor thread in gmaster will be started up.
  - Process monitor thread executes balancer process, dispatcher process, shared-server process.

Table 5-4 Updatable property in mount

Property name	Description
ARCHIVELOG_FILE	Prefix name of archive file
IN_DOUBT_DECISION	Decision about in-doubt transaction
LOCK_HASH_TABLE_SIZE	Hash table size of lock administrator
LOG_MIRROR_MODE	Log mirroring mode
LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE	Shared memory size for log mirroring
SUPPLEMENTAL_LOG_DATA_PRIMARY_KEY	Whether to perform supplemental logging at the database-level

Open Phase

The open phase is a state in which all the data file is loaded to memory, and it is ready for service. All operations are allowed in this phase.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup mount
```

```
Startup success
gSQL> alter system open database;
System altered.
gSQL>
```

Diagnosis

It is possible to execute several phases at a same time using a single command(\startup) when starting up instance. If a certain phase fails, the administrator should figure out in which phase the failure occurs. Check using to which phase the instance has come using V$INSTANCE. Then the administrator can continue operations of startup instance from the subsequent phase.

The following is an example of starting up instance to open phase after \startup failure.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup
ERR-42000(14051): media recovery required - 'TEST_TBS'
gSQL> select INSTANCE_STATUS from v$instance;
INSTANCE_STATUS
---------------
MOUNTED
1 row selected.
...
gSQL> alter system open database;
System altered.
```

Shutting down Instance

GOLDILOCKS instance can be terminated only by a user with SYSDBA privilege. It is not allowed to create new session during shutdown.

GOLDILOCKS instance can be shut down by Direct Attach (D/A) method and dedicated method of Client/Server (C/S), but it can not be shut down by shared method of C/S.

There are four types of instance shutdown mode, and they are shutdown normal, shutdown transactional, shutdown immediate and shutdown abort.

Shutdown Normal

The shutdown normal is set by default if a particular mode is not specified when shutting down. Use this type if a user wants to shut down an instance normally.

```
gSQL> \shutdown normal
Shutdown success
gSQL>
```

The followings describe the characteristics of shutdown normal.

- New session is not allowed.
- New transactios and statements are allowed in session which already have been connected.
- Waiting for all the sessions which are connected to the instance to be shut down.
- It does not execute instance recovery process when starting up the instance.

Shutdown Transactional

Use this type to shut down the currently proceeding transactions normally even when the session is forcib ly shut down.

```
gSQL> \shutdown transactional
Shutdown success
gSQL>
```

The followings describe the characteristics of shutdown transactional.

- Neither new session nor is new transaction allowed.
- New statements are allowed in ongoing transaction.
- Waiting for the ongoing transactions to be shut down.
- The session will be automatically terminated after the ongoing transactions is terminated.
- It does not execute instance recovery process when starting up the instance.

Shutdown Immediate

Use this type to terminate the instance when a user can not terminate current transactions.

```
gSQL> \shutdown immediate
Shutdown success
gSQL>
```

The followings describe the characteristics of shutdown immediate.

- Neither new session nor is new transaction allowed.
- Forcibly shut down ongoing sessions and transactions.
- Waiting until the background thread of the system to be completed.
- It does not execute instance recovery process when starting up the instance.

Shutdown Abort

Use this type when a user judged the instance is in an abnormal state.

```
gSQL> \shutdown abort
Shutdown success
gSQL>
```

The followings describe the characteristics of shutdown abort.

- Neither new session nor is new transaction allowed.
- Forcibly shut down ongoing sessions and transactions.
- Instantly shut down the background thread of the system.
- It executes instance recovery process when starting up the instance.

5.3 Managing Process

This chapter describes the background processes of GOLDILOCKS instance.

Master Process

Master process performs the asynchronous operation for database performance and monitoring. It consis ts of many threads.

The master process' executable file name is gmaster.

Checkpoint Thread

Checkpoint thread executes asynchronous checkpoint events which occur in the log flushing thread. The checkpoint event occurs whenever redo log file is switched.

Checkpoint event is executed asynchronously regardless of a user, and its log is recorded in system.trc as f ollows.

```
[2014-09-11 14:04:34.704465 THREAD(14497,140178383427328)] [INFORMATION]
[CHECKPOINT] begin
...
[2014-09-11 14:04:34.743933 THREAD(14497,140178383427328)] [INFORMATION]
[CHECKPOINT] save control file
[2014-09-11 14:04:34.759521 THREAD(14497,140178383427328)] [INFORMATION]
[CHECKPOINT] end
```

Log Flushing Thread

User transactions record redo log in log buffer, and it is periodically recorded in log file by log flushing thr ead.

Log switching occurs when redo log is recorded to the end of the log file, then it will be recorded in the n ext redo log file. When the log switching occurs, checkpoint event is transferred to a checkpoint thread.

If reusable log file does not exist when the log file is switched, all queries except for the read-only queries will wait until the reusable log file is created.

The message remains as follows in system.trc when logging is blocked.

```
...
[2014-09-11 14:31:44.315871 THREAD(19102,139674683647744)] [INFORMATION]
[LOG FLUSHER] disable logging - blocked lfsn(1)
...
```

Log Archiving Thread

The log archiving thread asynchronously archives redo log file. This thread is executed only when databas e is operated in ARCHIVELOG mode.

Log archiving is a part of checkpoint process, and it is executed by log archiving event in which the check point thread occurred.

The message remains as follows in system.trc when redo_0_0.log is archived to archive_0.log.

```
[2014-09-11 14:13:32.515996 THREAD(16913,140631135463168)] [INFORMATION]
[ARCHIVELOG BEGIN] LOG(/home/test/work/product/Gliese/home/wal/redo_0_0.log(0)) =>
ARCHIVE(/home/test/work/product/Gliese/home/archive_log/archive_0.log)
[2014-09-11 14:13:33.145850 THREAD(16913,140631135463168)] [INFORMATION]
[ARCHIVELOG END] (/home/test/work/product/Gliese/home/archive_log/archive_0.log) : SUCCESS
...
```

Ager Thread

Ager thread physically drops the logically dropped database objects.

DROP TABLE statement executes only logical drop operation to maintain statement level consistency in G OLDILOCKS. Therefore, the statement which was invoked before DROP TABLE can explore the records of dropped table even when DROP TABLE is executed.

The message remains as follows in system.trc when table and tablespaces are physically dropped.

```
[2014-09-11 14:13:37.966788 THREAD(16925,139892990408448)] [INFORMATION]
[AGER] aging table - object scn(4561), object view scn(4562), type(0), physical
id(25043954302976)
...
[2014-09-11 14:13:37.966917 THREAD(16925,139892990408448)] [INFORMATION]
[AGER] aging tablespace - object scn(4561), object view scn(4564), tablespace id(61)
```

Timer Thread

Timer thread asynchronously sets time to the system to reduce the time measuring cost of user transactio ns, and the user transactions read the time set in the system.
The time precision is set according to **TIMER_INTERVAL**, and the default value is 10 ms.

The followings describe the case of using the time set in the timer thread. The time error occurs as much as TIMER_INTERVAL value. For example, if TIMER_INTERVAL is 10 ms, then the time error is also 10 ms.

- Time out : QUERY_TIMEOUT, IDLE_TIMEOUT, DDL_LOCK_TIMEOUT, ...
- Message record time written in trace log
- Startup time of login statement or transaction.
- Time recorded in transaction commit redo log

Page Flusher & IO Slave Threads

It applies the updated data pages to the disk when a checkpoint occurs. The updated information is store d in multiple data files in a tablespace. For that, the page flusher thread distributes operations to IO slave threads per each tablespace and data files and manages them. Then the IO slave threads record the upda ted pages in the data file in parallel.

If tables and index pages stored in the disk tablespace are updated by caching them to the buffer, they ar e linked to the checkpoint list, and the pages updated for the reuse in the buffer cache are linked to the b uffer replace list. I/O slave threads reflect the pages in IO checkpoint list and the pages in the buffer repla ce list on the disk at the checkpoint or regularly.

Storing the updated pages as many as possible at a time improves performance. The number of written p ages at each time follow the properties in **MAXIMUM_FLUSH_PAGE_COUNT**.

After the updated pages are written to the data file, the message remains in system.trc is as follows.

```
[2014-09-11 14:13:38.329162 THREAD(16925,139893221086976)] [INFORMATION]
[IO SLAVE] flush datafile ( tablespace : 0, datafile : 0 )
[2014-09-11 14:13:38.552161 THREAD(16925,139893221086976)] [INFORMATION]
[IO SLAVE] flush datafile ( tablespace : 1, datafile : 0 )
[2014-09-11 14:13:38.587510 THREAD(16925,139893221086976)] [INFORMATION]
[IO SLAVE] flush datafile ( tablespace : 2, datafile : 0 )
[2014-09-11 14:13:38.587831 THREAD(16925,139893221086976)] [INFORMATION]
[IO SLAVE] flush datafile ( tablespace : 62, datafile : 0 )
[2014-09-11 14:13:38.620239 THREAD(16925,139893221086976)] [INFORMATION]
[IO SLAVE] flush datafile ( tablespace : 63, datafile : 0 )
```

Cleanup Thread

Cleanup thread cleans up the system resource asynchronously, and performs the following operations.

- It cleans up normally terminated session. GOLDILOCKS processes termination of a user session logical ly, and uses cleanup thread for physical termination of a session.
- It cleans up abnormally terminated session. If the session is using transactions, then they will be rolled back.
- It checks the time-out of snapshot statements. If a session exceeds the time-out, it is forced to be ter minated.

When cleaning up the abnormally terminated session, a message remains in system.trc as follows.

```
[2014-09-12 10:34:38.387349 THREAD(23003,140722556352256)] [WARNING]
[CLEANUP] cleaning session - env(19), session(20), transaction(FFFFFFFFFFFFFFFF),
program(gsql), pid(23209), thread(140080441665280)
[2014-09-12 10:34:38.387515 THREAD(23003,140722556352256)] [WARNING]
[CLEANUP] cleaning up 1 sessions
```

If a snapshot statement exceeds the time-out, a message remains in system.trc as follows.

```
[2014-09-12 10:49:21.842179 THREAD(3972,139706316711680)] [WARNING]
[CLEANUP] long statement timeout - pid(8029), thread(140053960505088), program(gsql),
statement start time(2014-09-12 10:48:49.963471)
```

If abnormally terminated session is terminated by 'kill-9' signal during changing shared memory when exc lusive latch is acquired, it is no longer possible to operate the database. In this situation, a message remai ns in system.trc as follows, and the instance should be terminated using *SHUTDOWN ABORT*.

```
[2014-09-12 11:12:58.809249 THREAD(15313,140671386121984)] [WARNING]
[CLEANUP] failed to cleaning session - server restart required
...... dead session in critical section - env(3), session(4), transaction(47001E0004),
pid(15296), thread(140178075756288)
```

Process Monitor Thread

The process monitor thread executes processes, and monitors them.

- It is executed only when "SHARED_SESSION" property is set to *YES*.
- It executes load-balancer (gbalancer), dispatcher(gdispatcher), shared-server(gserver), and re-execute s them when they are abnormally terminated.
- It does not monitor listener (glsnr) process.

Cluster Recover Thread

When starting up a node on a cluster system environment, if the node phases up to the mount phase, th en the cluster recover thread is created. If there is an in-doubt transaction, the cluster recover thread com municates with the cluster recover thread on the remote node, and recovers the in-doubt transaction.

If there is an in-doubt transaction, the cluster recover thread communicates with the cluster recover threa d on the remote node, and figures out the status of the in-doubt transaction. If the remote node is restar ted and it is not recovered yet, then it transfers a message requesting the preferential completion of reco very and recovers the in-doubt transaction status after the recovery is completed.

The in-doubt transaction statuses figured out through the remote node are NONE, PREPARE, COMMIT, a nd ROLLBACK. If the cluster recover thread received the response such as COMMIT, ROLLBACK from at le ast one remote node, then it performs COMMIT or ROLLBACK. If the cluster recover thread received the r esponse such as NONE, PREPARE from all remote nodes, then it performs ROLLBACK because COMMIT o r ROLLBACK never has been performed on any cluster node.

The in-doubt transaction recovery using the cluster recover thread leaves the following messages in syste m.trc.

```
[2018-11-22 16:52:00.466805 INSTANCE(G3N2) THREAD(7828,140557371479808)] [WARNING]

Failover Thread

When starting up a node on a cluster system environment, if the node phases up to the LOCAL OPEN pha se, then the cluster failover thread is created. Cluster failover thread performs the failover for the error no de by reselecting a coordinator or offlining when an error occurs on a specific node or the network in the cluster system.

In a situation requiring the failover, a normal node which acquired a failover lock among other normal no des communicates with failover threads of other nodes, then performs the failover.

The failover performed by the failover thread leaves the following messages in system.trc.

```
[2018-11-22 15:27:34.619208 INSTANCE(G1N1) THREAD(20140,140219957368576)] [INFORMATION]

Buffer Checkpoint Flusher, Buffer Replace Flusher

The table and index pages stored in disk table spaces are cached in a buffer and linked to a checkpoint lis t as changes are made. The buffer checkpoint flusher reflects pages linked to the checkpoint list to the co rresponding data file. The buffer checkpoint flusher is performed when a checkpoint event occurs, or is p eriodically performed after sleeping for the period set in the **BUFFER_FLUSHING_INTERVAL** property. The number of buffer checkpoint flushers is determined by **BUFFER_CHECKPOINT_LIST_COUNT** property.

If the requested page does not exist in the buffer cache, then it fills the buffer cache by reading pages fro m the data file. When looking for the available space in the buffer caches, then it links the updated pages which are not currently used to the buffer replace list. Then, the buffer replace flusher reflects the pages l inked to the buffer replace list to the corresponding data file. The buffer replace flusher wakes up by the event when an available space does not exist because the buffer is full, or is periodically performed after s leeping for the period set in the **BUFFER_FLUSHING_INTERVAL** property. The number of buffer replace flu shers is determined by **BUFFER_FLUSH_THREADS** property.

Listener Process

Listener process enables remote access through the network in a client/server environment. Listener proc ess waits for a client connection using **LISTEN_PORT**. If connected in dedicated mode, new gserver starts, and connects a client. If connected in shared mode, it selects underloaded dispatcher (gdispatcher) using load-balancer (gbalancer), and connects a client.

gserver is a kind of operation server, and it executes a client request.

If LISTEN_PORT is already in use, the following error occurs.

```
% glsnr --start
ERR-HY000(11077): given address is already in use
```

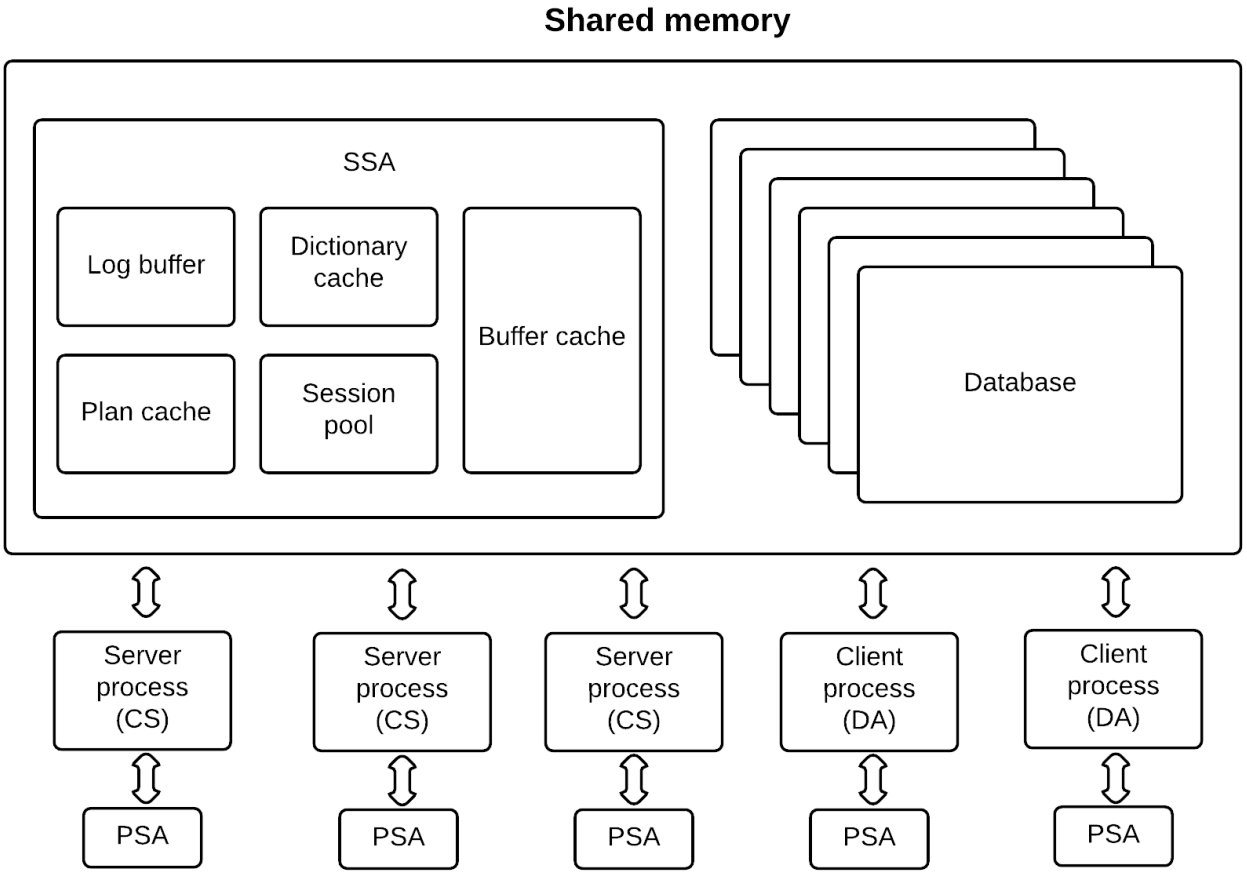
Listener process operates independently from the instance. In other words, listener process can start up a nd shut down regardless of instance start up anytime.

5.4 Managing Memory

GOLDILOCKS Memory Architecture

GOLDILOCKS uses SSA which is a memory shared by all sessions in the system, a shared memory for data base pages, and PSA (heap memory) which each session uses independently.

Figure 1 Shared memory



Managing SSA

Shared Static Area (SSA) is a memory area to store information which is shared by the system's all session s.

A new process should use the same physical address for using SSA. It is because the position of all inform ation referenced by SSA uses the physical address.

The physical starting address of SSA is determined by **SHARED_MEMORY_STATIC_KEY** and **SESSION_FATAL_BEHAVIOR**. The following error occurs when another program is already using shared memory key assigned by the same SHARED_MEMORY_STATIC_KEY, and the memory assigned by SHARED_MEMORY_ADDRESS.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup
ERR-HY000(11029): shared memory segment exists
gSQL>
```

SSA stores main information, and they are log buffer, dictionary cache, plan cache, session pool, lock pool, and transaction pool.

SSA size is determined by **SHARED_MEMORY_STATIC_SIZE**. The system automatically manages memories used in session/lock/transaction pool and dictionary cache, and a user can not arbitrarily manage them. However, a user can arbitrarily manage the usage of log buffer and plan cache.

If the default value of log buffer and plan cache are increased, SHARED_MEMORY_STATIC_SIZE should be increased accordingly. Otherwise, the following error occurs.

```
% gsql sys gliese --as sysdba
Connected to an idle instance.
gSQL> \startup
ERR-HY000(13010): Insufficient static area
gSQL>
```

Managing PSA

Private Static Area (PSA) is a heap memory area, and it is used independently by each session. **PRIVATE_STATIC_AREA_SIZE** determines the maximum size of PSA.

An initial size is allocated to PSA when a session is created. If additional memory is required in the session, PSA can be allocated up to its maximum size. The following error occurs when it exceeds the maximum size.

```
ERR-HY000(13011): Unable to extend memory: [MAX: 104857600, TOTAL: 102764408, ALLOC: 2097240]
DESC: private static area
```

5.5 Monitoring

Database monitoring is needed not only to detect and prevent the problem which can be an issue in the f uture, but also to find a way to improve database management. For monitoring, GOLDILOCKS database provides text file type trace log and several performance views.

Monitoring with Trace File

From when the instance starts up until it terminates, GOLDILOCKS database provides the system log whic h records the overall system error, warning, information. In addition, it provides XA transaction log, trace log such as DDL log, and SQL Trace Log. For more information, refer to **SQL Trace Log**.

Managing Trace Log File

GOLDILOCKS database's trace log file consists of system.trc file and xa.trc file. The system.trc file records system log and DDL log, and xa.trc file records XA transaction log. Trace log file is created in directory set in SYSTEM_LOGGER_DIR property. Therefore, it is generally created in trc directory below the directory s pecified in GOLDILOCKS_DATA environment variable. The trace log file's size is 10 Mbytes. If its space is i nsufficient, the existing trace log file with unique file extension is preserved, and the new trace log file is created.

Listener trace log file is created as *listener.trc* in trc directory below the directory specified by GOLDILOCK S_DATA environment variable. The log file size is 10 Mbytes. If the space is insufficient, the existing log fil e with unique file extension is preserved, and the new trace log file is created.

Except for system log, XA transaction log and DDL log can ON/OFF the monitoring. Set the TRACE_DDL p roperty value to 0 to turn off the DDL log, or set it to 1 to turn on the DDL log. XA log is set in the same way using the TRACE_XA property.

System Log

The errors, warnings, and information which occurred in database instance from when master process st arts up until it terminates are recorded in the system log.

System Log Format

System log is recorded in the following format.

```
['log record data and time' THREAD('process Id', 'thread handle')] ['log level']
['log prefix'] 'log body'
```

- 'log record date and time' is the date and time of the recorded log.
- THREAD('process Id', 'thread handle') is the information of log process id and thread handle.
- 'log prefix' is the entity or feature which created the log, and 'log body' is the detailed information.
- 'Log level' is the level of log recorded in system log, and its value is FATAL, ABORT, WARNING, INFO. 'log level' has the properties as follows.

Table 5-5 Log level properties

Log level	Description	Processing
FATAL	The state which master or client process is shut down abnormally.	The client should be reconnected in case of client process FATAL, and the database instance should be shut down and restarted in case of system FATAL. Backup the data file, control file, redo log file, system log file and contact the manufacturer.
ABORT	The state to continue service after rollback.	It is the normal state for system operation. Execute it again after eliminating the rollback cause.
WARNING	Operational warnings	The abnormal state of database instance. there is no operational problem but cause analysis is needed.
INFO	Operational information	-

For example, the following system log recorded the operational information at 17:30:55 on September 11 in 2014 by process id 21395 (The thread handle is 139982731163392). Log prefix is 'STARTUP-SM' and was executing the storage manager when the master process of GOLDILOCKS database started up. It means that the transition to NO-MOUNT phase had been done during multilevel startup.

```
[2014-09-11 17:30:55.758164 THREAD(21395,139982731163392)] [INFORMATION]
[STARTUP-SM] NO-MOUNT PHASE
```

Operational Information of GOLDILOCKS Database

It is the log for creating database instance, multilevel startup and shutdown, loading data file, recovering restart and media. It records the necessary information for the operation of the master process from when master process starts up until it terminates.

- GOLDILOCKS instance creation log

The system log records the following information when database instance is created. It creates the control file after the transition to NO-MOUNT phase to create database.

```

- The logs of master process checkpoint, log flusher, log archiving, ager, parallel IO, cleanup thread dur ing database operation

A checkpoint reflects to disk all data files which are updated only in memory and not written to the disk y et at checkpoint time. If it uses the parallel IO, it executes parallel IO in data file units. One unit of checkp oint log is from '[CHECKPOINT] begin' to '[CHECKPOINT] end'.

[IO SLAVE] is a log which is recorded by IO thread dedicated to parallel IO. '[IO SLAVE] flush data file (tablespace: 0, datafile: 0)' log is recorded after the data file (whose datafile id is '0' and whose tablespace id is 0) is reflected to the disk. These data file flush logs are repeatedly recorded as many as the number of data file at checkpoint time.

'[PAGE FLUSHER] flushed lsn(139039), flushed page count(9216)]' means that the reflected minimum Lsn in the disk is 139039, and reflected pages are 9216. The last log Lsn archives redo log files which are smaller than 139039. They record checkpoint log and control file, then stores them in the disk.

If a database is large its checkpoint time will be longer. Check if the datafile is continuously being recorded by tracking [IO SLAVE] logs. And if disk IO does not operate and stops, then check if log archiving is in progress. If the space is insufficient , then spare the space and ensure the log archiving proceed normally.

If checkpoint fails '[CHECKPOINT] CHECKPOINT was failed' log will be recorded. The checkpoint can be specially omitted at checkpoint time due to the log file switch, where '[CHECKPOINT] CHECKPOINT was skipped' log might be recorded.

- Log of creating, dropping, altering tablespace by a user

The system log records the operations of creating, deleting, updating of a user tablespace. Tablespace rel ated to DDL is recorded by default, regardless of TRACE_DDL ON/OFF. DDL failure will not be recorded in the system log. Therefore, a user should operate the system by setting TRACE_DDL to *ON* in order to figu re out more details about DDL log and the causes of its failure.

- System internal error and index creation failure log

An internal error occurs when GOLDILOCKS database system error occurs but the exact cause of the failu

re can not be defined. If an internal error occurs, the SQL statement which raised the error is rolled back. The service is continuously available because the error does not affect the system nor does other sessions.

By the way, if the error raising SQL statement is executed again, it could be failed for the same reason, or the cause of failure could disappear and the operation could succeed. Therefore, a user should not chang e the database at the point of failure, but should request cause analysis to find the cause.

The index creation fails if the same key index on a table exists when creating UNIQUE index. Even though the index creation fails, it does not affect the index tables which are already created. Therefore, it does n ot affect the service.

```

Trace Log Replication

Replication trace log is recorded in a separate file when using GOLDILOCKS' replication tool such as CYCL ONE and LOGMIRROR. For more information about replication trace log, refer to **operating CYCLONE** in CYCLONE chapter and **operating** in LOGMIRROR chapter.

Listener Log

The errors and information which occurs from the startup of listener process until the end of the process are recorded in the listener log.

Listener Log Format

The listener log is recorded in the following format.

```
['log recorded date and time' THREAD('process id', 'thread handle')]
['log prefix'] 'log body'
```

- 'log record date and time' is the date and time of the recorded log.
- THREAD ('process Id', 'thread handle') is the information of log process id and thread handle.
- 'log prefix' is the entity or feature which created the log, and 'log body' is the detailed information.

Monitoring Performance Using View

Concurrency control for multi-user is needed because database is accessed or updated by multiple users a t the same time. The concurrency should be provided for system data and shared resources as well as exp licit data by SQL statements. GOLDILOCKS controls the concurrency using latch.

The concurrency control using lock can cause a deadlock when same data is updated by multiple differen t transactions. The concurrency control using latch (supported by GOLDILOCKS) can cause a deadlock, to o. It is because the deadlock affects the performance, so a view is provided to handle the latch when a de adlock occurs.

The transactions generating the deadlock will be be found when using V$LOCK_WAIT. Then, the adminis trator should monitor them, and unlock the deadlock. For more information about V$LOCK_WAIT, refer t o **V$LOCK_WAIT**. For more information for monitoring latch item causing the deadlock, refer to **V$LATC H**.

6.

Structure and Storage Structure of GOLDILOCKS Database

6.1 Managing Control File

A database instance should be created to use GOLDILOCKS database, and the control file is created when creating a database instance. The information is written on the control file when GOLDILOCKS multilevel startup moves from nomount level to mount level. The absolute path and the size of the file to be used in database are recognized by using the recorded information on the control file. The control file is a binary file and database information is stored as follows.

Control File Contents

Table 6-1 GOLDILOCKS database system information

Item	Description
Data store mode	It stores mode which is set when database starts up. (TDS, CDS)
Server state	It is the database instance state. (NONE, RECOVERED, RECOVERING, SERVICE, SHUTDOWN)
Last checkpoint lsn	It is the LSN of the checkpoint which was executed last in the database.

Table 6-2 Log information

Item	Description
Checkpoint lid, lsn	It is the log information (LSN, log position) of the checkpoint which was executed last in the database.
Last inactivated log file sequence	It is the log file sequence which was changed to inactive last.
Archivelog mode	It is the archivelog mode of the database in operation.
Creation time	It is the database created time.

Database information stores information about database operating, all tablespace in use, and data. The database operating information stored in the control file is as follows.

Table 6-3 Database information

Item	Description
Transaction table size	It is the maximum number of using transaction table in database.
Undo relation count	It is the number of using undo relations in database.
Tablespace count	It is the number of tablespaces in use created in database.
New tablespace id	It is the tablespace ID to be created later.

Tablespace information is stored in the control file as follows.

Table 6-4 Tablespace information

Item	Description
Tablespace id	It is a unique tablespace ID.
Attributes	It is the attribute of a tablespace such as storage device (memory, disk), persistence at tribute (temporary, persistent), tablespace usage (dictionary, undo, data, temporary).
Page count in extent	It is the number of extent pages.
State	It is the tablespace status. (CREATING, CREATED, DROPPING, DROPPED, AGING)
Relation id	It is the relation ID to store pending operation of tablespace.
New data file id	It is the data file ID which is set when new data file is inserted to tablespace.
Is logging	It is the logging mode of a tablespace. (LOGGING, NOLOGGING)
Is online	It is the online or offline status of a tablespace. (ONLINE, OFFLINE)
Data file count	It is the number of data files used by a tablespace.
Offline lsn	It is the last LSN which executes recovery if needed, in order to shift offline tablespace to online.
Offline state	It is the status of offline tablespace. (CONSISTENT, INCONSISTENT) CONSISTENT offline tablespace does not have to be recovered when shifting the statu s to online. It is because the tablespace status is shifted to offline after the most recen t data in memory is stored to disk. On the other hand, INCONSISTENT offline tablespa ce executes recovery using the log when shifting to online.

Data file information is stored in the control file as follows.

Table 6-5 Data file information

Item	Description
Name	It is the data file name including the absolute path which stores data.
State	It is the data file status. (CREATING, CREATED, DROPPING, DROPPED, AGING)
Data file id	It is the unique data file ID in a tablespace.
Auto extend	It is whether to extended automatically or not when a data file is full.
Size	It is the data file size.
Next size	It is the size to be extend when a data file is full.
Max size	It is the maximum size of extendable data file.
Timestamp	It is the time when data file was created.
Checkpoint lsn, lid	It is the checkpoint log information when the last checkpoint is executed in the data file. (LS N, log position)
Creation lsn, lid	It is the checkpoint log information of when a data file is created. (LSN, log position)

It stores each incremental backup information operated in the database. GOLDILOCKS database supports the incremental backup for database and tablespaces, and the incremental backup information is stored i n the control file as follows.

Table 6-6 Incremental backup information

Item	Description
Backup lsn, lid	It is the checkpoint log information which was executed last at the beginning of back up. (LSN, log position)
Begin time	It is the incremental backup beginning time.
Completion time	It is the incremental backup completion time.
Tablespace id	It is the unique tablespace ID of which an incremental backup is executed. If incremental backup for a tablespace is executed, its tablespace ID is recorded. If the backup is not executed for a tablespace, then the maximum tablespace ID (65535) is recorded.
Level	It is the level of executed incremental backup.
Object type	It is the target of incremental backup. (database, control file, tablespace)
Backup file name	It is the name of the incremental backup file.
Backup option	It is the incremental backup option. (cumulative, differential)

Multiplexing Control File

The control file stores the physical structure of GOLDILOCKS database and the information on data consistency. If the control file is corrupted or deleted by mistake, it is not possible to operate database.

Therefore, GOLDILOCKS database recommends creating at least two or more control files and keep them in physically separated disks. GOLDILOCKS supports multiplexing up to 8. To add control files when creating a database, set the number of multiplexing control files in the property file, and set the path of each control file. To add control files when operating database, increase the property value for control file multiplexing, and add the control file paths.

Restoring Corrupted Control File

If a control file is corrupted due to database's abnormal termination, the corrupted control file is restored using a normal control file among multiplexed control files, and then it is restarted.

If all multiplexed control files are corrupted, the backup control file is restored, and the incomplete media recovery is executed for archive redo log files and redo log files, and then it is restarted. For more information about incomplete recovery using the backup control file, refer to **When all multiplexed control files are corrupted** in recovery examples.

Control File Information

A user can enquire the control file name by using V$CONTROLFILE which is the performance view to retri eve the location and the name of the control file as follows.

```
gSQL> SELECT CONTROLFILE_NAME FROM V$CONTROLFILE;
CONTROLFILE_NAME
------------------------------------------------------
/goldilocks_data/wal/control_0.ctl
/goldilocks_data/wal/control_1.ctl
2 rows selected.
```

A user can retrieve the correct information written in the control file using **gdump** the dump tool of GOL DILOCKS.

6.2 Managing Redo Log File

GOLDILOCKS uses the redo log files to ensure database persistency. In other words, the database can be restored to the state before shutdown database using the redo log files and data files when GOLDILOCKS database is abnormally terminated due to various reasons.

In order to do so, GOLDILOCKS database uses Write Ahead Logging (WAL) policy to store log of all updat e operations.

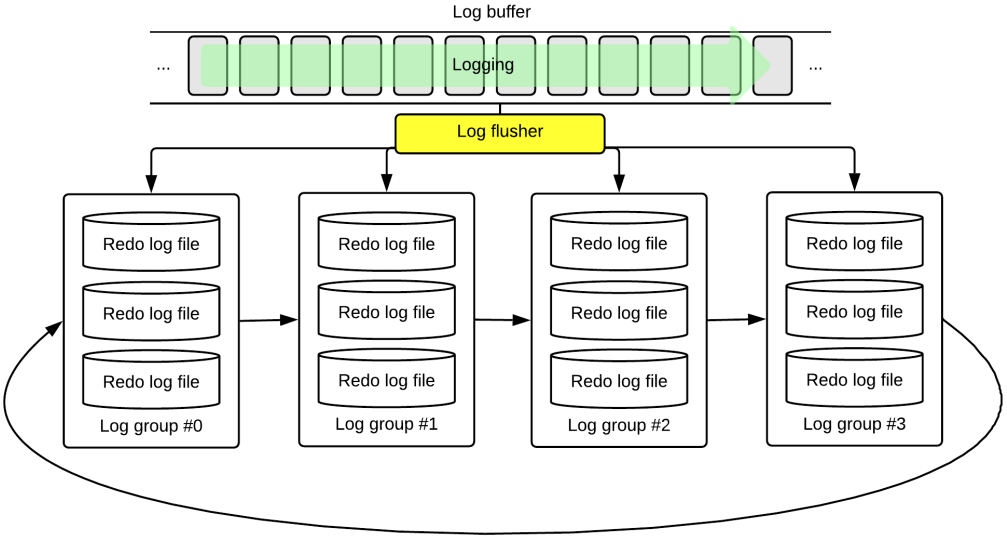
The updated data by the update operation is not recorded in the data file, but the log for the update ope ration is recorded in the redo log file. It is because it is much more efficient in the terms of database perfo rmance. Whenever each update operation is recorded in the data file, a random access occurs and the up date operations for the same file causes the excessive disk IO. However, the update log is smaller than th e updated data, and it performs the efficient disk IO in a way being appended at the end of log file.

GOLDILOCKS database uses log buffer in shared memory to record the updated logs to the log buffer, an d then records log buffer to the log file all together, and it leads to more efficient disk IO.

Redo Log File Structure

The redo log buffer and log file in GOLDILOCKS have a circular structure. The log files are created as man y as predefined number of log groups, and then they record logs. If a log file is full, the following log file i s used. When all log files are used up, the previously used log file is reused. The log file is a circular struct ure consisting of a single log group of several members. GOLDILOCKS performs the logging using minim um four log groups.

Figure 1 GOLDILOCKS redo log file, log buffer structure



Redo Log Group and Its Member

GOLDILOCKS database uses a log group and members to record logs to the disk log file during database operation. A single redo log file is a member of a log group, and a log group consists of several log members. Log group which consists of many members ensures high availability because other log members can be used when a particular disk fails or a particular log member is corrupted.

The system records logs to a log group, and if the log group is full, the following group is used. This is a circular log group. The currently used log group shifts to the following log group one and this is called as log switching.

A log group, the number of members and each of its position are set by the property when creating database. They can be altered by adding or dropping syntax when operating database.

Log Group State

The state of log group is initialized to UNUSED when creating it. It is changed to CURRENT, ACTIVE, and INACTIVE state by the system during operation.

Table 6-7 GOLDILOCKS log group state

Log group state	Description
UNUSED	The log group has never been used after creation.
CURRENT	The log group is being used by the current system.
ACTIVE	It is not yet ready to be reused after CURRENT log group is switched.
INACTIVE	ACTIVE state log group is ready to be reused.

ACTIVE log group can not be reused in the system, but it can be reused after it is changed to INACTIVE by archive log thread. Archive log thread wakes up by an event before the checkpoint is completed, and it changes ACTIVE log groups to INACTIVE state. In order to do so, log archiving thread archives log file in ACTIVE log group, then change it to INACTIVE when the system is operated in ARCHIVELOG mode. If the system is operated in NOARCHIVELOG mode, then the ACTIVE log group is immediately reusable after changing the log group state to INACTIVE.

Adding Log Group and Log Member

Adding Log Group

Adding log group is allowed only in mount phase of GOLDILOCKS database multilevel startup. The new log group is added next to the CURRENT state of the log group which is currently being used.
The following is an example to add a new log group whose file name is 'abc.log', and file size is 20 Mbytes to group ID 10.

```
ALTER DATABASE ADD LOGFILE GROUP 10 ('abc.log') SIZE 20M;
```

Adding Log Member

A new log member can be added for the stability of log group in use. It can be added in mount phase of GOLDILOCKS database multilevel startup in the same way of adding log group. The following is an exam ple to add the log file named as 'test log' to group ID 10. The log file size is not specified because the log member size in a log group is same.

```
ALTER DATABASE ADD LOGFILE MEMBER 'test.log' TO GROUP 10;
```

Altering Log Member Name

The position and the file name of the log member in use can be altered by executing RENAME in mount phase. RENAME is executed for log member when the log member's disk is physically failed or the log me mber should be transferred to another disk in terms of performance.
The following is an example to RENAME the log file '/disk1/goldilocks_data/wal/redo_0_0.log' to the log file '/disk2/goldilocks_data/wal/redo_0_0.log'.

```
ALTER DATABASE RENAME LOGFILE '/disk1/GOLDILOCKS_data/wal/redo_0_0.log' TO
'/disk2/GOLDILOCKS_data/wal/redo_0_0.log';
```

Dropping Log Group or Log Member

A log member or log group in use can be dropped in mount phase when a user wants to reduce log grou ps, log members or when log file disk is failed.
The following is an example to drop all members of log group ID 10.

```
ALTER DATABASE DROP LOGFILE GROUP 10;
```

Dropping log member is allowed only when at least two members exist in the log group.
The following is an example to drop the '/disk1/goldilocks_data/wal/redo_0_0.log' log member.

```
ALTER DATABASE DROP LOGFILE MEMBER '/disk1/GOLDILOCKS_data/wal/redo_0_0.log';
```

Restoring Corrupted Redo Log File

If the system fails and the redo log files are corrupted, then the restart recovery fails and the system can n ot be operated. If normal log members exist in the corrupted log group, the restart recovery and the syste

m operation can be executed by copying the log file of the normal log member to the corrupted log files.

If all log files in a log group are corrupted or there is only one log member, it can be restarted by executin g incomplete media recovery. The incomplete media recovery is restricted to the normal log file.
For more information about incomplete media recovery, refer to **Incomplete Recovery**.

Redo Log File Information

A user can enquire V$LOGFILE which is a performance view to retrieve the location and the name of the r edo log files. When inquiring V$LOGFILE, the log file name, its log group ID, its state, the file size are retri eved as follows.

```
gSQL> SELECT FILE_NAME, GROUP_ID, GROUP_STATE, FILE_SIZE FROM V$LOGFILE;
FILE_NAME                          GROUP_ID GROUP_STATE FILE_SIZE
---------------------------------- -------- ----------- ---------
/disk1/goldilocks_data/wal/redo_0_0.log        0 INACTIVE    104857600
/disk1/goldilocks_data/wal/redo_1_0.log        1 CURRENT     104857600
/disk1/goldilocks_data/wal/redo_2_0.log        2 UNUSED      104857600
/disk1/goldilocks_data/wal/redo_3_0.log        3 UNUSED      104857600
4 rows selected.
```

6.3 Managing Archive Redo Log File

The database should be operated in archive log mode for media recovery using backup, because GOLDILOCKS redo log file reuses log group which is used when *circular* structure log group is used. Then the written completed redo log files are copied to the archive redo log files.
For more information about GOLDILOCKS database's archive log mode, refer to **ARCHIVELOG Mode**.

Creating Archive Redo Log File

The redo log file is copied to archive redo log file directory by log archiving thread which is GOLDILOCKS database's system thread. Log archiving thread is activated by checkpoint thread during checkpoint, and it archives the proper object among redo log files.

Archive redo log file is created in the directory set by the ARCHIVELOG_DIR_ 1 property. The name of archive redo log file is composed of its prefix set by the ARCHIVELOG_FILE property and of the sequence number of each redo log file.

Maintaining and Dropping Archive Redo Log File

Media recovery using backup can fail if archive redo log files, similarly to the redo log files, are arbitrarily dropped. Therefore, archive redo log files should be saved with backup files, and the archive redo log files for media backup can be dropped when the backup file is not needed any more.

Backup is copying the data file which is downloaded to the disk by the most recent checkpoint. Therefore, the archive log files of the oldest LSN and later are needed to recover media using backup. Checkpoint is executed by the system when redo log file is switched, so one or more checkpoint logs exist in every log file except for the redo file in CURRENT state.

The followings describe how to get the archive redo log file required for media recovery using backup file.

1. Get the checkpoint LSN which is recorded in the file header of backup data files.
2. Dump the archive redo log file, and get the archive redo log file including checkpoint LSN.
3. The archive redo log file needed for the media recovery using backup begins just before the archive redo log file of No. 2.

Dump the control file and get the checkpoint LSN to get the archive redo log file needed for incremental backup. Subsequent process is as same as the entire backup process.

If backup files are not needed any more, the archive redo log file required for the media recovery using ba

ckup can be removed.

Multiplexing Archive Redo Log File Directory

If the archive redo log file is moved from the directory set in ARCHIVELOG_DIR_1 to the other directory o r media to preserve the archive redo log file, the media recovery fails because it can not find the required archive redo log file.

Move the archive redo log file back to the directory set in ARCHIVELOG_DIR_1 to resolve this problem. Or set the archive log files existing directory to ARCHIVELOG_DIR_2 ~ ARCHIVELOG_DIR_10, and add archiv e redo file directory for media recovery. READABLE_ARCHIVELOG_DIR_COUNT should be set as many as the number of directory when using ARCHIVELOG_DIR_2 ~ ARCHIVELOG_DIR_10 for the media recovery.

6.4 Managing Tablespace

All the data used in database are stored in physical disk file, and use the database's logical structure for ef ficient data management and performance. GOLDILOCKS manages the disk space efficiently by using the logical structure such as tablespace, segment, extent, and page.

A tablespace can include multiple data files, and each tablespace is set to online/offline to support high d ata availability. Distributing data storing disks improves the IO performance, and reduces the contention of physical disk IO.

Tablespace Type

GOLDILOCKS tablespace is divided into SYSTEM tablespace and non-SYSTEM tablespace. SYSTEM tables pace is created when database is created, and it is used and controlled only by the GOLDILOCKS system. Non-SYSTEM tablespace is created and used by a user.

SYSTEM Tablespace

It is created when GOLDILOCKS database is created, and it is essential for database operation. There are dictionary tablespace, undo tablespace and system temporary tablespace.

Non-SYSTEM Tablespace

It is a tablespace in which tables and indexes are stored for data storing, and a user can arbitrarily creates or drops.

Managing Tablespace and Data File

Managing Tablespace

Managing Tablespace State

The GOLDILOCKS database tablespace state is divided into online and offline. The offline tablespace is no t accessible. A user can arbitrarily set the tablespace state to offline. Or, an abnormal tablespace can be s et to offline by the system. The system tablespace should not be set to offline.

- Offline tablespace

GOLDILOCKS database flushes all data files in the tablespace to disk before the tablespace is set to offline. All related logs should be flushed to disk to flush data file. Therefore, a recovery is not needed when swit ching to online later. However, it is applied when DDLs occurred in the offline tablespace state is changed to online state.

A tablespace can be immediately set to offline using IMMEDIATE mode, without flushing data file. In this case, the tablespace state is changed to online after media recovery when setting the tablespace to onlin e.

Table 6-8 Tablespace offline option

Option	Description	Media recovery when setting the tablespace to online
NORMAL	Flushing all the data file related logs in tablespace to the disk, then set it to offline	Media recovery is not required.
IMMEDIATE	Immediately setting a tablespace to offline	Media recovery is required.

GOLDILOCKS can set tablespace to offline in mount phase. To do so, the service should be normally termi nated, or the server should be operated in ARCHIVELOG mode. This method provides high availability by performing service exclusing the unrecoverable tablespaces when starts up database.

```
gSQL> ALTER TABLESPACE TEST_TBS OFFLINE;

Tablespace altered.

gSQL> ALTER TABLESPACE TEST_TBS ONLINE;

Tablespace altered.
```

```
gSQL> ALTER TABLESPACE TEST_TBS OFFLINE IMMEDIATE;

Tablespace altered.

gSQL> ALTER TABLESPACE TEST_TBS ONLINE;

ERR-42000(14051): media recovery required - 'TEST_TBS'

gSQL> ALTER DATABASE RECOVER TABLESPACE TEST_TBS;

Database altered.

gSQL> ALTER TABLESPACE TEST_TBS ONLINE;
```

```
Tablespace altered.
```

Attributes of Tablespace

The followings are attributes of tablespace in GOLDILOCKS database. PERSISTENT or TEMPORARY indicates whether persistence is ensured or not. DATA or UNDO indicates the the type of tablespace and stored data.

Table 6-9 Tablespace attribute of GOLDILOCKS database

Attribute		Description
Persistence	PERSISTENT	It supports persistence of data stored in a tablespace. (A recovery is required.)
	TEMPORARY	It does not support persistence of data stored in a tablespace.
Type of stored data	DATA	It stores the user input data.
	UNDO	It stores data required for MVCC of database.
	DICT	It stores dictionary information for database operation.
	TEMPORARY	It stores data for SQL processing.
Type of stored media	DISK	Pages of the disk table space should be read from the disk data file by using the buffer cache. If it is cached, then it is accessible in the buffer cache.
	MEMORY	When creating a tablespace, the exclusive shared memory whose size is as same as that of the data file is created. Therefore, the instant access to the desired page is available in the memory.

Managing Tablespace

- Creating user tablespace

It creates a new user tablespace. The name of tablespace being used in the database instance should be unique when creating tablespace. A tablespace can have up to 1024 data files. The data file in the memory tablespace can store up to 30 GBytes, and the data file in the disk tablespace can store as much as the disk physically allows. The database can create tablespaces up to 65,535, including system tablespace.

The data file name including the absolute path in the data file should be unique. Use 'REUSE' option to reuse the existing data file which is not being used in database. An extent size of a tablespace is selectable among 64 Kbytes, 128 Kbytes, 256 Kbytes, 512 Kbytes and 1 Mbyte, and the default extent size is 256 Kbytes.

```
gSQL> CREATE TABLESPACE TEST_TBS DATAFILE
     '/goldilocks1/db/TEST_TBS1.dbf' SIZE 20M,
     '/goldilocks2/db/TEST_TBS2.dbf' SIZE 50M,
     '/goldilocks3/db/TEST_TBS3.dbf' SIZE 100M REUSE;
Tablespace created.
```

The following is an example of creating a disk tablespace.

```
gSQL> CREATE DISK TABLESPACE TEST_TBS DATAFILE
     '/goldilocks1/db/TEST_DISK_TBS1.dbf' AUTOEXTEND OFF MAXSIZE 20M,
     '/goldilocks2/db/TEST_DISK_TBS2.dbf' AUTOEXTEND ON NEXT 20M MAXSIZE UNLIMITED REUSE;
Tablespace created.
```

The state can be set to ONLINE/OFFLINE when creating tablespace, and the LOGGING/NOLOGGING prop erty also can be set.

- Dropping tablespace

The tablespace and data file can be dropped when the tablespace is not needed any more. The unused ta blespace should be dropped not to waste the resources. It is because once tablespace is created, the add ed disk data file and memory is created and remains.

```
gSQL> DROP TABLESPACE TEST_TBS;
Tablespace dropped.
```

Dropping the tablespace does not drop its table index in use by default. Therefore, *INCLUDING CONTENT S* option should be used together when dropping tablespace including tables or indexes in use.

```
gSQL> DROP TABLESPACE TEST_TBS;
ERR-42000(16148): tablespace not empty, use INCLUDING CONTENTS option :
drop tablespace TEST_TBS
                *
ERROR at line 1:
gSQL> DROP TABLESPACE TEST_TBS INCLUDING CONTENTS;
Tablespace dropped.
```

Use *AND DATAFILES* option to drop the data files added in the tablespace.

```
gSQL> DROP TABLESPACE TEST_TBS INCLUDING CONTENTS AND DATAFILES;
Tablespace dropped.
```

- Altering tablespace size

Add datafiles to the tablespace or drop datafiles from the tablespace to alter the tablespace size. Add ne w datafiles to tablespace to spare space when the storing space is not enough during database operation. Or, drop unused datafile from tablespace not to waste the space.

```
gSQL> ALTER TABLESPACE TEST_TBS ADD DATAFILE 'TEST_TBS2.dbf' SIZE 20M;
Tablespace altered.
gSQL> ALTER TABLESPACE TEST_TBS DROP DATAFILE 'TEST_TBS2.dbf;
Tablespace altered.
```

The data file could be dropped from tablespace only when is has never been used since its creation. The d ata file can not be dropped once it has been used even when all data was dropped.

```
ALTER TABLESPACE TEST_TBS DROP DATAFILE 'TEST_TBS2.dbf';
ERR-42000(14044): datafile not empty
```

- Managing temporary tablespace

Temporary tablespace does not store data file, but it allocates memory of specified size. Create the tempo rary tablespace as follows.

```
gSQL> CREATE TEMPORARY TABLESPACE TEST_TBS MEMORY 'TEST_TEMP_TBS' SIZE 10M EXTSIZE 256K;
Tablespace created.
```

Add memory to the temporary tablespace as follows.

```
gSQL> ALTER TABLESPACE TEST_TBS ADD MEMORY 'TEST_TBS2' SIZE 10M;
Tablespace altered.
```

Drop the unused memory from the temporary tablespace as follows.

```
gSQL> ALTER TABLESPACE TEST_TBS DROP MEMORY 'TEST_TBS2';
Tablespace altered.
```

Drop the temporary tablespace as follows.

```
gSQL> DROP TABLESPACE TEST_TBS INCLUDING CONTENTS AND DATAFILES;
Tablespace dropped.
```

Transferring Data File

The data file storage path stored in the database should be modified when altering the datafile storage di sk, or directory.

The following is an example to describe how to modify the path when transferring the datafile '/goldilock s1/db/TEST_TBS1.dbf' in tablespace TEST_TBS to '/goldilocks4/db/TEST_TBS1.dbf'.

```
gSQL> ALTER TABLESPACE TEST_TBS RENAME DATAFILE
    '/goldilocks1/db/TEST_TBS1.dbf' TO '/goldilocks4/db/TEST_TBS1.dbf';
Tablespace altered.
```

Tablespace Information

For more information about the tablespaces created in database, refer to **V$TABLESPACE**.

```
gSQL> \DESC V$TABLESPACE
COLUMN_NAME   TYPE                   IS_NULLABLE
------------- ---------------------- -----------
TBS_NAME      CHARACTER VARYING(128) FALSE
TBS_ID        NUMBER                 FALSE
TBS_ATTR      CHARACTER VARYING(128) FALSE
IS_LOGGING    BOOLEAN                FALSE
IS_ONLINE     BOOLEAN                FALSE
OFFLINE_STATE CHARACTER VARYING(32)  FALSE
EXTENT_SIZE   NUMBER                 FALSE
PAGE_SIZE     NUMBER                 FALSE
```

6.5 Managing Data File

Data File Matching

Data file can be corrupted due to disk failure, database defects or human error. If the corrupted data file i s used in database, serious problems occurs.

GOLDILOCKS database ensures the matching of the data file using a checksum for each page of the data file. GOLDILOCKS database's page checksum is generated using LSN and CRC value, and it is stored in ea ch page. A user sets the page checksum type using the value in **PAGE_CHECKSUM_TYPE**, and uses LSN f or the default value.

The page checksum is checked when loading the data file into the memory at database startup. If an erro r occurs concerning the checksum value, the database can not start up the service.

The following is an example to describe the database startup failure when the datafile TEST_TBS.dbf in th e tablespace TEST_TBS created by a user is not matching.

```
gSQL> \STARTUP MOUNT
Startup success
gSQL> ALTER SYSTEM OPEN DATABASE;
ERR-HY000(14094): datafile recovery required - datafile(/goldilocks/db/TEST_TBS.dbf) of
tablespace(TEST_TBS) corrupted
```

In case when the data file is not matching, set its tablespace having the data file to *OFFLINE*, or recover th e data file to restart the database.

The following describe how to start up the database after setting the tablespace to *OFFLINE*.

```
gSQL> \STARTUP MOUNT
Startup success
gSQL> ALTER SYSTEM OPEN DATABASE;
ERR-HY000(14094): datafile recovery required - datafile(/goldilocks/db/TEST_TBS.dbf) of
tablespace(TEST_TBS) corrupted
gSQL> ALTER TABLESPACE TEST_TBS OFFLINE IMMEDIATE;
Tablespace altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
System altered.
```

Data file full backup or incremental backup should exist when recovering the data file.
The following describes how to recover the data file when backup exists.

```
gSQL> \STARTUP MOUNT
Startup success
gSQL> ALTER SYSTEM OPEN DATABASE;
ERR-HY000(14094): datafile recovery required - datafile(/goldilocks/db/TEST_TBS.dbf) of
tablespace(TEST_TBS) corrupted
gSQL> ALTER DATABASE RECOVER DATAFILE 'TEST_TBS.dbf' CORRUPTION;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
System altered.
```

Data File Information

For more information about data files being used in database, refer to **V$DATAFILE**.

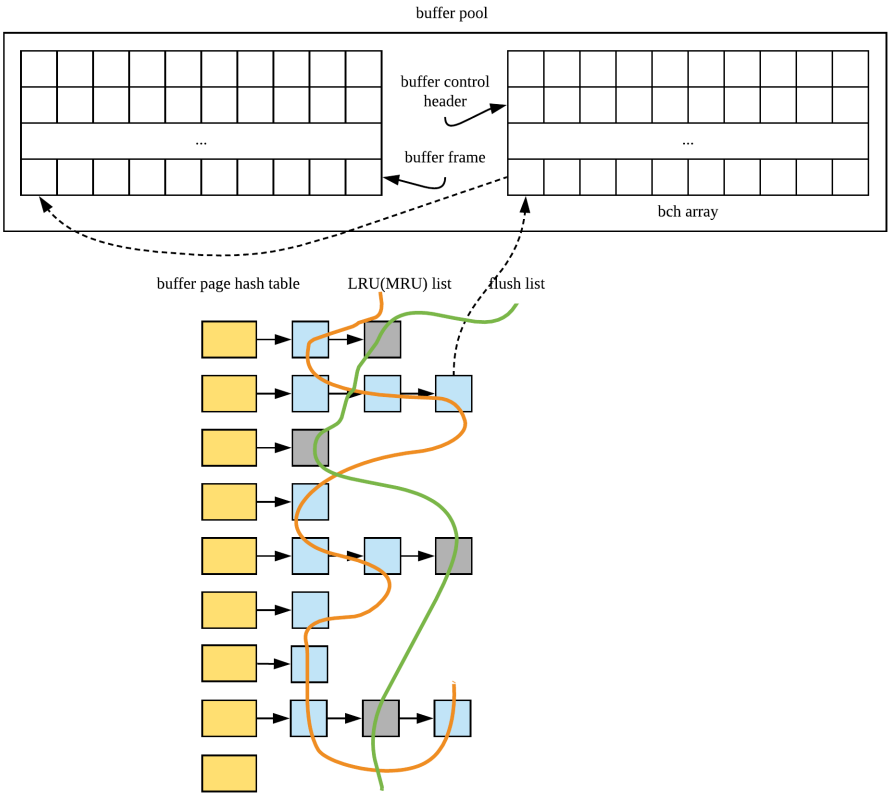
```
gSQL> \DESC V$DATAFILE
COLUMN_NAME    TYPE                           IS_NULLABLE
-------------- ------------------------------ -----------
TBS_NAME       CHARACTER VARYING(128)         FALSE
DATAFILE_NAME  CHARACTER VARYING(1024)        FALSE
CHECKPOINT_LSN NUMBER                         FALSE
CREATION_TIME  TIMESTAMP(6) WITHOUT TIME ZONE FALSE
FILE_SIZE      NUMBER                         FALSE
```

6.6 Buffer Cache

Structure of GOLDILOCKS Buffer Cache

It caches pages required from the disk data file to access index pages and tables stored in the disk table s pace to the buffer. GOLDILOCKS allocates the buffer cache as big as the size set in **BUFFER_CACHE_SIZE** property, and it retrieves the pages requested from the page cached in the buffer cache by using the has hash table as big as the size set in **BUFFER_HASH_BUCKETS** property. It increases the touch count whene ver accessing to the page. If the available space does not exist in the buffer cache, then it uses LRU strate gy which replaces the page whose touch count value is small.

Figure 2 Structure of GOLDILOCKS buffer cache



Buffer Cache List

The followings are lists which are used for the buffer cache in GOLDILOCKS.

Table 6-10 Buffer cache list

List	Description	Property
Buffer free list	It is a list of buffer frames which are immediately a vailable.	BUFFER_FREE_LIST_COUNT
Buffer LRU list	It is a list to retrieve the pages which is reusable ba sed on the touch count.	BUFFER_LRU_LIST_COUNT
Buffer flush list	It is a list of buffer frames to reflect the pages upd ated to reuse in the buffer LRU list to the data file.	BUFFER_FLUSH_THREADS
Buffer checkpoi nt list	It is a list of updated page frames which should be flushed to the data file at the time of checkpoint.	BUFFER_CHECKPOINT_LIST_COUNT

Page frames which were not used after the system startup are linked to the buffer free list, and used pag e frames are linked to the buffer LRU list. The page frame updated in the buffer cache is linked to the buf fer checkpoint list, but it is not dropped from the buffer LRU list.

After all page frames are used in the buffer free list and a page frame to cache a new fage does not exist, then it looks for an available page frame by retrieving the buffer LRU list. The page frame which were up dated but not in use is transferred to the buffer flush list at this moment.

A page frame can not be linked dundantly to the buffer free/ LRU/ flush list except for the buffer checkpo int list. In other words, a page frame in the buffer free list can not simultaneously exist in the buffer LRU/ flush list, nor can a page frame in the buffer LRU list exist in the buffer free/ flush list.

The buffer LRU list is divided into hot/ cold area, and if the touch count of the page frame in the cold are a is same or larger than the specified value (**BUFFER_HOT_REGION_CRITERIA**), then it is transferred to th e hot area. The touch count increases whenever the page frames in the buffer LRU list access, and if all of them belong to the hot area, then the page frame to replace is not available. Therefore, the hot area size is restricted to the **BUFFER_HOT_REGION_PERCENT** property value.

Page Frame Status

All page frames of the buffer cache have the following status.

Table 6-11 Buffer frame status

Status	Description	Page frame access
FREE	It is the page frame which is not currently used.	Inaccessible
PREPARED	It is allocated for the page caching, but is not completely read from t he disk.	Inaccessible
CLEAN	A page was cached to the buffer cache and the page frame never h as been updated.	Accessible
DIRTY	A page was cached to the buffer cache and the page frame is updat	Accessible

Status	Description	Page frame access
	ed.	
FLUSHING	A page was cached to the buffer cache and the page frame is updated., and it is being flushed to the disk data file.	Accessible
INCONSISTENT	The page frame status is abnormal in the buffer cache.	Inaccessible

7.

Backup and Recovery of GOLDILOCKS Database

This chapter describes GOLDILOCKS database backup and recovery, database ARCHIVELOG mode for the backup and recovery.

7.1 ARCHIVELOG Mode

GOLDILOCKS database executes logging using circular log group. A circular log group consists of at least four log groups, and if all log allocated to a log group are run out, then following log group is used. If all created log groups are run out, the first log group is reused. In this case, the new log file is not created b ut the previously recorded log file is reused.

The previously written logs are lost if a log group is reused in NOARCHIVELOG mode. Therefore, if an ad ministrator does not manage the completed logging group, the completed transactions logs disappears while operating in NOARCHIVELOG mode.

On the other hand, in ARCHIVELOG mode, the system archives log files prior to reusing it when using the following log groups after the completion of recording on log file in a log group. Then the completed log s are permanently preserved unless they are deliberately deleted.

ACHIVELOG Mode

Log files should be archived before they are reused. It is because all log files after backup moment is requi red for the recovery using backup, and the backup could be needed anytime. Therefore, the backup is su pported only in ARCHIVELOG mode.

The service can be interrupted in busy system due to archiving when operating in ARCHIVELOG mode. Al so, an additional space is needed to store files.

NOARCHIVELOG Mode

Backup is not supported in NOARCHIVELOG mode, because it can not be determined if the log files of be fore reusing exist.

However, system does not archive log files. Therefore, the interruption due to an archiving at checkpoint when bulk logs are continuously being recorded does not occur. Also, it does not need a storage space fo r archive log files.

NOARCHIIVELOG mode is set by the 'ARCHIVELOG_MODE' property value when creating database. Data

base is created in NOARCHIIVELOG mode if the 'ARCHIVELOG_MODE' value is 0, and it is created in ARC HIIVELOG mode when the 'ARCHIVELOG_MODE' value is 1. This property is valid only when creating dat abase, and it is not referenced when operating database.

Execute the following syntax in mount phase of GOLDILOCKS database startup level to change ARCHIVEL OG mode during database operation.

```
gSQL> ALTER DATABASE ARCHIVELOG;

Database altered.

gSQL> ALTER DATABASE NOARCHIVELOG;

Database altered.
```

Enquire *ARCHIVELOG_MODE* of *V$ARCHIVELOG* which is the performance view to retrieve archive log m ode set in database.

```
gSQL> SELECT ARCHIVELOG_MODE FROM V$ARCHIVELOG;
ARCHIVELOG_MODE
---------------
NOARCHIVELOG
1 row selected.
```

7.2 Backup and Recovery

Backup

The Purpose of Backup and Recovery

Database can protect and recover data when various failures or data loss occurs. There are many reasons for failures. The duplicated copy is required especially when the database is physically corrupted or dama ged by disaster, and this is called as backup.

When database service is not available due to various failures, it becomes available again by using current database or backup, and this is called as recovery. The restart recovery is to recover by using the current d atabase. The media recovery is to recover by using the backup. GOLDILOCKS automatically or manually p erforms the media recovery to recover the backup data file, then recover and restarts by the restart recov ery.

Backup

Database backup is divided into physical backup and logical backup. Generally, backup means making co py of data files online. This chapter describes the online physical backup.

Table 7-1 Database backup type

Backup type	Backup form	Database state	Description
Physical backup	Cold backup	Offline	Creating the copy of data file Stopping service to execute backup
	Hot backup	Online	Creating the copy of data file Executing backup during service operation Available only in ARCHIVELOG mode
Logical backup	Export backup	Online	Backup/recovery in table unit Exporting regardless of HW/OS

GOLDILOCKS uses data files and control files for executing service, and they should be recovered when th ey were corrupted from a failure. A control file is created when creating database, and stores necessary in formation to operate database. A data file stores actual data, and they are data files in system tablespace s created when database is created and datafiles in user made tablespace. Use backup files for recovery w hen some of those control files or data files are corrupted.

In other words, control files and data files should be backed up for recovery. In order to do so, GOLDILOC KS supports control file backup, database backup, and tablespace backup.

Depending on the backup method, it is divided into full backups and incremental backups. Full backup co

pies data files in time of backup, and an incremental backup copies only modified parts since the previous backup. The full backup copies data files, so the copy as big as the data file is created everytime of backup. Therefore, it consumes the storage space as much as the size of database or tablespace.

On the other hand, the size of the incremental backup is relatively small because it copies only the modified part after the previous backup.

Table 7-2 Full backup vs. incremental backup

Item	Full backup	Incremental backup
Backup object	• Database: Entire data file which is being used by database • Tablespace: Data files in database's specific tablespace	
Description	• Backup entire data file which is being used by database or tablespace • Creating a backup file per a data file • Restoring the required data file after failure by using appropriate backup method, then recover it	• Backup the modified part of the data file being used by database or tablespace after the previous backup • Creating an incremental backup file in which the modified part is recorded • Recovery by using multiple incremental backups after failure

Full Backup

Use full backup to execute database backup and tablespace backup. Database backup is to backup control files and data files.

Control File Backup

Backup the control file as follows. Specify the backup control file name including the absolute path, or specify the backup control file name only. If only the backup control file name is specified, the backup file is created in the path set in the 'LOG_DIR' property.

```
gSQL> ALTER DATABASE BACKUP CONTROLFILE TO '/goldilocks_data/backup/backup.ctl';
Database altered.
```

Database Backup

Database backup can backup entire data file being used in database. When backup data file, recording on the file should be prevented while coping the data file. If the file is used during copying, the data file becomes inconsistent, and even worse it will be inconsistent within a page. Set the database to the state which enables backup to prevent those inconsistencies.

```
gSQL> ALTER DATABASE BEGIN BACKUP;
Database altered.
```

Use operating system's file copy feature to create the copy of data file on database backup enabled state. Then set it as follows, then the database backup is completed, and it is writable.

```
gSQL> ALTER DATABASE END BACKUP;
Database altered.
```

Tablespace Backup

Tablespace backup can backup data files being used by a specified tablespace. Set it to backup enabled st ate by using the table space name (tablespace_name) as follows for the same reason of database backup.

```
gSQL> ALTER TABLESPACE TEST_TBS BEGIN BACKUP;
Tablespace altered.
```

Use operating system's file copy feature to create the copy of tablespace's data file on tablespace backup enabled state. Then, complete the tablespace backup as follows.

```
gSQL> ALTER TABLESPACE TEST_TBS END BACKUP;
Tablespace altered.
```

Incremental Backup

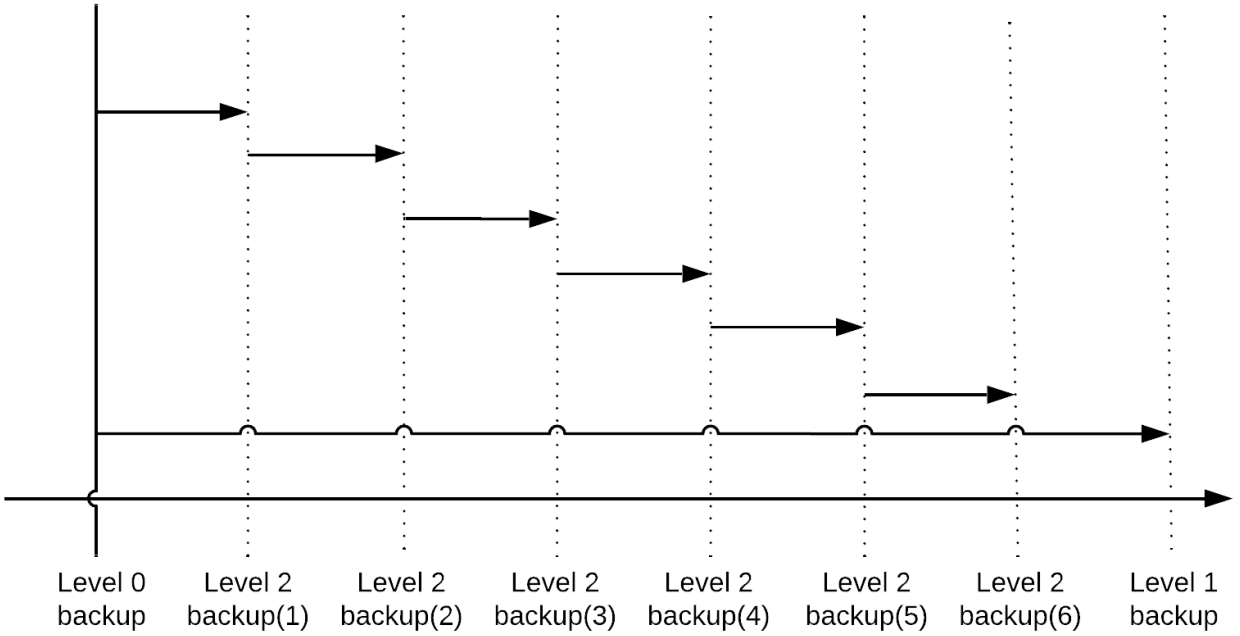
An incremental backup supports database unit backup and tablespace unit as same as full backup. An inc remental backup does not backup control files separately, but the control file is backed up together when executing the database incremental backup.

GOLDILOCKS supports incremental level from 0 to 4 for an incremental backup. When an incremental ba ckup is executed for the first time, the level should be set to 0, and backup the entire data file. Set the inc remental backup level to 1 or higher to back up only the modified parts since the last backup when execu ting the incremental backup later.

The given level of incremental backup searches for the time when the same level or lower level was execu ted. Then, it backups only the modified parts after the previous backup.

For example, after performing level 0 backup, level 2 backup(1) backs up only the modified parts after th e level 0 backup, and level 2 backup(2) backs up the modified part after the level 2(1) backup. In the sam e way, level 2 backup(3), (4), (5), (6) backs up the modified part after the level 2 backup. The level 1 back up which was executed lastly backs up all modified parts after the level 0 backup.

Figure 1 Incremental backup



Database Incremental Backup

Execute an incremental backup on the entire data file of database as follows. At first, the entire data file of database is backed up at level 0.

```
gSQL> ALTER DATABASE BACKUP INCREMENTAL LEVEL 0;
Database altered.
```

And then, the modified part after level 0 is backed up at level 1.

```
gSQL> ALTER DATABASE BACKUP INCREMENTAL LEVEL 1;
Database altered.
```

Tablespace Incremental Backup

At first, the entire data file of tablespace is backed up at level 0 as follows in the same way as the databas e backup.

```
gSQL> ALTER TABLESPACE TEST_TBS BACKUP INCREMENTAL LEVEL 0;
Tablespace altered.
```

And then, the modified part after level 0 is backed up at level 1.

```
gSQL> ALTER TABLESPACE TEST_TBS BACKUP INCREMENTAL LEVEL 1;
Tablespace altered.
```

Change Tracking

It should scan the entire data file to figure whether any page is updated after the previous backup to perform the incremental backup for the disk tablespace. Therefore, if the data file size is big, then the incremental backup takes a long time even when the number of actually updated pages is small because it should scan the entire data file.

Change tracking stores only updated pages after the incremental backup, then performs the next incremental backup by selecting updated pages only without full scan. Therefore, the backup time is decreased.

However, if most of the pages in the data file were updated, then it should backup the most part of the data file, so the the change tracking is not efficient. The change tracking is available when the database is in ARCHIVELOG mode only, but it is not available in NOARCHIVELOG mode.

The following is an example of enable/ disable the change tracking in the database.

```
gSQL> ALTER DATABASE ENABLE CHANGE TRACKING;
Database altered.
gSQL> ALTER DATABASE DISABLE CHANGE TRACKING;
Database altered.
```

If the change tracking is enabled, then it creates the tracking file and the shared memory. The structure of the change tracking file and that of the shared memory are same. It consists of blocks storing update flags for pages bound in a number specified in **CHANGE_TRACKING_EXTENT_SIZE** property.

The update flags are initialized when the incremental backup is performed for the first time after the change tracking is enabled. If a page is updated, then it is recorded on the flag of the page, so it scans only the pages which were recorded on the update flags in the change tracking file and backs up only updated pages at the next incremental backup.

If the change tracking is enabled, then it creates a file in the location specified in **CHANGE_TRACKING_FILE** property. If the file name and storing location for change tracking are specified when enabling it, then the file is created in the specified location. If the storing location is not specified, then the change tracking file is created in the location specified in BACKUP_DIR property.

```
gSQL> ALTER DATABASE ENABLE CHANGE TRACKING USING FILE '/tmp/change_tracking.ctf';
Database altered.
```

The change tracking file size is 10 M, and it increases by 10 M when the change tracking file is full due to the increased number of disk data files.

Recovery

Database guarantees data consistency by executing recovery when a failure occurs or database is corrupted.
The types of database failure are as follows.

Table 7-3 Database failure type

Failure type	Causes and symtoms	Solution
Transaction failure	Transaction failure and deadlock due to the logical error (bad input, overflow, data not found)	Abort transaction
System crash	Corruption of volatile storage device due to an abnormal termination (blackout) of DBMS or OS	Restart recovery
Media failure	Corruption of non-volatile storage device	Restore, restart recovery

Abort the executing transactions, rollback all database updates and release obtained lock items to solve transaction failure.

Database processes are abnormally terminated at system crash, so the recent information stored in volatile storage are not reflected in the non-volatile storage, and they are lost. Startup database, and recover the database to the state when it was consistent before abnormal termination. This process is called as restart recovery. To recover the database, the restart recovery uses control files, data files, and log files which were used by database before the failure.

The recovery using database file before failure is not possible if non-volatile storage device is corrupted. It is because control files, datafiles and log files are corrupted so that they can not be used for recovery. In this case, recover the database file by using previously archived backup files and log files, then execute the recovery.

GOLDILOCKS supports both the complete recovery and the incomplete recovery. The complete recovery recovers the datafile to the latest and consistent state by using the log file. The complete recovery targets database, tablespace and data file. For the tablespace and data file, the complete recovery is available for the offline tablespace even during the database service. The complete recovery is divided into the automatic recovery and the manual recovery. The automatic recovery is performed when restaring the database, and the manual recovery uses the recovery statement supported by GOLDILOCKS.

The incomplete recovery is available only for the database, and it recovers to the consistent state of a specific point. The incomplete recovery is performed only manually. It incompletely recovers at once up to the specific point, or it performs the user selective incomplete recovery. The user selective incomplete recovery is a method of which a user selects a log file available to recover and recovers up to that user selected log file.

If both the complete recovery and the incomplete recovery is required, then use redo log and archive log f

iles.

Table 7-4 Database recovery

Recovery	Target	Description
Complete recovery	Database, tablespace, datafile	• Automatic recovery (Recovers at the restart) • Manual recovery (Manually recovers the database, tablespace and data file.)
Incomplete recovery	Database	• Manual recovery only ◦ Incomplete recovery at once ◦ User selective incomplete recovery

Automatic Recovery

The automatic recovery is executed when restarting after a normal or abnormal termination of database. It uses the control files, data files and log files which were used just before the termination.
Especially when the latest database file is corrupted, the backed up database file is recovered and the automatic recovery is executed by using the archive log file.
The recovery is executed in three phases, and they are analysis, redo and undo.

Analysis

Two operations are executed in analysis phase.
First, it searches for the first log to perform the restart recovery. For that, it refers to the most recently executed checkpoint log, and looks for the most recent checkpoint log from the log information recorded in control file.
Second, it initialize the transaction table of the system. It uses transaction information which was executed at checkpoint written on checkpoint log to initialize system transaction table.

Restart Redo

All logs, from the first log obtained in the analysis phase for restart recovery to the last log recorded in the redo log files, execute restart redo. The transaction table is updated when a transaction is completed or a new transaction is started during this process.

Restart Undo

After restart redo is completed, it performs the transaction rollback by performing undo all incomplete transactions remained in the transaction table.

Recovery Using Backup

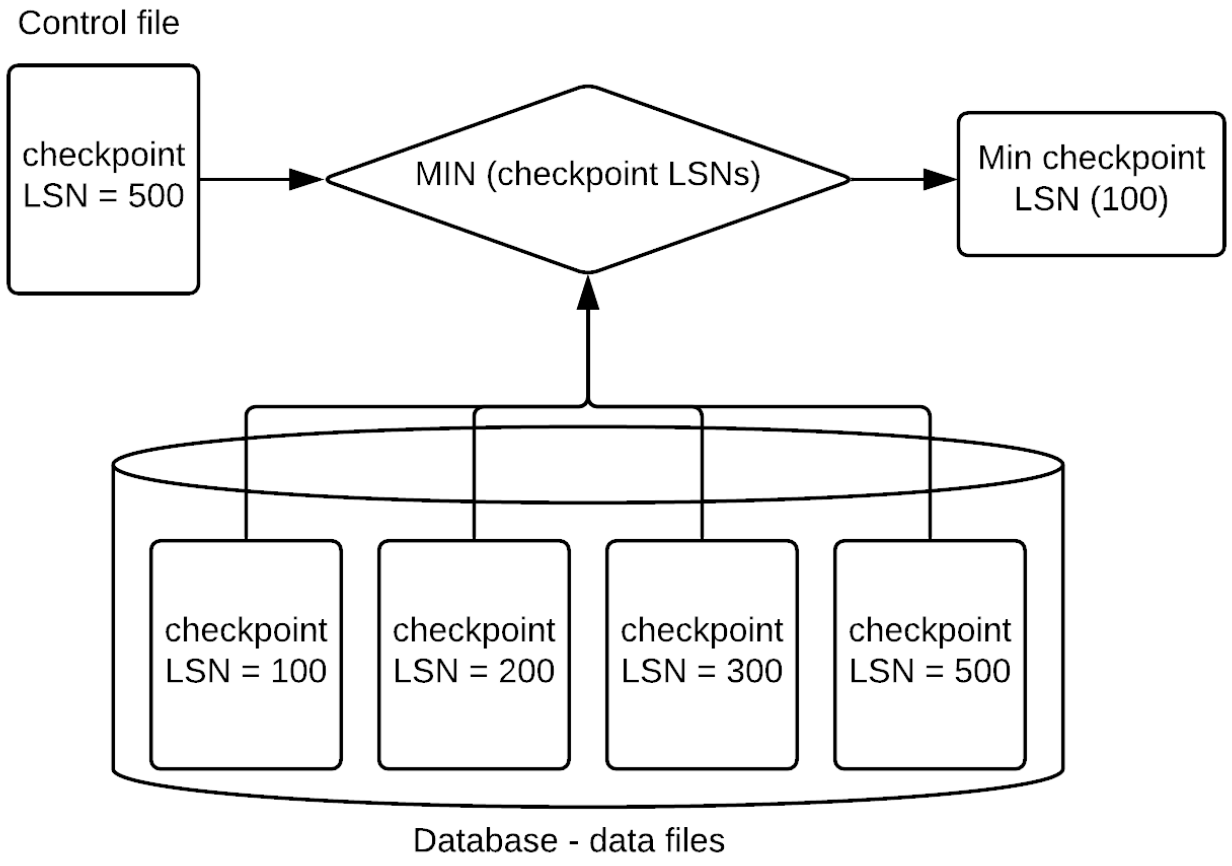
If control files, data files and log files are corrupted or does not exist, the recovery should be performed a fter it is recovered by using the backup file. It is complicated to find the log on which the recovery starts when performing the recovery by using the backed up control file or the data file.

Analysis for Recovery Using Backup

In analysis phase for the recovery using backup, like as the automatic recovery, it searches for the first log for recovery and initializes the transaction table. It searches for the oldest LSN among the checkpoint LSN recorded in all the data file's file header, then selects the minimum value by comparing it with checkpoint LSN recorded in control file to find the first log for recovery.

The checkpoint LSN recorded in data file header stores the checkpointed LSN of the corresponding data fi le. Therefore, when using the backup datafile, select the oldest checkpoint LSN, and then select the mini mum value comparing to the checkpoint LSN in the control file, then the minimum checkpoint LSN for th e recovery is determined.

Figure 2 Procedure to determine the minimum checkpoint LSN for the recovery



Recovery Using Archive Log Files

The recovery using archive log files uses not only redo log files but also archive log files, when the minimum checkpoint LSN defined for the recovery is in an archive log file. The recovery using the backup is executed in a unit of database, tablespace and data file. Database recovery is executed only on MOUNT phase, and the recovery in tablespace and data file unit is executed on MOUNT phase or OPEN phase.

- Restoring the backup data files

Restoring data files is executed by using the full backup or the incremental backup. A user directly executes the full backup by using operating system's file copy command to restore data. On the other hand, the incremental backup is executed by using restoring syntax of GOLDILOCKS. The tablespace should be OFF LINE to restore data files on OPEN phase.

The followings describe how to restore data files using incremental backup.

```
gSQL> ALTER DATABASE RESTORE;

Database altered.

gSQL> ALTER DATABASE RESTORE TABLESPACE TEST_TBS;

Database altered.
```

- Manual recovery after restoring data files

The followings describe how to execute recovery using the syntax of recovery after restoring data files.

```
gSQL> ALTER DATABASE RECOVER;

Database altered.

gSQL> ALTER DATABASE RECOVER TABLESPACE TEST_TBS;

Database altered.
```

Incomplete Recovery

If the restart recovery is not available due to a user mistake during operation, corrupted control files, or corrupted redo log files and archive log files nor can the recovery restore consistency of database, then execute the incomplete recovery. The incomplete recovery restores data only until the point-in-time.
The followings are when the incomplete recovery is required.

Corrupted Control File

Control files are multiplexed, so they can be recovered using uncorrupted files if not all of the multiplexed files are corrupted.
However, if all control files are corrupted, recovery should be executed using the backup control files. In t his case, the complete recovery is impossible because the log information of the control files can be chan ged. The recovery restores only until point-in-time.

Restoring Backup Control File

When control files are corrupted, copy other multiplexed control files to keep control files up-to-date. However, when all multiplexed control files are corrupted, restore the backup control files, then perform the recovery. The log information which is changed after the backup can not be recovered when executin g recovery using the backup data files.

Corrupted Redo Log File

GOLDILOCKS consists redo log files with several log members in a log group to prevent log file corruption. However, if all log members in a log group are corrupted, it can not be recovered using redo log file. In th is case, an incomplete recovery should be executed until uncorrupted log file.

Corrupted Archive Log File

In recovery, if archive log file is corrupted, then incomplete recovery should be executed until uncorrupte d log file. The process is as same as when redo log file is corrupted.

User's Mistake

When a user dropped an important table by mistake, or inserted, updated, deleted wrong data, it should be recovered back to the point before the mistake.

Incomplete Recovery of GOLDILOCKS Database

GOLDILOCKS supports two types of incomplete recovery. One of the recovery is executed until the point which an operator specified. The other recovery is executed in log file unit interactively between an opera tor and system.

The incomplete recovery until a specified point can specify the point-in-time by using a specified log's LSN, specified time, or a specified SCN.

Incomplete recovery is executed for the entire database only on MOUNT phase. Incomplete recovery in th e specific tablespace unit is not supported due to the database consistency problem.

- Incomplete recovery until specified LSN

It searches for log which will complete the incomplete recovery, then executes the recovery until the log's LSN.
The following is an example of executing the incomplete recovery until log LSN 1000.

```
gSQL> ALTER DATABASE RECOVER UNTIL CHANGE 1000;
Database altered;
gSQL> ALTER DATABASE RECOVER UNTIL CHANGE LSN 1000;
Database altered;
```

- Incomplete recovery until specified SCN

It searches for SCN which will complete the incomplete recovery, then executes the recovery until the log 's SCN.
The following is an example of executing the incomplete recovery until SCN 300.

```
gSQL> ALTER DATABASE RECOVER UNTIL CHANGE SCN 300;
Database altered;
```

SCN is not sequentially recorded so even when the incomplete recovery is executed until SCN 300, it may be recovered beyond SCN 300. The following is an example of the recovery when SCN is reversed.

Log: --- LSN 90 (SCN 3) -- LSN 91 (SCN 5) -- LSN 92 (SCN 4)

gSQL> ALTER DATABASE RECOVER UNTIL CHANGE SCN 3;
→ It is recovered until LSN 90.

gSQL> ALTER DATABASE RECOVER UNTIL CHANGE SCN 4;
→ It is recovered until LSN 92. (It is recovered until LSN 92 in which SCN 4 is.)

gSQL> ALTER DATABASE RECOVER UNTIL CHANGE SCN 5;
→ It is recovered until LSN 92. (Both SCN 4, SCN 5 are arbitrarily recovered until SCN5)

- Incomplete recovery until specified time

It searches for the time which will complete the incomplete recovery, then executes the recovery until the specified time.
The following is an example of executing the incomplete recovery until '2017-05-18 16:10:10.00000'.

```
gSQL> ALTER DATABASE RECOVER UNTIL TIME '2017-05-18 16:10:10.000000';
Database altered;
```

- Interactive incomplete recovery

If the log file is corrupted, it executes the recovery until just before the corrupted log file. For that, GOLDI LOCKS suggests an operator the required log files, and the operator executes the incomplete recovery by using the GOLDILOCKS' recommended log file or a new log file.

The following is an example of executing the interactive incomplete recovery of GOLDILOCKS. GOLDILOC KS suggests log files required for the recovery when executing BEGIN for the incomplete recovery. The op erator executes the incomplete recovery by using the GOLDILOCKS' recommended log file, or may descri be the log file for the recovery.

```
gSQL> ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_0.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 139992)
Database altered.
gSQL> ALTER DATABASE RECOVER AUTOMATICALLY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_1.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 144143)
Database altered.
gSQL> ALTER DATABASE END INCOMPLETE RECOVERY;
Database altered.
```

Restarting Database after Incomplete Recovery

After the incomplete recovery is completed, a user can not restart database in a normal way. It is because the recovered GOLDILOCKS database by the incomplete recovery has nothing to do with the current redo log files. A user should reset the redo log file to restart database because database is at the previous poin t, and the current redo log file is about the log after then. Use *RESETLOGS* option when restarting GOLDI LOCKS database after the incomplete recovery.

```
gSQL> ALTER SYSTEM OPEN DATABASE;
ERR-HY000(14083): must use RESETLOGS option for database open
gSQL> ALTER SYSTEM OPEN DATABASE RESETLOGS;
System altered.
```

Cautions for Incomplete Recovery

Incomplete recovery is executed until the specific point to create consistent database, but it is not easy to find the specific point. All redo log files are reset after the incomplete recovery. Therefore, all the control files, data files, redo log files in database should be backed up offline before the incomplete recovery. Th en the incomplete recovery should be executed several times to find the correct point.

Archive log files are needed during the incomplete recovery. However, the newly recovered database is di fferent from the previous database, so drop the archive redo log file created by the previous database.

Recovery Examples

Corrupted Control File

GOLDILOCKS database control files store the important information about the physical structure of datab ase and the database consistency. If it is corrupted or dropped by mistake, the database can not be opera ted.

GOLDILOCKS database multiplexes at least 2 up to 8 control files. If there is at least one valid control file, the remaining control files are restored, then the database can be restarted.

When a valid multiplexed control file exists

If the multiplexed control file *'/goldilocks_data/wal/control_1.ctl'* is corrupted, restarting database fails as follows.

```
gSQL> \STARTUP
ERR-HY000(14097): control file is corrupted - '/goldilocks_data/wal/control_1.ctl'
```

Copy the valid control file */goldilocks_data/wal/control_0.ctl* to */goldilocks_data/wal/control_1.ctl*, and dr op the shared memory which failed to restart. Then restart the database.

```
$ cp /goldilocks_data/wal/control_0.ctl /goldilocks_data/wal/control_1.ctl
gSQL> \SHUTDOWN
Shutdown success
gSQL> \STARTUP
Startup success
```

When all multiplexed control files are corrupted

If all multiplexed control files are corrupted, a user can restart the database using backup control files afte r incomplete recovery. The database's physical structure can be changed after backing up control files. Th erefore, the incomplete recovery should be executed when restoring control files using backup control fil es. Archive log files and redo log files still exist even after incomplete recovery. Therefore, an administrato r executes GOLDILOCKS interactive incomplete recovery to manually restore until 'CURRENT' state redo lo g file.

The backup control file can be copied to multiplexed control files by operating system's file copy feature, or they can be restored by GOLDILOCKS database's recovery feature as follows. The control file recovery c an be executed only in NOMOUNT phase of GOLDILOCKS multilevel startup.

```
gSQL> \STARTUP NOMOUNT
Startup success
gSQL> ALTER DATABASE RESTORE CONTROLFILE FROM '/goldilocks_data/backup/backup.ctl';
Database altered.
```

After restoring the backup control files, execute the incomplete recovery in MOUNT phase as follows.

```
gSQL> ALTER SYSTEM MOUNT DATABASE;
System altered.
gSQL> ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_0.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 137499)
Database altered.
gSQL> ALTER DATABASE RECOVER AUTOMATICALLY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_1.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 137667)
Database altered.
gSQL> ALTER DATABASE RECOVER '/goldilocks/wal/redo_1_0.log';
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_2.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 137672)
Database altered.
gSQL> ALTER DATABASE END INCOMPLETE RECOVERY;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE RESETLOGS;
System altered.
```

Corrupted Data File

If a data file is corrupted or dropped, the complete recovery is executed by using the backup data files. Th e full backup restores the data files by copying the backup files, and the incremental backup restores the data files by using the GOLDILOCKS' restoring syntax.
The restoration and recovery of data files are executed in database unit or in tablespace unit. It can also b e executed in the tablespace unit of the corresponding data file. The recovery in tablespace unit can be ex ecuted in MOUNT phase or OPEN phase. The tablespace should be in OFFLINE state to restore and recove r data files on OPEN phase.

- Recovering the corrupted data files using full backup in MOUNT phase

Execute the complete recovery after copying the backup data file */goldilocks/backup/test.dbf* to */goldiloc ks/db/test.dbf*.

```
$ cp /goldilocks/backup/test.dbf /goldilocks/db/test.dbf
gSQL> \STARTUP MOUNT
System altered.
gSQL> ALTER DATABASE RECOVER;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
```

```
System altered.
```

- Recovering the corrupted data files using full backup in OPEN phase

```
gSQL> SELECT IS_ONLINE FROM V$TABLESPACE WHERE TBS_NAME = 'TEST_TBS';
IS_ONLINE
---------
FALSE
1 row selected.
$ cp /goldilocks/backup/test.dbf /goldilocks/db/test.dbf
gSQL> ALTER DATABASE RECOVER TABLESPACE TEST_TBS;
Database altered.
gSQL> ALTER TABLESPACE TEST_TBS ONLINE;
Tablespace altered.
```

- Recovering the corrupted data files using incremental backup in MOUNT phase

```
gSQL> \STARTUP MOUNT
System altered.
gSQL> ALTER DATABASE RESTORE;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE;
System altered.
```

- Recovering the corrupted data files using incremental backup in OPEN phase

```
gSQL> SELECT IS_ONLINE FROM V$TABLESPACE WHERE TBS_NAME = 'TEST_TBS';
IS_ONLINE
---------
FALSE
1 row selected.
gSQL> ALTER DATABASE RESTORE TABLESPACE TEST_TBS;
Database altered.
gSQL> ALTER TABLESPACE TEST_TBS ONLINE;
Tablespace altered.
```

User's Mistake (Table Dropping or Wrong Insert/drop/update)

GOLDILOCKS database supports DDL rollback of table and index if the table *TEST* is dropped by mistake. Namely, a user can rollback to cancel the table dropping instead of committing as follows even if a user d ropped the table.

```
gSQL> DROP TABLE TEST;
Table dropped.
gSQL> ROLLBACK;
Rollback complete.
gSQL> \DESC TEST
COLUMN_NAME TYPE          IS_NULLABLE
----------- ------------- -----------
I1          NUMBER(10,0)  TRUE
I2          CHARACTER(10) TRUE
gSQL> DROP TABLE TEST;
Table dropped.
gSQL> COMMIT;
Commit complete.
gSQL> \DESC TEST
ERR-42000(16040): table or view does not exist :
SELECT *   FROM TEST  WHERE 1 = 0
               *
ERROR at line 1:
```

If table dropping is committed it can not be rolled back. Therefore, execute GOLDILOCKS incomplete rec overy to recover until the specific point of the database using backup. Then, the data is recovered until th e time before the table dropping. Restart the database after that.

The backup file at the point before the table dropping is used to restore the table in incomplete media re covery. The correct point can be found, as described above, by repeating the recovery several times to fin d the time of table dropped. At that time, the gdump tool is used to dump the log file and analyze it.

Assuming LSN is 1000 at the time after table dropping, the incomplete recovery is executed as follows.

```
gSQL> \STARTUP MOUNT
System altered.
gSQL> ALTER DATABASE RECOVER UNTIL CHANGE 1000;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE RESETLOGS;
System altered
gSQL> \DESC TEST
COLUMN_NAME TYPE          IS_NULLABLE
----------- ------------- -----------
I1          NUMBER(10,0)  TRUE
I2          CHARACTER(10) TRUE
```

Corrupted Log File (Archive File, Redo Log File)

- Corrupted archive log file during recovery

Assume that the data files are corrupted and a user are executing recovery using the backup data files. Al so, assume that the specific archive log file is corrupted during the recovery so that the recovery can not b e completed.

For example, there are archive log files such as 'archive_0.log', 'archive_1.log', 'archive_2.log', 'archive_3 .log'. An 'archive_3.log' is corrupted, and the recovery can not be executed. In this case, incomplete reco very is executed until 'archive_2.log', and the database is restarted.

```
gSQL> \STARTUP MOUNT
System altered
gSQL> ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_0.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 139992)
Database altered.
gSQL> ALTER DATABASE RECOVER AUTOMATICALLY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_3.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 194143)
Database altered.
gSQL> ALTER DATABASE END INCOMPLETE RECOVERY;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE RESETLOGS;
System altered
```

- Corrupted redo log file

Assume that a failure occurs when operating database so the CURRENT log group in which logs are flush ed is corrupted.

For example, when an abnormal termination occurs in the state of the following log groups, the manual r ecovery is executed and completes the incomplete recovery. It is because the log group 3, 0 is not archive d yet.

Table 7-5 Log group state

Log group	Log group state	Log file sequence no.	Prev last LSN
Log group 0	ACTIVE	8	80000
Log group 1	CURRENT	9	90000
Log group 2	INACTIVE	6	60000
Log group 3	ACTIVE	7	70000

```
gSQL> \STARTUP MOUNT
System altered
gSQL> ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_0.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 1000)
Database altered.
gSQL> ALTER DATABASE RECOVER AUTOMATICALLY;
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_7.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 70001)
Database altered.
gSQL> ALTER DATABASE RECOVER '/goldilocks/wal/redo_3_0.log';
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_8.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 80001)
Database altered.
gSQL> ALTER DATABASE RECOVER '/goldilocks/wal/redo_0_0.log';
ERR-01000(14104): Warning: suggestion '/goldilocks/archive_log/archive_9.log'
ERR-01000(14103): Warning: media recovery needs a logfile including log (Lsn 90001)
Database altered.
gSQL> ALTER DATABASE END INCOMPLETE RECOVERY;
Database altered.
gSQL> ALTER SYSTEM OPEN DATABASE RESETLOGS;
System altered
```

More Recent Datafile Than Log

All tablespaces created in GOLDILOCKS database consists of pages, and each page set the log LSN which was recorded by a transaction having updated that page last is set as the page LSN. Therefore, all page LSNs in the datafile have the same or smaller value than the LSN of the latest log recorded in the redo log file of the log group.

When restartig the database, if a specific page's LSN of the data file has a bigger value than the latest log's LSN, then it corrupts the database consistency and the normal service is not available. GOLDILOCKS database checks the data file and log when restarting so that this abnormal situation does not happen.

If any page whose LSN has bigger value than the latest log's LSN is in the data file, then restarting the database fails as follows.

```
gSQL> \STARTUP
ERR-HY000(14114): exist inconsistent datafiles; need to restore more older backup datafiles or
more recent redo logfiles
```

To solve this problem, restore the backup data file consisting of LSNs smaller than the latest log LSN. Or, restart the database after restoring the log file on which the LSN log bigger than the data file is recorded.

Check the trace file to find the data file to restore.

For example, if the following messages are output on the trace file when restarting fails, then the page w hose LSN is '126787' in '/data/db/system_dic.dbf' data file, and this value is bigger than the latest log LS N of the log file '126652'. Therefore, for the restart, restore the previous backup data file, or restore the l og file on which the log LSN same or bigger than '126787' is recorded. Also, if several pages of the data f ile has a LSN value bigger than the log file LSN, then restore the log file bigger than the maximum value a mong them to restart and provide the service.

```
[2016-01-15 12:41:14.045679 THREAD(10581,139799401453312)] [INFORMATION]
[STARTUP_SM] the max page lsn '126787' of datafile '/data/db/system_dict.dbf' is more recent
than the latest redo log lsn '126652'.

[STARTUP_SM] the max page lsn '126829' of datafile '/data/db/test_log.dbf' is more recent than
the latest redo log lsn '126652'.
```

in doubt Transaction Recovery in Cluster Environment

The transactions in the cluster environment are divided into global transaction, domain transaction and lo cal transaction. The global transaction is performed in two or more cluster groups, the domain transactio n is performed in a single cluster group and the local transaction is performed in a single cluter member.

The local transaction uses only the local member's log when performing the recovery. The domain transa ction uses the local member's log when performing the recovery, and performs the rollback when an abn ormal termination occurs without completing the transaction, and performs the synchronization with a gr oup member through the rebalance if needed

The global transaction uses 2 phase commit protocol to commit. 2 phase commit is performed as follows for GOLDILOCKS global transaction.

- PREPARE phase
  - It transfers PREPARE messages from the driver member to all members, and waits for the respon d message.
  - It moves on to COMMIT phase when it receives the respond message of PREPARE from all memb ers, or it rolls back when at least one member fails or does not respond.
- COMMIT phase
  - It transfers COMMIT messages from the driver member to all members, and waits for the respon d message.
  - It commits even when a member fails.

If a member is abnormally terminated without recording the commit log on COMMIT phase, it should obt ain the state information from other members when restarting. It is because it is unable to know if the gl obal transaction in 'PREPARE' state was committed or rolled back, when restarting.

For that, GOLDILOCKS records the committed global transaction information in transaction record form i n MEM_TRANS_TBS. Also, when recording a new record in that record, the previous record is recorded in the global transaction log file if needed. Later, the abnormally terminated member performs the restart re covery or the manual recovery by using the log. It performs the recovery by obtaining the transaction CO MMIT/ROLLBACK information from members in service when *in doubt* transaction in 'PREPARE' state is r emained.

GOLDILOCKS creates the global transaction log file consisting of two log groups in advance and records *i n doubt* transaction information in the log file when creating the database. In this case, if the log file is fu ll, then the next log file is used. Filled log file is reused after it is archived by the archive system thread. Th e global transaction log file is always archived in cluster environment regardless of ARCHIVELOG mode. It is because it is required to allow it to refer to the previous *in doubt* transaction information.

8.

GOLDILOCKS Database Replication

8.1 Overview

This chapter describes CYCLONE, LOGMIRROR and CYFILE.

GOLDILOCKS supports two types of replication, and they are CYCLONE and LOGMIRROR. CYCLONE repli cates transactions using CDC, and LOGMIRROR replicates redo log files in the source database.

CYFILE uses CDC method to store/ record the transaction which was applied to the original database in C omma-Separated Values (CSV) format file.

Table 8-1 Replication tool

Tool	Replication target	Description
CYCLONE	Transaction	It uses CDC method, and replicates the transaction reflected in mast er, then reflect it to slave.
LOGMIRROR	Redo log file	It identically replicates redo file in master database to slave.
CYFILE	Transaction	It uses CDC method to store/ record the transaction in CSV format fi le.

- CYCLONE
  - It uses Change Data Capture (CDC) method to analyze and treat redo log files of the source data base, then applies them to a remote database.
  - It supports only asynchronous (async) method because it analyzes contents stored in database's r edo log file.
- LOGMIRROR
  - It replicates redo log files stored in the source database to a remote database.
  - It is used to avoid the data loss of CYCLONE which is executed in async method.
- CYFILE
  - It analyzes the redo log file of the database in CDC method, and stores it in CSV format data file.
  - A user can perform the replication by using the corresponding file or perform ETL according to th e purpose of the development.

8.2 Operating Method

CYCLONE

For more information about general operating method and option, refer to **CYCLONE**.

Adding and Deleting Nodes

CYCLONE is performed in a group unit, and it is as same as the replication nodes. Add a group when add ing nodes, drop a group when deleting nodes.

Examples of Adding Nodes

- Record the group 2 to be added in master configuration file.
  - Set a unique port per each group.
  - The default master configuration file is $GOLDILOCKS_DATA/conf/cyclone.master.conf.
  - The following is an example of group 1 node in operation.

```
...
...
GROUP_NAME = Group1
{
    PORT = 21102
    CAPTURE_TABLE =
    (
        testTable1,
        testTable2
    )
}
```

  - The following is an example of group 2 node to be added.

```
GROUP_NAME = Group2
{
    PORT = 21103
    CAPTURE_TABLE =
    (
        testTable5,
```

```
        testTable6
    )
}
```

- Record the group 2 to be added in slave configuration file.
    - The port of group 2 should be as same as the port added to the existing master.
    - The default slave configuration file is $GOLDILOCKS_DATA/conf/cyclone.slave.conf.

    - The following is an example of group 1 node in operation.

```
...
...
GROUP_NAME = Group1
{
    PORT = 21102
    APPLY_TABLE =
    (
        testTable1 To testTable3,
        testTable2 To testTable4
    )
}
```

    - The following is an example of group 2 node to be added.

```
GROUP_NAME = Group2
{
    PORT = 21103
    APPLY_TABLE =
    (
        testTable5 To testTable7,
        testTable6 To testTable8
    )
}
```

- Execute and check the added group 2 node in the master device as follows.

```
prompt> cyclone --master --start --group Group2
[GROUP2] Startup done as Master.
prompt> cyclone --master --status
=====================================
¦       CYCLONE STATUS - MASTER      ¦
=====================================
```

```
 GROUP1 Running...
 GROUP2 Running...
-------------------------------------
```

- Execute and check the added group 2 node in the slave device as follows.

```
prompt> cyclone --slave --start --group Group2
[GROUP2] Startup done as Slave.
prompt> cyclone --slave --status
=====================================
        CYCLONE STATUS - SLAVE
=====================================
 GROUP1 Running...
 GROUP2 Running...
-------------------------------------
```

Examples of Deleting Nodes

- Terminate the group 2 node to be deleted in the slave device as follows.

```
prompt> cyclone --slave --stop --group Group2
stop done.
prompt> cyclone --slave --status
=====================================
CYCLONE STATUS - SLAVE
=====================================
GROUP1 Running...
-------------------------------------
```

- Terminate the group 2 node to be deleted in the master device as follows.

```
prompt> cyclone --master --stop --group Group2
stop done.
prompt> cyclone --master --status
=====================================
CYCLONE STATUS - MASTER
=====================================
GROUP1 Running...
-------------------------------------
```

- Drop the group 2 node to be deleted from the master configuration file.
  - The default master configuration file is $GOLDILOCKS_DATA/conf/cyclone.master.conf.

    - The following is an example of group 1 node in operation.

```
...
...
GROUP_NAME = Group1
{
    PORT = 21102
    CAPTURE_TABLE =
    (
        testTable1,
        testTable2
    )
}
```

    - The following is an example of deleting group 2 node.

```
~~GROUP_NAME = Group2~~
~~{~~
~~    PORT = 21103~~
~~    CAPTURE_TABLE =~~
~~    (~~
~~        testTable5,~~
~~        testTable6~~
~~    )~~
~~}~~
```

- Drop the group 2 node to be deleted from the slave configuration file as follows.
    - The default slave configuration file is $GOLDILOCKS_DATA/conf/cyclone.slave.conf.

    - The following is an example of group 1 node in operation.

```
...
...
GROUP_NAME = Group1
{
    PORT = 21102
    APPLY_TABLE =
    (
        testTable1 To testTable3,
        testTable2 To testTable4
    )
}
```

- The following is an example of deleting group 2 node.

```
GROUP_NAME = Group2
{
    PORT = 21103
    APPLY_TABLE =
    (
        testTable5 To testTable7,
        testTable6 To testTable8
    )
}
```

Initializing Replication

Initializing replication is executed when existing replication nodes or a group's table gives up execution due to DDL operation. A specific node or entire node can be initialized.

The initializing replication is performed by restarting replication being operated in slave using --reset option.
On the other hand, master does not require any operation.

Examples of Initializing Replication on a Specific Node

- Terminate the group 2 node to be initialized in the slave device as follows.

```
prompt> cyclone --slave --stop --group Group2
stop done.
prompt> cyclone --slave --status
=====================================
        CYCLONE STATUS - SLAVE
=====================================
 GROUP1 Running...
-------------------------------------
```

- Restart group 2 node in slave device using --reset option.
  - Master device does not require any operation.
  - Replication restarts from the current point.

```
prompt> cyclone --slave --start --reset --group Group2
[GROUP2] Startup done as Slave.
prompt> cyclone --slave --status
=====================================
```

```
        CYCLONE STATUS - SLAVE
=====================================
 GROUP1 Running...
 GROUP2 Running...
-------------------------------------
```

Examples of Initializing Replication of All Nodes

- Terminate all CYCLONE in operation in the slave device as follows.

```
prompt> cyclone --stop --slave
```

- Restart CYCLONE in slave device using --reset option.
  - Master device does not require any operation.
  - Replication starts from the current point.

```
prompt> cyclone --slave --start --reset
[GROUP1] Startup done as Slave.
[GROUP2] Startup done as Slave.
prompt> cyclone --slave --status
=====================================
        CYCLONE STATUS - SLAVE
=====================================
 GROUP1 Running...
 GROUP2 Running...
-------------------------------------
```

LOGMIRROR

For more information about general operation method and options, refer to **LOGMIRROR**.

Retrieving LOGMIRROR State

GOLDILOCKS includes the response waiting procedure of LOGMIRROR when GOLDILOCKS interworks wi th LOGMIRROR. If LOGMIRROR is waiting for response, GOLDILOCKS is also waiting in a blocked state. T his state can be retrieved in v$system_stat.

```
gSQL> SELECT * FROM V$SYSTEM_STAT WHERE STAT_NAME='LOG_MIRROR_SYNC_STATE';
STAT_NAME             STAT_VALUE COMMENTS
--------------------- ---------- ----------------------------------------------
```

```
LOG_MIRROR_SYNC_STATE      0 logmirror sync state( 0 : sync, 1 : blocked )
1 row selected.
```

If STAT_VALUE is 0, it is not a standby state but an ordinary state. If STAT_VALUE is 1, it is a blocked state waiting for a response. To restart GOLDILOCKS service while LOGMIRROR is waiting for a response, LOG MIRROR service can be stopped by modifying LOG_MIRROR_TIMEOUT as follows.

```
gSQL> ALTER SYSTEM SET LOG_MIRROR_TIMEOUT = 20;
System altered.
```

Initializing Replication

Initializing replication of LOGMIRROR should be done manually. This is to prevent data dropping or the u nrecoverable situation driven by the user's incorrect option usage.

Control files and redo log files are stored in LOGMIRROR slave. The required information for the operation is stored and updated in the control files.

Examples of Initializing Replication

- Terminate LOGMIRROR in operation in the slave device as follows.

```
prompt> logmirror --slave --stop
stop done.
```

- Terminate LOGMIRROR in operation in the master device as follows.

```
prompt> logmirror --master --stop
stop done.
```

- Drop the replicated control files and redo log files from the slave device.
  - For more information about the path, refer to 'LOG_PATH' option described in the slave configur ation file.
  - The default LOGMIRROR slave configuration file is $GOLDILOCKS_DATA/conf/logmirror.slave.co nf.

CYFILE

For more information about how to operate and its options, refer to **CYFILE**.

Starting, Stopping and Status Checking of cyfile

Example

- Start cyfile from the current moment by using the default configuration file.

```
prompt> cyfile --start --reset all
Startup done.
```

- Stop cyfile.

```
prompt> cyfile --stop
Stop done.
```

- CYFILE is operated in groups and the data file is created in groups.

```
prompt> cyfile --status
cyfile --status
=====================================
¦          CYFILE STATUS            ¦
=====================================
 GROUP1 Running...
=====================================
```

8.3 Trace Log

The followings are detailed information about the trace log.

Table 8-2 Trace log

Name	Category	File name
CYCLONE	Master	cyclone_master_GROUP_NAME.trc
	Slave	cyclone_slave_GROUP_NAME.trc
LOGMIRROR	Master	LogMirror_master.trc
	Slave	LogMirror_slave.trc
CYFILE	-	cyfile_GROUP_NAME.trc

Troubleshooting of CYCLONE

The followings are error messages and troubleshooting of CYCLONE.

Table 8-3 Troubleshooting of CYCLONE

Error message	Solution
Service is not available	Ensure that GOLDILOCKS is normally running.
table does not exist	Check the table name described in the configuration file.
schema does not exist	Check the schema name described in the configuration file.
previously added. Maybe duplicated	Check if a table is duplicated in the configuration file.
table must have a primary key	Ensure that a table in the configuration file has the primary key.
internal error occurred.	Check the error details.
table must set supplemental log	Ensure that supplemental logging is executed in GOLDILOCKS.
group XXX is already running	Check if the corresponding group is already running.
GOLDILOCKS_DATA system environment is invalid	Ensure that GOLDILOCKS_DATA environment variable is set.
log file reused or invalid. restart cyclone with '--reset' option	This error occurs when the redo log file is reused or archived redo log file does not exist. In this case, initialize CYCLONE and restart it.
fail to analyze flow	This error occurs when analyzing an abnormal redo log file. Ensure that the release version between master and slave are same.
Communication link failure	Check the network state. Restart CYCLONE.
Master disconnect abnormally	Check the network state. Restart CYCLONE.
Protocol error occurred	Check the error details.
Already slave connected	Check if the slave is already running.
Invalid group name	Check the specified group name at the startup/termination. The group name

Error message	Solution
	should be same as described in the configuration file.
Invalid capture information	This error occurs when the existing operating information is abnormal. In this case, initialize CYCLONE and restart it.
Redo log file read timeout	Ensure that the archived redo log files normally exist.
Invalid archive log file	The archived redo log file is not normal. In this case, initialize CYCLONE and r estart it.
Fail to write file	Check the available space in the disk, and restart CYCLONE.
Invalid Meta File	This error occurs when the meta files which are managed by CYCLONE are co rrupted. In this case, initialize CYCLONE and restart it.
Redo log file does not exist	Ensure that GOLDILOCKS which is operated as master is normally running.
[APPLIER-INSERT] XXX	INSERT is failed due to XXX.
[APPLIER-DELETE] XXX	DELETE is failed due to XXX.
[APPLIER-UPDATE] XXX	UPDATE is failed due to XXX.

Troubleshooting of LOGMIRROR

The followings are error messages and troubleshooting of LOGMIRROR.

Table 8-4 Troubleshooting of LOGMIRROR

Error message	Solution
Service is not available	Ensure that GOLDILOCKS is normally running.
Invalid Protocol value	Check the error details.
file does not exist	Ensure that the corresponding file normally exists.
invalid Control file	The control file is corrupted. Initialize and restart LOGMIRROR.
Communication link failure	Check the network state. Restart LOGMIRROR.
GOLDILOCKS_DATA system en vironment is invalid	Ensure that GOLDILOCKS_DATA environment variable is set.
There is no Shared Memory Are a for LogMirror	Ensure that LOG_MIRROR_MODE property is normally set to 'enabled' in properti es of GOLDILOCKS which is operated as master.
Master disconnect abnormally	Check the network state. Restart LOGMIRROR.
Invalid Log File	Ensure that the corresponding file normally exists.
Connection Information does n ot exist	Ensure that GOLDILOCKS connecting information in configuration files is normal.
Archive Log File does not exist	Ensure that ARCHIVELOG_MODE in GOLDILOCKS which is operated as master is normally set.

Troubleshooting of CYFILE

The followings are error messages and troubleshooting of CYFILE.

Error message	Solution
Service is not available	Ensure that GOLDILOCKS is normally running.
table does not exist	Check the table name described in the configuration file.
schema does not exist	Check the schema name described in the configuration file.
previously added. Maybe duplicated	Check if a table is duplicated in the configuration file.
table must have a primary key	Ensure that a table in the configuration file has the primary key.
internal error occurred.	Check the error details.
table must set supplemental log	Ensure that supplemental logging is executed in GOLDILOCKS.
group XXX is already running	Check if the corresponding group is already running.
GOLDILOCKS_DATA system environment is invalid	Ensure that GOLDILOCKS_DATA environment variable is set.
log file reused or invalid. restart cyfile with '--reset' option	This error occurs when the redo log file is reused or archived redo log file does not exist. In this case, initialize cyfile and restart it.
fail to analyze flow	This error occurs when analyzing an abnormal redo log file. Ensure that the release version between master and slave are same.
Invalid group name	Check the specified group name at the startup/termination. The group name should be same as described in the configuration file.
Invalid capture information	This error occurs when the existing operating information is abnormal. In this case, initialize cyfile and restart it.
Redo log file read timeout	Ensure that the archived redo log files normally exist.
Invalid archive log file	The archived redo log file is not normal. In this case, initialize cyfile and restart it.
Fail to write file	Check the available space in the disk, and restart cyfile.
Invalid Meta File	This error occurs when the meta files which are managed by cyfile are corrupted. In this case, initialize cyfile and restart it.
Redo log file does not exist	Ensure that GOLDILOCKS is normally running.
Control has broken(CRC Error)	The control file of cyfile is damaged. Retry it by using the mirror file.

9.

Database Information

9.1 DICTIONARY_SCHEMA

DICTIONARY_SCHEMA contains views or tables to get SQL objects and their information in the system.

Views and tables of DICTIONARY_SCHEMA can be retrieved only in open phase.

Execute *DictionarySchema.sql* as follows to use the views.

- For standalone

```
% gsql sys gliese --as sysdba --import $GOLDILOCKS_HOME/admin/standalone/DictionarySchema.sql
```

- For cluster

```
% gsql sys gliese --as sysdba --import $GOLDILOCKS_HOME/admin/cluster/DictionarySchema.sql
```

Information is retrieved as follows according to the names of views or tables.

- ALL-family view
  - The view name begins with ALL_
  - Information about accessible objects by a current user
- DBA-family view
  - The view name begins with DBA_
  - Information about all objects whose current user has DBA privileges (ACCESS CONTROL ON DAT ABASE).
- USER-family view
  - The view name begins with USER_
  - Information about objects which are owned by the current user

Views of ALL_family

It retrieves information about objects accessible by a current user.

ALL_ALL_TABLES

ALL_ALL_TABLES describes the object tables and relational tables accessible to the current user.

Table 9-1 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	If a previous DROP TABLE operation failed, indicates whether the table is un usable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification (Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table

Column name	Data type	Description
BLOCKS	NUMBER	Number of used blocks in the table
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
AVG_SPACE	NUMBER	• reserved Average available free space in the table
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
OBJECT_ID_TYPE	VARCHAR(32)	• reserved Indicates whether the object ID (OID) is USER-DEFINED or SYSTEM GENERATED
TABLE_TYPE_OWNER	VARCHAR(128)	• reserved If an object table, owner of the type from which the table is created
TABLE_TYPE	VARCHAR(128)	• reserved If an object table, type of the table

Column name	Data type	Description
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	Cell flash cache hint to be used for table blocks
ROW_MOVEMENT	VARCHAR(32)	• reserved If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during table and index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNER	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABLED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLED)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)

Column name	Data type	Description
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)

ALL_ARGUMENTS

ALL_ARGUMENTS lists all arguments of functions, procedures.

Table 9-2 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of function, procedures or pacakage
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures
PACKAGE_NAME	VARCHAR(128)	Package Name of function, procedures
OBJECT_ID	NUMBER	ID of a function, procedures
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
ARGUMENT_NAME	VARCHAR(128)	Name of argument or attribute name of record type argument
POSITION	NUMBER	Position of argument or position of attribute in record type
SEQUENCE	NUMBER	Sequential order of argument and its attributes
DATA_LEVEL	NUMBER	Nesting depth of the argument for composite types
DATA_TYPE	VARCHAR(128)	Data type of the argument
DEFAULTED	VARCHAR(1)	Whether or not the argument is defaulted
DEFAULT_VALUE	VARCHAR(1)	Reserved for future use
DEFAULT_LENGTH	VARCHAR(1)	Reserved for future use
IN_OUT	VARCHAR(32)	Direction of the argument (IN, OUT, IN/OUT)
DATA_LENGTH	NUMBER	Length of the column(in bytes)
DATA_PRECISION	NUMBER	Length in decimal digits(NUMBER) or binary digits(FLOAT)
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
RADIX	NUMBER	Argument radix for a number
CHARACTER_SET_NAME	VARCHAR(128)	Character set name for the argument
TYPE_OWNER	VARCHAR(128)	Owner of the type of the argument
TYPE_NAME	VARCHAR(128)	Name of the type of the argument
TYPE_SUBNAME	VARCHAR(128)	Name of the type of the argument declared in package
TYPE_LINK	VARCHAR(128)	Name of the type of the argument declared in a remote package
PLS_TYPE	VARCHAR(128)	Name of the type of the argument at PSM
CHAR_LENGTH	NUMBER	Character limit for string datatypes
CHAR_USED	VARCHAR(1)	Whether the byte limit(B) or char limit(C) is official for the string
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

ALL_CATALOG

ALL_CATALOG displays the tables, views, synonyms, and sequences accessible to the current user.

Table 9-3 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_SCHEMA	VARCHAR(128)	Schema of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_NAME	VARCHAR(128)	Name of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_TYPE	VARCHAR(32)	Type of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED

ALL_CLUSTER_TABLES

ALL_CLUSTER_TABLES describes all cluster tables accessible to the current user in the cluster system.

It is available only on a cluster.

Table 9-4 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (CLONED, HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_PLACEMENT	VARCHAR(32)	Shard placement of the table: the value in (AT CLUSTER WIDE or AT CLUSTER GROUP)
SHARD_COUNT	NUMBER	Shard count of the table (if cloned table, the value is null)
SHARD_KEY_COUNT	NUMBER	Shard key column count of the table (if cloned table, the value is null)
HAS_GSI	VARCHAR(3)	Indicate whether the table has global secondary index: (YES) or (NO)
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

ALL_COL_COMMENTS

ALL_COL_COMMENTS displays comments on the columns of the tables and views accessible to the curre nt user.

Table 9-5 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
COMMENTS	VARCHAR(1024)	Comment on the column

ALL_COL_PRIVS

ALL_COL_PRIVS describes the object grants, for which the current user is the object owner, grantor, or gr antee, or for which an enabled role or PUBLIC is the grantee.

Table 9-6 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_COL_PRIVS_MADE

ALL_COL_PRIVS_MADE describes the column object grants for which the current user is the object owner or grantor.

Table 9-7 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_COL_PRIVS_RECD

ALL_COL_PRIVS_RECD describes the column object grants, for which the current user is the grantee, or f or which an enabled role or PUBLIC is the grantee.

Table 9-8 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_CONSTRAINTS

ALL_CONSTRAINTS describes constraint definitions on tables accessible to the current user.

Table 9-9 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
CONSTRAINT_TYPE	VARCHAR(1)	Type of the constraint definition: the value in (C: check constraint, P: Primary key, U: Unique Key, R: Referential intgrity)
TABLE_OWNER	VARCHAR(128)	Owner of the table (or view) associated with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table (or view) associated with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table (or view) associated with the constraint definition
SEARCH_CONDITION	LONG VARCHAR	Text of search condition for a check constraint
R_OWNER	VARCHAR(128)	Owner of the unique constraint definition for the referenced table
R_SCHEMA	VARCHAR(128)	Schema of the unique constraint definition for the referenced table
R_CONSTRAINT_NAME	VARCHAR(128)	Name of the unique constraint definition for the referenced table
DELETE_RULE	VARCHAR(32)	Delete rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
UPDATE_RULE	VARCHAR(32)	Update rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
STATUS	VARCHAR(32)	Enforcement status of the constraint: the value in (ENABLED, DISABLE)
DEFERRABLE	VARCHAR(32)	Indicates whether the constraint is deferrable (DEFERRABLE) or not (NOT DEFERRABLE)
DEFERRED	VARCHAR(32)	Indicates whether the constraint was initially deferred (DEFERRED) or not (IMMEDIATE)
VALIDATED	VARCHAR(32)	Indicates whether all data may obey the constraint or not: the value in (VALIDATED, NOT VALIDATED)
GENERATED	VARCHAR(32)	Indicates whether the name of the constraint is user-generated (USER NAME) or system-generated (GENERATED NAME)
BAD	VARCHAR(32)	• reserved Indicates whether this constraint specifies a century in an ambiguous manner (BAD) or not (NULL)
RELY	VARCHAR(32)	• reserved When NOT VALIDATED, indicates whether the constraint is to be taken in to account for query rewrite (RELY) or not (NULL)
LAST_CHANGE	TIMESTAMP(6) WITHOUT TIME ZONE	When the constraint was last enabled or disabled

Column name	Data type	Description
INDEX_OWNER	VARCHAR(128)	Owner of the index associated with the key constraint
INDEX_SCHEMA	VARCHAR(128)	Schema of the index associated with the key constraint
INDEX_NAME	VARCHAR(128)	Name of the index associated with the key constraint
INVALID	VARCHAR(32)	Indicates whether the constraint is invalid (INVALID) or not (NULL)
VIEW_RELATED	VARCHAR(32)	Indicates whether the constraint depends on a view (DEPEND ON VIEW) or not (NULL)
DROPPED	VARCHAR(3)	Indicates whether the constraint has been dropped and is in the recycle bi n (YES) or not (NO)
COMMENTS	VARCHAR(1024)	Comments of the constraint definition

ALL_CONS_COLUMNS

ALL_CONS_COLUMNS describes columns that are accessible to the current user and that are specified in constraints.

Table 9-10 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
TABLE_OWNER	VARCHAR(128)	Owner of the table with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table with the constraint definition
COLUMN_NAME	VARCHAR(128)	Name of the column or attribute of the object type column specified in the constraint definition
POSITION	NUMBER	Original position of the column or attribute in the definition of the object

ALL_DB_PRIVS

ALL_DB_PRIVS describes the database grants, for which the current user is the grantor, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-11 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PRIVILEGE	VARCHAR(32)	Privilege on the database
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_DB_PRIVS_MADE

ALL_DB_PRIVS_MADE describes the database grants for which the current user is the grantor.

Table 9-12 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the database
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_DB_PRIVS_RECD

ALL_DB_PRIVS_RECD describes the database grants, for which the current user is the grantee, or for whic h an enabled role or PUBLIC is the grantee.

Table 9-13 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the database
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_DEPENDENCIES

ALL_DEPENDENCIES describes dependencies between objects accessible to the current user

Table 9-14 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of object
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, VIEW, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_OWNER	VARCHAR(128)	Owner of the referenced object
REFERENCED_SCHEMA_NAME	VARCHAR(128)	Schema Name of the referenced object
REFERENCED_TYPE	VARCHAR(32)	Type of the referenced object: FUNCTION, PROCEDURE, TABLE, VIEW, SEQUENCE, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_LINK_NAME	VARCHAR(128)	Name of the link to the parent object
REFERENCED_NAME	VARCHAR(128)	Name of the referenced object
DEPENDENCY_TYPE	VARCHAR(32)	Indicates whether the dependency is a REF dependency (REF) or not (HARD)

ALL_GLOBAL_SECONDARY_INDEXES

ALL_GLOBAL_SECONDARY_INDEXES describes the global secondary indexes on the tables accessible to t he current user.

It is available only on a cluster.

Table 9-15 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	Owner of the global secondary indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the global secondary index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	Indicates whether or not changes to the global secondary index are l ogged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the global secondary index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the global secondary index
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)

ALL_GSI_PLACE

ALL_GSI_PLACE describes node placement of all global secondary indexes on the tables accessible to the current user in the cluster system.

It is available only on a cluster.

Table 9-16 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	Owner of the global secondary indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
GROUP_ID	NUMBER	Group identifier of the node where the global secondary index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the global secondary index placed
MEMBER_ID	NUMBER	Member identifier of the node where the global secondary index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the global secondary index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)
BLOCKS	NUMBER	Number of used blocks of the node where the global secondary index placed

ALL_INDEXES

ALL_INDEXES describes the indexes on the tables accessible to the current user.

Table 9-17 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
INDEX_TYPE	VARCHAR(32)	Type of the index: the value in (NORMAL, NORMAL/REV, BITMAP, FUNCTION-BASED NORMAL, FUNCTION-BASED NORMAL/REV, FUNCTION-BASED BITMAP, IOT - TOP, DOMAIN)
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
TABLE_TYPE	VARCHAR(32)	Type of the indexed object: the value in (NEXT OBJECT, INDEX, TABLE, VIEW, SYNONYM, SEQUENCE)
UNIQUENESS	VARCHAR(32)	Indicates whether the index is unique (UNIQUE) or nonunique (NONUNIQUE)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether index compression is enabled (ENABLED) or not (DISABLED)
PREFIX_LENGTH	NUMBER	• reserved Number of columns in the prefix of the compression key
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
PCT_THRESHOLD	NUMBER	• reserved Threshold percentage of block space allowed per index entry
INCLUDE_COLUMN	NUMBER	• reserved Column ID of the last column to be included in index-organized table primary key (non-overflow) index
FREELISTS	NUMBER	• reserved Number of process freelists allocated to this segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to this segment

Column name	Data type	Description
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	Indicates whether or not changes to the index are logged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the index
ANAL_BLOCKS	NUMBER	Number of used blocks in the index when most recently analyzed
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index
BLEVEL	NUMBER	B-Tree level (depth of the index from its root block to its leaf blocks)
LEAF_BLOCKS	NUMBER	Number of leaf blocks in the index
DISTINCT_KEYS	NUMBER	Number of distinct indexed values.
AVG_LEAF_BLOCKS_PER_KEY	NUMBER	• reserved Average number of leaf blocks in which each distinct value in the in dex appears, rounded to the nearest integer
AVG_DATA_BLOCKS_PER_KEY	NUMBER	• reserved Average number of data blocks in the table that are pointed to by a distinct value in the index rounded to the nearest integer
CLUSTERING_FACTOR	NUMBER	Indicates the amount of order of the rows in the table based on the values of the index
STATUS	VARCHAR(32)	Indicates whether a nonpartitioned index is VALID or UNUSABLE
NUM_ROWS	NUMBER	• reserved Number of rows in the index
SAMPLE_SIZE	NUMBER	Size of the sample used to analyze the index
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this index was most recently analyzed
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the index, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the indexes to be scanned, or DE FAULT
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the index is partitioned (YES) or not (NO)
TEMPORARY	VARCHAR(1)	Indicates whether the index is on a temporary table (Y) or not (N)
GENERATED	VARCHAR(1)	Indicates whether the name of the index is system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	Indicates whether the index is a secondary object created by the me thod of the Data Cartridge (Y) or not (N)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for index blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for index blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for index blocks

Column name	Data type	Description
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) o r not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSA CTION, SESSION)
PCT_DIRECT_ACCES S	NUMBER	• reserved For a secondary index on an index-organized table, the percentage of rows with VALID guess
ITYP_OWNER	VARCHAR(128)	• reserved For a domain index, the owner of the indextype
ITYP_NAME	VARCHAR(128)	• reserved For a domain index, the name of the indextype
PARAMETERS	VARCHAR(1024)	• reserved For a domain index, the parameter string
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned indexes, indicates whether statistics were collected b y analyzing the index as a whole (YES) or were estimated from statis tics on underlying index partitions and subpartitions (NO)
DOMIDX_STATUS	VARCHAR(32)	• reserved Status of a domain index
DOMIDX_OPSTATUS	VARCHAR(32)	• reserved Status of the operation on a domain index
FUNCIDX_STATUS	VARCHAR(32)	• reserved Status of a function-based index
JOIN_INDEX	VARCHAR(3)	• reserved Indicates whether the index is a join index (YES) or not (NO)
IOT_REDUNDANT_P KEY_ELIM	VARCHAR(3)	• reserved Indicates whether redundant primary key columns are eliminated fro m secondary indexes on index-organized tables (YES) or not (NO)
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
VISIBILITY	VARCHAR(3)	• reserved Indicates whether the index is VISIBLE or INVISIBLE to the optimizer
DOMIDX_MANAGE MENT	VARCHAR(32)	• reserved If this is a domain index, indicates whether the domain index is syste m-managed (SYSTEM_MANAGED) or user-managed (USER_MANA GED)
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the index segment has been created (YES) or not (NO)
COMMENTS	VARCHAR(1024)	Comments of the index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index

ALL_IND_COLUMNS

ALL_IND_COLUMNS describes the columns of indexes on all tables accessible to the current user.

Table 9-18 Column information

Column name	Data type	Description
INDEX_OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_OWNER	VARCHAR(128)	Owner of the table or cluster
TABLE_SCHEMA	VARCHAR(128)	Schema of the table or cluster
TABLE_NAME	VARCHAR(128)	Name of the table or cluster
COLUMN_NAME	VARCHAR(128)	Column name or attribute of the object type column
COLUMN_POSITION	NUMBER	Position of the column or attribute within the index
COLUMN_LENGTH	NUMBER	Indexed length of the column
CHAR_LENGTH	NUMBER	Maximum codepoint length of the column
DESCEND	VARCHAR(32)	Indicates whether the column is sorted in descending order (DESC) or ascending order (ASC)
NULL_ORDER	VARCHAR(32)	Indicates whether the null value of the column is sorted in nulls first order (NULLS FIRST) or nulls last order (NULLS LAST)

ALL_IND_PLACE

ALL_IND_PLACE describes node placement of the indexes on the tables accessible to the current user in t he cluster system.

It is available only on a cluster.

Table 9-19 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
GROUP_ID	NUMBER	Group identifier of the node where the index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the index placed
MEMBER_ID	NUMBER	Member identifier of the node where the index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
DISTINCT_KEYS	NUMBER	(deprecated)
SAMPLE_SIZE	NUMBER	(deprecated)
BLOCKS	NUMBER	Number of used blocks of the node where the index placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	(deprecated)

ALL_NONSCHEMA_COMMENTS

ALL_NONSCHEMA_COMMENTS displays comments on all non-schema objects (database, authorizations, schemas, tablespaces) accessible to the current user.

Table 9-20 Column information

Column name	Data type	Description
OBJECT_NAME	VARCHAR(128)	Name of the non-schema object
OBJECT_TYPE	VARCHAR(32)	Type of the non-schema object: DATABASE, AUTHORIZATION, SCHEMA, TABLESPACE
COMMENTS	VARCHAR(1024)	Comments of the non-schema object

ALL_OBJECTS

ALL_OBJECTS describes all objects accessible to the current user.

Table 9-21 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
SCHEMA_NAME	VARCHAR(128)	Schema of the object
OBJECT_NAME	VARCHAR(128)	Name of the object
SUBOBJECT_NAME	VARCHAR(128)	Name of the subobject (for example, partition)
OBJECT_ID	NUMBER	Dictionary object number of the object
DATA_OBJECT_ID	NUMBER	Dictionary object number of the segment that contains the object
OBJECT_TYPE	VARCHAR(32)	Type of the object (such as TABLE, INDEX)
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp for the creation of the object
LAST_DDL_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp for the last modification of the object resulting from a DDL statement
TIMESTAMP	VARCHAR(32)	Timestamp for the specification of the object (character data)
STATUS	VARCHAR(32)	Status of the object: the value in (VALID, INVALID, N/A)
TEMPORARY	VARCHAR(1)	Indicates whether the object is temporary (the current session can see only data that it placed in this object itself) (Y) or not (N)
GENERATED	VARCHAR(1)	• reserved Indicates whether the name of this object was system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y) or not (N)
NAMESPACE	NUMBER	Namespace for the object
EDITION_NAME	VARCHAR(128)	• reserved Name of the edition in which the object is actual
DROPPED	VARCHAR(3)	Indicates whether the object has been dropped and is in the recycle bin (YES) or not (NO)

ALL_PACKAGE_PRIVS

ALL_PACKAGE_PRIVS describes the package grants, for which the current user is the package owner, gra ntor, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-22 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_PACKAGE_PRIVS_MADE

ALL_PACKAGE_PRIVS_MADE describes the package grants for which the current user is the package owner or grantor.

Table 9-23 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_PACKAGE_PRIVS_RECD

ALL_PACKAGE_PRIVS_RECD describes the package grants, for which the current user is the grantee, or f or which an enabled role or PUBLIC is the grantee.

Table 9-24 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_PROCEDURES

ALL_PROCEDURES lists all function, procedures or pacakage

Table 9-25 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of function, procedures or pacakage
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures or pacakage
PROCEDURE_NAME	VARCHAR(128)	Name when a procedures in pacakage
OBJECT_ID	NUMBER	ID of a function, procedures or pacakage
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
OVERLOAD	VARCHAR(32)	ID of overloading procedure in pacakage
OBJECT_TYPE	VARCHAR(32)	Type of function, procedures or package
AGGREGATE	VARCHAR(3)	Indicate whether the procedure is an aggreage function(YES) or not (NO)
PIPELINED	VARCHAR(3)	Indicate whether the procedure is a pipelined table function(YES) or not(NO)
IMPLTYPEOWNER	VARCHAR(128)	Name of the owner of the implementation type, if any
IMPLTYPENAME	VARCHAR(128)	Name of the implementation type, if any
PARALLEL	VARCHAR(3)	Indicates whether the procedure or function is parallel-enabled (YES) or not (NO)
INTERFACE	VARCHAR(3)	YES, if the procedure/function is a table function implemented usin g the SQLCLI interface; otherwise NO
DETERMINISTIC	VARCHAR(3)	YES, if the procedure/function is declared to be deterministic; other wise NO
AUTHID	VARCHAR(32)	Indicates whether the procedure/function is declared to execute as DEFINER or CURRENT_USER (invoker)

ALL_PROC_PRIVS

ALL_PROC_PRIVS describes the procedure grants, for which the current user is the procedure owner, gra ntor, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-26 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_PROC_PRIVS_MADE

ALL_PROC_PRIVS_MADE describes the procedure grants for which the current user is the procedure owner or grantor.

Table 9-27 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_PROC_PRIVS_RECD

ALL_PROC_PRIVS_RECD describes the procedure grants, for which the current user is the grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-28 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SCHEMAS

Identify the schemata in a catalog that are owned by given user or accessible to given user or role.

Table 9-29 Column information

Column name	Data type	Description
SCHEMA_OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Created time of the schema
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Last modified time of the schema
COMMENTS	VARCHAR(1024)	Comments of the schema

ALL_SCHEMA_PATH

ALL_SCHEMA_PATH describes the schema search order of the current user and PUBLIC, for naming resol ution of unqualified SQL schema objects.

Table 9-30 Column information

Column name	Data type	Description
AUTH_NAME	VARCHAR(128)	Name of the authorization
SCHEMA_NAME	VARCHAR(128)	Name of the schema
SEARCH_ORDER	NUMBER	Schema search order of the authorization

ALL_SCHEMA_PRIVS

ALL_SCHEMA_PRIVS describes the schema grants, for which the current user is the schema owner, grant or, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-31 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SCHEMA_PRIVS_MADE

ALL_SCHEMA_PRIVS_MADE describes the schema grants, for which the current user is the grantor.

Table 9-32 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SCHEMA_PRIVS_RECD

ALL_SCHEMA_PRIVS_RECD describes the schema grants, for which the current user is the grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-33 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SEQUENCES

ALL_SEQUENCES describes all sequences accessible to the current user.

Table 9-34 Column information

Column name	Data type	Description
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Sequence name
MIN_VALUE	NUMBER	Minimum value of the sequence
MAX_VALUE	NUMBER	Maximum value of the sequence
INCREMENT_BY	NUMBER	Value by which sequence is incremented
CYCLE_FLAG	VARCHAR(1)	Indicates whether the sequence wraps around on reaching the limit (Y) or not (N)
ORDER_FLAG	VARCHAR(1)	Indicates whether sequence numbers are generated in order (Y) or not (N)
CACHE_SIZE	NUMBER	Number of sequence numbers to cache
LAST_NUMBER	NUMBER	Last sequence number written to database. If a sequence uses caching, the number written to database is the last number placed in the sequence cache.
COMMENTS	VARCHAR(1024)	Comments of the sequence

ALL_SEQ_PRIVS

ALL_SEQ_PRIVS describes the sequence grants, for which the current user is the sequence owner, grantor, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-35 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SEQ_PRIVS_MADE

ALL_SEQ_PRIVS_MADE describes the sequence grants for which the current user is the sequence owner or grantor.

Table 9-36 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_SEQ_PRIVS_RECD

ALL_SEQ_PRIVS_RECD describes the sequence grants, for which the current user is the grantee, or for wh ich an enabled role or PUBLIC is the grantee.

Table 9-37 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEM A	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_SHARD_KEY_COLUMNS

ALL_SHARD_KEY_COLUMNS describes shard key columns of all shareded tables accessible to the current user in the cluster system.

It is available only on a cluster.

Table 9-38 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Column name of the shard key
COLUMN_POSITION	NUMBER	Position of the column within the shard key

ALL_SOURCE

ALL_SOURCE describes the text source of the stored objects accessible to the current user.

Table 9-39 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of object
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, PACKAGE, PACKAGE BODY, TRIGGER
LINE	NUMBER	Line number of this line of source
TEXT	LONG VARCHAR	Text source of the strored object
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

ALL_SYNONYMS

ALL_SYNONYMS describes all synonyms.

Table 9-40 Column information

Column name	Data type	Description
SYNONYM_OWNER	VARCHAR(128)	Owner of the synonym
SYNONYM_SCHEMA	VARCHAR(128)	Schema of the synonym
SYNONYM_NAME	VARCHAR(128)	Synonym name
OBJECT_SCHEMA_NAME	VARCHAR(128)	Object schema name
OBJECT_NAME	VARCHAR(128)	Object name
DB_LINK	VARCHAR(128)	Reserved for future use

ALL_TABLES

ALL_TABLES describes the relational tables accessible to the current user.

Table 9-41 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	• reserved If a previous DROP TABLE operation failed, indicates whether the table is unusable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification (Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks in the table
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
AVG_SPACE	NUMBER	• reserved Average available free space in the table

Column name	Data type	Description
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for table blocks
		• reserved

Column name	Data type	Description
ROW_MOVEMENT	VARCHAR(32)	If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) o r not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSA CTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during ta ble and index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNER	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABL ED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLED)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle b in (YES) or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)
RESULT_CACHE	VARCHAR(32)	• reserved Result cache mode annotation for the table: the value in (NULL, DE FAULT, FORCE, MANUAL)

ALL_TAB_COLS

ALL_TAB_COLS describes the columns(including hidden columns) of the tables, views, and clusters access ible to the current user.

Table 9-42 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column dis plays the selectivity of a value that spans fewer than 2 endpoints in t he histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_N AME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LE NGTH	NUMBER	• reserved Declaration length of the character type column
		• reserved

Column name	Data type	Description
GLOBAL_STATS	VARCHAR(3)	For partitioned tables, indicates whether column statistics were collected for the table
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or CHAR length semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image format (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HIDDEN_COLUMN	VARCHAR(3)	Indicates whether the column is a hidden column (YES) or not (NO)
VIRTUAL_COLUMN	VARCHAR(3)	• reserved Indicates whether the column is a virtual column (YES) or not (NO)
SEGMENT_COLUMN_ID	NUMBER	Sequence number of the column in the segment
INTERNAL_COLUMN_ID	NUMBER	Internal sequence number of the column
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
QUALIFIED_COL_NAME	VARCHAR(4000)	Qualified column name
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

ALL_TAB_COLUMNS

ALL_TAB_COLUMNS describes the columns of the tables, views, and clusters accessible to the current use r.

Table 9-43 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column dis plays the selectivity of a value that spans fewer than 2 endpoints in t he histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_N AME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LE NGTH	NUMBER	Declaration length of the character type column
		• reserved

Column name	Data type	Description
GLOBAL_STATS	VARCHAR(3)	For partitioned tables, indicates whether column statistics were collected for the table
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or CHAR length semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image format (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

ALL_TAB_COMMENTS

ALL_TAB_COMMENTS displays comments on the tables and views accessible to the current user.

Table 9-44 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
TABLE_TYPE	VARCHAR(32)	Type of the object
COMMENTS	VARCHAR(1024)	Comment on the object

ALL_TAB_IDENTITY_COLS

ALL_TAB_IDENTITY_COLS describes all table identity columns.

Table 9-45 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Name of the identity column
GENERATION_TYPE	VARCHAR(32)	Generation type of the identity column. Possible values are ALWAYS or BY DEFAULT
IDENTITY_OPTIONS	VARCHAR(1024)	Options for the identity column sequence generator

ALL_TAB_PLACE

ALL_TAB_PLACE describes node placement of all cluster tables accessible to the current user in the cluste r system.

It is available only on a cluster.

Table 9-46 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
GROUP_ID	NUMBER	Group identifier of the node where the table placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the table placed
MEMBER_ID	NUMBER	Member identifier of the node where the table placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the table placed
MEMBER_POSITION	NUMBER	Member position of the node where the table placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
IS_UPDATE_MASTER	BOOLEAN	whether the cluster member is update master or not
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle b in (YES) or not (NO)
SCN	VARCHAR(64)	table scn of the node where the table placed
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks of the node where the table placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which the table was most recently analyzed

ALL_TAB_SHARDS

ALL_TAB_SHARDS describes shard information of sharded tables accessible to the current user in the clus ter system.

It is available only on a cluster.

Table 9-47 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_NAME	VARCHAR(128)	Shard name
SHARD_NUMBER	NUMBER	Shard number
SHARD_DEFINITION	LONG VARCHAR	Shard definition (if hash sharded, the value is null)
GROUP_ID	NUMBER	Group identifier where the shard placed
GROUP_NAME	VARCHAR(128)	Group Name where the shard placed
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

ALL_TAB_PRIVS

ALL_TAB_PRIVS describes the object grants, for which the current user is the object owner, grantor, or gr antee, or for which an enabled role or PUBLIC is the grantee.

Table 9-48 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY O PTION (YES) or not (NO)

ALL_TAB_PRIVS_MADE

ALL_TAB_PRIVS_MADE describes the object grants for which the current user is the object owner or gran tor.

Table 9-49 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY O PTION (YES) or not (NO)

ALL_TAB_PRIVS_RECD

ALL_TAB_PRIVS_RECD describes object grants, for which the current user is the grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-50 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY OPTION (YES) or not (NO)

ALL_TBS_PRIVS

ALL_TBS_PRIVS describes the tablespace grants, for which the current user is the grantor, or grantee, or f or which an enabled role or PUBLIC is the grantee.

Table 9-51 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
PRIVILEGE	VARCHAR(32)	Privilege on the tablespace
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_TBS_PRIVS_MADE

ALL_TBS_PRIVS_MADE describes the tablespace grants for which the current user is the grantor.

Table 9-52 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
PRIVILEGE	VARCHAR(32)	Privilege on the tablespace
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

ALL_TBS_PRIVS_RECD

ALL_TBS_PRIVS_RECD describes the tablespace grants, for which the current user is the grantee, or for w hich an enabled role or PUBLIC is the grantee.

Table 9-53 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
PRIVILEGE	VARCHAR(32)	Privilege on the tablespace
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

ALL_USERS

ALL_USERS lists all users of the database visible to the current user.

Table 9-54 Column information

Column name	Data type	Description
USERNAME	VARCHAR(128)	Name of the user
USER_ID	NUMBER	ID number of the user
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	User creation timestamp

ALL_VIEWS

ALL_VIEWS describes the views accessible to the current user.

Table 9-55 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the view
VIEW_SCHEMA	VARCHAR(128)	Schema of the view
VIEW_NAME	VARCHAR(128)	Name of the view
TEXT_LENGTH	NUMBER	Length of the view text
TEXT	LONG VARCHAR	View text
TYPE_TEXT_LENGTH	NUMBER	• reserved Length of the type clause of the typed view
TYPE_TEXT	VARCHAR(4000)	• reserved Type clause of the typed view
OID_TEXT_LENGTH	NUMBER	• reserved Length of the WITH OID clause of the typed view
OID_TEXT	VARCHAR(4000)	• reserved WITH OID clause of the typed view
VIEW_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the type of the view if the view is a typed view
VIEW_TYPE	VARCHAR(32)	• reserved Type of the view if the view is a typed view
SUPERVIEW_NAME	VARCHAR(128)	• reserved Name of the superview
EDITIONING_VIEW	VARCHAR(1)	• reserved Reserved for future use
READ_ONLY	VARCHAR(1)	Indicates whether the view is read-only (Y) or not (N)

Views of DBA_family

The current user has DBA privileges (ACCESS CONTROL ON DATABASE), and the user can retrieve inform ation about all objects.

DBA_ALL_TABLES

DBA_ALL_TABLES describes all object tables and relational tables in the database.

Table 9-56 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	• reserved If a previous DROP TABLE operation failed, indicates whether the table is u nusable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification

Column name	Data type	Description
		(Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks in the table
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
AVG_SPACE	NUMBER	• reserved Average available free space in the table
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
OBJECT_ID_TYPE	VARCHAR(32)	• reserved Indicates whether the object ID (OID) is USER-DEFINED or SYSTEM GENERATED
TABLE_TYPE_OWNER	VARCHAR(128)	• reserved If an object table, owner of the type from which the table is created

Column name	Data type	Description
TABLE_TYPE	VARCHAR(128)	• reserved If an object table, type of the table
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for table blocks
ROW_MOVEMENT	VARCHAR(32)	• reserved If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during table and index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNER	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABLED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLED)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
		Indicates whether the table has been dropped and is in the recycle bin (YES)

Column name	Data type	Description
DROPPED	VARCHAR(3)	or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)

DBA_ARGUMENTS

DBA_ARGUMENTS lists all arguments of functions, procedures.

Table 9-57 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of function, procedures or pacakage
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures
PACKAGE_NAME	VARCHAR(128)	Package Name of function, procedures
OBJECT_ID	NUMBER	ID of a function, procedures
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
ARGUMENT_NAME	VARCHAR(128)	Name of argument or attribute name of record type argument
POSITION	NUMBER	Position of argument or position of attribute in record type
SEQUENCE	NUMBER	Sequential order of argument and its attributes
DATA_LEVEL	NUMBER	Nesting depth of the argument for composite types
DATA_TYPE	VARCHAR(128)	Data type of the argument
DEFAULTED	VARCHAR(1)	Whether or not the argument is defaulted
DEFAULT_VALUE	VARCHAR(1)	Reserved for future use
DEFAULT_LENGTH	VARCHAR(1)	Reserved for future use
IN_OUT	VARCHAR(32)	Direction of the argument (IN, OUT, IN/OUT)
DATA_LENGTH	NUMBER	Length of the column(in bytes)
DATA_PRECISION	NUMBER	Length in decimal digits(NUMBER) or binary digits(FLOAT)
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
RADIX	NUMBER	Argument radix for a number
CHARACTER_SET_NAME	VARCHAR(128)	Character set name for the argument
TYPE_OWNER	VARCHAR(128)	Owner of the type of the argument
TYPE_NAME	VARCHAR(128)	Name of the type of the argument
TYPE_SUBNAME	VARCHAR(128)	Name of the type of the argument declared in package
TYPE_LINK	VARCHAR(128)	Name of the type of the argument declared in a remote package
PLS_TYPE	VARCHAR(128)	Name of the type of the argument at PSM
CHAR_LENGTH	NUMBER	Character limit for string datatypes
CHAR_USED	VARCHAR(1)	Whether the byte limit(B) or char limit(C) is official for the string
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

DBA_CATALOG

DBA_CATALOG lists all tables, views, synonyms, and sequences in the database.

Table 9-58 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_SCHEMA	VARCHAR(128)	Schema of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_NAME	VARCHAR(128)	Name of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_TYPE	VARCHAR(32)	Type of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED

DBA_CLUSTER

DBA_CLUSTER describes all cluster members in the cluster system.

It is available only on a cluster.

Table 9-59 Column information

Column name	Data type	Description
GROUP_ID	NUMBER	Group identifier of the cluster member
GROUP_NAME	VARCHAR(128)	Group name of the cluster member
MEMBER_ID	NUMBER	Member identifier of the cluster member
MEMBER_NAME	VARCHAR(128)	Member name of the cluster member
MEMBER_HOST	VARCHAR(256)	Host name or IP address of the cluster member
MEMBER_PORT	NUMBER	Port number of the cluster member
MEMBER_POSITION	NUMBER	Member position number of the cluster member

DBA_CLUSTER_COMMENTS

DBA_CLUSTER_COMMENTS displays comments on the cluster objects in the cluster system.

It is available only on a cluster.

Table 9-60 Column information

Column name	Data type	Description
OBJECT_NAME	VARCHAR(128)	Name of the cluster object
OBJECT_TYPE	VARCHAR(32)	Type of the cluster object: CLUSTER GROUP, CLUSTER MEMBER
COMMENTS	VARCHAR(1024)	Comment on the cluster object

DBA_CLUSTER_TABLES

DBA_CLUSTER_TABLES describes all cluster tables in the cluster system.

It is available only on a cluster.

Table 9-61 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (CLONED, HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_PLACEMENT	VARCHAR(32)	Shard placement of the table: the value in (AT CLUSTER WIDE or AT CLUSTER GROUP)
SHARD_COUNT	NUMBER	Shard count of the table (if cloned table, the value is null)
SHARD_KEY_COUNT	NUMBER	Shard key column count of the table (if cloned table, the value is null)
HAS_GSI	VARCHAR(3)	Indicate whether the table has global secondary index: (YES) or (NO)
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

DBA_COL_COMMENTS

DBA_COL_COMMENTS displays comments on the columns of all tables and views in the database.

Table 9-62 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
COMMENTS	VARCHAR(1024)	Comment on the column

DBA_COL_PRIVS

DBA_COL_PRIVS describes all column object grants in the database.

Table 9-63 Column information

Column name	Data type	Description
GRANTOR	CHARACTER VARYING(128)	Name of the user who performed the grant
GRANTEE	CHARACTER VARYING(128)	Name of the user or role to whom access was granted
OWNER	CHARACTER VARYING(128)	Owner of the object
TABLE_SCHEMA	CHARACTER VARYING(128)	Schema of the object
TABLE_NAME	CHARACTER VARYING(128)	Name of the object
COLUMN_NAME	CHARACTER VARYING(128)	Name of the column
PRIVILEGE	CHARACTER VARYING(32)	Privilege on the column
GRANTABLE	CHARACTER VARYING(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

DBA_CONSTRAINTS

DBA_CONSTRAINTS describes all constraint definitions on all tables in the database.

Table 9-64 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
CONSTRAINT_TYPE	VARCHAR(1)	Type of the constraint definition: the value in (C: check constraint, P: Primary key, U: Unique Key, R: Referential intgrity)
TABLE_OWNER	VARCHAR(128)	Owner of the table (or view) associated with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table (or view) associated with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table (or view) associated with the constraint definition
SEARCH_CONDITION	LONG VARCHAR	Text of search condition for a check constraint
R_OWNER	VARCHAR(128)	Owner of the unique constraint definition for the referenced table
R_SCHEMA	VARCHAR(128)	Schema of the unique constraint definition for the referenced table
R_CONSTRAINT_NAME	VARCHAR(128)	Name of the unique constraint definition for the referenced table
DELETE_RULE	VARCHAR(32)	Delete rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
UPDATE_RULE	VARCHAR(32)	Update rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
STATUS	VARCHAR(32)	Enforcement status of the constraint: the value in (ENABLED, DISABLE)
DEFERRABLE	VARCHAR(32)	Indicates whether the constraint is deferrable (DEFERRABLE) or not (NOT DEFERRABLE)
DEFERRED	VARCHAR(32)	Indicates whether the constraint was initially deferred (DEFERRED) or not (IMMEDIATE)
VALIDATED	VARCHAR(32)	Indicates whether all data may obey the constraint or not: the value in (VALIDATED, NOT VALIDATED)
GENERATED	VARCHAR(32)	Indicates whether the name of the constraint is user-generated (USER NAME) or system-generated (GENERATED NAME)
BAD	VARCHAR(32)	• reserved Indicates whether this constraint specifies a century in an ambiguous manner (BAD) or not (NULL)
RELY	VARCHAR(32)	• reserved When NOT VALIDATED, indicates whether the constraint is to be taken into account for query rewrite (RELY) or not (NULL)
	TIMESTAMP(6) WITH	

Column name	Data type	Description
LAST_CHANGE	OUT TIME ZONE	When the constraint was last enabled or disabled
INDEX_OWNER	VARCHAR(128)	Owner of the index associated with the key constraint
INDEX_SCHEMA	VARCHAR(128)	Schema of the index associated with the key constraint
INDEX_NAME	VARCHAR(128)	Name of the index associated with the key constraint
INVALID	VARCHAR(32)	Indicates whether the constraint is invalid (INVALID) or not (NULL)
VIEW_RELATED	VARCHAR(32)	• reserved Indicates whether the constraint depends on a view (DEPEND ON VIEW) or not (NULL)
DROPPED	VARCHAR(3)	Indicates whether the constraint has been dropped and is in the recycle bin (YES) or not (NO)
COMMENTS	VARCHAR(1024)	Comments of the constraint definition

DBA_CONS_COLUMNS

DBA_CONS_COLUMNS describes all columns in the database that are specified in constraints.

Table 9-65 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
TABLE_OWNER	VARCHAR(128)	Owner of the table with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table with the constraint definition
COLUMN_NAME	VARCHAR(128)	Name of the column or attribute of the object type column specified in the constraint definition
POSITION	NUMBER	Original position of the column or attribute in the definition of the object

DBA_DB_PRIVS

DBA_DB_PRIVS describes all database grants in the database.

Table 9-66 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PRIVILEGE	VARCHAR(32)	Privilege on the database
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

DBA_DEPENDENCIES

DBA_DEPENDENCIES describes all dependencies between objects in the database

Table 9-67 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of object
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, VIEW, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_OWNER	VARCHAR(128)	Owner of the referenced object
REFERENCED_SCHEMA_NAME	VARCHAR(128)	Schema Name of the referenced object
REFERENCED_TYPE	VARCHAR(32)	Type of the referenced object: FUNCTION, PROCEDURE, TABLE, VIEW, SEQUENCE, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_LINK_NAME	VARCHAR(128)	Name of the link to the parent object
REFERENCED_NAME	VARCHAR(128)	Name of the referenced object
DEPENDENCY_TYPE	VARCHAR(32)	Indicates whether the dependency is a REF dependency (REF) or not (HARD)

DBA_EXTENTS

DBA_EXTENTS describes the extents comprising the segments in all tablespaces in the database.

Table 9-68 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the segment associated with the extent
SEGMENT_SCHEMA	VARCHAR(128)	Schema of the segment associated with the extent
SEGMENT_NAME	VARCHAR(128)	Name of the segment associated with the extent
PARTITION_NAME	VARCHAR(128)	• reserved Object Partition Name (Set to NULL for non-partitioned objects)
SEGMENT_TYPE	VARCHAR(32)	Type of the segment: TABLE, INDEX
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the extent
EXTENT_ID	NUMBER	• reserved Extent number in the segment
FILE_ID	NUMBER	• reserved File identifier number of the file containing the extent
BLOCK_ID	NUMBER	• reserved Starting block number of the extent
BYTES	NUMBER	Size of the extent in bytes
BLOCKS	NUMBER	Size of the extent in Oracle blocks
RELATIVE_FNO	NUMBER	• reserved Relative file number of the first extent block

DBA_GLOBAL_SECONDARY_INDEXES

DBA_GLOBAL_SECONDARY_INDEXES describes all global secondary indexes in the database.

It is available only on a cluster.

Table 9-69 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	Owner of the global secondary indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the global secondary index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	Indicates whether or not changes to the global secondary index are l ogged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the global secondary index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the global secondary index
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)

DBA_GSI_PLACE

DBA_GSI_PLACE describes node placement of all global secondary indexes in the cluster system.

It is available only on a cluster.

Table 9-70 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	Owner of the global secondary indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
GROUP_ID	NUMBER	Group identifier of the node where the global secondary index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the global secondary index placed
MEMBER_ID	NUMBER	Member identifier of the node where the global secondary index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the global secondary index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)
BLOCKS	NUMBER	Number of used blocks of the node where the global secondary index placed

DBA_INDEXES

DBA_INDEXES describes all indexes in the database.

Table 9-71 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
INDEX_TYPE	VARCHAR(32)	Type of the index: the value in (NORMAL, NORMAL/REV, BITMAP, FUNCTION-BASED NORMAL, FUNCTION-BASED NORMAL/REV, FUNCTION-BASED BITMAP, IOT - TOP, DOMAIN)
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
TABLE_TYPE	VARCHAR(32)	Type of the indexed object: the value in (NEXT OBJECT, INDEX, TABLE, VIEW, SYNONYM, SEQUENCE)
UNIQUENESS	VARCHAR(32)	Indicates whether the index is unique (UNIQUE) or nonunique (NONUNIQUE)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether index compression is enabled (ENABLED) or not (DISABLED)
PREFIX_LENGTH	NUMBER	• reserved Number of columns in the prefix of the compression key
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
PCT_THRESHOLD	NUMBER	• reserved Threshold percentage of block space allowed per index entry
INCLUDE_COLUMN	NUMBER	• reserved Column ID of the last column to be included in index-organized table primary key (non-overflow) index
FREELISTS	NUMBER	• reserved Number of process freelists allocated to this segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to this segment

Column name	Data type	Description
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	Indicates whether or not changes to the index are logged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the index
ANAL_BLOCKS	NUMBER	Number of used blocks in the index when most recently analyzed
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index
BLEVEL	NUMBER	B-Tree level (depth of the index from its root block to its leaf blocks)
LEAF_BLOCKS	NUMBER	Number of leaf blocks in the index
DISTINCT_KEYS	NUMBER	Number of distinct indexed values.
AVG_LEAF_BLOCKS_PER_KEY	NUMBER	• reserved Average number of leaf blocks in which each distinct value in the in dex appears, rounded to the nearest integer
AVG_DATA_BLOCKS_PER_KEY	NUMBER	• reserved Average number of data blocks in the table that are pointed to by a distinct value in the index rounded to the nearest integer
CLUSTERING_FACTOR	NUMBER	Indicates the amount of order of the rows in the table based on the values of the index
STATUS	VARCHAR(32)	• reserved Indicates whether a nonpartitioned index is VALID or UNUSABLE
NUM_ROWS	NUMBER	• reserved Number of rows in the index
SAMPLE_SIZE	NUMBER	Size of the sample used to analyze the index
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this index was most recently analyzed
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the index, or DEFAUL T
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the indexes to be scanned, or DE FAULT
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the index is partitioned (YES) or not (NO)
TEMPORARY	VARCHAR(1)	Indicates whether the index is on a temporary table (Y) or not (N)
GENERATED	VARCHAR(1)	Indicates whether the name of the index is system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the index is a secondary object created by the me thod of the Data Cartridge (Y) or not (N)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for index blocks
		• reserved

Column name	Data type	Description
FLASH_CACHE	VARCHAR(32)	Database Smart Flash Cache hint to be used for index blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for index blocks
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
PCT_DIRECT_ACCESS	NUMBER	• reserved For a secondary index on an index-organized table, the percentage of rows with VALID guess
ITYP_OWNER	VARCHAR(128)	• reserved For a domain index, the owner of the indextype
ITYP_NAME	VARCHAR(128)	• reserved For a domain index, the name of the indextype
PARAMETERS	VARCHAR(1024)	• reserved For a domain index, the parameter string
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned indexes, indicates whether statistics were collected by analyzing the index as a whole (YES) or were estimated from statistics on underlying index partitions and subpartitions (NO)
DOMIDX_STATUS	VARCHAR(32)	• reserved Status of a domain index
DOMIDX_OPSTATUS	VARCHAR(32)	• reserved Status of the operation on a domain index
FUNCIDX_STATUS	VARCHAR(32)	• reserved Status of a function-based index
JOIN_INDEX	VARCHAR(3)	• reserved Indicates whether the index is a join index (YES) or not (NO)
IOT_REDUNDANT_PKEY_ELIM	VARCHAR(3)	• reserved Indicates whether redundant primary key columns are eliminated from secondary indexes on index-organized tables (YES) or not (NO)
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
VISIBILITY	VARCHAR(3)	• reserved Indicates whether the index is VISIBLE or INVISIBLE to the optimizer
DOMIDX_MANAGEMENT	VARCHAR(32)	• reserved If this is a domain index, indicates whether the domain index is system-managed (SYSTEM_MANAGED) or user-managed (USER_MANAGED)
		Indicates whether the index segment has been created (YES) or not

Column name	Data type	Description
SEGMENT_CREATED	VARCHAR(3)	(NO)
COMMENTS	VARCHAR(1024)	Comments of the index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index

DBA_IND_COLUMNS

DBA_IND_COLUMNS describes the columns of all the indexes on all tables and clusters in the database.

Table 9-72 Column information

Column name	Data type	Description
INDEX_OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_OWNER	VARCHAR(128)	Owner of the table or cluster
TABLE_SCHEMA	VARCHAR(128)	Schema of the table or cluster
TABLE_NAME	VARCHAR(128)	Name of the table or cluster
COLUMN_NAME	VARCHAR(128)	Column name or attribute of the object type column
COLUMN_POSITION	NUMBER	Position of the column or attribute within the index
COLUMN_LENGTH	NUMBER	Indexed length of the column
CHAR_LENGTH	NUMBER	• reserved Maximum codepoint length of the column
DESCEND	VARCHAR(32)	Indicates whether the column is sorted in descending order (DESC) or ascending order (ASC)
NULL_ORDER	VARCHAR(32)	Indicates whether the null value of the column is sorted in nulls first order (NULLS FIRST) or nulls last order (NULLS LAST)

DBA_IND_PLACE

DBA_IND_PLACE describes node placement of all indexes in the cluster system.

It is available only on a cluster.

Table 9-73 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the index
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
GROUP_ID	NUMBER	Group identifier of the node where the index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the index placed
MEMBER_ID	NUMBER	Member identifier of the node where the index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
DISTINCT_KEYS	NUMBER	(deprecated)
SAMPLE_SIZE	NUMBER	(deprecated)
BLOCKS	NUMBER	Number of used blocks of the node where the index placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	(deprecated)

DBA_NONSCHEMA_COMMENTS

DBA_NONSCHEMA_COMMENTS displays comments on all non-schema objects (database, authorizations, schemas, tablespaces).

Table 9-74 Column information

Column name	Data type	Description
OBJECT_NAME	VARCHAR(128)	Name of the non-schema object
OBJECT_TYPE	VARCHAR(32)	Type of the non-schema object: DATABASE, PROFILE, AUTHORIZATION, SCHEMA, TABLESPACE
COMMENTS	VARCHAR(1024)	Comments of the non-schema object

DBA_OBJECTS

DBA_OBJECTS describes all objects in the database.

Table 9-75 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
SCHEMA_NAME	VARCHAR(128)	Schema of the object
OBJECT_NAME	VARCHAR(128)	Name of the object
SUBOBJECT_NAME	VARCHAR(128)	Name of the subobject (for example, partition)
OBJECT_ID	NUMBER	Dictionary object number of the object
DATA_OBJECT_ID	NUMBER	Dictionary object number of the segment that contains the object
OBJECT_TYPE	VARCHAR(32)	Type of the object (such as TABLE, INDEX)
CREATED	TIMESTAMP(6) WITH OUT TIME ZONE	Timestamp for the creation of the object
LAST_DDL_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	Timestamp for the last modification of the object resulting from a DDL statement
TIMESTAMP	VARCHAR(32)	Timestamp for the specification of the object (character data)
STATUS	VARCHAR(32)	Status of the object: the value in (VALID, INVALID, N/A)
TEMPORARY	VARCHAR(1)	Indicates whether the object is temporary (the current session can see only data that it placed in this object itself) (Y) or not (N)
GENERATED	VARCHAR(1)	Indicates whether the name of this object was system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	Indicates whether this is a secondary object created by the ODCIIndexCreate method of the Oracle Data Cartridge (Y) or not (N)
NAMESPACE	NUMBER	Namespace for the object
EDITION_NAME	VARCHAR(128)	• reserved Name of the edition in which the object is actual
DROPPED	VARCHAR(3)	Indicates whether the object has been dropped and is in the recycle bin (YES) or not (NO)

DBA_PACKAGE_PRIVS

DBA_PACKAGE_PRIVS describes all packages grants in the database.

Table 9-76 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure, function or package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure, function or package
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure, function or package
PRIVILEGE	VARCHAR(32)	Privilege on the procedure, function or package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTI ON (YES) or not (NO)

DBA_PROCEDURES

DBA_PROCEDURES lists all function, procedures or pacakage

Table 9-77 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of function, procedures or pacakage
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures or pacakage
PROCEDURE_NAME	VARCHAR(128)	Name when a procedures in pacakage
OBJECT_ID	NUMBER	ID of a function, procedures or pacakage
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
OVERLOAD	VARCHAR(32)	ID of overloading procedure in pacakage
OBJECT_TYPE	VARCHAR(32)	Type of function, procedures or package
AGGREGATE	VARCHAR(3)	Indicate whether the procedure is an aggreage function(YES) or not (NO)
PIPELINED	VARCHAR(3)	Indicate whether the procedure is a pipelined table function(YES) or not(NO)
IMPLTYPEOWNER	VARCHAR(128)	Name of the owner of the implementation type, if any
IMPLTYPENAME	VARCHAR(128)	Name of the implementation type, if any
PARALLEL	VARCHAR(3)	Indicates whether the procedure or function is parallel-enabled (YES) or not (NO)
INTERFACE	VARCHAR(3)	YES, if the procedure/function is a table function implemented usin g the SQLCLI interface; otherwise NO
DETERMINISTIC	VARCHAR(3)	YES, if the procedure/function is declared to be deterministic; other wise NO
AUTHID	VARCHAR(32)	Indicates whether the procedure/function is declared to execute as DEFINER or CURRENT_USER (invoker)

DBA_PROC_PRIVS

DBA_PROC_PRIVS describes the procedure grants, for which the current user is the procedure owner, gra ntor, or grantee, or for which an enabled role or PUBLIC is the grantee.

Table 9-78 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure, function or package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure, function or package
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure, function or package
PRIVILEGE	VARCHAR(32)	Privilege on the procedure, function or package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTI ON (YES) or not (NO)

DBA_PROFILES

DBA_PROFILES displays all profiles and their limits.

Table 9-79 Column information

Column name	Data type	Description
PROFILE_NAME	VARCHAR(128)	Profile name
RESOURCE_NAME	VARCHAR(128)	Resource name
RESOURCE_TYPE	VARCHAR(32)	Indicates whether the resource profile is a KERNEL or a PASSWORD parameter
LIMIT_VALUE	LONG VARCHAR	Limit placed on this resource for this profile
COMMON	VARCHAR(3)	Indicates whether a given profile is common. (YES or NO)

DBA_RECYCLEBIN

DBA_RECYCLEBIN describes all recycle bins in the database.

Table 9-80 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
SCHEMA_NAME	VARCHAR(128)	Schema name of the object
OBJECT_NAME	VARCHAR(128)	Name of the object
ORIGINAL_NAME	VARCHAR(128)	Original name of the object
OPERATION	VARCHAR(4)	Operation carried out on the object
OBJECT_TYPE	VARCHAR(32)	Type of the object
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the object
CREATED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	Created time of the object
DROPPED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	Dropped time of the object
DROP_SCN	VARCHAR(128)	System change number (SCN) of the transaction which moved the object to the recycle bin
DROP_GCN	NUMBER	Global change number (GCN) of the transaction which moved the object to the recycle bin
DROP_DCN	NUMBER	Domain change number (DCN) of the transaction which moved the object to the recycle bin
DROP_LCN	NUMBER	Local change number (LCN) of the transaction which moved the object to the recycle bin
CAN_UNDROP	VARCHAR(3)	Indicates whether the object can be undropped (YES) or not (NO)
CAN_PURGE	VARCHAR(3)	Indicates whether the object can be purged (YES) or not (NO)
BASE_OBJECT	NUMBER	Object number of the base object
PURGE_OBJECT	NUMBER	Object number for the object which gets purged

DBA_SCHEMAS

Identify the schemata in the database.

Table 9-81 Column information

Column name	Data type	Description
SCHEMA_OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Created time of the schema
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Last modified time of the schema
COMMENTS	VARCHAR(1024)	Comments of the schema

DBA_SCHEMA_PATH

DBA_SCHEMA_PATH describes the schema search order of all authorizations in the database.

Table 9-82 Column information

Column name	Data type	Description
AUTH_NAME	VARCHAR(128)	Name of the authorization
SCHEMA_NAME	VARCHAR(128)	Name of the schema
SEARCH_ORDER	NUMBER	Schema search order of the authorization

DBA_SCHEMA_PRIVS

DBA_SCHEMA_PRIVS describes all schema grants in the database.

Table 9-83 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

DBA_SEQUENCES

DBA_SEQUENCES describes all sequences in the database.

Table 9-84 Column information

Column name	Data type	Description
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Sequence name
MIN_VALUE	NUMBER	Minimum value of the sequence
MAX_VALUE	NUMBER	Maximum value of the sequence
INCREMENT_BY	NUMBER	Value by which sequence is incremented
CYCLE_FLAG	VARCHAR(1)	Indicates whether the sequence wraps around on reaching the limit (Y) or not (N)
ORDER_FLAG	VARCHAR(1)	• reserved Indicates whether sequence numbers are generated in order (Y) or not (N)
CACHE_SIZE	NUMBER	Number of sequence numbers to cache
LAST_NUMBER	NUMBER	Last sequence number written to database. If a sequence uses caching, the number written to database is the last number placed in the sequence cache.
COMMENTS	VARCHAR(1024)	Comments of the sequence

DBA_SEQ_PRIVS

DBA_SEQ_PRIVS describes all sequence grants in the database.

Table 9-85 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

DBA_SHARD_KEY_COLUMNS

DBA_SHARD_KEY_COLUMNS describes shard key columns of all shareded tables in the cluster system.

It is available only on a cluster.

Table 9-86 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Column name of the shard key
COLUMN_POSITION	NUMBER	Position of the column within the shard key

DBA_SOURCE

DBA_SOURCE describes the text source of the stored objects accessible to the current user.

Table 9-87 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of object
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, PACKAGE, PACKAGE BODY, TRIGGER
LINE	NUMBER	Line number of this line of source
TEXT	LONG VARCHAR	Text source of the strored object
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

DBA_STAT_SYSTEM

DBA_STAT_SYSTEM describes analyzed system statistics.

Table 9-88 Column information

Column name	Data type	Description
CPU_OPS	NATIVE_BIGINT	OPS(operations per second) of CPU
NETWORK_IOPS	NATIVE_BIGINT	IOPS(I/O operations per second) of Cluster NETWORK
NETWORK_BUFSIZE	NATIVE_BIGINT	buffer size of Cluster NETWORK when analyzed
BUFFER_MISS_PERCENT	NATIVE_BIGINT	disk buffer miss percent
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed

DBA_SYS_PRIVS

DBA_SYS_PRIVS describes all system (database, tablespace, schema) privileges in the database.

Table 9-89 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the grantee
PRIVILEGE	VARCHAR(256)	System(database, tablespace, schema) privilege
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
ADMIN_OPTION	VARCHAR(3)	equal to GRANTABLE column

DBA_SYNONYMS

DBA_SYNONYMS describes all synonyms in the database.

Table 9-90 Column information

Column name	Data type	Description
SYNONYM_OWNER	VARCHAR(128)	Owner of the synonym
SYNONYM_SCHEMA	VARCHAR(128)	Schema of the synonym
SYNONYM_NAME	VARCHAR(128)	Synonym name
OBJECT_SCHEMA_NAME	VARCHAR(128)	Object schema name
OBJECT_NAME	VARCHAR(128)	Object name
DB_LINK	VARCHAR(128)	Reserved for future use

DBA_TABLES

DBA_TABLES describes all relational tables in the database.

Table 9-91 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	• reserved If a previous DROP TABLE operation failed, indicates whether the table is unusable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification (Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks in the table
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
		• reserved

Column name	Data type	Description
AVG_SPACE	NUMBER	Average available free space in the table
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for table blocks
		• reserved

Column name	Data type	Description
ROW_MOVEMENT	VARCHAR(32)	If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during table and index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNER	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABLED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLED)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)
RESULT_CACHE	VARCHAR(32)	• reserved Result cache mode annotation for the table: the value in (NULL, DEFAULT, FORCE, MANUAL)

DBA_TABLESPACES

DBA_TABLESPACES describes all tablespaces in the database.

Table 9-92 Column information

Column name	Data type	Description
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
BLOCK_SIZE	NUMBER	Tablespace block size
INITIAL_EXTENT	NUMBER	• reserved Default initial extent size (in bytes)
NEXT_EXTENT	NUMBER	• reserved Default incremental extent size (in bytes)
MIN_EXTENTS	NUMBER	• reserved Default minimum number of extents
MAX_EXTENTS	NUMBER	• reserved Default maximum number of extents
MAX_SIZE	NUMBER	• reserved Default maximum size of segments
PCT_INCREASE	NUMBER	• reserved Default percent increase for extent size
MIN_EXTLEN	NUMBER	• reserved Minimum extent size for this tablespace (in bytes)
STATUS	VARCHAR(32)	Tablespace status: the value in (ONLINE, OFFLINE, READ ONLY)
CONTENTS	VARCHAR(32)	Tablespace contents: the value in (SYSTEM, DATA, TEMPORARY, UNDO)
LOGGING	VARCHAR(32)	Default logging attribute: LOGGING, NOLOGGING
FORCE_LOGGING	VARCHAR(3)	• reserved Indicates whether the tablespace is under force logging mode (YES) or not (NO)
EXTENT_MANAGEMENT	VARCHAR(32)	• reserved Indicates whether the extents in the tablespace are dictionary managed (DICTIONARY) or locally managed (LOCAL)
ALLOCATION_TYPE	VARCHAR(32)	• reserved Type of extent allocation in effect for the tablespace: the value in (SYSTEM, UNIFORM, USER)
PLUGGED_IN	VARCHAR(3)	• reserved Indicates whether the tablespace is plugged in (YES) or not (NO)
SEGMENT_SPACE_MANAGEMENT	VARCHAR(32)	• reserved Indicates whether the free and used segment space in the tablespace is managed using free lists (MANUAL) or bitmaps (AUTO)
DEF_TAB_COMPRESSION	VARCHAR(32)	• reserved Indicates whether default table compression is enabled (ENABLED)

Column name	Data type	Description
		or not (DISABLED)
RETENTION	VARCHAR(32)	• reserved Undo tablespace retention: the value in (GUARANTEE, NOGUARANTEE, NOT APPLY)
BIGFILE	VARCHAR(3)	• reserved Indicates whether the tablespace is a bigfile tablespace (YES) or a smallfile tablespace (NO)
PREDICATE_EVALUATION	VARCHAR(32)	• reserved Indicates whether predicates are evaluated by host (HOST) or by storage (STORAGE)
ENCRYPTED	VARCHAR(3)	• reserved Indicates whether the tablespace is encrypted (YES) or not (NO)
COMPRESS_FOR	VARCHAR(32)	• reserved Indicates whether the tablespace is encrypted (YES) or not (NO)

DBA_TAB_COLS

DBA_TAB_COLS describes the columns (including hidden columns) of all tables, views, and clusters in the database.

Table 9-93 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column dis plays the selectivity of a value that spans fewer than 2 endpoints in t he histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_N AME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LE NGTH	NUMBER	Declaration length of the character type column
		• reserved

Column name	Data type	Description
GLOBAL_STATS	VARCHAR(3)	For partitioned tables, indicates whether column statistics were collected for the table
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or CHAR length semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image format (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HIDDEN_COLUMN	VARCHAR(3)	Indicates whether the column is a hidden column (YES) or not (NO)
VIRTUAL_COLUMN	VARCHAR(3)	• reserved Indicates whether the column is a virtual column (YES) or not (NO)
SEGMENT_COLUMN_ID	NUMBER	Sequence number of the column in the segment
INTERNAL_COLUMN_ID	NUMBER	Internal sequence number of the column
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
QUALIFIED_COL_NAME	VARCHAR(4000)	Qualified column name
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

DBA_TAB_COLUMNS

DBA_TAB_COLUMNS describes the columns of the tables, views, and clusters accessible to the current us er.

Table 9-94 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column dis plays the selectivity of a value that spans fewer than 2 endpoints in t he histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_N AME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LE NGTH	NUMBER	Declaration length of the character type column
		• reserved

Column name	Data type	Description
GLOBAL_STATS	VARCHAR(3)	For partitioned tables, indicates whether column statistics were collected for the table
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or CHAR length semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image format (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

DBA_TAB_COMMENTS

DBA_TAB_COMMENTS displays comments on all tables and views in the database.

Table 9-95 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
TABLE_TYPE	VARCHAR(32)	Type of the object
COMMENTS	VARCHAR(1024)	Comment on the object

DBA_TAB_IDENTITY_COLS

DBA_TAB_IDENTITY_COLS describes all table identity columns.

Table 9-96 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Name of the identity column
GENERATION_TYPE	VARCHAR(32)	Generation type of the identity column. Possible values are ALWAYS or BY DEFAULT
IDENTITY_OPTIONS	VARCHAR(1024)	Options for the identity column sequence generator

DBA_TAB_PLACE

DBA_TAB_PLACE describes node placement of all cluster tables in the cluster system.

It is available only on a cluster.

Table 9-97 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
GROUP_ID	NUMBER	Group identifier of the node where the table placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the table placed
MEMBER_ID	NUMBER	Member identifier of the node where the table placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the table placed
MEMBER_POSITION	NUMBER	Member position of the node where the table placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
IS_UPDATE_MASTER	BOOLEAN	whether the cluster member is update master or not
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle b in (YES) or not (NO)
SCN	VARCHAR(64)	table scn of the node where the table placed
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks of the node where the table placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which the table was most recently analyzed

DBA_TAB_PRIVS

DBA_TAB_PRIVS describes all object grants in the database.

Table 9-98 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY O PTION (YES) or not (NO)

DBA_TAB_SHARDS

DBA_TAB_SHARDS describes shard information of all sharded tables in the cluster system.

It is available only on a cluster.

Table 9-99 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the table
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_NAME	VARCHAR(128)	Shard name
SHARD_NUMBER	NUMBER	Shard number
SHARD_DEFINITION	LONG VARCHAR	Shard definition (if hash sharded, the value is null)
GROUP_ID	NUMBER	Group identifier where the shard placed
GROUP_NAME	VARCHAR(128)	Group Name where the shard placed
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

DBA_TBS_PRIVS

DBA_TBS_PRIVS describes all tablespace grants in the database.

Table 9-100 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
PRIVILEGE	VARCHAR(32)	Privilege on the tablespace
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

DBA_USERS

DBA_USERS describes all users of the database.

Table 9-101 Column information

Column name	Data type	Description
USERNAME	VARCHAR(128)	Name of the user
USER_ID	NUMBER	ID number of the user
PASSWORD	VARCHAR(128)	encrypted password
ACCOUNT_STATUS	VARCHAR(32)	Account status: the value in (OPEN, EXPIRED, EXPIRED(GRACE), LOCKED(TIMED), LOCKED, EXPIRED & LOCKED(TIMED), EXPIRED(GRACE) & LOCKED (TIMED), EXPIRED & LOCKED, EXPIRED(GRACE) & LOCKED)
LOCK_DATE	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp the account was locked if account status was LOCKED
EXPIRY_DATE	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp of expiration of the account
FAILED_LOGIN_ATTEMPTS	NUMBER	Consecutive failed login attempts count
DEFAULT_TABLESPACE	VARCHAR(128)	Default tablespace for data
TEMPORARY_TABLESPACE	VARCHAR(128)	Name of the default tablespace for temporary tables or the name of a tablespace group
INDEX_TABLESPACE	VARCHAR(128)	Default tablespace for index
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	User creation timestamp
PROFIL_NAME	VARCHAR(128)	User resource profile name
INITIAL_RSRC_CONSUMER_GROUP	VARCHAR(128)	• reserved Initial resource consumer group for the user
EXTERNAL_NAME	VARCHAR(128)	• reserved User external name
PASSWORD_VERSIONS	VARCHAR(32)	• reserved Shows the list of versions of the password hashes (verifiers).
EDITIONS_ENABLED	VARCHAR(1)	Indicates whether editions have been enabled for the corresponding user (Y) or not (N).
AUTHENTICATION_TYPE	VARCHAR(32)	• reserved Indicates the authentication mechanism for the user.

DBA_VIEWS

DBA_VIEWS describes all views in the database.

Table 9-102 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the view
VIEW_SCHEMA	VARCHAR(128)	Schema of the view
VIEW_NAME	VARCHAR(128)	Name of the view
TEXT_LENGTH	NUMBER	Length of the view text
TEXT	LONG VARCHAR	View text
TYPE_TEXT_LENGTH	NUMBER	• reserved Length of the type clause of the typed view
TYPE_TEXT	VARCHAR(4000)	• reserved Type clause of the typed view
OID_TEXT_LENGTH	NUMBER	• reserved Length of the WITH OID clause of the typed view
OID_TEXT	VARCHAR(4000)	• reserved WITH OID clause of the typed view
VIEW_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the type of the view if the view is a typed view
VIEW_TYPE	VARCHAR(32)	• reserved Type of the view if the view is a typed view
SUPERVIEW_NAME	VARCHAR(128)	• reserved Name of the superview
EDITIONING_VIEW	VARCHAR(1)	Reserved for future use
READ_ONLY	VARCHAR(1)	Indicates whether the view is read-only (Y) or not (N)

Views of USER_family

It retrieves information about objects which are owned by current user.

USER_ALL_TABLES

USER_ALL_TABLES describes the object tables and relational tables owned by the current user.

Table 9-103 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	• reserved If a previous DROP TABLE operation failed, indicates whether the table is unusable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification (Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks in the table

Column name	Data type	Description
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
AVG_SPACE	NUMBER	• reserved Average available free space in the table
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
OBJECT_ID_TYPE	VARCHAR(32)	• reserved Indicates whether the object ID (OID) is USER-DEFINED or SYSTEM GENERATED
TABLE_TYPE_OWNER	VARCHAR(128)	• reserved If an object table, owner of the type from which the table is created
TABLE_TYPE	VARCHAR(128)	• reserved If an object table, type of the table
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)

Column name	Data type	Description
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for table blocks
ROW_MOVEMENT	VARCHAR(32)	• reserved If a partitioned table, indicates whether row movement is enabled (ENABLED) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during table and index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNER	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABLED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLED)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)

Column name	Data type	Description
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)

USER_ARGUMENTS

USER_ARGUMENTS lists all arguments of functions, procedures.

Table 9-104 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures
PACKAGE_NAME	VARCHAR(128)	Package Name of function, procedures
OBJECT_ID	NUMBER	ID of a function, procedures
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
ARGUMENT_NAME	VARCHAR(128)	Name of argument or attribute name of record type argument
POSITION	NUMBER	Position of argument or position of attribute in record type
SEQUENCE	NUMBER	Sequential order of argument and its attributes
DATA_LEVEL	NUMBER	Nesting depth of the argument for composite types
DATA_TYPE	VARCHAR(128)	Data type of the argument
DEFAULTED	VARCHAR(1)	Whether or not the argument is defaulted
DEFAULT_VALUE	VARCHAR(1)	Reserved for future use
DEFAULT_LENGTH	VARCHAR(1)	Reserved for future use
IN_OUT	VARCHAR(32)	Direction of the argument (IN, OUT, IN/OUT)
DATA_LENGTH	NUMBER	Length of the column(in bytes)
DATA_PRECISION	NUMBER	Length in decimal digits(NUMBER) or binary digits(FLOAT)
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
RADIX	NUMBER	Argument radix for a number
CHARACTER_SET_NAME	VARCHAR(128)	Character set name for the argument
TYPE_OWNER	VARCHAR(128)	Owner of the type of the argument
TYPE_NAME	VARCHAR(128)	Name of the type of the argument
TYPE_SUBNAME	VARCHAR(128)	Name of the type of the argument declared in package
TYPE_LINK	VARCHAR(128)	Name of the type of the argument declared in a remote package
PLS_TYPE	VARCHAR(128)	Name of the type of the argument at PSM
CHAR_LENGTH	NUMBER	Character limit for string datatypes
CHAR_USED	VARCHAR(1)	Whether the byte limit(B) or char limit(C) is official for the string
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

USER_CATALOG

USER_CATALOG lists tables, views, synonyms, and sequences owned by the current user.

Table 9-105 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_NAME	VARCHAR(128)	Name of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED
TABLE_TYPE	VARCHAR(32)	Type of the TABLE, VIEW, SYNONYM, SEQUENCE, or UNDEFINED

USER_COL_COMMENTS

USER_COL_COMMENTS displays comments on the columns of the tables and views owned by the curren t user.

Table 9-106 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
COMMENTS	VARCHAR(1024)	Comment on the column

USER_CLUSTER_TABLES

USER_CLUSTER_TABLES describes all cluster tables owned by the current user in the cluster system.

It is available only on a cluster.

Table 9-107 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (CLONED, HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_PLACEMENT	VARCHAR(32)	Shard placement of the table: the value in (AT CLUSTER WIDE or AT CLUSTER GROUP)
SHARD_COUNT	NUMBER	Shard count of the table (if cloned table, the value is null)
SHARD_KEY_COUNT	NUMBER	Shard key column count of the table (if cloned table, the value is null)
HAS_GSI	VARCHAR(3)	Indicate whether the table has global secondary index: (YES) or (NO)
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

USER_COL_PRIVS

USER_COL_PRIVS describes the column object grants for which the current user is the object owner, gran tor, or grantee.

Table 9-108 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

USER_COL_PRIVS_MADE

USER_COL_PRIVS_MADE describes the column object grants for which the current user is the object owner.

Table 9-109 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_COL_PRIVS_RECD

USER_COL_PRIVS_RECD describes the column object grants for which the current user is the grantee.

Table 9-110 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Name of the column
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the column
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

USER_CONSTRAINTS

USER_CONSTRAINTS describes all constraint definitions on tables owned by the current user.

Table 9-111 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
CONSTRAINT_TYPE	VARCHAR(1)	Type of the constraint definition: the value in (C: check constraint, P: Primary key, U: Unique Key, R: Referential intgrity)
TABLE_OWNER	VARCHAR(128)	Owner of the table (or view) associated with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table (or view) associated with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table (or view) associated with the constraint definition
SEARCH_CONDITION	LONG VARCHAR	Text of search condition for a check constraint
R_OWNER	VARCHAR(128)	Owner of the unique constraint definition for the referenced table
R_SCHEMA	VARCHAR(128)	Schema of the unique constraint definition for the referenced table
R_CONSTRAINT_NAME	VARCHAR(128)	Name of the unique constraint definition for the referenced table
DELETE_RULE	VARCHAR(32)	Delete rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
UPDATE_RULE	VARCHAR(32)	Update rule for a referential constraint: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
STATUS	VARCHAR(32)	Enforcement status of the constraint: the value in (ENABLED, DISABLE)
DEFERRABLE	VARCHAR(32)	Indicates whether the constraint is deferrable (DEFERRABLE) or not (NOT DEFERRABLE)
DEFERRED	VARCHAR(32)	Indicates whether the constraint was initially deferred (DEFERRED) or not (IMMEDIATE)
VALIDATED	VARCHAR(32)	Indicates whether all data may obey the constraint or not: the value in (VALIDATED, NOT VALIDATED)
GENERATED	VARCHAR(32)	Indicates whether the name of the constraint is user-generated (USER NAME) or system-generated (GENERATED NAME)
BAD	VARCHAR(32)	• reserved Indicates whether this constraint specifies a century in an ambiguous manner (BAD) or not (NULL)
RELY	VARCHAR(32)	• reserved When NOT VALIDATED, indicates whether the constraint is to be taken in to account for query rewrite (RELY) or not (NULL)
LAST_CHANGE	TIMESTAMP(6) WITHOUT TIME ZONE	When the constraint was last enabled or disabled

Column name	Data type	Description
INDEX_OWNER	VARCHAR(128)	Owner of the index associated with the key constraint
INDEX_SCHEMA	VARCHAR(128)	Schema of the index associated with the key constraint
INDEX_NAME	VARCHAR(128)	Name of the index associated with the key constraint
INVALID	VARCHAR(32)	Indicates whether the constraint is invalid (INVALID) or not (NULL)
VIEW_RELATED	VARCHAR(32)	• reserved Indicates whether the constraint depends on a view (DEPEND ON VIEW) o r not (NULL)
DROPPED	VARCHAR(3)	Indicates whether the constraint has been dropped and is in the recycle bi n (YES) or not (NO)
COMMENTS	VARCHAR(1024)	Comments of the constraint definition

USER_CONS_COLUMNS

USER_CONS_COLUMNS describes columns that are owned by the current user and that are specified in c onstraint definitions.

Table 9-112 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the constraint definition
CONSTRAINT_SCHEMA	VARCHAR(128)	Schema of the constraint definition
CONSTRAINT_NAME	VARCHAR(128)	Name of the constraint definition
TABLE_OWNER	VARCHAR(128)	Owner of the table with the constraint definition
TABLE_SCHEMA	VARCHAR(128)	Schema of the table with the constraint definition
TABLE_NAME	VARCHAR(128)	Name of the table with the constraint definition
COLUMN_NAME	VARCHAR(128)	Name of the column or attribute of the object type column specified in the constraint definition
POSITION	NUMBER	Original position of the column or attribute in the definition of the object

USER_DEPENDENCIES

USER_DEPENDENCIES describes dependencies between objects accessible to the current user

Table 9-113 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, VIEW, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_OWNER	VARCHAR(128)	Owner of the referenced object
REFERENCED_SCHEMA_NAME	VARCHAR(128)	Schema Name of the referenced object
REFERENCED_TYPE	VARCHAR(32)	Type of the referenced object: FUNCTION, PROCEDURE, TABLE, VIEW, SEQUENCE, PACKAGE, PACKAGE BODY, TRIGGER
REFERENCED_LINK_NAME	VARCHAR(128)	Name of the link to the parent object
REFERENCED_NAME	VARCHAR(128)	Name of the referenced object
DEPENDENCY_TYPE	VARCHAR(32)	Indicates whether the dependency is a REF dependency (REF) or not (HARD)

USER_EXTENTS

USER_EXTENTS describes the extents comprising the segments owned by the current user's objects.

Table 9-114 Column information

Column name	Data type	Description
SEGMENT_SCHEMA	VARCHAR(128)	Schema of the segment associated with the extent
SEGMENT_NAME	VARCHAR(128)	Name of the segment associated with the extent
PARTITION_NAME	VARCHAR(128)	• reserved Object Partition Name (Set to NULL for non-partitioned objects)
SEGMENT_TYPE	VARCHAR(32)	Type of the segment: TABLE, INDEX
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the extent
EXTENT_ID	NUMBER	• reserved Extent number in the segment
BYTES	NUMBER	Size of the extent in bytes
BLOCKS	NUMBER	Size of the extent in Oracle blocks

USER_GLOBAL_SECONDARY_INDEXES

USER_GLOBAL_SECONDARY_INDEXES describes the global secondary indexes on the tables owned by th e current user.

It is available only on a cluster.

Table 9-115 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the global secondary index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	Indicates whether or not changes to the global secondary index are l ogged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the global secondary index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the global secondary index
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)

USER_GSI_PLACE

USER_GSI_PLACE describes node placement of all global secondary indexes on the tables owned by the current user in the cluster system.

It is available only on a cluster.

Table 9-116 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the global secondary indexed object
TABLE_NAME	VARCHAR(128)	Name of the global secondary indexed object
GROUP_ID	NUMBER	Group identifier of the node where the global secondary index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the global secondary index placed
MEMBER_ID	NUMBER	Member identifier of the node where the global secondary index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the global secondary index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the global secondary index has been dropped and is in the recycle bin (YES) or not (NO)
BLOCKS	NUMBER	Number of used blocks of the node where the global secondary index placed

USER_INDEXES

USER_INDEXES describes indexes owned by the current user.

Table 9-117 Column information

Column name	Data type	Description
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
INDEX_TYPE	VARCHAR(32)	Type of the index: the value in (NORMAL, NORMAL/REV, BITMAP, FUNCTION-BASED NORMAL, FUNCTION-BASED NORMAL/REV, FUNCTION-BASED BITMAP, IOT - TOP, DOMAIN)
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
TABLE_TYPE	VARCHAR(32)	Type of the indexed object: the value in (NEXT OBJECT, INDEX, TABLE, VIEW, SYNONYM, SEQUENCE)
UNIQUENESS	VARCHAR(32)	Indicates whether the index is unique (UNIQUE) or nonunique (NONUNIQUE)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether index compression is enabled (ENABLED) or not (DISABLED)
PREFIX_LENGTH	NUMBER	• reserved Number of columns in the prefix of the compression key
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the index
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent
NEXT_EXTENT	NUMBER	Size of secondary extents
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
PCT_THRESHOLD	NUMBER	• reserved Threshold percentage of block space allowed per index entry
INCLUDE_COLUMN	NUMBER	• reserved Column ID of the last column to be included in index-organized table primary key (non-overflow) index
FREELISTS	NUMBER	• reserved Number of process freelists allocated to this segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to this segment

Column name	Data type	Description
PCT_FREE	NUMBER	Minimum percentage of free space in a block
LOGGING	VARCHAR(3)	ndicates whether or not changes to the index are logged: (YES) or (NO)
BLOCKS	NUMBER	Number of used blocks in the index
ANAL_BLOCKS	NUMBER	Number of used blocks in the index when most recently analyzed
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index
BLEVEL	NUMBER	B-Tree level (depth of the index from its root block to its leaf blocks)
LEAF_BLOCKS	NUMBER	Number of leaf blocks in the index
DISTINCT_KEYS	NUMBER	Number of distinct indexed values.
AVG_LEAF_BLOCKS_PER_KEY	NUMBER	• reserved Average number of leaf blocks in which each distinct value in the index app ears, rounded to the nearest integer
AVG_DATA_BLOCKS_PER_KEY	NUMBER	• reserved Average number of data blocks in the table that are pointed to by a distinct value in the index rounded to the nearest integer
CLUSTERING_FACTOR	NUMBER	Indicates the amount of order of the rows in the table based on the values o f the index
STATUS	VARCHAR(32)	• reserved Indicates whether a nonpartitioned index is VALID or UNUSABLE
NUM_ROWS	NUMBER	• reserved Number of rows in the index
SAMPLE_SIZE	NUMBER	Size of the sample used to analyze the index
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which this index was most recently analyzed
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the index, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the indexes to be scanned, or DEFAULT
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the index is partitioned (YES) or not (NO)
TEMPORARY	VARCHAR(1)	Indicates whether the index is on a temporary table (Y) or not (N)
GENERATED	VARCHAR(1)	Indicates whether the name of the index is system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the index is a secondary object created by the method of the Data Cartridge (Y) or not (N)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for index blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for index blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for index blocks

Column name	Data type	Description
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
PCT_DIRECT_ACCESS	NUMBER	• reserved For a secondary index on an index-organized table, the percentage of rows with VALID guess
ITYP_OWNER	VARCHAR(128)	• reserved For a domain index, the owner of the indextype
ITYP_NAME	VARCHAR(128)	• reserved For a domain index, the name of the indextype
PARAMETERS	VARCHAR(1024)	• reserved For a domain index, the parameter string
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned indexes, indicates whether statistics were collected by analyzing the index as a whole (YES) or were estimated from statistics on underlying index partitions and subpartitions (NO)
DOMIDX_STATUS	VARCHAR(32)	• reserved Status of a domain index
DOMIDX_OPSTATUS	VARCHAR(32)	• reserved Status of the operation on a domain index
FUNCIDX_STATUS	VARCHAR(32)	• reserved Status of a function-based index
JOIN_INDEX	VARCHAR(3)	• reserved Indicates whether the index is a join index (YES) or not (NO)
IOT_REDUNDANT_PKEY_ELIM	VARCHAR(3)	• reserved Indicates whether redundant primary key columns are eliminated from secondary indexes on index-organized tables (YES) or not (NO)
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
VISIBILITY	VARCHAR(3)	• reserved Indicates whether the index is VISIBLE or INVISIBLE to the optimizer
DOMIDX_MANAGEMENT	VARCHAR(32)	• reserved If this is a domain index, indicates whether the domain index is system-managed (SYSTEM_MANAGED) or user-managed (USER_MANAGED)
SEGMENT_CREATED	VARCHAR(3)	Indicates whether the index segment has been created (YES) or not (NO)
COMMENTS	VARCHAR(1024)	Comments of the index
EMPTY_BLOCKS	NUMBER	Number of empty blocks in the index

USER_IND_COLUMNS

USER_IND_COLUMNS describes the columns of the indexes owned by the current user and columns of in dexes on tables owned by the current user.

Table 9-118 Column information

Column name	Data type	Description
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_SCHEMA	VARCHAR(128)	Schema of the table or cluster
TABLE_NAME	VARCHAR(128)	Name of the table or cluster
COLUMN_NAME	VARCHAR(128)	Column name or attribute of the object type column
COLUMN_POSITION	NUMBER	Position of the column or attribute within the index
COLUMN_LENGTH	NUMBER	Indexed length of the column
CHAR_LENGTH	NUMBER	• reserved Maximum codepoint length of the column
DESCEND	VARCHAR(32)	Indicates whether the column is sorted in descending order (DESC) or ascending order (ASC)
NULL_ORDER	VARCHAR(32)	Indicates whether the null value of the column is sorted in nulls first order (NULLS FIRST) or nulls last order (NULLS LAST)

USER_IND_PLACE

USER_IND_PLACE describes node placement of the indexes owned by the current user in the cluster system.

It is available only on a cluster.

Table 9-119 Column information

Column name	Data type	Description
INDEX_SCHEMA	VARCHAR(128)	Schema of the index
INDEX_NAME	VARCHAR(128)	Name of the index
TABLE_OWNER	VARCHAR(128)	Owner of the indexed object
TABLE_SCHEMA	VARCHAR(128)	Schema of the indexed object
TABLE_NAME	VARCHAR(128)	Name of the indexed object
GROUP_ID	NUMBER	Group identifier of the node where the index placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the index placed
MEMBER_ID	NUMBER	Member identifier of the node where the index placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the index placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
DROPPED	VARCHAR(3)	Indicates whether the index has been dropped and is in the recycle bin (YES) or not (NO)
DISTINCT_KEYS	NUMBER	(deprecated)
SAMPLE_SIZE	NUMBER	(deprecated)
BLOCKS	NUMBER	Number of used blocks of the node where the index placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	(deprecated)

USER_OBJECTS

USER_OBJECTS describes all objects owned by the current user.

Table 9-120 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema of the object
OBJECT_NAME	VARCHAR(128)	Name of the object
SUBOBJECT_NAME	VARCHAR(128)	Name of the subobject (for example, partition)
OBJECT_ID	NUMBER	Dictionary object number of the object
DATA_OBJECT_ID	NUMBER	Dictionary object number of the segment that contains the object
OBJECT_TYPE	VARCHAR(32)	Type of the object (such as TABLE, INDEX)
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp for the creation of the object
LAST_DDL_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp for the last modification of the object resulting from a DDL statement
TIMESTAMP	VARCHAR(32)	Timestamp for the specification of the object (character data)
STATUS	VARCHAR(32)	• reserved Status of the object: the value in (VALID, INVALID, N/A)
TEMPORARY	VARCHAR(1)	Indicates whether the object is temporary (the current session can see only data that it placed in this object itself) (Y) or not (N)
GENERATED	VARCHAR(1)	Indicates whether the name of this object was system-generated (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether this is a secondary object created by the ODCIIndex Create method of the Oracle Data Cartridge (Y) or not (N)
NAMESPACE	NUMBER	Namespace for the object
EDITION_NAME	VARCHAR(128)	• reserved Name of the edition in which the object is actual
DROPPED	VARCHAR(3)	Indicates whether the object has been dropped and is in the recycle bin (YES) or not (NO)

USER_PACKAGE_PRIVS

USER_PACKAGE_PRIVS describes the package grants for which the current user is the package owner, gr antor, or grantee.

Table 9-121 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTI ON (YES) or not (NO)

USER_PACKAGE_PRIVS_MADE

USER_PACKAGE_PRIVS_MADE describes the package grants for which the current user is the package owner.

Table 9-122 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_PACKAGE_PRIVS_RECD

USER_PACKAGE_PRIVS_RECD describes the package grants for which the current user is the grantee.

Table 9-123 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the package
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the package
PROCEDURE_NAME	VARCHAR(128)	Name of the package
PRIVILEGE	VARCHAR(32)	Privilege on the package
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_PROCEDURES

USER_PROCEDURES lists of procedures owned by the current user.

Table 9-124 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema Name of function, procedures or package
OBJECT_NAME	VARCHAR(128)	Name of function, procedures or pacakage
PROCEDURE_NAME	VARCHAR(128)	Name when a procedures in pacakage
OBJECT_ID	NUMBER	ID of a function, procedures or pacakage
SUBPROGRAM_ID	NUMBER	ID of procedures in pacakage
OVERLOAD	VARCHAR(32)	ID of overloading procedure in pacakage
OBJECT_TYPE	VARCHAR(32)	Type of function, procedures or package
AGGREGATE	VARCHAR(3)	Indicate whether the procedure is an aggreage function(YES) or not (NO)
PIPELINED	VARCHAR(3)	Indicate whether the procedure is a pipelined table function(YES) or not(NO)
IMPLTYPEOWNER	VARCHAR(128)	Name of the owner of the implementation type, if any
IMPLTYPENAME	VARCHAR(128)	Name of the implementation type, if any
PARALLEL	VARCHAR(3)	Indicates whether the procedure or function is parallel-enabled (YES) or not (NO)
INTERFACE	VARCHAR(3)	YES, if the procedure/function is a table function implemented usin g the SQLCLI interface; otherwise NO
DETERMINISTIC	VARCHAR(3)	YES, if the procedure/function is declared to be deterministic; other wise NO
AUTHID	VARCHAR(32)	Indicates whether the procedure/function is declared to execute as DEFINER or CURRENT_USER (invoker)

USER_PROC_PRIVS

USER_PROC_PRIVS describes the procedure grants for which the current user is the procedure owner, gr antor, or grantee.

Table 9-125 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTI ON (YES) or not (NO)

USER_PROC_PRIVS_MADE

USER_PROC_PRIVS_MADE describes the procedure grants for which the current user is the procedure owner or grantor.

Table 9-126 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_PROC_PRIVS_RECD

USER_PROC_PRIVS_RECD describes the procedure grants, for which the current user is the grantee, or fo r which an enabled role or PUBLIC is the grantee.

Table 9-127 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
PROCEDURE_OWNER	VARCHAR(128)	Owner of the procedure and function
PROCEDURE_SCHEMA	VARCHAR(128)	Schema of the procedure and function
PROCEDURE_NAME	VARCHAR(128)	Name of the procedure and function
PRIVILEGE	VARCHAR(32)	Privilege on the procedure and function
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTI ON (YES) or not (NO)

USER_RECYCLEBIN

USER_RECYCLEBIN describes recycle bins owned by the current user.

Table 9-128 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema name of the object
OBJECT_NAME	VARCHAR(128)	Name of the object
ORIGINAL_NAME	VARCHAR(128)	Original name of the object
OPERATION	VARCHAR(4)	Operation carried out on the object
OBJECT_TYPE	VARCHAR(32)	Type of the object
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the object
CREATED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	Created time of the object
DROPPED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	Dropped time of the object
DROP_SCN	VARCHAR(128)	System change number (SCN) of the transaction which moved the object to the recycle bin
DROP_GCN	NUMBER	Global change number (GCN) of the transaction which moved the object to the recycle bin
DROP_DCN	NUMBER	Domain change number (DCN) of the transaction which moved the object to the recycle bin
DROP_LCN	NUMBER	Local change number (LCN) of the transaction which moved the object to the recycle bin
CAN_UNDROP	VARCHAR(3)	Indicates whether the object can be undropped (YES) or not (NO)
CAN_PURGE	VARCHAR(3)	Indicates whether the object can be purged (YES) or not (NO)
BASE_OBJECT	NUMBER	Object number of the base object
PURGE_OBJECT	NUMBER	Object number for the object which gets purged

USER_SCHEMAS

Identify the schemata in a catalog that are owned by current user.

Table 9-129 Column information

Column name	Data type	Description
SCHEMA_OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Created time of the schema
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	Last modified time of the schema
COMMENTS	VARCHAR(1024)	Comments of the schema

USER_SCHEMA_PATH

USER_SCHEMA_PATH describes the schema search order of the current user, for naming resolution of un qualified SQL schema objects.

Table 9-130 Column information

Column name	Data type	Description
AUTH_NAME	VARCHAR(128)	Name of the user
SCHEMA_NAME	VARCHAR(128)	Name of the schema
SEARCH_ORDER	NUMBER	Schema search order of the user

USER_SCHEMA_PRIVS

USER_SCHEMA_PRIVS describes the schema grants, for which the current user is the schema owner, gra ntor, or grantee.

Table 9-131 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)

USER_SCHEMA_PRIVS_MADE

USER_SCHEMA_PRIVS_MADE describes the schema grants for which the current user is the schema owner.

Table 9-132 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_SCHEMA_PRIVS_RECD

USER_SCHEMA_PRIVS_RECD describes the schema grants for which the current user is the grantee.

Table 9-133 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the schema
SCHEMA_NAME	VARCHAR(128)	Name of the schema
PRIVILEGE	VARCHAR(32)	Privilege on the schema
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_SEQUENCES

USER_SEQUENCES describes all sequences owned by the current user.

Table 9-134 Column information

Column name	Data type	Description
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Sequence name
MIN_VALUE	NUMBER	Minimum value of the sequence
MAX_VALUE	NUMBER	Maximum value of the sequence
INCREMENT_BY	NUMBER	Value by which sequence is incremented
CYCLE_FLAG	VARCHAR(1)	Indicates whether the sequence wraps around on reaching the limit (Y) or not (N)
ORDER_FLAG	VARCHAR(1)	• reserved Indicates whether sequence numbers are generated in order (Y) or not (N)
CACHE_SIZE	NUMBER	Number of sequence numbers to cache
LAST_NUMBER	NUMBER	Last sequence number written to database. If a sequence uses caching, the number written to database is the last number placed in the sequence cache.
COMMENTS	VARCHAR(1024)	Comments of the sequence

USER_SEQ_PRIVS

USER_SEQ_PRIVS describes the sequence grants for which the current user is the sequence owner, grant or, or grantee.

Table 9-135 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_SEQ_PRIVS_MADE

USER_SEQ_PRIVS_MADE describes the sequence grants for which the current user is the sequence owner.

Table 9-136 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_SEQ_PRIVS_RECD

USER_SEQ_PRIVS_RECD describes the sequence grants for which the current user is the grantee.

Table 9-137 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
SEQUENCE_OWNER	VARCHAR(128)	Owner of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	Schema of the sequence
SEQUENCE_NAME	VARCHAR(128)	Name of the sequence
PRIVILEGE	VARCHAR(32)	Privilege on the sequence
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)

USER_SHARD_KEY_COLUMNS

USER_SHARD_KEY_COLUMNS describes shard key columns of shareded tables owned by the current use r in the cluster system.

It is available only on a cluster.

Table 9-138 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Column name of the shard key
COLUMN_POSITION	NUMBER	Position of the column within the shard key

USER_SOURCE

USER_SOURCE describes the text source of the stored objects accessible to the current user.

Table 9-139 Column information

Column name	Data type	Description
SCHEMA_NAME	VARCHAR(128)	Schema Name of object
NAME	VARCHAR(128)	Name of object
TYPE	VARCHAR(32)	Type of object: FUNCTION, PROCEDURE, PACKAGE, PACKAGE BODY, TRIGGER
LINE	NUMBER	Line number of this line of source
TEXT	LONG VARCHAR	Text source of the strored object
ORIGIN_CON_ID	VARCHAR(256)	ID of the container where the data originates

USER_SYNONYMS

USER_SYNONYMS describes all synonyms owned by the current user.

Table 9-140 Column information

Column name	Data type	Description
SYNONYM_OWNER	VARCHAR(128)	Owner of the synonym
SYNONYM_SCHEMA	VARCHAR(128)	Schema of the synonym
SYNONYM_NAME	VARCHAR(128)	Synonym name
OBJECT_SCHEMA_NAME	VARCHAR(128)	Object schema name
OBJECT_NAME	VARCHAR(128)	Object name
DB_LINK	VARCHAR(128)	Reserved for future use

USER_SYS_PRIVS

USER_SYS_PRIVS describes system (database, tablespace, schema) privileges granted to the current user or PUBLIC.

Table 9-141 Column information

Column name	Data type	Description
USERNAME	VARCHAR(128)	Name of the user, or PUBLIC
PRIVILEGE	VARCHAR(256)	System(database, tablespace, schema) privilege
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
ADMIN_OPTION	VARCHAR(3)	equal to GRANTABLE column

USER_TABLES

USER_TABLES describes the relational tables owned by the current user.

Table 9-142 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace containing the table
CLUSTER_NAME	VARCHAR(128)	• reserved Name of the cluster
IOT_NAME	VARCHAR(128)	• reserved Name of the index-organized table
STATUS	VARCHAR(32)	• reserved If a previous DROP TABLE operation failed, indicates whether the table is unusable (UNUSABLE) or valid (VALID)
PCT_FREE	NUMBER	Minimum percentage of free space in a block
PCT_USED	NUMBER	Minimum percentage of used space in a block
INI_TRANS	NUMBER	Initial number of transactions
MAX_TRANS	NUMBER	Maximum number of transactions
INITIAL_EXTENT	NUMBER	Size of the initial extent (in bytes)
NEXT_EXTENT	NUMBER	Size of secondary extents (in bytes)
MIN_EXTENTS	NUMBER	Minimum number of extents allowed in the segment
MAX_EXTENTS	NUMBER	Maximum number of extents allowed in the segment
PCT_INCREASE	NUMBER	• reserved Percentage increase in extent size
FREELISTS	NUMBER	• reserved Number of process freelists allocated to the segment
FREELIST_GROUPS	NUMBER	• reserved Number of freelist groups allocated to the segment
LOGGING	VARCHAR(3)	Indicates whether or not changes to the table are logged
BACKED_UP	VARCHAR(1)	• reserved Indicates whether the table has been backed up since the last modification (Y) or not (N)
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks in the table
ANAL_BLOCKS	NUMBER	Number of used blocks in the table when most recently analyzed
EMPTY_BLOCKS	NUMBER	• reserved Number of empty (never used) blocks in the table
AVG_SPACE	NUMBER	• reserved Average available free space in the table

Column name	Data type	Description
CHAIN_CNT	NUMBER	• reserved Number of rows in the table that are chained from one data block to another or that have migrated to a new block, requiring a link to preserve the old rowid
AVG_ROW_LEN	NUMBER	• reserved Average row length, including row overhead
AVG_SPACE_FREELIST_BLOCKS	NUMBER	• reserved Average freespace of all blocks on a freelist
NUM_FREELIST_BLOCKS	NUMBER	• reserved Number of blocks on the freelist
DEGREE	VARCHAR(32)	• reserved Number of threads per instance for scanning the table, or DEFAULT
INSTANCES	VARCHAR(32)	• reserved Number of instances across which the table is to be scanned, or DEFAULT
CACHE	VARCHAR(1)	• reserved Indicates whether the table is to be cached in the buffer cache (Y) or not (N)
TABLE_LOCK	VARCHAR(32)	Indicates whether table locking is enabled (ENABLED) or disabled (DISABLED)
SAMPLE_SIZE	NUMBER	Sample size used in analyzing the table
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which the table was most recently analyzed
PARTITIONED	VARCHAR(3)	• reserved Indicates whether the table is partitioned (YES) or not (NO)
IOT_TYPE	VARCHAR(32)	• reserved If the table is an index-organized table, then IOT_TYPE is IOT, IOT_OVERFLOW, or IOT_MAPPING.
TEMPORARY	VARCHAR(1)	Indicates whether the table is temporary (Y) or not (N)
SECONDARY	VARCHAR(1)	• reserved Indicates whether the table is a secondary object created by cartridge
NESTED	VARCHAR(3)	• reserved Indicates whether the table is a nested table (YES) or not (NO)
BUFFER_POOL	VARCHAR(32)	• reserved Buffer pool to be used for table blocks
FLASH_CACHE	VARCHAR(32)	• reserved Database Smart Flash Cache hint to be used for table blocks
CELL_FLASH_CACHE	VARCHAR(32)	• reserved Cell flash cache hint to be used for table blocks
ROW_MOVEME	VARCHAR(32)	• reserved If a partitioned table, indicates whether row movement is enabled (ENABLE

Column name	Data type	Description
NT		D) or disabled (DISABLED)
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether statistics for the table as a whole (global statistics) are accurate (YES)
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
DURATION	VARCHAR(32)	Indicates the duration of a temporary table, the value is in (TRANSACTION, SESSION)
SKIP_CORRUPT	VARCHAR(32)	• reserved Indicates whether Database ignores blocks marked corrupt during table an d index scans (ENABLED) or raises an error (DISABLED)
MONITORING	VARCHAR(3)	• reserved Indicates whether the table has the MONITORING attribute set (YES) or not (NO)
CLUSTER_OWNE R	VARCHAR(128)	• reserved Owner of the cluster, if any
DEPENDENCIES	VARCHAR(32)	• reserved Indicates whether row-level dependency tracking is enabled (ENABLED) or disabled (DISABLED)
COMPRESSION	VARCHAR(32)	• reserved Indicates whether table compression is enabled (ENABLED) or not (DISABLE D)
COMPRESS_FOR	VARCHAR(32)	• reserved Default compression for what kind of operations
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)
READ_ONLY	VARCHAR(3)	Indicates whether the table IS READ-ONLY (YES) or not (NO)
SEGMENT_CREA TED	VARCHAR(3)	Indicates whether the table segment has been created (YES) or not (NO)
RESULT_CACHE	VARCHAR(32)	• reserved Result cache mode annotation for the table: the value in (NULL, DEFAULT, FORCE, MANUAL)

USER_TABLESPACES

USER_TABLESPACES describes the tablespaces accessible to the current user.

Table 9-143 Column information

Column name	Data type	Description
TABLESPACE_NAME	VARCHAR(128)	Name of the tablespace
BLOCK_SIZE	NUMBER	Tablespace block size
INITIAL_EXTENT	NUMBER	• reserved Default initial extent size (in bytes)
NEXT_EXTENT	NUMBER	• reserved Default incremental extent size (in bytes)
MIN_EXTENTS	NUMBER	• reserved Default minimum number of extents
MAX_EXTENTS	NUMBER	• reserved Default maximum number of extents
MAX_SIZE	NUMBER	• reserved Default maximum size of segments
PCT_INCREASE	NUMBER	• reserved Default percent increase for extent size
MIN_EXTLEN	NUMBER	• reserved Minimum extent size for this tablespace (in bytes)
STATUS	VARCHAR(32)	Tablespace status: the value in (ONLINE, OFFLINE, READ ONLY)
CONTENTS	VARCHAR(32)	Tablespace contents: the value in (SYSTEM, DATA, TEMPORARY, UNDO)
LOGGING	VARCHAR(32)	Default logging attribute: LOGGING, NOLOGGING
FORCE_LOGGING	VARCHAR(3)	• reserved Indicates whether the tablespace is under force logging mode (YES) or not (NO)
EXTENT_MANAGEMENT	VARCHAR(32)	• reserved Indicates whether the extents in the tablespace are dictionary managed (DICTIONARY) or locally managed (LOCAL)
ALLOCATION_TYPE	VARCHAR(32)	• reserved Type of extent allocation in effect for the tablespace: the value in (SYSTEM, UNIFORM, USER)
SEGMENT_SPACE_MANAGEMENT	VARCHAR(32)	• reserved Indicates whether the free and used segment space in the tablespace is managed using free lists (MANUAL) or bitmaps (AUTO)
DEF_TAB_COMPRESSION	VARCHAR(32)	• reserved Indicates whether default table compression is enabled (ENABLED) or not (DISABLED)
		• reserved

Column name	Data type	Description
RETENTION	VARCHAR(32)	Undo tablespace retention: the value in (GUARANTEE, NOGUARANTEE, NOT APPLY)
BIGFILE	VARCHAR(3)	• reserved Indicates whether the tablespace is a bigfile tablespace (YES) or a smallfile tablespace (NO)
PREDICATE_EVALUATION	VARCHAR(32)	• reserved Indicates whether predicates are evaluated by host (HOST) or by storage (STORAGE)
ENCRYPTED	VARCHAR(3)	• reserved Indicates whether the tablespace is encrypted (YES) or not (NO)
COMPRESS_FOR	VARCHAR(32)	• reserved Indicates whether the tablespace is encrypted (YES) or not (NO)

USER_TAB_COLS

USER_TAB_COLS describes the columns (including hidden columns) of the tables, views, and clusters owned by the current user.

Table 9-144 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column displays the selectivity of a value that spans fewer than 2 endpoints in the histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_NAME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LENGTH	NUMBER	Declaration length of the character type column
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether column statistics were collected for the table

Column name	Data type	Description
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or C HAR length semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image f ormat (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HIDDEN_COLUMN	VARCHAR(3)	Indicates whether the column is a hidden column (YES) or not (NO)
VIRTUAL_COLUMN	VARCHAR(3)	• reserved Indicates whether the column is a virtual column (YES) or not (NO)
SEGMENT_COLUMN_ID	NUMBER	Sequence number of the column in the segment
INTERNAL_COLUMN_ID	NUMBER	Internal sequence number of the column
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
QUALIFIED_COL_NAME	VARCHAR(4000)	Qualified column name
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

USER_TAB_COLUMNS

USER_TAB_COLUMNS describes the columns of the tables, views, and clusters owned by the current user.

Table 9-145 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COLUMN_NAME	VARCHAR(128)	Column name
DATA_TYPE	VARCHAR(128)	Datatype of the column
DATA_TYPE_MOD	VARCHAR(3)	• reserved Datatype modifier of the column
DATA_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the datatype of the column
DATA_LENGTH	NUMBER	Length of the column (in bytes)
DATA_PRECISION	NUMBER	Decimal precision for NUMBER datatype; binary precision for FLOAT datatype; NULL for all other datatypes
DATA_SCALE	NUMBER	Digits to the right of the decimal point in a number
NULLABLE	VARCHAR(1)	Indicates whether a column allows NULLs.
COLUMN_ID	NUMBER	Sequence number of the column as created
DEFAULT_LENGTH	NUMBER	Length of the default value for the column
DATA_DEFAULT	LONG VARCHAR	Default value for the column
NUM_DISTINCT	NUMBER	Number of distinct values in the column
LOW_VALUE	VARBINARY(32)	Low value in the column
HIGH_VALUE	VARBINARY(32)	High value in the column
DENSITY	NUMBER	• reserved If a histogram is available on COLUMN_NAME, then this column displays the selectivity of a value that spans fewer than 2 endpoints in the histogram.
NUM_NULLS	NUMBER	Number of NULLs in the column
NUM_BUCKETS	NUMBER	• reserved Number of buckets in the histogram for the column
LAST_ANALYZED	TIMESTAMP(6) WITHOUT TIME ZONE	Date on which this column was most recently analyzed
SAMPLE_SIZE	NUMBER	Sample size used in analyzing this column
CHARACTER_SET_NAME	VARCHAR(128)	• reserved Name of the character set
CHAR_COL_DECL_LENGTH	NUMBER	Declaration length of the character type column
GLOBAL_STATS	VARCHAR(3)	• reserved For partitioned tables, indicates whether column statistics were collected for the table

Column name	Data type	Description
USER_STATS	VARCHAR(3)	• reserved Indicates whether statistics were entered directly by the user (YES) or not (NO)
AVG_COL_LEN	NUMBER	Average length of the column (in bytes)
CHAR_LENGTH	NUMBER	Displays the length of the column in characters.
CHAR_USED	VARCHAR(1)	Indicates that the column uses BYTE length semantics (B) or CHAR l ength semantics (C)
V80_FMT_IMAGE	VARCHAR(3)	• reserved Indicates whether the column data is in release older image format (YES) or not (NO)
DATA_UPGRADED	VARCHAR(3)	• reserved Indicates whether the column data has been upgraded to the latest type version format (YES) or not (NO)
HISTOGRAM	VARCHAR(32)	• reserved Indicates existence/type of histogram
IDENTITY_COLUMN	VARCHAR(3)	Indicates whether this is an identity column (YES) or not (NO)

USER_TAB_COMMENTS

USER_TAB_COMMENTS displays comments on the tables and views owned by the current user.

Table 9-146 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
TABLE_TYPE	VARCHAR(32)	Type of the object
COMMENTS	VARCHAR(1024)	Comment on the object

USER_TAB_IDENTITY_COLS

USER_TAB_IDENTITY_COLS describes all table identity columns.

Table 9-147 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
COLUMN_NAME	VARCHAR(128)	Name of the identity column
GENERATION_TYPE	VARCHAR(32)	Generation type of the identity column. Possible values are ALWAYS or BY DEFAULT
IDENTITY_OPTIONS	VARCHAR(1024)	Options for the identity column sequence generator

USER_TAB_PLACE

USER_TAB_PLACE describes node placement of cluster tables owned by the current user in the cluster sys tem.

It is available only on a cluster.

Table 9-148 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
GROUP_ID	NUMBER	Group identifier of the node where the table placed
GROUP_NAME	VARCHAR(128)	Group name of the node where the table placed
MEMBER_ID	NUMBER	Member identifier of the node where the table placed
MEMBER_NAME	VARCHAR(128)	Member name of the node where the table placed
MEMBER_POSITION	NUMBER	Member position of the node where the table placed
MEMBER_OFFLINE	BOOLEAN	data of the cluster member is offline or not
IS_UPDATE_MASTER	BOOLEAN	whether the cluster member is update master or not
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle b in (YES) or not (NO)
SCN	VARCHAR(64)	table scn of the node where the table placed
NUM_ROWS	NUMBER	Number of rows in the table
BLOCKS	NUMBER	Number of used blocks of the node where the table placed
LAST_ANALYZED	TIMESTAMP(6) WITH OUT TIME ZONE	Date on which the table was most recently analyzed

USER_TAB_PRIVS

USER_TAB_PRIVS describes the object grants for which the current user is the object owner, grantor, or g rantee.

Table 9-149 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY O PTION (YES) or not (NO)

USER_TAB_PRIVS_MADE

USER_TAB_PRIVS_MADE describes the object grants for which the current user is the object owner.

Table 9-150 Column information

Column name	Data type	Description
GRANTEE	VARCHAR(128)	Name of the user or role to whom access was granted
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTIO N (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY O PTION (YES) or not (NO)

USER_TAB_PRIVS_RECD

USER_TAB_PRIVS_RECD describes the object grants for which the current user is the grantee.

Table 9-151 Column information

Column name	Data type	Description
OWNER	VARCHAR(128)	Owner of the object
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
GRANTOR	VARCHAR(128)	Name of the user who performed the grant
PRIVILEGE	VARCHAR(32)	Privilege on the object
GRANTABLE	VARCHAR(3)	Indicates whether the privilege was granted with the GRANT OPTION (YES) or not (NO)
HIERARCHY	VARCHAR(3)	Indicates whether the privilege was granted with the HIERARCHY OPTION (YES) or not (NO)

USER_TAB_SHARDS

USER_TAB_SHARDS describes shard information of sharded tables owned by the current user in the clust er system.

It is available only on a cluster.

Table 9-152 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the table
TABLE_NAME	VARCHAR(128)	Name of the table
SHARD_STRATEGY	VARCHAR(32)	Sharding strategy of the table: the value in (HASH SHARDING, RANGE SHARDING, LIST SHARDING)
SHARD_NAME	VARCHAR(128)	Shard name
SHARD_NUMBER	NUMBER	Shard number
SHARD_DEFINITION	LONG VARCHAR	Shard definition (if hash sharded, the value is null)
GROUP_ID	NUMBER	Group identifier where the shard placed
GROUP_NAME	VARCHAR(128)	Group Name where the shard placed
DROPPED	VARCHAR(3)	Indicates whether the table has been dropped and is in the recycle bin (YES) or not (NO)

USER_USERS

USER_USERS describes the current user.

Table 9-153 Column information

Column name	Data type	Description
USERNAME	VARCHAR(128)	Name of the user
USER_ID	NUMBER	ID number of the user
ACCOUNT_STATUS	VARCHAR(32)	Account status: the value in (OPEN, EXPIRED, EXPIRED(GRACE), LOCKED(TIMED), LOCKED, EXPIRED & LOCKED(TIMED), EXPIRED(GRACE) & LOCKED(TIMED), EXPIRED & LOCKED, EXPIRED(GRACE) & LOCKED)
LOCK_DATE	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp the account was locked if account status was LOCKED
EXPIRY_DATE	TIMESTAMP(6) WITHOUT TIME ZONE	Timestamp of expiration of the account
DEFAULT_TABLESPACE	VARCHAR(128)	Default tablespace for data
TEMPORARY_TABLESPACE	VARCHAR(128)	Name of the default tablespace for temporary tables or the name of a tablespace group
INDEX_TABLESPACE	VARCHAR(128)	Default tablespace for index
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	User creation timestamp
INITIAL_RSRC_CONSUMER_GROUP	VARCHAR(128)	• reserved Initial resource consumer group for the user
EXTERNAL_NAME	VARCHAR(128)	• reserved User external name

USER_VIEWS

USER_VIEWS describes the views owned by the current user.

Table 9-154 Column information

Column name	Data type	Description
VIEW_SCHEMA	VARCHAR(128)	Schema of the view
VIEW_NAME	VARCHAR(128)	Name of the view
TEXT_LENGTH	NUMBER	Length of the view text
TEXT	LONG VARCHAR	View text
TYPE_TEXT_LENGTH	NUMBER	• reserved Length of the type clause of the typed view
TYPE_TEXT	VARCHAR(4000)	• reserved Type clause of the typed view
OID_TEXT_LENGTH	NUMBER	• reserved Length of the WITH OID clause of the typed view
OID_TEXT	VARCHAR(4000)	• reserved WITH OID clause of the typed view
VIEW_TYPE_OWNER	VARCHAR(128)	• reserved Owner of the type of the view if the view is a typed view
VIEW_TYPE	VARCHAR(32)	• reserved Type of the view if the view is a typed view
SUPERVIEW_NAME	VARCHAR(128)	• reserved Name of the superview
EDITIONING_VIEW	VARCHAR(1)	Reserved for future use
READ_ONLY	VARCHAR(1)	Indicates whether the view is read-only (Y) or not (N)

Other Views

There are other views or tables which are none of All-family, DBA-family or USER-family.

AUDIT_POLICIES

AUDIT_POLICIES contains one row for each audit policy.

Table 9-155 Column information

Column name	Data type	Description
POLICY_NAME	VARCHAR(128)	audit policy name
ENABLED	VARCHAR(3)	indicates whether the audit policy is enabled (YES) or not (NO)
CREATED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	created time of the audit policy
MODIFIED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	last modified time of the audit policy
COMMENTS	VARCHAR(1024)	comments of the audit policy

AUDIT_POLICY_OPTIONS

AUDIT_POLICY_OPTIONS describes all audit policies created in the database.

Table 9-156 Column information

Column name	Data type	Description
POLICY_NAME	VARCHAR(128)	audit policy name
AUDIT_OPTION	VARCHAR(32)	auditing option defined in the audit policy
AUDIT_OPTION_TYPE	VARCHAR(32)	The values of AUDIT_OPTION_TYPE_NAME in ('DATABASE PRIVILEGE', 'SYSTEM ACTION', 'OBJECT ACTION')
OBJECT_SCHEMA	VARCHAR(128)	schema name, for an object-specific auditing option
OBJECT_NAME	VARCHAR(128)	object name, for an object-specific auditing option
OBJECT_TYPE	VARCHAR(32)	object type name, for an object-specific auditing option
DROPPED	VARCHAR(3)	Indicates whether the object has been dropped and is in the recycle bin (YES) or not (NO)

AUDIT_POLICY_ENABLED

AUDIT_POLICY_ENABLE describes all the audit policies that are enable in the database.

Table 9-157 Column information

Column name	Data type	Description
POLICY_NAME	VARCHAR(128)	audit policy name
ENABLED_OPT	VARCHAR(32)	enable option of the audit policy, the possible values are BY, EXCEPT
USER_NAME	VARCHAR(128)	user name for whom the audit policy is enable
WHEN_SUCCESS	VARCHAR(3)	indicates whether the audit policy is enable for auditing successful events or not
WHEN_FAILURE	VARCHAR(3)	indicates whether the audit policy is enable for auditing unsuccessful events or not

AUDIT_TRAIL

AUDIT_TRAIL displays audit records from the audit trail.

Table 9-158 Column information

Column name	Data type	Description
MEMBER_NAME	VARCHAR(128)	cluster member name
SESSION_ID	NUMBER	session identifier
SESSION_SERIAL	NUMBER	session serial number
LOGON_USERNAME	VARCHAR(128)	logon user name of the user whose actions were audited
CURRENT_USERNAME	VARCHAR(128)	effective user for the statement execution
SERVER_PROCESS	NUMBER	server process identifer for the session
CLIENT_PROGRAM_NAME	VARCHAR(128)	client program used for session
CLIENT_USERNAME	VARCHAR(128)	client operating system user name for the session
CLIENT_PROCESS	NUMBER	client process identifer for the session
CLIENT_HOST	VARCHAR(128)	client host ip address for the session
CLIENT_PORT	NUMBER	client port number for the session
CLIENT_TERMINAL	VARCHAR(128)	client terminal name for the session
TRANSACTION_ID	NUMBER	transaction identifier
SCN	VARCHAR(128)	system change number (SCN) string of the query at the time of the event
GCN	NUMBER	global change number (GCN) of the query at the time of the event
DCN	NUMBER	domain change number (DCN) of the query at the time of the event
LCN	NUMBER	local change number (LCN) of the query at the time of the event
STMT_NO	NUMBER	numeric number for each statement run in a session
SQL_TEXT	LONG VARCHAR	SQL associated with the event
SQL_BINDS	LONG VARCHAR	list of bind variables, if any, associated with SQL_TEXT
RETURN_CODE	NUMBER	error code generated by the action, zero if the action succeeded
ERROR_MESSAGE	VARCHAR(1024)	error message generated by the action, null if the action succeeded
ENTRY_ID	NUMBER	audit trail entry identifier in the session
EVENT_TIMESTAMP	TIMESTAMP(6) WITHOUT TIME ZONE	timestamp of the creation of the audit trail entry in local time zone
POLICY_NAME	VARCHAR(128)	audit policy name that caused the current audit record
PRIVILEGE_USED	VARCHAR(32)	database privilege used to execute the action
ACTION_NAME	VARCHAR(32)	action name executed by the user

Column name	Data type	Description
OBJECT_TYPE	VARCHAR(32)	object type of object affected by the action
OBJECT_SCHEMA	VARCHAR(128)	schema name of object affected by the action
OBJECT_NAME	VARCHAR(128)	object name of object affected by the action

DATABASE_PROPERTIES

DATABASE_PROPERTIES lists permanent database properties.

Table 9-159 Column information

Column name	Data type	Description
PROPERTY_NAME	VARCHAR(128)	Property name
PROPERTY_VALUE	VARCHAR(4000)	Property value
DESCRIPTION	VARCHAR(4000)	Property description

DBC_TABLE_TYPE_INFO

Identify the ODBC/JDBC table types available in this database.

Table 9-160 Column information

Column name	Data type	Description
DBC_TABLE_TYPE_ID	NUMBER	number identifier of the table type in ODBC/JDBC
DBC_TABLE_TYPE	VARCHAR(128)	name of the table type in ODBC/JDBC
IS_SUPPORTED	BOOLEAN	is supported feature
COMMENTS	VARCHAR(1024)	comments of the table type

DICTIONARY

DICTIONARY contains descriptions of data dictionary tables and views.

Table 9-161 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
COMMENTS	VARCHAR(1024)	Text comment on the object

DICT_COLUMNS

DICT_COLUMNS contains descriptions of columns in data dictionary tables and views.

Table 9-162 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object that contains the column
TABLE_NAME	VARCHAR(128)	Name of the object that contains the column
COLUMN_NAME	VARCHAR(128)	Name of the column
COMMENTS	VARCHAR(1024)	Text comment on the column

IMPLEMENTATION_INFO

IMPLEMENTATION_INFO contains information about various aspects that are left implementation-defined.

Table 9-163 Column information

Column name	Data type	Description
IMPLEMENTATION_INFO_ID	NUMBER	identifier of the implementation item
IMPLEMENTATION_INFO_NAME	VARCHAR(1024)	descriptive name of the implementation item
INTEGER_VALUE	NUMBER	Value of the implementation item, or null if the value is contained in the column CHARACTER_VALUE
CHARACTER_VALUE	VARCHAR(1024)	Value of the implementation item, or null if the value is contained in the column INTEGER_VALUE
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the implementation item

IMPLEMENTATION_INFO_BASE

The IMPLEMENTATION_INFO_BASE table has one row for each implementation information item.

Table 9-164 Column information

Column name	Data type	Description
ID	VARCHAR(32)	identifier string of the implementation item
SUB_ID	VARCHAR(32)	identifier string of the implementation item
NAME	VARCHAR(1024)	descriptive name of the implementation item
SUB_NAME	VARCHAR(1024)	descriptive name of the implementation item
IS_SUPPORTED	BOOLEAN	TRUE if the implementation item is supported, FALSE if not
INTEGER_VALUE	NUMBER	Value of the implementation item, or null if the value is contained in the column CHARACTER_VALUE
CHARACTER_VALUE	VARCHAR(1024)	Value of the implementation item, or null if the value is contained in the column INTEGER_VALUE
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the implementation item

JDBC_CLIENT_PROPS

JDBC_CLIENT_PROPS is the set of jdbc client properties.

Table 9-165 Column information

Column name	Data type	Description
NAME	VARCHAR(128)	property name
MAX_LEN	NATIVE_INTEGER	max length of a value
DEFAULT_VALUE	VARCHAR(128)	default value
DESCRIPTION	VARCHAR(256)	descrption on that property

PRODUCT

PRODUCT is about the product name, version for ODBC, JDBC interface.

Table 9-166 Column information

Column name	Data type	Description
NAME	VARCHAR(32)	the product name
VERSION	VARCHAR(128)	product full version information
PRODUCT_VERSION	NUMBER	product version
MAJOR_VERSION	NUMBER	major version
MINOR_VERSION	NUMBER	minor version
PATCH_VERSION	NUMBER	patch version

SESSION_PRIVS

SESSION_PRIVS describes the privileges that are currently available to the user.

Table 9-167 Column information

Column name	Data type	Description
PRIVILEGE	VARCHAR(256)	Name of the privilege

SUPPLEMENTAL_LOG_TABLE_INFO

SUPPLEMENTAL_LOG_TABLE_INFO describes table-level supplemental logging status.

Table 9-168 Column information

Column name	Data type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema of the object
TABLE_NAME	VARCHAR(128)	Name of the object
SUPPLEMENTAL_LOG_DATA_PK	VARCHAR(32)	Status of table-level PRIMARY KEY COLUMNS supplemental logging: IMPLICIT, EXPLICIT, NO
DROPPED	VARCHAR(3)	Indicates whether the object has been dropped and is in the recycle bin (YES) or not (NO)

Aliased Synonym

It is the public synonym which indicates the view or table in DICTIONARY_SCHEMA.

COLS

COLS is a public synonym for USER_TAB_COLUMNS.

DICT

DICT is a public synonym for DICTIONARY.

IND

IND is a public synonym for USER_INDEXES.

OBJ

OBJ is a public synonym for USER_OBJECTS.

SEQ

SEQ is a public synonym for USER_SEQUENCES.

TABS

TABS is a public synonym for USER_TABLES.

RECYCLEBIN

RECYCLEBIN is a public synonym for USER_RECYCLEBIN.

9.2 INFORMATION_SCHEMA

Views of INFORMATION_SCHEMA schema provides the same information as those defined in the SQL sta
ndard.

Execute *InformationSchema.sql* as follows to use the views.

- For standalone

```
% gsql sys gliese --as sysdba --import
$GOLDILOCKS_HOME/admin/standalone/InformationSchema.sql
```

- For cluster

```
% gsql sys gliese --as sysdba --import  $GOLDILOCKS_HOME/admin/cluster/InformationSchema.sql
```

- Views and tables of INFORMATION_SCHEMA can be retrieved from OPEN phase.
- Objects stored in the recyclebin can not be retrieved in the view of INFORMATION_SCHEM
  A.

COLUMNS

Identify the columns of tables defined in this cataog that are accessible to given user or role.

Table 9-169 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the column
TABLE_OWNER	VARCHAR(128)	owner name of the column
TABLE_SCHEMA	VARCHAR(128)	schema name of the column
TABLE_NAME	VARCHAR(128)	table name of the column
COLUMN_NAME	VARCHAR(128)	column name
ORDINAL_POSITION	NUMBER	the ordinal position (> 0) of the column in the table
COLUMN_DEFAULT	LONG VARCHAR	the default for the column
IS_NULLABLE	BOOLEAN	is nullable of the column
DATA_TYPE	VARCHAR(128)	the standard name of the data type
CHARACTER_MAXIMUM_LENGTH	NUMBER	the maximum length in characters
CHARACTER_OCTET_LENGTH	NUMBER	the maximum length in octets
NUMERIC_PRECISION	NUMBER	the numeric precision of the numerical Data type
NUMERIC_PRECISION_RADIX	NUMBER	the radix (2 or 10) of the precision of the numerical data type
NUMERIC_SCALE	NUMBER	the numeric scale of the exact numerical data type
DATETIME_PRECISION	NUMBER	for a datetime or interval type, the value is the fractional seconds precision
INTERVAL_TYPE	VARCHAR(32)	for a interval type, the value is in (YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, YEAR TO MONTH, DAY TO HOUR, DAY TO MINUTE, DAY TO SECOND, HOUR TO MINUTE, HOUR TO SECOND, MINUTE TO SECOND)
INTERVAL_PRECISION	NUMBER	for a interval type, the value is the leading precision
CHARACTER_SET_CATALOG	VARCHAR(128)	catalog name of the character set if is is a character string type
CHARACTER_SET_SCHEMA	VARCHAR(128)	schema name of the character set if is is a character string type
CHARACTER_SET_NAME	VARCHAR(128)	character set name of the character set if is is a character string type
COLLATION_CATALOG	VARCHAR(128)	catalog name of the applicable collation if is is a character string type
COLLATION_SCHEMA	VARCHAR(128)	schema name of the applicable collation if is is a character string type
COLLATION_NAME	VARCHAR(128)	collation name of the applicable collation if is is a character

Column name	Data type	Description
		string type
DOMAIN_CATALOG	VARCHAR(128)	catalog name of the domain used by the column being described
DOMAIN_SCHEMA	VARCHAR(128)	schema name of the domain used by the column being described
DOMAIN_NAME	VARCHAR(128)	domain name of the domain used by the column being described
UDT_CATALOG	VARCHAR(128)	catalog name of the user-defined type of the data type being described
UDT_SCHEMA	VARCHAR(128)	schema name of the user-defined type of the data type being described
UDT_NAME	VARCHAR(128)	user-defined type name of the user-defined type of the data type being described
SCOPE_CATALOG	VARCHAR(128)	catalog name of the referenceable table if DATA_TYPE is REF
SCOPE_SCHEMA	VARCHAR(128)	schema name of the referenceable table if DATA_TYPE is REF
SCOPE_NAME	VARCHAR(128)	scope name of the referenceable table if DATA_TYPE is REF
MAXIMUM_CARDINALITY	NUMBER	maximum cardinality if DATA_TYPE is ARRAY
DTD_IDENTIFIER	NUMBER	data type descriptor identifier
IS_SELF_REFERENCING	BOOLEAN	is a self-referencing column
IS_IDENTITY	BOOLEAN	is an identity column
IDENTITY_GENERATION	VARCHAR(32)	for an identity column, the value is in (ALWAYS, BY DEFAULT)
IDENTITY_START	NUMBER	for an identity column, the start value of the identity column
IDENTITY_INCREMENT	NUMBER	for an identity column, the increment of the identity column
IDENTITY_MAXIMUM	NUMBER	for an identity column, the maximum value of the identity column
IDENTITY_MINIMUM	NUMBER	for an identity column, the minimum value of the identity column
IDENTITY_CYCLE	BOOLEAN	for an identity column, the cycle option
IS_GENERATED	BOOLEAN	is a generated column
GENERATION_EXPRESSION	VARCHAR(128)	for a generated column, the text of the generation expression
IS_SYSTEM_VERSION_START	BOOLEAN	is a system-version start column
IS_SYSTEM_VERSION_END	BOOLEAN	is a system-version end column
SYSTEM_VERSION_TIMESTAMP_GENERATION	VARCHAR(32)	for a system-version column, the value is ALWAYS
IS_UPDATABLE	BOOLEAN	is an updatable column
DECLARED_DATA_TYPE	VARCHAR(128)	the data type name that a user declared

Column name	Data type	Description
DECLARED_NUMERIC_PRECISION	NUMBER	the precision value that a user declared
DECLARED_NUMERIC_SCALE	NUMBER	the scale value that a user declared
COMMENTS	VARCHAR(1024)	comments of the column

COLUMN_PRIVILEGES

Identify the privileges on columns of tables defined in this catalog that are available to or granted by a giv en user or role.

Table 9-170 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	authorization name of the user who granted column privileges
GRANTEE	VARCHAR(128)	authorization name of some user or role, or PUBLIC to indicate all us ers, to whom the column privilege being described is granted
TABLE_CATALOG	VARCHAR(128)	catalog name of the column on which the privilege being described was granted
TABLE_OWNER	VARCHAR(128)	table owner name of the column on which the privilege being descri bed was granted
TABLE_SCHEMA	VARCHAR(128)	schema name of the column on which the privilege being described was granted
TABLE_NAME	VARCHAR(128)	table name of the column on which the privilege being described w as granted
COLUMN_NAME	VARCHAR(128)	column name of the column on which the privilege being described was granted
PRIVILEGE_TYPE	VARCHAR(32)	the value is in (SELECT, INSERT, UPDATE, REFERENCES)
IS_GRANTABLE	BOOLEAN	is grantable

CONSTRAINT_COLUMN_USAGE

Identify the columns used by referential constraints, unique constraints, check constraints, and assertions defined in this catalog and owned by a given user or role.

Table 9-171 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the column that participates in the constraint being described
TABLE_OWNER	VARCHAR(128)	owner name of the column that participates in the constraint being described
TABLE_SCHEMA	VARCHAR(128)	schema name of the column that participates in the constraint bein g described
TABLE_NAME	VARCHAR(128)	table name of the column that participates in the constraint being d escribed
COLUMN_NAME	VARCHAR(128)	column name that participates in the constraint being described
CONSTRAINT_CATAL OG	VARCHAR(128)	catalog name of the constraint
CONSTRAINT_OWNE R	VARCHAR(128)	owner name of the constraint
CONSTRAINT_SCHE MA	VARCHAR(128)	schema name of the constraint
CONSTRAINT_NAME	VARCHAR(128)	constraint name

CONSTRAINT_TABLE_USAGE

Identify the tables that are used by referential constraints, unique constraints, check constraints, and asse rtions defined in this catalog and owned by a given user or role.

Table 9-172 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the table that participates in the constraint being d escribed
TABLE_OWNER	VARCHAR(128)	owner name of the table that participates in the constraint being de scribed
TABLE_SCHEMA	VARCHAR(128)	schema name of the table that participates in the constraint being d escribed
TABLE_NAME	VARCHAR(128)	table name that participates in the constraint being described
CONSTRAINT_CATAL OG	VARCHAR(128)	catalog name of the constraint
CONSTRAINT_OWNE R	VARCHAR(128)	owner name of the constraint
CONSTRAINT_SCHE MA	VARCHAR(128)	schema name of the constraint
CONSTRAINT_NAME	VARCHAR(128)	constraint name

INFORMATION_SCHEMA_CATALOG_NAME

Identify the catalog that contains the Information Schema

Table 9-173 Column information

Column name	Data type	Description
CATALOG_NAME	VARCHAR(128)	the name of catalog in which this Information Schema resides

KEY_COLUMN_USAGE

Identify the columns defined in this catalog that are constrained as keys and that are accessible by a given user or role.

Table 9-174 Column information

Column name	Data type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	catalog name of the constraint
CONSTRAINT_OWNER	VARCHAR(128)	owner name of the constraint
CONSTRAINT_SCHEMA	VARCHAR(128)	schema name of the constraint
CONSTRAINT_NAME	VARCHAR(128)	constraint name
TABLE_CATALOG	VARCHAR(128)	catalog name of the column that participates in the constraint being described
TABLE_OWNER	VARCHAR(128)	owner name of the column that participates in the constraint being described
TABLE_SCHEMA	VARCHAR(128)	schema name of the column that participates in the constraint being described
TABLE_NAME	VARCHAR(128)	table name of the column that participates in the constraint b eing described
COLUMN_NAME	VARCHAR(128)	column name that participates in the constraint being describe d
ORDINAL_POSITION	NUMBER	the ordinal position of the specific column in the constraint be ing described. If the constraint described is a key of cardinality 1 (one), then the value of ORDINAL_POSITION is always 1 (on e).
POSITION_IN_UNIQUE_CO NSTRAINT	NUMBER	If the constraint being described is a foreign key constraint, th en the value of POSITION_IN_UNIQUE_CONSTRAINT is the ord inal position of the referenced column corresponding to the re ferencing column being described, in the corresponding uniqu e key constraint.

MODULES

Identify the SQL-server modules in this catalog that are accessible to a given user or role.

Table 9-175 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
DEFAULT_CHARACTER_SET_CATALOG	VARCHAR(128)	default character set catalog name of the SQL-server module
DEFAULT_CHARACTER_SET_SCHEMA	VARCHAR(128)	default character set schema name of the SQL-server module
DEFAULT_CHARACTER_SET	VARCHAR(128)	default character set name of the SQL-server module
DEFAULT_SCHEMA_CATALOG	VARCHAR(128)	catalog name of default schema of SQL-server module
DEFAULT_SCHEMA_NAME	VARCHAR(128)	default scheam name of the SQL-server module
MODULE_DEFINITION	LONG VARCHAR	definition of the SQL-server module
MODULE_AUTHORIZATION	VARCHAR(32)	authorization of the SQL-server module(DEFINER/INVOKER)
SQL_PATH	VARCHAR(1024)	described SQL PATH when the SQL-server module is defined
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	creation time of the SQL-server module
LAST_ALTERED	TIMESTAMP(6) WITHOUT TIME ZONE	most lately altered time of the SQL-server module

MODULE_BODY

Identify the SQL-server module bodies in this catalog that are accessible to a given user or role.

Table 9-176 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module'
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
MODULE_DEFINITION	LONG VARCHAR	definition of the SQL-server module body
CREATED	TIMESTAMP(6) WITH OUT TIME ZONE	creation time of the SQL-server module body
LAST_ALTERED	TIMESTAMP(6) WITH OUT TIME ZONE	most lately altered time of the SQL-server module body

MODULE_BODY_MODULE_USAGE

Identify the SQL-server modules owned by a given user or role on which SQL-server module bodies define d in this catalog are dependent.

Table 9-177 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
REF_MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module of contained in definit ion text of the SQL-server module body
REF_MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module of contained in definiti on text of the SQL-server module body
REF_MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module of contained in defini tion text of the SQL-server module body
REF_MODULE_NAME	VARCHAR(128)	SQL-server module name of contained in definition text of the SQL-server module body

MODULE_BODY_ROUTINE_USAGE

Identify the SQL-invoked routines owned by a given user or role on which SQL-server module bodies defi ned in this catalog are dependent.

Table 9-178 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
ROUTINE_CATALOG	VARCHAR(128)	catalog name of the SQL-invoked routine of contained in definition t ext of the SQL-server module body
ROUTINE_OWNER	VARCHAR(128)	owner name of the SQL-invoked routine of contained in definition t ext of the SQL-server module body
ROUTINE_SCHEMA	VARCHAR(128)	schema name of the SQL-invoked routine of contained in definition text of the SQL-server module body
ROUTINE_NAME	VARCHAR(128)	SQL-invoked routine name of contained in definition text of the SQL -server module body

MODULE_BODY_SEQUENCE_USAGE

Identify the sequences owned by a given user or role on which SQL-server module bodies defined in this c atalog are dependent.

Table 9-179 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
SEQUENCE_CATALOG	VARCHAR(128)	catalog name of the sequence of contained in definition text of t he SQL-server module body
SEQUENCE_OWNER	VARCHAR(128)	owner name of the sequence of contained in definition text of t he SQL-server module body
SEQUENCE_SCHEMA	VARCHAR(128)	schema name of the sequence of contained in definition text of the SQL-server module body
SEQUENCE_NAME	VARCHAR(128)	sequence name of contained in definition text of the SQL-server module body

MODULE_BODY_TABLE_USAGE

Identify the tables owned by a given user or role on which SQL-server module bodies defined in this catal og are dependent.

Table 9-180 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
TABLE_CATALOG	VARCHAR(128)	catalog name of the table of contained in definition text of the SQL-server module body
TABLE_OWNER	VARCHAR(128)	owner name of the table of contained in definition text of the SQL-s erver module body
TABLE_SCHEMA	VARCHAR(128)	schema name of the table of contained in definition text of the SQL-server module body
TABLE_NAME	VARCHAR(128)	table name of contained in definition text of the SQL-server module body

MODULE_MODULE_USAGE

Identify the SQL-server modules owned by a given user or role on which SQL-server modules defined in th is catalog are dependent.

Table 9-181 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
REF_MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module of contained in definit ion text of the SQL-server module
REF_MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module of contained in definiti on text of the SQL-server module
REF_MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module of contained in defini tion text of the SQL-server module
REF_MODULE_NAME	VARCHAR(128)	SQL-server module name of contained in definition text of the SQL-server module

MODULE_PRIVILEGES

Identify the privileges on SQL-server modules defined in this catalog that are available to or granted by a given user or role.

Table 9-182 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	authorization name of the user who granted SQL-server module privileges
GRANTEE	VARCHAR(128)	authorization name of some user or role, or PUBLIC to indicate all users, to whom the SQL-server module privilege being described is granted
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module on which the privilege being described was granted
MODULE_OWNER	VARCHAR(128)	owner name of the the SQL-server module on which the privilege being described was granted
MODULE_SCHEMA	VARCHAR(128)	schema name of the the SQL-server module on which the privilege being described was granted
MODULE_NAME	VARCHAR(128)	name of the the SQL-server module on which the privilege being described was granted
PRIVILEGE_TYPE	VARCHAR(32)	the value is in (EXECUTE)
IS_GRANTABLE	BOOLEAN	is grantable

MODULE_ROUTINE_USAGE

Identify the SQL-invoked routines owned by a given user or role on which SQL-server modules defined in this catalog are dependent.

Table 9-183 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
ROUTINE_CATALOG	VARCHAR(128)	catalog name of the SQL-invoked routine of contained in definition text of the SQL-server module
ROUTINE_OWNER	VARCHAR(128)	owner name of the SQL-invoked routine of contained in definition text of the SQL-server module
ROUTINE_SCHEMA	VARCHAR(128)	schema name of the SQL-invoked routine of contained in definition text of the SQL-server module
ROUTINE_NAME	VARCHAR(128)	SQL-invoked routine name of contained in definition text of the SQL-server module

MODULE_SEQUENCE_USAGE

Identify the sequences owned by a given user or role on which SQL-server modules defined in this catalog are dependent.

Table 9-184 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
SEQUENCE_CATALOG	VARCHAR(128)	catalog name of the sequence of contained in definition text of t he SQL-server module
SEQUENCE_OWNER	VARCHAR(128)	owner name of the sequence of contained in definition text of t he SQL-server module
SEQUENCE_SCHEMA	VARCHAR(128)	schema name of the sequence of contained in definition text of the SQL-server module
SEQUENCE_NAME	VARCHAR(128)	sequence name of contained in definition text of the SQL-server module

MODULE_TABLE_USAGE

Identify the tables owned by a given user or role on which SQL-server modules defined in this catalog are dependent.

Table 9-185 Column information

Column name	Data type	Description
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module
MODULE_NAME	VARCHAR(128)	name of the SQL-server module
TABLE_CATALOG	VARCHAR(128)	catalog name of the table of contained in definition text of the SQL-server module
TABLE_OWNER	VARCHAR(128)	owner name of the table of contained in definition text of the SQL-server module
TABLE_SCHEMA	VARCHAR(128)	schema name of the table of contained in definition text of the SQL-server module
TABLE_NAME	VARCHAR(128)	table name of contained in definition text of the SQL-server module

PARAMETERS

Identify the SQL parameters of SQL-invoked routines defined in this catalog that are accessible to a given user or role.

Table 9-186 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	catalog name of the specific name of the SQL- invoke d routine that contains the SQL parameter being descr ibed
SPECIFIC_OWNER	VARCHAR(128)	owner name of the specific name of the SQL- invoked routine that contains the SQL parameter being describ ed
SPECIFIC_SCHEMA	VARCHAR(128)	schema name of the specific name of the SQL- invoke d routine that contains the SQL parameter being descr ibed
SPECIFIC_NAME	VARCHAR(128)	specific name of the SQL- invoked routine that contai ns the SQL parameter being described
ORDINAL_POSITION	NUMBER	ordinal position of the SQL- invoked routine that cont ains the SQL parameter being described
PARAMETER_MODE	VARCHAR(32)	parameter mode of the SQL parameter being describe d
IS_RESULT	BOOLEAN	the parameter is RESULT parameter of type-preserving function
AS_LOCATOR	BOOLEAN	the parameter is passed as locator
PARAMETER_NAME	VARCHAR(128)	name of the SQL parameter being descaibed
FROM_SQL_SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the from-sql routine for the i nput parameter being described
FROM_SQL_SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the from-sql routine for the i nput parameter being described
FROM_SQL_SPECIFIC_NAME	VARCHAR(128)	specific name of the from-sql routine for the input par ameter being described
TO_SQL_SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the to-sql routine for the inp ut parameter being described
TO_SQL_SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the to-sql routine for the inp ut parameter being described
TO_SQL_SPECIFIC_NAME	VARCHAR(128)	specific name of the to-sql routine for the input para meter being described
DATA_TYPE	VARCHAR(128)	data type of the SQL parameter being described
CHARACTER_MAXIMUM_LENGTH	NUMBER	maximum length of the SQL parameter being describe d
		maximum length in octets of the SQL parameter bein

Column name	Data type	Description
CHARACTER_OCTET_LENGTH	NUMBER	g described
CHARACTER_SET_CATALOG	VARCHAR(128)	character set catalog name of the data type of the SQL parameter being described
CHARACTER_SET_SCHEMA	VARCHAR(128)	character set schema name of the data type of the SQL parameter being described
CHARACTER_SET_NAME	VARCHAR(128)	character set name of the data type of the SQL parameter being described
COLLATION_CATALOG	VARCHAR(128)	collation catalog name of the data type of the SQL parameter being described
COLLATION_SCHEMA	VARCHAR(128)	collation schema name of the data type of the SQL parameter being described
COLLATION_NAME	VARCHAR(128)	collation name of the data type of the SQL parameter being described
NUMERIC_PRECISION	NUMBER	precision of the data type of the SQL parameter being described
NUMERIC_PRECISION_RADIX	NUMBER	precision radix of the data type of the SQL parameter being described
NUMERIC_SCALE	NUMBER	scale of the data type of the SQL parameter being described
DATETIME_PRECISION	NUMBER	fractional second precisions of the data type of the SQL parameter being described
INTERVAL_TYPE	VARCHAR(32)	interval qualifier of the data type of the SQL parameter being described
INTERVAL_PRECISION	NUMBER	interval precision of the data type of the SQL parameter being described
UDT_CATALOG	VARCHAR(128)	catalog name of UDT of the data type of the SQL parameter being described
UDT_SCHEMA	VARCHAR(128)	schema name of UDT of the data type of the SQL parameter being described
UDT_NAME	VARCHAR(128)	name of UDT of the data type of the SQL parameter being described
SCOPE_CATALOG	VARCHAR(128)	catalog name of referenceable tables of the data type of the SQL parameter being described
SCOPE_SCHEMA	VARCHAR(128)	schema name of referenceable tables of the data type of the SQL parameter being described
SCOPE_NAME	VARCHAR(128)	name of referenceable tables of the data type of the SQL parameter being described
MAXIMUM_CARDINALITY	NUMBER	maximum cardinality of the data type of the SQL parameter being described
DTD_IDENTIFIER	NUMBER	dtd identifier of the data type of the SQL parameter being described
		declared data type of the SQL parameter being descri

Column name	Data type	Description
DECLARED_DATA_TYPE	VARCHAR(128)	bed
DECLARED_NUMERIC_PRECISION	NUMBER	precision of declared data type of the SQL parameter being described
DECLARED_NUMERIC_SCALE	NUMBER	scale of declared data type of the SQL parameter bein g described
PARAMETER_DEFAULT	LONG VARCHAR	default value of the SQL parameter being described

REFERENTIAL_CONSTRAINTS

Identify the referential constraints defined on tables in this catalog that are accssible to a given user or rol e.

Table 9-187 Column information

Column name	Data type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	catalog name of the referential constraint
CONSTRAINT_OWNER	VARCHAR(128)	owner name who owns the referential constraint
CONSTRAINT_SCHEMA	VARCHAR(128)	schema name of the referential constraint being described
CONSTRAINT_NAME	VARCHAR(128)	referential constraint name
CONSTRAINT_TABLE_NAME	VARCHAR(128)	name of the table to which the referential constraint being described applies
CONSTRAINT_COLUMN_NAME	VARCHAR(128)	column name of the table to which the referential constraint being described applies
ORDINAL_POSITION	NUMBER	the ordinal position of the specific column in the referentail constraint being described.
UNIQUE_CONSTRAINT_CATALOG	VARCHAR(128)	catalog name of the unique or primary key constraint applied to the referenced column list being described
UNIQUE_CONSTRAINT_OWNER	VARCHAR(128)	owner name of the unique or primary key constraint applied to the referenced column list being described
UNIQUE_CONSTRAINT_SCHEMA	VARCHAR(128)	schema name of the unique or primary key constraint applied to the referenced column list being described
UNIQUE_CONSTRAINT_NAME	VARCHAR(128)	constraint name of the unique or primary key constraint applied to the referenced column list being described
UNIQUE_CONSTRAINT_TABLE_NAME	VARCHAR(128)	table name of the unique or primary key constraint applied to the referenced column list being described
UNIQUE_CONSTRAINT_COLUMN_NAME	VARCHAR(128)	column name of the unique or primary key constraint applied to the referenced column list being described
IS_PRIMARY_KEY	BOOLEAN	whether the constraint applied to the referenced column list being described, is primary key or not
MATCH_OPTION	VARCHAR(32)	the referential constraint that has a match option: the value in (SIMPLE, PARTIAL, FULL)
UPDATE_RULE	VARCHAR(32)	the referential constraint that has an update rule: the value in (NO ACTION, RESTRICT, CASCADE, SET NULL, SET DEFAULT)
		the referential constraint that has a delete rule: the value in (NO ACTION, R

Column name	Data type	Description
DELETE_RULE	VARCHAR(32)	ESTRICT, CASCADE, SET NULL, SET DEFAULT)
IS_DEFERRABLE	BOOLEAN	is a deferrable constraint
INITIALLY_DEFERRED	BOOLEAN	is an initially deferred constraint

ROUTINES

Identify the SQL-invoked routines in this catalog that are accessible to a given user or role.

Table 9-188 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the routine
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the routine
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the routine
SPECIFIC_NAME	VARCHAR(128)	specific name of the routine
ROUTINE_CATALOG	VARCHAR(128)	catalog name of the routine
ROUTINE_OWNER	VARCHAR(128)	owner name of the routine
ROUTINE_SCHEMA	VARCHAR(128)	schema name of the routine
ROUTINE_NAME	VARCHAR(128)	null
ROUTINE_TYPE	VARCHAR(128)	name of the routine
MODULE_CATALOG	VARCHAR(128)	module name of the routine
MODULE_SCHEMA	VARCHAR(128)	schema name of the module in which the routine is defined
MODULE_NAME	VARCHAR(128)	name of the module in which the routine is defined
UDT_CATALOG	VARCHAR(128)	catalog name of the user-defined data type which defined the routine as a method function
UDT_SCHEMA	VARCHAR(128)	schema name of the user-defined data type which defined the routine as a method function
UDT_NAME	VARCHAR(128)	name of the user-defined data type which defined the routine as a method function
DATA_TYPE	VARCHAR(128)	data type the routine returns
CHARACTER_MAXIMUM_LENGTH	NUMBER	maximum character length of data type the routine returns
CHARACTER_OCTET_LENGTH	NUMBER	maximum character length in octets of data type the routine returns
CHARACTER_SET_CATALOG	VARCHAR(128)	character set catalog name of data type the routine returns
CHARACTER_SET_SCHEMA	VARCHAR(128)	character set schema name of data type the routine returns
CHARACTER_SET_NAME	VARCHAR(128)	character set name of data type the routine returns
COLLATION_CATALOG	VARCHAR(128)	collation catalog name of data type the routine returns
COLLATION_SCHEMA	VARCHAR(128)	collation schema name of data type the routine returns
COLLATION_NAME	VARCHAR(128)	collation name of data type the routine returns
NUMERIC_PRECISION	NUMBER	precision of data type the routine returns
NUMERIC_PRECISION_RADIX	NUMBER	precision radix of data type the routine returns
NUMERIC_SCALE	NUMBER	scale of data type the routine returns

Column name	Data type	Description
DATETIME_PRECISION	NUMBER	fractional seconds precision of data type the routine returns
INTERVAL_TYPE	VARCHAR(32)	interval qualifier for data type the routine returns
INTERVAL_PRECISION	NUMBER	interval leading field precision of data type the routine returns
TYPE_UDT_CATALOG	VARCHAR(128)	catalog name of the user-defined data type, which is the data type the routine returns
TYPE_UDT_SCHEMA	VARCHAR(128)	schema name of the user-defined data type, which is the data type the routine returns
TYPE_UDT_NAME	VARCHAR(128)	name of the user-defined data type, which is the data type the routine returns
SCOPE_CATALOG	VARCHAR(128)	catalog name of referenceable table
SCOPE_SCHEMA	VARCHAR(128)	schema name of referenceable table
SCOPE_NAME	VARCHAR(128)	name of referenceable table
MAXIMUM_CARDINALITY	NUMBER	maximum cardinality of data type the routine returns
DTD_IDENTIFIER	NUMBER	dtd ientifier of data type the routine returns
ROUTINE_BODY	VARCHAR(32)	type of the routine body
ROUTINE_DEFINITION	LONG VARCHAR	catalog name of the routine
EXTERNAL_NAME	VARCHAR(128)	external name of the external routine
EXTERNAL_LANGUAGE	VARCHAR(32)	language of the external routine
PARAMETER_STYLE	VARCHAR(32)	SQL parameter passing style of the external routine
IS_DETERMINISTIC	BOOLEAN	the routine is deterministic or not
SQL_DATA_ACCESS	VARCHAR(32)	routine possibly contains SQL or access data
IS_NULL_CALL	BOOLEAN	routine returns NULL if any of parameter values are NULL
SQL_PATH	VARCHAR(1024)	described SQL PATH when the routine is defined
SCHEMA_LEVEL_ROUTINE	BOOLEAN	the routine is schema-level routine
MAX_DYNAMIC_RESULT_SETS	NUMBER	max result set count of the routine
IS_USER_DEFINED_CAST	BOOLEAN	the routine is a function that is a user-defined cast function
IS_IMPLICITLY_INVOCABLE	BOOLEAN	the user-defined cast function is implicitly invocable
SECURITY_TYPE	VARCHAR(32)	security type of the routine(DEFINER/INVOKER)
TO_SQL_SPECIFIC_CATALOG	VARCHAR(128)	catalog name of the to-sql routine of the result type of routine
TO_SQL_SPECIFIC_SCHEMA	VARCHAR(128)	schema name of the to-sql routine of the result type of routine
TO_SQL_SPECIFIC_NAME	VARCHAR(128)	name of the to-sql routine of the result type of routine
AS_LOCATOR	BOOLEAN	return value of the routine is passed as locator
CREATED	TIMESTAMP(6) WITHOUT TIME ZONE	creation time of the routine
LAST_ALTERED	TIMESTAMP(6) WITHOUT TIME ZONE	most lately altered time of the routine
NEW_SAVEPOINT_LEVEL	BOOLEAN	specifiy new savepoint level or not

Column name	Data type	Description
IS_UDT_DEPENDENT	BOOLEAN	routine is dependent
RESULT_CAST_FROM_DATA_TYPE	VARCHAR(128)	data type which is specificed in result cast clause of the routine definition
RESULT_CAST_AS_LOCATOR	BOOLEAN	locator indication which is specificed in result cast clause of the routine definition
RESULT_CAST_CHAR_MAX_LENGTH	NUMBER	maximum character length of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_CHAR_OCTET_LENGTH	NUMBER	maximum character length in octets of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_CHAR_SET_CATALOG	VARCHAR(128)	character set catalog name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_CHAR_SET_SCHEMA	VARCHAR(128)	character set schema name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_CHARACTER_SET_NAME	VARCHAR(128)	character set name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_COLLATION_CATALOG	VARCHAR(128)	collation catalog name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_COLLATION_SCHEMA	VARCHAR(128)	collation schema name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_COLLATION_NAME	VARCHAR(128)	collation name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_NUMERIC_PRECISION	NUMBER	precision of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_NUMERIC_RADIX	NUMBER	precision radix of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_NUMERIC_SCALE	NUMBER	scale of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_DATETIME_PRECISION	NUMBER	fractional seconds precision of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_INTERVAL_TYPE	VARCHAR(32)	interval qualifier of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_INTERVAL_PRECISION	NUMBER	interval precision of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_TYPE_UDT_CATALOG	VARCHAR(128)	UDT catalog name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_TYPE_UDT_SCHEMA	VARCHAR(128)	UDT schema name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_TYPE_UDT_NAME	VARCHAR(128)	UDT name of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_SCOPE_CATALOG	VARCHAR(128)	catalog name of referenceable table described in result cast clause of the routine definition
RESULT_CAST_SCOPE_SCH		schema name of referenceable table described in result cast cl

Column name	Data type	Description
EMA	VARCHAR(128)	ause of the routine definition
RESULT_CAST_SCOPE_NAME	VARCHAR(128)	name of referenceable table described in result cast clause of the routine definition
RESULT_CAST_MAX_CARDINALITY	NUMBER	maximum cardinality of data type which is specificed in result cast clause of the routine definition
RESULT_CAST_DTD_IDENTIFIER	NUMBER	dtd identifier of data type which is specificed in result cast clause of the routine definition
DECLARED_DATA_TYPE	VARCHAR(128)	declared data type of the routine returns
DECLARED_NUMERIC_PRECISION	NUMBER	declared data type precision of the routine returns
DECLARED_NUMERIC_SCALE	NUMBER	declared data type scale of the routine returns
RESULT_CAST_FROM_DECLARED_DATA_TYPE	VARCHAR(128)	declared data type which is specificed in result cast clause of the routine definition
RESULT_CAST_DECLARED_NUMERIC_PRECISION	NUMBER	declared data type precision which is specificed in result cast clause of the routine definition
RESULT_CAST_DECLARED_NUMERIC_SCALE	NUMBER	declared data type scale which is specificed in result cast clause of the routine definition

ROUTINE_MODULE_USAGE

Identify the SQL-server modules owned by a given user or role on which SQL routines defined in this catal og are dependent.

Table 9-189 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the routine
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the routine
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the routine
SPECIFIC_NAME	VARCHAR(128)	specific name of the routine
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module of contained in routine bod y of the SQL-invoked routine
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module of contained in routine body of the SQL-invoked routine
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module of contained in routine bod y of the SQL-invoked routine
MODULE_NAME	VARCHAR(128)	SQL-server module name of contained in routine body of the SQL-in voked routine

ROUTINE_PRIVILEGES

Identify the privileges on SQL-invoked routines defined in this catalog that are available to or granted by a given user or role.

Table 9-190 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	authorization name of the user who granted routine privileges
GRANTEE	VARCHAR(128)	authorization name of some user or role, or PUBLIC to indicate all users, to whom the routine privilege being described is granted
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the SQL-invoked routine on which the privilege being described was granted
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the the SQL-invoked routine on which the privilege being described was granted
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the the SQL-invoked routine on which the privilege being described was granted
SPECIFIC_NAME	VARCHAR(128)	specific name of the the SQL-invoked routine on which the privilege being described was granted
ROUTINE_CATALOG	VARCHAR(128)	routine catalog name of the SQL-invoked routine on which the privilege being described was granted
ROUTINE_OWNER	VARCHAR(128)	null
ROUTINE_SCHEMA	VARCHAR(128)	routine schema name of the the SQL-invoked routine on which the privilege being described was granted
ROUTINE_NAME	VARCHAR(128)	routine name of the the SQL-invoked routine on which the privilege being described was granted
PRIVILEGE_TYPE	VARCHAR(32)	the value is in (EXECUTE)
IS_GRANTABLE	BOOLEAN	is grantable

ROUTINE_ROUTINE_USAGE

Identify each SQL-invoked routine owned by a given user or role on which an SQL routine defined in this catalog is dependent.

Table 9-191 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the routine
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the routine
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the routine
SPECIFIC_NAME	VARCHAR(128)	specific name of the routine
ROUTINE_CATALOG	VARCHAR(128)	routine catalog name of a routine contained in routine body of the SQL-invoked routine
ROUTINE_OWNER	VARCHAR(128)	routine owner name of a routine contained in routine body of the SQL-invoked routine
ROUTINE_SCHEMA	VARCHAR(128)	routine schema name of a routine contained in routine body of the SQL-invoked routine
ROUTINE_NAME	VARCHAR(128)	routine name of a routine contained in routine body of the SQL-invoked routine

ROUTINE_SEQUENCE_USAGE

Identify each external sequence generator owned by a given user or role on which some SQL routine defi ned in this catalog is dependent.

Table 9-192 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the routine
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the routine
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the routine
SPECIFIC_NAME	VARCHAR(128)	specific name of the routine
SEQUENCE_CATALOG	VARCHAR(128)	catalog name of the sequence of contained in routine body of the SQL-invoked routine
SEQUENCE_OWNER	VARCHAR(128)	owner name of the sequence of contained in routine body of the SQL-invoked routine
SEQUENCE_SCHEMA	VARCHAR(128)	schema name of the sequence of contained in routine body of th e SQL-invoked routine
SEQUENCE_NAME	VARCHAR(128)	sequence name of contained in routine body of the SQL-invoked r outine

ROUTINE_TABLE_USAGE

Identify the tables owned by a given user or role on which SQL routines defined in this catalog are depen dent.

Table 9-193 Column information

Column name	Data type	Description
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of the routine
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of the routine
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of the routine
SPECIFIC_NAME	VARCHAR(128)	specific name of the routine
TABLE_CATALOG	VARCHAR(128)	catalog name of the table of contained in routine body of the SQL-i nvoked routine
TABLE_OWNER	VARCHAR(128)	owner name of the table of contained in routine body of the SQL-in voked routine
TABLE_SCHEMA	VARCHAR(128)	schema name of the table of contained in routine body of the SQL-i nvoked routine
TABLE_NAME	VARCHAR(128)	table name of contained in routine body of the SQL-invoked routine

SCHEMATA

Identify the schemata in a catalog that are owned by given user or accessible to given user or role.

Table 9-194 Column information

Column name	Data type	Description
CATALOG_NAME	VARCHAR(128)	catalog name of the schema
SCHEMA_NAME	VARCHAR(128)	schema name
SCHEMA_OWNER	VARCHAR(128)	authorization name who owns the schema
DEFAULT_CHARACTER_SET_CATALOG	VARCHAR(128)	catalog name of the default character set for columns and domains in the schemata
DEFAULT_CHARACTER_SET_SCHEMA	VARCHAR(128)	schema name of the default character set for columns and domains in the schemata
DEFAULT_CHARACTER_SET_NAME	VARCHAR(128)	character set name of the default character set for columns and domains in the schemata
SQL_PATH	VARCHAR(1024)	character representation of schema path specification
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	created time of the schema
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	last modified time of the schema
COMMENTS	VARCHAR(1024)	comments of the schema

SEQUENCES

Identify the external sequence generators defined in this catalog that are accesible to a given user or role.

Table 9-195 Column information

Column name	Data type	Description
SEQUENCE_CATALOG	VARCHAR(128)	catalog name of the sequence
SEQUENCE_OWNER	VARCHAR(128)	owner name of the sequence
SEQUENCE_SCHEMA	VARCHAR(128)	schema name of the sequence
SEQUENCE_NAME	VARCHAR(128)	sequence name
DATA_TYPE	VARCHAR(128)	the standard name of the data type
NUMERIC_PRECISION	NUMBER	the numeric precision of the numerical data type
NUMERIC_PRECISION_RADIX	NUMBER	the radix (2 or 10) of the precision of the numerical data type
NUMERIC_SCALE	NUMBER	the numeric scale of the exact numerical data type
START_VALUE	NUMBER	the start value of the sequence generator
MINIMUM_VALUE	NUMBER	the minimum value of the sequence generator
MAXIMUM_VALUE	NUMBER	the maximum value of the sequence generator
INCREMENT	NUMBER	the increment of the sequence generator
CYCLE_OPTION	BOOLEAN	cycle option
CACHE_SIZE	NATIVE_INTEGER	number of sequence numbers to cache
DECLARED_DATA_TYPE	VARCHAR(128)	the data type name that a user declared
DECLARED_NUMERIC_PRECISION	NUMBER	the precision value that a user declared
DECLARED_NUMERIC_SCALE	NUMBER	the scale value that a user declared
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	created time of the sequence generator
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	last modified time of the sequence generator
COMMENTS	VARCHAR(1024)	comments of the sequence generator

SQL_FEATURES

List the features and subfeatures of this ISO/IEC 9075 standard, and indicate which of these the SQL-implementation supports.

Table 9-196 Column information

Column name	Data type	Description
FEATURE_ID	VARCHAR(32)	identifier string of the conformance element
FEATURE_NAME	VARCHAR(1024)	descriptive name of the conformance element
SUB_FEATURE_ID	VARCHAR(32)	identifier string of the subfeature, or a single space if not a subfeature
SUB_FEATURE_NAME	VARCHAR(1024)	descriptive name of the subfeature, or a single space if not a subfeature
IS_SUPPORTED	BOOLEAN	TRUE if an SQL-implementation fully supports that conformance element described when SQL-data in the identified catalog is accessed through that implementation, FALSE if not
IS_VERIFIED_BY	VARCHAR(1024)	If full support for the conformance element described has been verified by testing, then the IS_VERIFIED_BY column shall contain information identifying the conformance test used to verify the conformance claim; otherwise, IS_VERIFIED_BY shall be the null value
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the conformance element

SQL_IMPLEMENTATION_INFO

List the SQL-implementation information items defined in this ISO/IEC 9075 standard and, for each of the se, indicate the value supported by the SQL-implementation.

Table 9-197 Column information

Column name	Data type	Description
IMPLEMENTATION_INFO_ID	VARCHAR(32)	identifier string of the implementation information item
IMPLEMENTATION_INFO_NAME	VARCHAR(1024)	descriptive name of the implementation information item
INTEGER_VALUE	NATIVE_INTEGER	value of the implementation information item, or null if the value is contained in the column CHARACTER_VALUE
CHARACTER_VALUE	VARCHAR(32)	value of the implementation information item, or null if the value is contained in the column INTEGER_VALUE
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the implementation information it em

SQL_PACKAGES

List the packages of this ISO/IEC 9075 standard, and indicate which of these the SQL-implementation sup ports.

Table 9-198 Column information

Column name	Data type	Description
ID	VARCHAR(32)	identifier string of the conformance element
NAME	VARCHAR(1024)	descriptive name of the conformance element
IS_SUPPORTED	BOOLEAN	TRUE if an SQL-implementation fully supports that conformance ele ment described when SQL-data in the identified catalog is accessed through that implementation, FALSE if not
IS_VERIFIED_BY	VARCHAR(1024)	If full support for the conformance element described has been verif ied by testing, then the IS_VERIFIED_BY column shall contain inform ation identifying the conformance test used to verify the conforman ce claim; otherwise, IS_VERIFIED_BY shall be the null value
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the conformance element

SQL_PARTS

List the parts of this ISO/IEC 9075 standard, and indicate which of these the SQL-implementation supports.

Table 9-199 Column information

Column name	Data type	Description
ID	VARCHAR(32)	identifier string of the conformance element
NAME	VARCHAR(1024)	descriptive name of the conformance element
IS_SUPPORTED	BOOLEAN	TRUE if an SQL-implementation fully supports that conformance element described when SQL-data in the identified catalog is accessed through that implementation, FALSE if not
IS_VERIFIED_BY	VARCHAR(1024)	If full support for the conformance element described has been verified by testing, then the IS_VERIFIED_BY column shall contain information identifying the conformance test used to verify the conformance claim; otherwise, IS_VERIFIED_BY shall be the null value
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the conformance element

SQL_SIZING

List the sizing items of this ISO/IEC 9075 standard, for each of these, indicate the size supported by the SQL-implementation.

Table 9-200 Column information

Column name	Data type	Description
SIZING_ID	NATIVE_INTEGER	identifier of the sizing item
SIZING_NAME	VARCHAR(1024)	descriptive name of the sizing item
SUPPORTED_VALUE	NATIVE_INTEGER	value of the sizing item, or 0 if the size is unlimited or cannot be determined, or null if the features for which the sizing item is applicable are not supported
COMMENTS	VARCHAR(1024)	possibly a comment pertaining to the sizing item

STATISTICS

Provide a list of statistics about a single table and the indexes associated with the table that are accessible to a given user or role.

Table 9-201 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the table
TABLE_OWNER	VARCHAR(128)	owner name of the table
TABLE_SCHEMA	VARCHAR(128)	schema name of the table
TABLE_NAME	VARCHAR(128)	table name of the table
STAT_TYPE	VARCHAR(32)	statistics type: the value in (TABLE STAT, INDEX CLUSTERED, INDEX HASHED, INDEX OTHER)
NON_UNIQUE	BOOLEAN	indicates whether the index does not allow duplicate values
INDEX_CATALOG	VARCHAR(128)	catalog name of the index
INDEX_OWNER	VARCHAR(128)	owner name of the index
INDEX_SCHEMA	VARCHAR(128)	schema name of the index
INDEX_NAME	VARCHAR(128)	name of the index
COLUMN_NAME	VARCHAR(128)	column name that participates in the index
ORDINAL_POSITION	NUMBER	ordinal position of the specific column in the index described
IS_ASCENDING_ORDER	BOOLEAN	index key column being described is sorted in ASCENDING(TRUE) or DESCENDING(FALSE) order
IS_NULLS_FIRST	BOOLEAN	the null values of the key column are sorted before(TRUE) or after(FALSE) non-null values
CARDINALITY	NUMBER	if STAT_TYPE is (TABLE TYPE), then this is the number of rows in the table; otherwise, it is the number of unique values in the index
PAGES	NUMBER	if STAT_TYPE is (TABLE TYPE), then this is the number of pages used for the table; otherwise, it is the number of pages used for the current index.
FILTER_CONDITION	VARCHAR(1024)	filter condition, if any.
COMMENTS	VARCHAR(1024)	if STAT_TYPE is (TABLE TYPE), then this is the table comments; otherwise, it is the index comments.

TABLES

Identify the tables defined in this catalog that are accessible to a given user or role

Table 9-202 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the table
TABLE_OWNER	VARCHAR(128)	owner name of the table
TABLE_SCHEMA	VARCHAR(128)	schema name of the table
TABLE_NAME	VARCHAR(128)	table name of the table
TABLE_TYPE	VARCHAR(32)	the value is in (BASE TABLE, VIEW, GLOBAL TEMPORARY, LOCAL TEMPORARY, SYSTEM VERSIONED, FIXED TABLE, DUMP TABLE)
DBC_TABLE_TYPE	VARCHAR(32)	ODBC/JDBC table type: the value is in (TABLE, VIEW, GLOBAL TEMPORARY, LOCAL TEMPORARY, IMMUTABLE TABLE, SYSTEM TABLE, ALIAS, SYNONYM)
TABLESPACE_NAME	VARCHAR(128)	tablespace name of the table, NULL if view
SYSTEM_VERSION_START_COLUMN_NAME	VARCHAR(128)	if the table is a system-versioned table, then the name of the system-version start column of the table
SYSTEM_VERSION_END_COLUMN_NAME	VARCHAR(128)	if the table is a system-versioned table, then the name of the system-version end column of the table
SYSTEM_VERSION_RETENTION_PERIOD	VARCHAR(32)	if the table is a system-versioned table, then the character representation of the value of the retention period of the table
SELF_REFERENCING_COLUMN_NAME	VARCHAR(128)	if the table is a typed table, then the name of the self-referencing column of the table
REFERENCE_GENERATION	VARCHAR(32)	if the table has a self-referencing column, the value is in (SYSTEM GENERATED, USER GENERATED, DERIVED)
USER_DEFINED_TYPE_CATALOG	VARCHAR(128)	if the table being described is a table of a structured type, the catalog name of the structured type
USER_DEFINED_TYPE_SCHEMA	VARCHAR(128)	if the table being described is a table of a structured type, the schema name of the structured type
USER_DEFINED_TYPE_NAME	VARCHAR(128)	if the table being described is a table of a structured type, the name of the structured type
IS_INSERTABLE_INTO	BOOLEAN	is an insertable-into table
IS_TYPED	BOOLEAN	is a typed table
COMMIT_ACTION	VARCHAR(32)	if the table is a temporary table, the value is in (DELETE, PRESERVE)
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	created time of the table
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	last modified time of the table
COMMENTS	VARCHAR(1024)	comments of the table

TABLE_CONSTRAINTS

Identify the table constraints defined on tables in this catalog that are accessible to a given user or role

Table 9-203 Column information

Column name	Data type	Description
CONSTRAINT_CATALOG	VARCHAR(128)	catalog name of the constraint
CONSTRAINT_OWNER	VARCHAR(128)	authorization name who owns the constraint
CONSTRAINT_SCHEMA	VARCHAR(128)	schema name of the constraint being described
CONSTRAINT_NAME	VARCHAR(128)	constraint name
TABLE_CATALOG	VARCHAR(128)	catalog name of the table to which the table constraint being described applies
TABLE_OWNER	VARCHAR(128)	authorization name who owns the table to to which the table constraint being described applies
TABLE_SCHEMA	VARCHAR(128)	schema name of the table to to which the table constraint bei ng described applies
TABLE_NAME	VARCHAR(128)	table name of the table to to which the table constraint being described applies
CONSTRAINT_TYPE	VARCHAR(32)	the value is in (PRIMARY KEY, UNIQUE, FOREIGN KEY, NOT N ULL, CHECK)
IS_DEFERRABLE	BOOLEAN	is a deferrable constraint
INITIALLY_DEFERRED	BOOLEAN	is an initially deferred constraint
ENFORCED	BOOLEAN	is an enforced constraint
CREATED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	created time of the constraint
MODIFIED_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	last modified time of the constraint
COMMENTS	VARCHAR(1024)	comments of the constraint

TABLE_PRIVILEGES

Identify the privileges on tables of tables defined in this catalog that are available to or granted by a given user or role.

Table 9-204 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	authorization name of the user who granted table privileges
GRANTEE	VARCHAR(128)	authorization name of some user or role, or PUBLIC to indicate all users, to whom the table privilege being described is granted
TABLE_CATALOG	VARCHAR(128)	catalog name of the table on which the privilege being described was granted
TABLE_OWNER	VARCHAR(128)	table owner name of the table on which the privilege being described was granted
TABLE_SCHEMA	VARCHAR(128)	schema name of the table on which the privilege being described was granted
TABLE_NAME	VARCHAR(128)	table name on which the privilege being described was granted
PRIVILEGE_TYPE	VARCHAR(32)	the value is in (CONTROL, SELECT, INSERT, UPDATE, DELETE, REFERENCES, LOCK, INDEX, ALTER)
IS_GRANTABLE	BOOLEAN	is grantable
WITH_HIERARCHY	BOOLEAN	whether the privilege was granted WITH HIERARCHY OPTION or not

USAGE_PRIVILEGES

Identify the USAGE privileges on objects defined in this catalog that are available to or granted by a given user or role.

Table 9-205 Column information

Column name	Data type	Description
GRANTOR	VARCHAR(128)	authorization name of the user who granted usage privileges, on the object of the type identified by OBJECT_TYPE
GRANTEE	VARCHAR(128)	authorization identifier of some user or role, or PUBLIC to indicate all users, to whom the usage privilege being described is granted
OBJECT_CATALOG	VARCHAR(128)	catalog name of the object of the type identified by OBJECT_TYPE on which the privilege being described was granted
OBJECT_OWNER	VARCHAR(128)	owner name of the object of the type identified by OBJECT_TYPE on which the privilege being described was granted
OBJECT_SCHEMA	VARCHAR(128)	schema name of the object of the type identified by OBJECT_TYPE on which the privilege being described was granted
OBJECT_NAME	VARCHAR(128)	object name of the type identified by OBJECT_TYPE on which the privilege being described was granted
OBJECT_TYPE	VARCHAR(32)	the value is in (DOMAIN, CHARACTER SET, COLLATION, TRANSLATION, SEQUENCE)
PRIVILEGE_TYPE	VARCHAR(32)	the value is in (USAGE)
IS_GRANTABLE	BOOLEAN	is grantable

VIEWS

Identify the viewed tables defined in this catalog that are accessible to a given user or role.

Table 9-206 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the viewed table
TABLE_OWNER	VARCHAR(128)	owner name of the viewed table
TABLE_SCHEMA	VARCHAR(128)	schema name of the viewed table
TABLE_NAME	VARCHAR(128)	view name of the viewed table
VIEW_DEFINITION	LONG VARCHAR	the character representation of the user-specified query expression contained in the corresponding view descriptor
CHECK_OPTION	VARCHAR(32)	the value is in (CASCADED, LOCAL, NONE)
IS_UPDATABLE	BOOLEAN	is an updatable view
INSERTABLE_INTO	BOOLEAN	is an insertable view
IS_TRIGGER_UPDATABLE	BOOLEAN	whether an update INSTEAD OF trigger is defined on the view or not
IS_TRIGGER_DELETABLE	BOOLEAN	whether a delete INSTEAD OF trigger is defined on the view or not
IS_TRIGGER_INSERTABLE_INTO	BOOLEAN	whether an insert INSTEAD OF trigger is defined on the view or not
IS_COMPILED	BOOLEAN	whether the view is compiled or not
IS_AFFECTED	BOOLEAN	whether the view is affected by modification of underlying object or not
COMMENTS	VARCHAR(1024)	comments of the view

VIEW_MODULE_USAGE

Identify the SQL-server modules owned by a given user or role on which views defined in this catalog are dependent.

Table 9-207 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the viewed table
TABLE_OWNER	VARCHAR(128)	owner name of the viewed table
TABLE_SCHEMA	VARCHAR(128)	schema name of the viewed table
TABLE_NAME	VARCHAR(128)	view name of the viewed table
MODULE_CATALOG	VARCHAR(128)	catalog name of the SQL-server module of contained in definition te xt of the view
MODULE_OWNER	VARCHAR(128)	owner name of the SQL-server module of contained in definition tex t of the view
MODULE_SCHEMA	VARCHAR(128)	schema name of the SQL-server module of contained in definition te xt of the view'
MODULE_NAME	VARCHAR(128)	SQL-server module name of contained in definition text of the view

VIEW_ROUTINE_USAGE

Identify each routine owned by a given user or role on which a view defined in this catalog is dependent.

Table 9-208 Column information

Column name	Data type	Description
TABLE_CATALOG	VARCHAR(128)	catalog name of the viewed table
TABLE_OWNER	VARCHAR(128)	owner name of the viewed table
TABLE_SCHEMA	VARCHAR(128)	schema name of the viewed table
TABLE_NAME	VARCHAR(128)	view name of the viewed table
SPECIFIC_CATALOG	VARCHAR(128)	specific catalog name of a routine contained in the query expression of the view being described
SPECIFIC_OWNER	VARCHAR(128)	specific owner name of a routine contained in the query expression of the view being described
SPECIFIC_SCHEMA	VARCHAR(128)	specific schema name of a routine contained in the query expression of the view being described
SPECIFIC_NAME	VARCHAR(128)	specific name of a routine contained in the query expression of the v iew being described

VIEW_TABLE_USAGE

Identify the tables on which viewed tables defined in this catalog and owned by a given user or role are dependent.

Table 9-209 Column information

Column name	Data type	Description
VIEW_CATALOG	VARCHAR(128)	catalog name of the viewed table
VIEW_OWNER	VARCHAR(128)	owner name of the viewed table
VIEW_SCHEMA	VARCHAR(128)	schema name of the viewed table
VIEW_NAME	VARCHAR(128)	view name of the viewed table
TABLE_CATALOG	VARCHAR(128)	catalog name of a table that is explicitly or implicitly referenced in the original query expression of the compiled view being described
TABLE_OWNER	VARCHAR(128)	owner name of a table that is explicitly or implicitly referenced in the original query expression of the compiled view being described
TABLE_SCHEMA	VARCHAR(128)	schema name of a table that is explicitly or implicitly referenced in the original query expression of the compiled view being described
TABLE_NAME	VARCHAR(128)	table name of a table that is explicitly or implicitly referenced in the original query expression of the compiled view being described

9.3 PERFORMANCE_VIEW_SCHEMA

PERFORMANCE_VIEW_SCHEMA schema consists of views which can retrieve the current state of the syst em.

Execute *PerformanceViewSchema.sql* as follows to use the views.

- For standalone

```
% gsql sys gliese --as sysdba --import
$GOLDILOCKS_HOME/admin/standalone/PerformanceViewSchema.sql
```

- For cluster

```
% gsql sys gliese --as sysdba --import
$GOLDILOCKS_HOME/admin/cluster/PerformanceViewSchema.sql
```

The retrievable information of PERFORMANCE_VIEW_SCHEMA views vary upon its phase of the startup. (nomount, mount, open)
Execute the followings to figure out the startup phase in which each views are retrieved.

```
gSQL> select table_name, startup_phase from v$tables order by 1;
TABLE_NAME                 STARTUP_PHASE
-------------------------- -------------
V$AGABLE_INFO              OPEN
V$ARCHIVELOG               MOUNT
V$AUDITABLE_DB_PRIVILEGES  NO_MOUNT
V$AUDITABLE_SYSTEM_ACTIONS NO_MOUNT
V$BACKUP                   MOUNT
V$BALANCER                 OPEN
V$BCH                      MOUNT
V$BUFFER_STAT              MOUNT
V$COLUMNS                  OPEN
V$CONTROLFILE              MOUNT
V$DATAFILE                 MOUNT
V$DB_CHANGE_TRACKING       MOUNT
V$DB_FILE                  MOUNT
V$DB_PROPERTY              OPEN
V$DISPATCHER               OPEN
V$ERROR_CODE               NO_MOUNT
V$INCREMENTAL_BACKUP       MOUNT
```

```
V$INSTANCE                NO_MOUNT
V$KEYWORDS                NO_MOUNT
V$LATCH                   NO_MOUNT
V$LOCK_WAIT               OPEN
TABLE_NAME             STARTUP_PHASE
---------------------- -------------
V$LOGFILE              MOUNT
V$OPEN_CURSOR          NO_MOUNT

V$WAIT_EVENT_CLASS_NAME OPEN
V$WAIT_EVENT_NAME       OPEN
V$XA_TRANSACTION        OPEN
62 rows selected.
```

GV$ Global View

The cluster provides GV$ view corresponding to almost every V$ views.
V$ view retrieves the information of the currently connected server, but GV$ view retrieves the informati on of all servers.
GV$ view includes all column information of V$ view, and it additionally has ORIGIN_MEMBER_NAME co lumn which is a server having acquired the data (cluster member).

It is available only on a cluster.

For example, V$TRANSACTION information retrieves the transaction information of the currently connect ed server as follows.

```
gSQL> SELECT TRANS_ID, SESSION_ID, TRANS_VIEW_SCN, START_TIME FROM V$TRANSACTION;
TRANS_ID SESSION_ID TRANS_VIEW_SCN START_TIME
-------- ---------- -------------- --------------------------
40501296         48 1098.1.26      2017-04-07 17:14:01.912637
```

On the other hand, GV$TRANSACTION information retrieves the transaction information of all servers as follows.

```
gSQL> SELECT ORIGIN_MEMBER_NAME, TRANS_ID, SESSION_ID, TRANS_VIEW_SCN, START_TIME FROM
GV$TRANSACTION;
ORIGIN_MEMBER_NAME TRANS_ID SESSION_ID TRANS_VIEW_SCN START_TIME
------------------ -------- ---------- -------------- --------------------------
G1N1               40501296         48 1098.1.26      2017-04-07 17:14:01.912637
G2N2               40304688         48 1098.0.888     2017-04-07 17:14:55.134015
G2N1               42205232         48 1098.0.888     2017-04-07 17:14:55.135996
G1N2               40435760         48 1098.1.889     2017-04-07 17:14:01.910138
```

In the example above, ORIGIN_MEMBER_NAME information acquired each transaction information from the cluster member corresponding to G1N1, G2N1, G1N2, G2N2 each.

The information of a specific remote server can be retrieved by using the condition for ORIGIN_MEMBER_ NAME column as follows.

```
gSQL>
SELECT ORIGIN_MEMBER_NAME, TRANS_ID, SESSION_ID, TRANS_VIEW_SCN, START_TIME
  FROM GV$TRANSACTION
WHERE ORIGIN_MEMBER_NAME IN ( 'G2N1', 'G3N2' );
```

```
ORIGIN_MEMBER_NAME TRANS_ID SESSION_ID TRANS_VIEW_SCN START_TIME
------------------ -------- ---------- -------------- --------------------------
G3N2               32178224         48 1099.0.888     2017-04-07 17:33:10.934752
G2N1               42270768         48 1099.0.888     2017-04-07 17:31:14.726007
2 rows selected.
```

V$AGABLE_INFO

The V$AGABLE_INFO displays the system agable information.

Table 9-210 Column information

Column name	Data type	Description
SCN	VARCHAR(32)	system scn
AGABLE_SCN	VARCHAR(32)	system agable scn
AGABLE_SCN_GAP	VARCHAR(32)	gap between system scn and agable scn
OLDEST_SESSION_ID	NUMBER	identifier of session blocking aging

V$ARCHIVELOG

The V$ARCHIVELOG displays information of log archiving.

Table 9-211 Column information

Column name	Data type	Description
ARCHIVELOG_MODE	VARCHAR(32)	database log mode: the value in (NOARCHIVELOG, ARCHIVELOG)
LAST_ARCHIVED_LOG	NUMBER	sequence number of last archived log file
ARCHIVELOG_DIR	VARCHAR(1024)	archive destination path
ARCHIVELOG_FILE_PREFIX	VARCHAR(128)	file prefix name of the archived log

V$AUDITABLE_DB_PRIVILEGES

The V$AUDITABLE_DB_PRIVILEGES displays auditable database privileges.

Table 9-212 Column information

Column name	Data type	Description
PRIVILEGE_ID	NUMBER	database privilege identifier
PRIVILEGE_NAME	VARCHAR(128)	database privilege name

V$AUDITABLE_SYSTEM_ACTIONS

The V$AUDITABLE_SYSTEM_ACTIONS displays auditable system actions.

Table 9-213 Column information

Column name	Data type	Description
ACTION_ID	NUMBER	auditable system action identifier
ACTION_NAME	VARCHAR(128)	auditable system action name

V$BACKUP

The V$BACKUP displays information of backup.

Table 9-214 Column information

Column name	Data type	Description
TBS_NAME	VARCHAR(128)	tablespace name
BACKUP_STATUS	VARCHAR(16)	indicates whether the tablespace begin backup (ACTIVE) or not (INACTIVE)
BACKUP_LSN	NUMBER	the last checkpoint lsn of tablespace when backup started

V$BALANCER

The V$BALANCER displays information of balancer.

Table 9-215 Column information

Column name	Data type	Description
PROCESS_ID	NUMBER	balancer process identifier
CUR_CONNECTIONS	NUMBER	current number of connections
CONNECTIONS	NUMBER	total number of connections
CONNECTIONS_HIGHWATER	NUMBER	highest number of connections
MAX_CONNECTIONS	NUMBER	maximum connections
STATUS	VARCHAR(16)	status

V$BCH

The V$BCH displays information of database buffer control header array.

Table 9-216 Column information

Column name	Data type	Description
BCH_SEQ	NUMBER	bch sequence
TABLESPACE_ID	NUMBER	tablespace identifier of the page cached in the frame of bch
PAGE_ID	NUMBER	page identifier of the page cached in the frame of bch
LOGICAL_ADDRESS	VARCHAR(18)	logical address of the frame of bch
DIRTY	BOOLEAN	dirty state of the page cached in the frame of bch
PGAE_TYPE	VARCHAR(20)	page type of the page cached in the frame of bch
FIRST_DIRTY_LSN	NUMBER	first dirty lsn of the page cached in the frame of bch
RECOVERY_LSN	NUMBER	recovery lsn of the page cached in the frame of bch
LAST_FLUSHED_LSN	NUMBER	last flushed lsn of the page cached in the frame of bch
FIXED_COUNT	NUMBER	fixed count of the page cached in the frame of bch
TOUCHED_COUNT	NUMBER	touched count of the page cached in the frame of bch
RECENT_TOUCH_COUNT_INCREASED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	timestamp that touch count of the page cached in the frame of bch increased most recently
BCH_LIST_TYPE	VARCHAR(16)	list type to which the bch belongs
BCH_STATE	VARCHAR(16)	bch state

V$BUFFER_STAT

The V$BUFFER_STAT displays database buffer statistics.

Table 9-217 Column information

Column name	Data type	Description
BUFFER_POOL_SIZE	NUMBER	total buffer frame size (page count)
HASH_BUCKET_COUNT	NUMBER	buffer hash bucket count
LRU_LIST_COUNT	NUMBER	buffer lru list count
HOT_REGION_PERCENTAGE	NUMBER	percentage of lru hot region
HOT_REGION_CRITERIA	NUMBER	touch count criteria of lru hot region
CHECKPOINT_LIST_COUNT	NUMBER	buffer checkpoint list count
FLUSH_LIST_COUNT	NUMBER	buffer flush list count
FREE_LIST_COUNT	NUMBER	buffer free list count
FREE_BUFFER_WAIT	NUMBER	total number of waiting for free list
READ_COMPLETE_WAIT	NUMBER	total number of waiting for read page complete
BUFFER_LOOKUPS	NUMBER	total number of lookups in the buffer for requested pages
BUFFER_HIT	NUMBER	total number of hits in the buffer for requested pages
BUFFER_MISS	NUMBER	total number of misses in the buffer for requested pages
TOTAL_WRITES	NUMBER	total number of physical writes
TOTAL_READS	NUMBER	total number of physical reads
FLUSH_PER_SECOND	NUMBER	total number of disk writes per one second
READ_PER_SECOND	NUMBER	total number of disk reads per one second
AVERAGE_WRITE_LATENCY	NUMBER	average latency of disk writes
AVERAGE_READ_LATENCY	NUMBER	average latency of disk reads

V$CLUSTER_DISPATCHER

The V$CLUSTER_DISPATCHER displays cluster dispatcher information.

It is available only on a cluster.

Table 9-218 Column information

Column name	Data type	Description
DISPATCHER_ID	NUMBER	dispatcher identifier
IS_SYNC	BOOLEAN	whether the dispatcher is sync or not
RX_BYTES	NUMBER	total amount of data that has received through the dispatcher
TX_BYTES	NUMBER	total amount of data that has transmitted through the dispatcher
RX_JOBS	NUMBER	the total number of jobs received
TX_JOBS	NUMBER	the total number of jobs transmitted

V$CLUSTER_LOCATION

The V$CLUSTER_LOCATION displays cluster location information.

It is available only on a cluster.

Table 9-219 Column information

Column name	Data type	Description
MEMBER_NAME	VARCHAR(128)	member name
HOST	VARCHAR(128)	host name or IP address of a member
PORT	NUMBER	host port of a member

V$CLUSTER_MEMBER

The V$CLUSTER_MEMBER displays cluster member information.

It is available only on a cluster.

Table 9-220 Column information

Column name	Data type	Description
MEMBER_ID	NUMBER	member identifier
MEMBER_POSITION	NUMBER	member position
STATUS	VARCHAR(64)	status of the member: the value in (ACTIVE, INACTIVE)
IS_GLOBAL_COORD	BOOLEAN	indicates whether a member is global coordnator (TRUE) or not (FALSE)
IS_GROUP_COORD	BOOLEAN	indicates whether a member is group coordnator (TRUE) or not (FALSE)

V$COLUMNS

The V$COLUMNS has one row for each column of all the performance views (views beginning with V$).

Execute \desc as follows to retrieve the column information of performance view in nomount or mount p hase in which V$COLUMNS is not available.

```
gSQL> \desc V$INSTANCE
COLUMN_NAME     TYPE                            IS_NULLABLE
--------------- ------------------------------- -----------
RELEASE_VERSION VARCHAR(64)          FALSE
STARTUP_TIME    TIMESTAMP(6) WITHOUT TIME ZONE FALSE
INSTANCE_STATUS VARCHAR(16)          FALSE
```

Table 9-221 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	owner name who owns the performance view
TABLE_SCHEMA	VARCHAR(128)	schema name of the performance view
TABLE_NAME	VARCHAR(128)	name of the performance view
COLUMN_NAME	VARCHAR(128)	column name
ORDINAL_POSITION	NUMBER	the ordinal position (> 0) of the column in the performance view
DATA_TYPE	VARCHAR(128)	the data type name that a user declared
DATA_PRECISION	NUMBER	the precision value that a user declared
DATA_SCALE	NUMBER	the scale value that a user declared
COMMENTS	VARCHAR(1024)	comments of the column

V$CONTROLFILE

This view displays information about GOLDILOCKS control files.

Table 9-222 Column information

Column name	Data type	Description
STATUS	VARCHAR(16)	control file status (VALID, CORRUPTED)
CONTROLFILE_NAME	VARCHAR(1152)	control file name (absolute path)
LAST_CHECKPOINT_LSN	NATIVE_BIGINT	the last checkpoint lsn
IS_PRIMARY	BOLLEAN	indicates whether the control file is primary

V$DATAFILE

The V$DATAFILE displays information of all datafiles.

Table 9-223 Column information

Column name	Data type	Description
TBS_NAME	VARCHAR(128)	tablepsace name
DATAFILE_NAME	VARCHAR(1024)	datafile name (absolute path)
CHECKPOINT_LSN	NUMBER	LSN at last checkpoint (null if temporary tablespace)
CREATION_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	timestamp of the datafile creation
FILE_SIZE	NUMBER	datafile size (in bytes)
LOADED_CHECKPOINT_LSN	NUMBER	checkpoint LSN of the datafile loaded in memory
CORRUPT_PAGE_COUNT	NUMBER	number of corrupt pages in the datafile

V$DB_CHANGE_TRACKING

The V$DB_CHANGE_TRACKING displays information of database change tracking.

Table 9-224 Column information

Column name	Data type	Description
TABLESPACE_ID	NUMBER	tablespage identifier
DATAFILE_ID	NUMBER	datafile identifier
CHANGE_TRACKING_STATE	VARCHAR(32)	state of dtafile change tracking
CHANGE_TRACKING_CHUNK_SEQ	NUMBER	sequence of change tracking chunk for datafile
MAX_SIZE	NUMBER	maximum size of datafile (byte)
BITMAP_BLOCK_COUNT	NUMBER	bitmap block count of change tracking chunk
LAST_PAGE_SEQ	NUMBER	the last page sequence of change tracking chunk

V$DB_FILE

The V$DB_FILE displays a list of all files using in database.

Table 9-225 Column information

Column name	Data type	Description
FILE_NAME	VARCHAR(1024)	file name
FILE_TYPE	VARCHAR(16)	file type

V$DB_PROPERTY

The V$DB_PROPERTY displays a list of permanent property.

Table 9-226 Column information

Column name	Data type	Description
PROPERTY_NAME	VARCHAR(128)	name of the property
DESCRIPTION	VARCHAR(2048)	description of the property
DATA_TYPE	VARCHAR(32)	data type of the property
VALUE_UNIT	VARCHAR(32)	unit of the property value: the value in (NONE, BYTE, MS(milisec))
PROPERTY_VALUE	VARCHAR(2048)	property value for the session. otherwise, the instance-wide value
MIN_VALUE	NUMBER	minimum value for property. null if type is varchar
MAX_VALUE	NUMBER	maximum value for property. null if type is varchar
SES_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SESSION or not: the value in (TRUE, FALSE)
SYS_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SYSTEM and when the change takes effect: the value in (NONE, FALSE, IMMEDIATE, DEFERRED)
IS_MODIFIABLE	VARCHAR(32)	property can be changed or not: the value in (TRUE, FALSE)
IS_DEPRECATED	VARCHAR(32)	whether a property is deprecated or not: the value in (TRUE, FALSE)
IS_GLOBAL	VARCHAR(32)	whether a property scope is global or not: the value in (TRUE, FALSE)

V$DISPATCHER

The V$DISPATCHER displays information of dispatchers.

Table 9-227 Column information

Column name	Data type	Description
PROCESS_ID	NUMBER	dispatcher process identifier
RESPONSE_JOB_COUNT	NUMBER	response job count
ACCEPT	NUMBER	indicates whether this dispatcher is accepting new connections
START_TIME	NUMBER	process start time
CUR_CONNECTIONS	NUMBER	current number of connections
CONNECTIONS	NUMBER	total number of connections
CONNECTIONS_HIGHWATER	NUMBER	highest number of connections
MAX_CONNECTIONS	NUMBER	maximum connections
RECV_STATUS	VARCHAR(16)	receive status
RECV_BYTES	NUMBER	total bytes of received
RECV_UNITS	NUMBER	total units of received
RECV_IDLE	NUMBER	total idle time of receive (1/100 second)
RECV_BUSY	NUMBER	total busy time of receive (1/100 second)
SEND_STATUS	VARCHAR(16)	send status
SEND_BYTES	NUMBER	total bytes of sent
SEND_UNITS	NUMBER	total units of sent
SEND_IDLE	NUMBER	total idle time of send (1/100 second)
SEND_BUSY	NUMBER	total busy time of send (1/100 second)

V$ERROR_CODE

The V$ERROR_CODE displays a list of all GOLDILOCKS error codes.

Table 9-228 Column information

Column name	Data type	Description
ERROR_CODE	NUMBER	GOLDILOCKS error code
SQL_STATE	VARCHAR(32)	standard SQLSTATE code
ERROR_MESSAGE	VARCHAR(1024)	error message

V$GLOBAL_TRANSACTION

The V$GLOBAL_TRANSACTION displays information on the currently active global transactions.

Table 9-229 Column information

Column name	Data type	Description
GLOBAL_TRANS_ID	VARCHAR(1024)	global transaction identifier
LOCAL_TRANS_ID	NUMBER	local transaction identifier
GLOBAL_TRANS_STATE	VARCHAR(32)	state of the global transaction: the value in (NOTR, ACTIVE, IDLE, PREPARED, ROLLBACK_ONLY, HEURISTIC_COMPLETED)
ASSO_STATE	VARCHAR(32)	associate state of the global transaction: the value in (NOT_ASSOCIATED, ASSOCIATED, ASSOCIATION_SUSPENDED)
START_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	global transaction start time
IS_REPREPARABLE	BOOLEAN	indicates whether the global transaction is repreparable

V$INCREMENTAL_BACKUP

The V$INCREMENTAL_BACKUP displays information about control files and datafiles in backup sets from the control file.

Table 9-230 Column information

Column name	Data type	Description
BACKUP_NAME	VARCHAR(1024)	backup file name (absolute path)
BACKUP_SCOPE	VARCHAR(128)	incremental backup scope: the value in (database, tablespace, control)
INCREMENTAL_LEVEL	NUMBER	incremental backup level: the value in (0, 1, 2, 3, 4)
INCREMENTAL_TYPE	VARCHAR(32)	incremental backup type: the value in (DIFFERENTIAL, CUMULATIVE)
LSN	NUMBER	all changes up to checkpoint LSN are included in this backup
BEGIN_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	incremental backup beginning time
COMPLETION_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	incremental backup completion time

V$INSTANCE

This view displays the state of the current instance.

Table 9-231 Column information

Column name	Data type	Description
RELEASE_VERSION	VARCHAR(64)	release version
STARTUP_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	time when the instance was started
INSTANCE_STATUS	VARCHAR(16)	status of the instance: the value in (STARTED, MOUNTED, OPEN)

V$JOURNALING

The V$JOURNALING displays journaling information.

It is available only on a cluster.

Table 9-232 Column information

Column name	Data type	Description
TABLE_NAME	VARCHAR(128)	table name
SHARD_ID	NUMBER	shard identifier
RECORD_COUNT	NUMBER	journaled record count
TOTAL_SIZE	NUMBER	total size of journaled records (byte)

V$KEYWORDS

The V$KEYWORDS displays a list of all SQL keywords.

Table 9-233 Column information

Column name	Data type	Description
KEYWORD_NAME	VARCHAR(128)	name of keyword
KEYWORD_LENGTH	NUMBER	length of the keyword
IS_RESERVED	BOOLEAN	indicates whether the keyword cannot be used as an identifier (TRUE) or whether the keyword is not reserved (FALSE)

V$LATCH

The V$LATCH shows latch information.

Table 9-234 Column information

Column name	Data type	Description
LATCH_DESCRIPTION	VARCHAR(64)	latch description
REF_COUNT	NUMBER	reference count
SPIN_LOCK	VARCHAR(3)	indicates whether the spin lock is locked (YES) or not (NO)
WAIT_COUNT	NUMBER	wait count
CURRENT_MODE	VARCHAR(32)	current latch mode: the value in (INITIAL, SHARED, EXCLUSIVE)

V$LICENSE

The V$LICENSE displays information of current license.

Table 9-235 Column information

Column name	Data type	Description
LICENSE_TYPE	VARCHAR(8)	license type
START_DATE	DATE	start date of the license
EXPIRE_DATE	DATE	expire date of the license

V$LOGFILE

The V$LOGFILE displays information of all redo log members.

Table 9-236 Column information

Column name	Data type	Description
GROUP_ID	NUMBER	redo log group identifier
FILE_NAME	VARCHAR(1024)	name of the log member
GROUP_STATE	VARCHAR(32)	state of the log group: the value in (UNUSED, ACTIVE, CURRENT, IN ACTIVE)
FILE_SEQ	NUMBER	file sequence number of the log member
FILE_SIZE	NUMBER	file size of the log member (in bytes)

V$LOCK_WAIT

This view lists the locks currently held and outstanding requests for a lock.

Table 9-237 Column information

Column name	Data type	Description
GRANT_TRANS_ID	NUMBER	transaction identifier that holds the lock
REQUEST_TRANS_ID	NUMBER	transaction identifier that requests the lock

V$LOCKED_OBJECT

This view shows locked object information.

Table 9-238 Column information

Column name	Data type	Description
LOCK_SLOT_ID	NUMBER	lock slot identifier
TABLE_OWNER	VARCHAR(128)	owner name who owns the locked table
TABLE_SCHEMA	VARCHAR(128)	schema of the locked table
TABLE_NAME	VARCHAR(128)	locked table name
LOCK_MODE	VARCHAR(8)	granted lock mode (IS, IX, S, X, SIX)

V$OPEN_CURSOR

The view lists display cursor status information for each current session.

Table 9-239 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	ID of the session
USER_NAME	VARCHAR(128)	NAME of the user
CURSOR_NAME	VARCHAR(128)	NAME of the cursor
PSM_CURSOR_ID	NUMBER	ID of the PSM cursor
SQL_TEXT	LONG VARCHAR	SQL text for the cursor
IS_PSM_CURSOR	BOOLEAN	is PSM cursor
IS_OPEN	BOOLEAN	is open
OPEN_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	cursor open time
LAST_EXEC_TIME	NATIVE_BIGINT	last execution time(us)
IS_SENSITIVE	BOOLEAN	is sensitive
IS_SCROLLABLE	BOOLEAN	is scrollable
IS_HOLDABLE	BOOLEAN	is holdable
IS_UPDATABLE	BOOLEAN	is updatable

V$PLAN_HISTORY

The V$PLAN_HISTORY displays information of SQL plans.

Table 9-240 Column information

Column name	Data type	Description
DRIVER_MEMBER_POS	NUMBER	driver member position
DRIVER_SESSION_ID	NUMBER	driver session identifier
SESSION_ID	NUMBER	session identifier
STMT_ID	NUMBER	statement identifier in a session
CL_STMT_ID	NUMBER	cluster statement identifier in a session
DRIVER_CL_STMT_ID	NUMBER	driver cluster statement identifier in a session
PLAN_HISTORY_POS	NUMBER	plan history position
PLAN_HISTORY_ID	NUMBER	plan history identifier
SQL_TEXT	LONG VARCHAR	SQL text for the statement
PLAN_TEXT	LONG VARCHAR	plan text for the statement
LAST_EXEC_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	statement last execution time

V$PLAN_HISTORY_LATEST

The V$PLAN_HISTORY_LATEST displays information of the latest SQL plan.

Table 9-241 Column information

Column name	Data type	Description
DRIVER_MEMBER_POS	NUMBER	driver member position
DRIVER_SESSION_ID	NUMBER	driver session identifier
SESSION_ID	NUMBER	session identifier
STMT_ID	NUMBER	statement identifier in a session
CL_STMT_ID	NUMBER	cluster statement identifier in a session
DRIVER_CL_STMT_ID	NUMBER	driver cluster statement identifier in a session
PLAN_HISTORY_POS	NUMBER	plan history position
PLAN_HISTORY_ID	NUMBER	plan history identifier
SQL_TEXT	LONG VARCHAR	SQL text for the statement
PLAN_TEXT	LONG VARCHAR	plan text for the statement
LAST_EXEC_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	statement last execution time

V$PROCESS_STAT

The V$PROCESS_STAT displays goldilocks process statistics.

Table 9-242 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
PROC_ID	NUMBER	goldilocks process identifier
STAT_VALUE	NUMBER	statistic value

V$PROCESS_MEM_STAT

The V$PROCESS_MEM_STAT displays goldilocks process memory statistics.

Table 9-243 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
PROC_ID	NUMBER	goldilocks process identifier
STAT_VALUE	NUMBER	statistic value

V$PROCESS_SQL_STAT

The V$PROCESS_SQL_STAT displays goldilocks process SQL statistics.

Table 9-244 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
PROC_ID	NUMBER	goldilocks process identifier
STAT_VALUE	NUMBER	statistic value

V$PROPERTY

The V$PROPERTY displays a list of all properties at current session. Otherwise, the instance-wide value.

Table 9-245 Column information

Column name	Data type	Description
PROPERTY_NAME	VARCHAR(128)	name of the property
DESCRIPTION	VARCHAR(2048)	description of the property
DATA_TYPE	VARCHAR(32)	data type of the property
STARTUP_PHASE	VARCHAR(32)	modifiable startup-phase: the value IN (NO MOUNT / MOUNT / OPEN & [BELOW|ABOVE])
VALUE_UNIT	VARCHAR(32)	unit of the property value: the value in (NONE, BYTE, MS(milisec))
PROPERTY_VALUE	VARCHAR(2048)	property value for the session. otherwise, the instance-wide value
PROPERTY_SOURCE	VARCHAR(32)	source of the current property value: the value IN (USER, DEFAULT, ENV_VAR, BINARY_FILE, FILE, SYSTEM)
INIT_VALUE	VARCHAR(2048)	property init value for the session
INIT_SOURCE	VARCHAR(32)	source of the current property INIT_VALUE: the value IN (USER, DEFAULT, ENV_VAR, BINARY_FILE, FILE, SYSTEM)
MIN_VALUE	NUMBER	minimum value for property. null if type is varchar
MAX_VALUE	NUMBER	maximum value for property. null if type is varchar
SES_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SESSION or not: the value in (TRUE, FALSE)
SYS_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SYSTEM and when the change takes effect: the value in (NONE, FALSE, IMMEDIATE, DEFERRED)
IS_MODIFIABLE	VARCHAR(32)	property can be changed or not: the value in (TRUE, FALSE)
IS_DEPRECATED	VARCHAR(32)	whether a property is deprecated or not: the value in (TRUE, FALSE)
IS_GLOBAL	VARCHAR(32)	whether a property scope is global or not: the value in (TRUE, FALSE)

V$PROPERTY_ALIAS

The V$PROPERTY_ALIAS displays a list of all properties alias.

Table 9-246 Column information

Column name	Data type	Description
PROPERTY_NAME	VARCHAR(128)	original name of the property
PROPERTY_ALIAS	VARCHAR(128)	alias name of the property

V$PSM_RESERVED_WORDS

The V$PSM_RESERVED_WORDS displays a list of all PSM reserved keywords. Reserved words cannot be used in variable name or procedure name.

Table 9-247 Column information

Column name	Data type	Description
KEYWORD_NAME	VARCHAR(128)	name of keyword
KEYWORD_LENGTH	NUMBER	length of the keyword

V$QUEUE

The V$QUEUE displays information of queue.

Table 9-248 Column information

Column name	Data type	Description
TYPE	NUMBER	queue type (COMMON or DISPATCHER)
INDEX	NUMBER	index
QUEUED	NUMBER	number of items in the queue
WAIT	NUMBER	total time that all items in this queue have waited (1/100 second)
TOTALQ	VARCHAR(128)	total number of items that have ever been in the queue

V$RESERVED_WORDS

The V$RESERVED_WORDS displays a list of all SQL reserved keywords. Reserved words cannot be used in table name or column name.

Table 9-249 Column information

Column name	Data type	Description
KEYWORD_NAME	VARCHAR(128)	name of keyword
KEYWORD_LENGTH	NUMBER	length of the keyword

V$SEQUENCE

The V$SEQUENCE displays information of sequences

Table 9-250 Column information

Column name	Data type	Description
SEQUENCE_NAME	VARCHAR(128)	sequence name
PHYSICAL_ID	NUMBER	sequence physical identifier
START_WITH	NUMBER	start with value
INCREMENT_BY	NUMBER	increment value
MAXVALUE	NUMBER	maximum value
MINVALUE	NUMBER	minimum value
CACHE_SIZE	NUMBER	cache size
LOCAL_NEXT_VALUE	NUMBER	local next value
LOCAL_CURR_VALUE	NUMBER	local current value
RESTART_VALUE	NUMBER	restart value
CYCLE	BOOLEAN	allow cycle
USE_LAST_VALUE	BOOLEAN	use last value or not
LOCAL_CACHE_COUNT	NUMBER	current local cache count
GLOBAL_NEXT_VALUE	NUMBER	global next cache chunk start value
SYNC_COMPARE_SN	NUMBER	serial number for global sequence synchronization
GLOBAL_LATCH_SESSION_ID	NUMBER	identifier of the session acquiring the global latch (-1 if the latch is not acquired)
GLOBAL_LATCH_SESSION_SERIAL	NUMBER	serial number of the session acquiring the global latch (-1 if the latch is not acquired)
DDL_LATCH_SESSION_ID	NUMBER	identifier of the session acquiring the ddl latch (-1 if the latch is not acquired)
DDL_LATCH_SESSION_SERIAL	NUMBER	serial number of the session acquiring the ddl latch (-1 if the latch is not acquired)
LOCAL_LATCH_SESSION_ID	NUMBER	identifier of the session acquiring the local latch (-1 if the latch is not acquired)
LOCAL_LATCH_SESSION_SERIAL	NUMBER	serial number of the session acquiring the local latch (-1 if the latch is not acquired)
IS_ONLINE	BOOLEAN	is online
LAST_SYNC_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	last time the sequence was synchronized

V$SESSION

The V$SESSION displays session information for each current session.

Table 9-251 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	session identifier
SERIAL_NO	NUMBER	session serial number
TRANS_ID	NUMBER	transaction identifier (-1 if inactive transaction)
CONNECTION_TYPE	VARCHAR(32)	connection type: the value in (DA, TCP)
USER_NAME	VARCHAR(128)	user name
SESSION_STATUS	VARCHAR(32)	status of the session: the value in (CONNECTED, SIGNALED, SNIPED, DEAD)
SERVER_TYPE	VARCHAR(32)	server type: the value in (DEDICATED, SHARED)
PROCESS_ID	NUMBER	client process identifier
LOGON_TIME	TIMESTAMP(6) WITH OUT TIME ZONE	logon time
PROGRAM_NAME	VARCHAR(128)	program name
CLIENT_ADDRESS	VARCHAR(1024)	client address (null if DA)
CLIENT_PORT	NUMBER	client port (0 if DA)
FAILOVER_TYPE	VARCHAR(13)	indicates whether and to what extent transparent application failover (TAF) is enabled for the session (NONE, SESSION)
FAILED_OVER	VARCHAR(3)	indicates whether the session is running in failover mode and failover has occurred (YES) or not (NO)
IS_AUDITED	VARCHAR(3)	indicates whether the session is audited (YES) or not (NO)

V$SESSION_AUDIT

The V$SESSION_AUDIT displays audited session information.

Table 9-252 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	session identifier
SERIAL_NO	NUMBER	session serial number
POLICY_NAME	VARCHAR(128)	active audit policy name
WHEN_SUCCESS	VARCHAR(3)	indicates whether the audit policy is enable for auditing successful events or not
WHEN_FAILURE	VARCHAR(3)	indicates whether the audit policy is enable for auditing unsuccessful events or not

V$SESSION_CONNECT_INFO

The V$SESSION_CONNECT_INFO displays information about network connections for the current session.

Table 9-253 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	session identifier
SERIAL_NO	NUMBER	session serial number
CLIENT_CHARSET	VARCHAR(40)	client character set

V$SESSION_EVENT

The V$SESSION_EVENT displays information on waits for an event by a session.

Table 9-254 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	ID of the session
WAIT_EVENT_ID	NUMBER	Identifier of the wait event
WAIT_EVENT_NAME	VARCHAR(64)	Name of the wait event
TOTAL_WAITS	NUMBER	Total number of waits for the event
TOTAL_TIMEOUTS	NUMBER	Total number of timeouts for the event
TIME_WAITED	NUMBER	Total amount of time waited for the event (microsecond)
AVERAGE_WAIT	NUMBER	Average amount of time waited for the event (microsecond)
MAX_WAIT	NUMBER	Maximum time waited for the event by the session (microsecond)
CLASS_NAME	VARCHAR(64)	Name of the class of the wait event

V$SESSION_STAT

The V$SESSION_STAT displays session statistics.

Table 9-255 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
SESS_ID	NUMBER	session identifier
STAT_VALUE	NUMBER	statistic value

V$SESSION_MEM_STAT

The V$SESSION_MEM_STAT displays session memory statistics.

Table 9-256 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
SESS_ID	NUMBER	session identifier
STAT_VALUE	NUMBER	statistic value

V$SESSION_MEM_USAGE

The V$SESSION_MEM_USAGE displays session memory usage for each session.

Table 9-257 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	session identifier
ALLOCATOR_ID	NUMBER	memory allocator identifier
ALLOCATOR_TYPE	VARCHAR(7)	memory allocator type (REGION or DYNAMIC)
MEMORY_TYPE	VARCHAR(4)	memory type (HEAP, SHM)
TOTAL_SIZE	NUMBER	total memory size

V$SESSION_SQL_STAT

The V$SESSION_SQL_STAT displays session SQL statistics.

Table 9-258 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
SESS_ID	NUMBER	session identifier
STAT_VALUE	NUMBER	statistic value

V$SESSION_WAIT

The V$SESSION_WAIT displays the current or last wait for each session.

Table 9-259 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	ID of the session
SEQ_NO	NUMBER	Identifier of the wait event
WAIT_EVENT_ID	NUMBER	Name of the wait event
WAIT_EVENT_NAME	VARCHAR(64)	A number that uniquely identifies the current or last wait (incremented for each wait)
P1TEXT	VARCHAR(64)	Description of the first parameter for the wait event
P1	NUMBER	First wait event parameter (in decimal)
P1HEX	VARCHAR(32)	First wait event parameter (in hex)
P2TEXT	VARCHAR(64)	Description of the second parameter for the wait event
P2	NUMBER	Second wait event parameter (in decimal)
P2HEX	VARCHAR(32)	Second wait event parameter (in hex)
P3TEXT	VARCHAR(64)	Description of the third parameter for the wait event
P3	NUMBER	Third wait event parameter (in decimal)
P3HEX	VARCHAR(32)	Third wait event parameter (in hex)
STATE	VARCHAR(64)	Wait state
WAIT_TIME	NUMBER	If the session is currently waiting, then the value is time waited for the current wait. If the session is not in a wait, then the value is the duration of the last wait (in microseconds)
TIME_SINCE_LAST_WAIT	NUMBER	Time elapsed since the end of the last wait (in microseconds). If the session is currently in a wait, then the value is 0.
CLASS_NAME	VARCHAR(64)	Name of the class of the wait event

V$SHARED_MODE

The V$SHARED_MODE displays information of shared mode.

Table 9-260 Column information

Column name	Data type	Description
NAME	VARCHAR(128)	name
VALUE	VARCHAR(128)	value

V$SHARED_SERVER

The V$SHARED_SERVER displays information of shared servers.

Table 9-261 Column information

Column name	Data type	Description
PROCESS_ID	NUMBER	shared server process identifier
PROCESSED_JOB_COUNT	NUMBER	processed job count
STATUS	VARCHAR(128)	status
IDLE	NUMBER	total idle time (1/100 second)
BUSY	NUMBER	total busy time (1/100 second)

V$SHM_SEGMENT

The V$SHM_SEGMENT displays a list of all shared memory segments.

Table 9-262 Column information

Column name	Data type	Description
SHM_NAME	VARCHAR(32)	shared memory segment name
SHM_ID	NUMBER	shared memory segment identifier
SHM_SIZE	NUMBER	shared memory segment size (in bytes)
SHM_KEY	NUMBER	shared memory segment key
SHM_SEQ	NUMBER	shared memory segment sequence
SHM_ADDR	VARCHAR(32)	start address of the shared memory segment
LARGE_PAGES	BOOLEAN	indicates whether the shared memory segment use large pages

V$SPROPERTY

The V$SPROPERTY displays a list of Properties. This is store a binary property file.

Table 9-263 Column information

Column name	Data type	Description
PROPERTY_NAME	VARCHAR(128)	name of the property
DESCRIPTION	VARCHAR(2048)	description of the property
DATA_TYPE	VARCHAR(32)	data type of the property
STARTUP_PHASE	VARCHAR(32)	modifiable startup-phase: the value IN (NO MOUNT / MOUNT / OPEN & [BELOW|ABOVE])
VALUE_UNIT	VARCHAR(32)	unit of the property value: the value in (NONE, BYTE, MS(milisec))
PROPERTY_VALUE	VARCHAR(2048)	property value stored in the binary property file
PROPERTY_SOURCE	VARCHAR(32)	source of the current property value: the value is BINARY_FILE
INIT_VALUE	VARCHAR(2048)	property init value for the system
INIT_SOURCE	VARCHAR(32)	source of the current property INIT_VALUE: the value IN (USER, DEFAULT, ENV_VAR, BINARY_FILE, FILE, SYSTEM)
MIN_VALUE	NUMBER	minimum value for property. null if type is varchar
MAX_VALUE	NUMBER	maximum value for property. null if type is varchar
SES_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SESSION or not: the value in (TRUE, FALSE)
SYS_MODIFIABLE	VARCHAR(32)	property can be changed with ALTER SYSTEM and when the change takes effect: the value in (NONE, FALSE, IMMEDIATE, DEFERRED)
IS_MODIFIABLE	VARCHAR(32)	property can be changed or not: the value in (TRUE, FALSE)

V$SQLFN_METADATA

The V$SQLFN_METADATA contains metadata about operators and built-in functions

Table 9-264 Column information

Column name	Data type	Description
FUNC_NAME	VARCHAR(128)	name of the built-in function
MINARGS	NUMBER	minimum number of arguments for the function
MAXARGS	NUMBER	maximum number of arguments for the function
IS_AGGREGATE	BOOLEAN	indicates whether the function is an aggregate function (TRUE) or not (FALSE)

V$SQL_CACHE

The V$SQL_CACHE lists statistics of shared SQL plan.

Table 9-265 Column information

Column name	Data type	Description
SQL_HANDLE	NUMBER	SQL handle
HASH_VALUE	NUMBER	hash value of the SQL statement
REF_COUNT	NUMBER	count of prepared statements referencing the statement
PLAN_SIZE	NUMBER	the total plan size of the SQL statement (in bytes)
CLOCK_ID	NUMBER	clock identifier
PLAN_AGE	NUMBER	plan age
USER_NAME	VARCHAR(128)	user name
BIND_PARAM_COUNT	NUMBER	count of bind parameters
SQL_TEXT	LONG VARCHAR	SQL full text
PLAN_COUNT	NUMBER	physical plan count of the SQL statement
PLAN_ID	NUMBER	plan identifier
PLAN_SIZE	NUMBER	the total plan size of the SQL statement (in bytes)
PLAN_IS_ATOMIC	BOOLEAN	plan is atomic array insert or not
PLAN_TEXT	LONG VARCHAR	plan text for SQL statement

V$SQL_COMMAND

The V$SQL_COMMAND lists attribute information of each SQL command.

Table 9-266 Column information

Column name	Data type	Description
COMMAND	VARCHAR(128)	SQL command
FROM_PHASE	VARCHAR(32)	executable from start-up phase
UNTIL_PHASE	VARCHAR(32)	executable until start-up phase
ACCESS_MODE	VARCHAR(32)	database access mode: values in (NONE, READ & WRITE, READ, READ & LOCK)
NEED_FETCH	VARCHAR(32)	the command is a query which has result set and need fetch
IS_DDL	VARCHAR(3)	the command is a DDL(Data Defintion Language) or not
CLUSTER_LOCK_MODE	VARCHAR(32)	cluster lock mode: values in (NONE, SERIAL, MANUAL)
AUTO_COMMIT	VARCHAR(3)	the command is auto-commit or not
IS_CACHEABLE	VARCHAR(3)	the command is plan-cacheable or not
AUDIT_ACTION	VARCHAR(128)	auditiable action name for the SQL command

V$SQL_HISTORY

The V$SQL_HISTORY displays information of SQLs.

Table 9-267 Column information

Column name	Data type	Description
DRIVER_MEMBER_POS	NUMBER	driver member position
SESSION_ID	NUMBER	session identifier
START_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	statement start time
EXEC_TIME	NUMBER	execution time(us)
PREPARED	BOOLEAN	indicates whether the statement is prepared (YES) or not (NO)
SUCCESS	BOOLEAN	indicates whether the statement is success (YES) or not (NO)
STATUS	CHARACTER VARYING(16)	status of the statement: the value in (RUNNING, DONE)
SQL_TEXT	CHARACTER VARYING(1024)	first 1024 bytes of the SQL text for the statement

V$STATEMENT

The V$STATEMENT lists all statements.

Table 9-268 Column information

Column name	Data type	Description
SESSION_ID	NUMBER	session identifier
STMT_ID	NUMBER	statement identifier in a session
STMT_VIEW_SCN	NUMBER	statement view scn
SQL_TEXT	VARCHAR(1024)	first 1024 bytes of the SQL text for the statement
START_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	statement start time
TOTAL_EXEC_TIME	NATIVE_BIGINT	total execution time(us)
LAST_EXEC_TIME	NATIVE_BIGINT	last execution time(us)
EXECUTIONS	NATIVE_BIGINT	number of executions

V$SYSTEM_EVENT

The V$SYSTEM_EVENT displays information on total waits for an event.

Table 9-269 Column information

Column name	Data type	Description
WAIT_EVENT_ID	NUMBER	Identifier of the wait event
WAIT_EVENT_NAME	VARCHAR(64)	Name of the wait event
TOTAL_WAITS	NUMBER	Total number of waits for the event
TOTAL_TIMEOUTS	NUMBER	Total number of timeouts for the event
TIME_WAITED	NUMBER	Total amount of time waited for the event (microsecond)
AVERAGE_WAIT	NUMBER	Average amount of time waited for the event (microsecond)
CLASS_NAME	VARCHAR(64)	Name of the class of the wait event

V$SYSTEM_STAT

The V$SYSTEM_STAT displays system statistics.

Table 9-270 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
STAT_VALUE	NUMBER	statistic value
COMMENTS	VARCHAR(1024)	comments

V$SYSTEM_MEM_STAT

The V$SYSTEM_MEM_STAT displays system memory statistics.

Table 9-271 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
STAT_VALUE	NUMBER	statistic value
COMMENTS	VARCHAR(1024)	comments

V$SYSTEM_SQL_STAT

The V$SYSTEM_SQL_STAT displays system SQL statistics.

Table 9-272 Column information

Column name	Data type	Description
STAT_NAME	VARCHAR(128)	statistic name
STAT_VALUE	NUMBER	statistic value
COMMENTS	VARCHAR(1024)	comments

V$TABLES

The V$TABLES contains the definitions of all the performance views (views beginning with V$).

Table 9-273 Column information

Column name	Data type	Description
TABLE_OWNER	VARCHAR(128)	owner name who owns the performance view
TABLE_SCHEMA	VARCHAR(128)	schema name of the performance view
TABLE_NAME	VARCHAR(128)	name of the performance view
STARTUP_PHASE	VARCHAR(32)	visible startup phase of the performance view
CREATED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	• available only in OPEN phase created time of the performance view
MODIFIED_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	• available only in OPEN phase modified time of the performance view
COMMENTS	VARCHAR(1024)	• available only in OPEN phase comments of the performance view

V$TABLESPACE

This view displays tablespace information.

Table 9-274 Column information

Column name	Data type	Description
TBS_NAME	VARCHAR(128)	tablespace name
TBS_ID	NUMBER	tablespace identifier
TBS_ATTR	VARCHAR(128)	tablespace attribute: the value in (device attribute (MEMORY) | temporary attribute (TEMPORARY, PERSISTENT) | usage attribute(DICT, UNDO, DATA, TEMPORARY))
IS_LOGGING	BOOLEAN	indicates whether the tablespace is a logging tablespace (YES) or not (NO)
IS_ONLINE	BOOLEAN	indicates whether the tablespace is ONLINE (YES) or OFFLINE (NO)
OFFLINE_STATE	VARCHAR(32)	indicates whether the tablespace can be taken online normally (CONSISTENT) or not (INCONSISTENT). null if the tablespace is ONLINE
EXTENT_SIZE	NUMBER	extent size of the tablespace (in bytes)
PAGE_SIZE	NUMBER	page size of the tablespace (in bytes)

V$TABLESPACE_STAT

This view displays tablespace statistical information.

Table 9-275 Column information

Column name	Data type	Description
TBS_NAME	VARCHAR(128)	tablespace name
TBS_ID	NUMBER	tablespace identifier
TOTAL_EXT_COUNT	NUMBER	total extent count of the tablespace
USED_META_EXT_COUNT	NUMBER	meta extent count currently used on the tablespace
USED_DATA_EXT_COUNT	NUMBER	data extent count currently used on the tablespace
FREE_EXT_COUNT	NUMBER	free extent count of the tablespace
EXTENT_SIZE	NUMBER	extent size of the tablespace (in bytes)

V$TRANSACTION

The V$TRANSACTION lists the active transactions in the system.

Table 9-276 Column information

Column name	Data type	Description
TRANS_ID	NUMBER	transaction identifier
SESSION_ID	NUMBER	session identifier (null if the global transaction is unassociated
TRANS_SLOT_ID	NUMBER	transaction slot identifier
PHYSICAL_TRANS_ID	NUMBER	physical transaction identifier
TRANS_STATE	VARCHAR(32)	transaction state: the value in (ACTIVE, BLOCK, PREPARE, COMMIT, ROLLBACK, IDLE, PRECOMMIT)
IS_GLOBAL	BOOLEAN	indicates whether the transaction is global or not
TRANS_ATTRIBUTE	VARCHAR(32)	transaction attribute: the value in (READ_ONLY, UPDATABLE, LOCKABLE, UPDATABLE | LOCKABLE)
ISOLATION_LEVEL	VARCHAR(32)	transaction isolation level: the value in (READ COMMITTED, SERIALIZABLE)
TRANS_VIEW_SCN	NUMBER	transaction view scn
TCN	NUMBER	transaction change number
TRANS_SEQ	NUMBER	transaction sequence number
START_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	transaction start time
UNDO_SEGMENT_ID	NUMBER	undo segment identifier

V$WAIT_EVENT_CLASS_NAME

The V$WAIT_EVENT_CLASS_NAME displays information about Class of wait event.

Table 9-277 Column information

Column name	Data type	Description
CLASS_ID	NUMBER	Identifier of the class of the wait event
NAME	VARCHAR(64)	Name of the class of the wait event
DESCRIPTION	VARCHAR(128)	Description of the class of the wait event

V$WAIT_EVENT_NAME

The V$WAIT_EVENT_NAME displays information about wait events.

Table 9-278 Column information

Column name	Data type	Description
CLASS_ID	NUMBER	Identifier of the wait event
NAME	VARCHAR(64)	Name of the wait event
DESCRIPTION	VARCHAR(128)	Description of the wait event
PARAMETER1	NUMBER	Description of the first parameter for the wait event
PARAMETER1	NUMBER	Description of the second parameter for the wait event
PARAMETER1	NUMBER	Description of the third parameter for the wait event
CLASS_ID	NUMBER	Identifier of the class of the wait event
CLASS_NAME	VARCHAR(64)	Name of the class of the wait event

V$XA_TRANSACTION

The V$XA_TRANSACTION displays information on the currently active XA transactions.

Table 9-279 Column information

Column name	Data type	Description
XA_TRANS_ID	VARCHAR(1024)	XA transaction identifier
LOCAL_TRANS_ID	NUMBER	local transaction identifier
DRIVER_TRANS_ID	NUMBER	driver transaction identifier
DRIVER_MEMBER_POS	NUMBER	driver member position
XA_TRANS_STATE	VARCHAR(32)	state of the XA transaction: the value in (NOTR, ACTIVE, IDLE, PREPARED, ROLLBACK_ONLY, HEURISTIC_COMPLETED)
ASSO_STATE	VARCHAR(32)	associate state of the XA transaction: the value in (NOT_ASSOCIATED, ASSOCIATED, ASSOCIATION_SUSPENDED)
START_TIME	TIMESTAMP(6) WITHOUT TIME ZONE	XA transaction start time
IS_REPREPARABLE	BOOLEAN	indicates whether the XA transaction is repreparable

10.

Server Property

10.1 Server Property Information

For more information about SQL syntax to change properties, refer to the followings.

- **ALTER SYSTEM SET property_name**
- **ALTER SESSION SET property_name**

For more information about property types, refer to the followings.

- **V$PROPERTY**: It displays the property list which can be altered while the system is operating or is rest arting.
- **V$SPROPERTY**: It is either the property which was set by reading the binary file, or the property list w hich is stored in the binary file.
- **V$DB_PROPERTY**: It is a read-only property list which can be altered only when creating the database, and it can not be altered afterwards.

The followings describe basic information items of property in this manual.

Item	Description
Name	Property name
Summary	Short description of the property
Data type	Data type of the property value
Applicable phase	A startup phase which can be updated with ALTER SYSTEM or ALTER SESSION • NONE: Applicable phase does not exist. (If it can be updated, but applicable pha se is NONE, then use *SCOPE = FILE* option.)
Updatable	Whether property is updatable or not • If the property value is TRUE, it is updatable. • If the property value is FALSE, only the read-only is possible.
ALTER SESSION	Whether property is updatable or not by using **ALTER SESSION SET property_name**
ALTER SYSTEM	Whether property is updatable or not by using **ALTER SYSTEM SET property_name** • IMMEDIATE: The updated value is immediately reflected in all session after exec ution. • DEFERRED: The updated value is reflected only in the session which is connected after execution. However, it is not reflected in already connected session. • FALSE: The updated value is not reflected in the session during execution. Howe ver, the updated value is reflected after restart, (Properties are updatable by usin g only *SCOPE=FILE* option.) • NONE: It is not updatable.
MIN	If the data type is BIGINT, it is the minimum value of property. If the data type is VARCHAR, the minimum value of property is N/A.
MAX	If the data type is BIGINT, it is the maximum value of property. If the data type is VARCHAR, the maximum value of property is N/A.

Item	Description
Default value	Default value of the property

10.2 Property Alias Information

The information about the property alias is viewed through **V$PROPERTY_ALIAS**.

The basic information about the property alias written in this manual is as follows.

Item	Description
Original name	It is the original name of the property.
ALIAS	It is the name of the property alias.

For more information about property alias list, refer to **Property Alias**.

CDISPATCHER_THREADS

It is an alias of **CDISPATCHER_LOCKABLE_THREADS**.

CLUSTER_COMMIT_SLAVES

It is an alias of **CLUSTER_COMMIT_SLAVE_CSERVERS**.

CLUSTER_SERVER_RESPONSE_ QUEUE_SIZE

It is an alias of **CLUSTER_GSERVER_RESPONSE_QUEUE_SIZE**.

CSERVER

It is an alias of **CLUSTER_LOCKABLE_CSERVERS**.

INCREMENTAL_CHECKPOINT_CRITERIA

It is an alias of **BUFFER_DIRTY_PAGE_LIMIT**.

LOCKLESS_CSERVERS

It is an alias of **CLUSTER_LOCKLESS_CSERVERS**.

MEMORY_MERGE_RUN_COUNT

It is an alias of **INDEX_MERGE_RUN_COUNT**.

MEMORY_SORT_RUN_SIZE

It is an alias of **INDEX_SORT_RUN_SIZE**.

SYSTEM_LOGGER_DIR

It is an alias of **TRACE_SYSTEM_DIR**.

10.3 ADMIN_SESSION_POOL_INIT_SIZE

Basic Information

Item	Description
Name	ADMIN_SESSION_POOL_INIT_SIZE
Summary	initial memory size for admin session pool
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1099511627776 (1T)
Default value	10485760 (10M)

Description

It sets the initial memory size of the admin session pool.

10.4 ADMIN_SESSION_POOL_NEXT_SIZE

Basic Information

Item	Description
Name	ADMIN_SESSION_POOL_NEXT_SIZE
Summary	memory size to be expanded in admin session pool
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	131072 (128K)
MAX	1073741824 (1G)
Default value	1048576 (1M)

Description

It sets how much to extend the memory size in the session pool when expanding the admin session pool space.
It is valid only when ADMIN_SESSION_POOL_INIT_SIZE is bigger than 0.

10.5 AGING_INTERVAL

Basic Information

Item	Description
Name	AGING_INTERVAL
Summary	aging interval time(ms)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	100000000
Default value	10

Description

It sets the idle time (second) when an ager thread which deletes the previous version data does not have a job to process in MVCC based database.

10.6 AGING_PLAN_INTERVAL

Basic Information

Item	Description
Name	AGING_PLAN_INTERVAL
Summary	aging plan interval time(s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	31536000
Default value	0

Description

The SQL plan which is older than AGING_PLAN_INTERVAL becomes the aging target.

10.7 ARCHIVELOG_DIR_1 ~ ARCHIVELOG_DIR_10

Basic Information

Item	Description
Name	ARCHIVELOG_DIR_1 ~ ARCHIVELOG_DIR_10
Summary	archive log directory
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE(ARCHIVELOG_DIR_1), TRUE(ARCHIVELOG_DIR_2 ~ ARCHIVELOG_DIR_10)
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/archive_log

Description

It specifies archiving directory of GOLDILOCKS database's online redo log file. Also, it specifies where to r ead of archive redo log file at media recovery. The online redo log file creates archive redo log file only in ARCHIVELOG_DIR_1.

ARCHIVELOG_DIR_1 sets only the system, but ARCHIVELOG_DIR_2 ~ ARCHIVELOG_DIR_10 sets the sessi on.

10.8 ARCHIVELOG_FILE

Basic Information

Item	Description
Name	ARCHIVELOG_FILE
Summary	default archive log file
Data type	VARCHAR
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	archive

Description

It sets the prefix of the targeted file name stored in archive directory when archiving online redo logfile. The archive logfile's name consists of prefix '_' set in ARCHIVELOG_FILE, the file sequence and the file extension 'log'. For example, the online logfile whose file sequence is 0 is archived as 'archive_0.log'.

10.9 ARCHIVELOG_MODE

Basic Information

Item	Description
Name	ARCHIVELOG_MODE
Summary	archive log mode(0:disable, 1:enable)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	0

Description

The property is applied at database creation. The archivelog mode can be set to one of the following valu e.

- 0: NOARCHIVELOG
- 1: ARCHIVELOG

It does not affect archive log mode during operation after database is created. The archive log mode can be modified by using *ALTER DATABASE {ARCHIVELOG | NOARCHIVELOG}* in MOUNT phase.

10.10 BACKUP_DIR_1 ~ BACKUP_DIR_10

Basic Information

Item	Description
Name	BACKUP_DIR_1 ~ BACKUP_DIR_10
Summary	backup directory
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE(BACKUP_DIR_1), TRUE(BACKUP_DIR_2 ~ BACKUP_DIR_10)
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/backup

Description

A backup file is created when incremental backup is executed. Then it sets a directory of backup file to be read when restoring files using incremental backup. Incremental backups are created only in the directory set in BACKUP_DIR_1.

BACKUP_DIR_1 sets only the system, but BACKUP_DIR_2 ~ BACKUP_DIR_10 sets the session.

10.11 BLOCK_READ_COUNT

Basic Information

Item	Description
Name	BLOCK_READ_COUNT
Summary	value count for a block read
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	65536
Default value	20

Description

The SQL executes operation by reading row in the unit of BLOCK_READ_COUNT which is a row bundle. BLOCK_READ_COUNT means the number of rows to be processed at a time when operation is executed. It is a basic unit of pipe-lining process of execution nodes whiich are used in SQL query processing.

If BLOCK_READ_COUNT value is big the processing performance improves, but many memory resources are used.
The value between 10 and 100 is recommended.
If the value becomes bigger than 100 the resource usage increases proportionately, but, the performance improvement does not increase proportionately.

10.12 BROADCAST_INDEX_REBUILD_PROTOCOL

Basic Information

Item	Description
Name	BROADCAST_INDEX_REBUILD_PROTOCOL
Summary	broadcast index rebuild protocol
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to simultaneously rebuild the indexes on multiple members when rebuilding the index in c luster environment.

10.13 BROADCAST_REBALANCE_PROTOCOL

Basic Information

Item	Description
Name	BROADCAST_REBALANCE_PROTOCOL
Summary	broadcast rebalance protocol
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to simultaneously process protocol which can be processed on multiple members at the sa me time when performing table rebalancing in a cluster environment.

10.14 BUFFER_CACHE_SIZE

Basic Information

Item	Description
Name	BUFFER_CACHE_SIZE
Summary	buffer cache size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1 MB
MAX	1 TB
Default value	64 MB

Description

It sets the size of the buffer which cashes the page in the disk tablespace.

10.15 BUFFER_CHECKPOINT_LIST_COUNT

Basic Information

Item	Description
Name	BUFFER_CHECKPOINT_LIST_COUNT
Summary	number of buffer checkpoint lists
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	36
Default value	1

Description

It is linked to the checklist when pages of disk tablespace cached to the buffer are updated. Each checkp oint list flushes updated pages linked to the checkpoint list by its own flush thread to the disk, and BUFFE R_CHECKPOINT_LIST_COUNT sets the number of checkpoint lists and the number of flush threads.

10.16 BUFFER_DIRTY_PAGE_LIMIT

Basic Information

Item	Description
Name	BUFFER_DIRTY_PAGE_LIMIT
Summary	a limit on the number of dirty pages in the buffer cache
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	134217728
Default value	0

Description

Pages updated in the system buffer cache is applied to the disk at checkpoint, and if the buffer cache size is big and updated pages are a lot, then the checkpoint takes a long time and it affects the service. GOLDILOCKS performs the incremental checkpoint which applies updated pages to the disk when the number of updated pages are over a specified number in the system. And BUFFER_DIRTY_PAGE_LIMIT sets the criteria to perform the incremental checkpoint.

For example, when this value is set to 1000, if the updated pages are less than 1000 in the system, then the updated pages are not applied to the disk. However, if the updated pages are 1000 or above, then the updated pages in the buffer are applied to the disk.

The default value is 0, and it means infinity. In this case, it does not perform the incremental checkpoint even when all cached pages in the buffer are updated.

Set the appropriate value for BUFFER_DIRTY_PAGE_LIMIT and **INCREMENTAL_DATAFILE_HEADER_UPDATE_CRITERIA** considering the restart recovery time and its effect on the service.

ALIAS

Item	Description
Original name	BUFFER_DIRTY_PAGE_LIMIT
ALIAS	INCREMENTAL_CHECKPOINT_CRITERIA

10.17 BUFFER_FLUSH_THREADS

Basic Information

Item	Description
Name	BUFFER_FLUSH_THREADS
Summary	number of buffer flush threads
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	36
Default value	1

Description

It is linked to the flush list then requests flush to the buffer flusher, to reuse bch which cached the update d pages in the buffer lru list. In this case, BUFFER_FLUSH_THREADS sets the number of buffer flushers an d flush lists to be used in the database.

10.18 BUFFER_FLUSHING_INTERVAL

Basic Information

Item	Description
Name	BUFFER_FLUSHING_INTERVAL
Summary	buffer flushing interval time (sec)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	86400 (1 day)
Default value	3

Description

It sets the idle time (sec) when the job to be processed by the buffer flusher flushing updated disk tablesp ace pages to the disk does not exist.

10.19 BUFFER_FREE_LIST_COUNT

Basic Information

Item	Description
Name	BUFFER_FREE_LIST_COUNT
Summary	number of buffer free lists
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	64
Default value	16

Description

It sets the number of buffer free lists connecting bch which are instantly available to use in the buffer cac he.

10.20 BUFFER_HASH_BUCKETS

Basic Information

Item	Description
Name	BUFFER_HASH_BUCKETS
Summary	number of buffer hash buckets
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1073741824
Default value	0

Description

It sets the number of hash buckets for the disk tablespace pages cached in the buffer. It can be set from 0 to 1073741824, and 0 is set by calculating hash buckets as many as pages which can be cached to the b uffer which is set according to BUFFER_CACHE_SIZE. If the buffer size is smaller than the specified value, then it adjusts the number of hash buckets to the buffer size.

10.21 BUFFER_HOT_REGION_CRITERIA

Basic Information

Item	Description
Name	BUFFER_HOT_REGION_CRITERIA
Summary	threshold touch count of hot region in the buffer lru list
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	2
MAX	100
Default value	2

Description

It sets touch count to transfer pages existing in the cold region to the hot region in buffer lru list.

10.22 BUFFER_HOT_REGION_PERCENT

Basic Information

Item	Description
Name	BUFFER_HOT_REGION_PERCENT
Summary	the percentage of hot region in the buffer lru list
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	80
Default value	20

Description

It sets the proportion (percentage) of hot region pages to the entire page in the buffer lru list.

10.23 BUFFER_LRU_LIST_COUNT

Basic Information

Item	Description
Name	BUFFER_LRU_LIST_COUNT
Summary	number of buffer LRU lists
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	64
Default value	16

Description

It sets the number of lru lists to select a victim among pages in use by caching when the free buffer for ca ching disk tablespace pages does not exist.

10.24 BUFFER_LRU_SCAN_PERCENT

Basic Information

Item	Description
Name	BUFFER_LRU_SCAN_PERCENT
Summary	the percentage of buffers to inspect when looking for free
Data type	NO MOUNT or above
Applicable phase	TRUE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10
MAX	100
Default value	40

Description

If the free buffer available right now does not exist in the system, then it searches for the reusable buffer from the lru list to cache the disk tablespace page to the buffer. BUFFER_LRU_SCAN_PERCENT sets the p ercent of the buffer pages set in BUFFER_CACHE_SIZE, so that it can determine the number of pages to c heck to find the reusable buffer from lru list.

10.25 BUFFER_MULTIPAGE_READ_COUNT

Basic Information

Item	Description
Name	BUFFER_MULTIPAGE_READ_COUNT
Summary	maximum number of pages read in one I/O operation during a full scan
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	128
Default value	32

Description

It sets the maximum number of pages to be used for one time disk IO when full scanning the disk table.

10.26 BUFFER_PREFETCH_PAGE_COUNT

Basic Information

Item	Description
Name	BUFFER_PREFETCH_PAGE_COUNT
Summary	the maximum number of pages to be prefetched to the buffer per I/O operation
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	128
Default value	32

Description

It sets the maximum number of pages nearby to be prefetched per a disk I/O when accessing to the page in the disk tablespace which does not exist in the buffer.

10.27 BULK_IO_PAGE_COUNT

Basic Information

Item	Description
Name	BULK_IO_PAGE_COUNT
Summary	page count for bulk IO operation
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	128
MAX	131072
Default value	3840

Description

It is used when IO READ of the data file occurs during server restart, or when IO WRITE occurs during creating a data file.

The heap memory is allocated as big as BULK_IO_PAGE_COUNT * 8192 when server restarts or data file is created. If the session's PRIVATE_STATIC_AREA_SIZE is smaller than the heap memory size, an error of insufficient memory may occur. In this case, extend PRIVATE_STATIC_AREA_SIZE.

10.28 CDISPATCHER_HOT_POLICY_INTERVAL

Basic Information

Item	Description
Name	CDISPATCHER_HOT_POLICY_INTERVAL
Summary	cdispatcher dequeue interval for busy waiting (micro second)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	86400000000 (1day)
Default value	0

Description

It is the time of the busy waiting when performing the dequeue in the cdispatcher. It is a micro second un it. If this value is big, it uses more cpu but the user response time (latency) is decreased.
The default value is 0, and the busy waiting is not allowed.

10.29 CDISPATCHER_LOCKABLE_THREADS

Basic Information

Item	Description
Name	CDISPATCHER_LOCKABLE_THREADS
Summary	cdispatcher lockable sender, receiver thread count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	30
Default value	1

Description

It sets the number of cdispatcher threads of lockble data sender and receiver. However, the number of cd ispatcher threads of lockless data sender and receiver is set by using **CDISPATCHER_LOCKLESS_THREADS**.

ALIAS

Item	Description
Original name	CDISPATCHER_LOCKABLE_THREADS
ALIAS	CDISPATCHER_THREADS

10.30 CDISPATCHER_LOCKLESS_THREADS

Basic Information

Item	Description
Name	CDISPATCHER_LOCKLESS_THREADS
Summary	cdispatcher lockless sender, receiver thread count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	30
Default value	1

Description

It sets the number of cdispatcher threads of lockless data sender and receiver. However, the number of c dispatcher threads of lockable data sender and receiver is set by using **CDISPATCHER_LOCKABLE_THREADS**.

10.31 CDISPATCHER_MAX_PACKET_BUFFER_SIZE

Basic Information

Item	Description
Name	CDISPATCHER_MAX_PACKET_BUFFER_SIZE
Summary	maximum packet buffer size for cdipatcher sender and receiver threads
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10 Mega
MAX	32 Giga
Default value	1 Giga

Description

It sets the maximum size of the buffer where the data sender and receiver of cdispatcher stores the sent/received packets.

10.32 CDISPATCHER_SOCKET_BUFFER_SIZE

Basic Information

Item	Description
Name	CDISPATCHER_SOCKET_BUFFER_SIZE
Summary	cdispatcher socket buffer(sender, receiver) size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	64
MAX	100 Mega
Default value	32768

Description

It is the socket buffer(sender, receiver) size of cdispatcher.

10.33 CDISPATCHER_SYNC_THREADS

Basic Information

Item	Description
Name	CDISPATCHER_SYNC_THREADS
Summary	cdispatcher sync thread count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	30
Default value	1

Description

It is the thread count of cdispatcher sync.

10.34 CHANGE_TRACKING

Basic Information

Item	Description
Name	CHANGE_TRACKING
Summary	enable change tracking for incremental backup
Data type	BOOLEAN
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to track the updated pages to perform the incremental backup of disk tablespace.

- NO: disable change tracking
- YES: enable change tracking

change tracking can be enabled by using ALTER DATABASE { ENABLE | DISABLE } CHANGE TRACKING on mount or above phase only when the database is operated in archivelog.

10.35 CHANGE_TRACKING_EXTENT_SIZE

Basic Information

Item	Description
Name	CHANGE_TRACKING_EXTENT_SIZE
Summary	number of pages to track changed of incremental backup
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	16
MAX	128
Default value	32

Description

It sets the number of pages to display with one dirty flag when change tracking. For example, if it is set to 32, then one dirty flag is used per 32 pages, and if it is set to 128, then then one dirty flag is used per 12 8 pages.

10.36 CHANGE_TRACKING_FILE

Basic Information

Item	Description
Name	CHANGE_TRACKING_FILE
Summary	default change tracking file
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/backup/gl_change_tracking_file.ctf

Description

It sets the file directory which stores the change tracking, and the file name.

10.37 CHAR_LENGTH_UNITS

Basic Information

Item	Description
Name	CHAR_LENGTH_UNITS
Summary	char length units
Data type	VARCHAR
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	OCTETS

Description

It is the value of char length units used when defining character string such as CHAR, VARCHAR and omit ting char length unit as follows.

```
CREATE TABLE t1
(
   id   CHAR( 10 OCTETS ),
   name VARCHAR( 128 CHARACTERS ),
   addr VARCHAR( 128 )
);
```

- id CHAR(10 OCTETS) means 10 bytes.
- name VARCHAR(128 CHARACTERS) means 128 characters.
- addr VARCHAR(128) means that this value is referenced when char length unit is omitted.

When database is created, the property is set to either OCTETS or CHARACTERS. OCTETS is the number o f bytes, and CHARACTERS is the number of characters.

The SQL standard defines CHARACTERS as default value. Other DBMS defines the default value of char length unit as follows.

- Oracle and DB2 define OCTETS as default value.
- MS-SQL, MySQL, PostgreSQL define CHARACTERS as default value.

10.38 CHARACTER_SET

Basic Information

Item	Description
Name	CHARACTER_SET
Summary	character set
Data type	VARCHAR
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	UTF8

Description

It is a character set of database, and it is applied when database is created.
The property is set to one of the following values.

Character set	Description
SQL_ASCII	ASCII standards
UTF8	Unicode, 8-bit
UHC	Unified Hangul code
GB18030	Chinese government standards

10.39 CHECK_DEDICATE_CONNECTION_INTERVAL

Basic Information

Item	Description
Name	CHECK_DEDICATE_CONNECTION_INTERVAL
Summary	check dedicate socket
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000
Default value	1000

Description

It is the interval of checking for when the client forcibly cut the connection in C/S dedicate environment. The dedicate server(gserver) checks the socket, and it terminates it if it was cut. The default value is 1,000 millisecond (1 second).

10.40 CHECKPOINT_LIST_COUNT_PER_IO_GROUP

Basic Information

Item	Description
Name	CHECKPOINT_LIST_COUNT_PER_IO_GROUP
Summary	number of checkpoint lists per each io group
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	8192
Default value	0

Description

It sets the number of checkpoint lists to be processed by each IO slave set by **PARALLEL_IO_FACTOR**. It specifies the appropriate value to efficiently process the concurrency when connecting the updated pages to the checkpoint lists. The default value is 0, and in this case, each IO slave creates the checkpoint lists as many as the number of CPU and processes it.

10.41 CLIENT_MAX_COUNT

Basic Information

Item	Description
Name	CLIENT_MAX_COUNT
Summary	maximum session count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	12
MAX	65535
Default value	128

Description

It sets the maximum number of sessions to connect.

10.42 CLIENT_NUMA_POLICY

Basic Information

Item	Description
Name	CLIENT_NUMA_POLICY
Summary	client numa policy(0: by modualar, 1: by statistics , 2: by manunal)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	2
Default value	0

Description

It determines the policy to distribute client processes to NUMA nodes. This property is operated when NU MA property is set to on.

- 0: It determines the NUMA node to be connected by modularizing the session ID.
- 1: It connects to the NUMA node of which is the least connected based on the statistics information.
- 2: C/S clientis determined by TCP_CLIENT_NUMA_NODE property, D/A client is determined by DA_CL IENT_ NUMA_NODE property.

10.43 CLOSE_PSM_CHILD_STMTS

Basic Information

Item	Description
Name	CLOSE_PSM_CHILD_STMTS
Summary	close child statements of PSM at the end of each execution
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It closes the child statement of PSM at the end of each execution.

10.44 CLUSTER_ASYNC_COMMIT

Basic Information

Item	Description
Name	CLUSTER_ASYNC_COMMIT
Summary	enable asynchronous commit in cluster system
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

It determines whether to internally process the commit protocol on an async mode in cluster system.

If this property is set to on, it asynchronously commits each node, so the temporary inconsistency among nodes may occur. On the other hand, if it is set to off, it synchronizes everytime it commits, so it may reduce the performance. Therefore, it is required to determine the appropriate property depending on the purpose.

10.45 CLUSTER_CM_BUFFER_SIZE

Basic Information

Item	Description
Name	CLUSTER_CM_BUFFER_SIZE
Summary	communication buffer size for cluster
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	10 Mega
MAX	32 Giga
Default value	10 Mega

Description

It is the communication buffer size for cluster.

10.46 CLUSTER_CM_READ_BUFFER_SIZE

Basic Information

Item	Description
Name	CLUSTER_CM_READ_BUFFER_SIZE
Summary	communication read block size
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	8192
MAX	10485,760
Default value	65536

Description

It is the communication read block size.

10.47 CLUSTER_COMMIT_SLAVE_CSERVERS

Basic Information

Item	Description
Name	CLUSTER_COMMIT_SLAVE_CSERVERS
Summary	number of commit slave cservers
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	8
Default value	0

Description

It is the number of commit slaves.

ALIAS

Item	Description
Original name	CLUSTER_COMMIT_SLAVE_CSERVERS
ALIAS	CLUSTER_COMMIT_SLAVES

10.48 CLUSTER_COMMIT_STREAM_ISOLATION

Basic Information

Item	Description
Name	CLUSTER_COMMIT_STREAM_ISOLATION
Summary	isolate cluster dispatcher stream for commit protocol
Data type	BOOLEAN
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	0

Description

It determines whether to internally perform the commit process flow in the cluster system separately from other protocol process. The performance may be improved when seperating the commit process accordin g to the system environment.

10.49 CLUSTER_CONNECTION

Basic Information

Item	Description
Name	CLUSTER_CONNECTION
Summary	connection mode for cluster (socket:0, rdma:1)
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	0: socket

Description

It is the connection mode for cluster. (socket:0, rdma:1)

10.50 CLUSTER_CONNECTION_TIMEOUT_SEC

Basic Information

Item	Description
Name	CLUSTER_CONNECTION_TIMEOUT_SEC
Summary	connection timeout for cluster
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	86400
Default value	10

Description

It is the connection timeout for cluster.

10.51 CLUSTER_DATA_SYNC_SERVERS

Basic Information

Item	Description
Name	CLUSTER_DATA_SYNC_SERVERS
Summary	count of data synchroniztion server
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	128
Default value	3

Description

It is the count of data synchroniztion server.

10.52 CLUSTER_DEADLOCK_TIMEOUT

Basic Information

Item	Description
Name	CLUSTER_DEADLOCK_TIMEOUT
Summary	a time limit (sec) for resolving cluster deadlock
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	3600 (1 hour)
Default value	3600 (1 hour)

Description

If the competition to occupy the cluster server becomes keen due to the lack of the lockable cluster server, then the cluster deadlock may occur. When cluster deadlock occurs, it waits for the deadlock to be resolved as long as the time set in this property. However, if it is not resolved, then CLUSTER_DEADLOCK_TIMEOUT error occurs.

10.53 CLUSTER_DISPATCHER_IN_QUEUE_SIZE

Basic Information

Item	Description
Name	CLUSTER_DISPATCHER_IN_QUEUE_SIZE
Summary	in-queue size for cluster dispatcher
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1024
MAX	32768
Default value	1024

Description

It is the in-queue size for cluster dispatcher

10.54 CLUSTER_DISPATCHER_NUMA_STREAM_MAP

Basic Information

Item	Description
Name	CLUSTER_DISPATCHER_NUMA_STREAM_MAP
Summary	numa stream map for cluster dispatcher
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	'x' : no binding

Description

It determines a NUMA node to which the cluster dispatcher is to be connected. This property is operated when NUMA property is set to on.

If CLUSTER_COMMIT_STREAM_ISOLATION property is set to on, then the 0 stream is set to NUMA node of a commit stream.

The following is an example of three dispatchers. It connects number 0 stream to number 0 NUMA node, connects number 1 stream to number 1 NUMA node, and number 2 stream to number 2 NUMA node.

```
CLUSTER_DISPATCHER_NUMA_STREAM_MAP = '0:1:2'
```

10.55 CLUSTER_DISPATCHER_OUT_QUEUE_SIZE

Basic Information

Item	Description
Name	CLUSTER_DISPATCHER_OUT_QUEUE_SIZE
Summary	out-queue size for cluster dispatcher
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1024
MAX	32768
Default value	1024

Description

It is the out-queue size for cluster dispatcher.

10.56 CLUSTER_GSERVER_RESPONSE_QUEUE_SIZE

Basic Information

Item	Description
Name	CLUSTER_GSERVER_RESPONSE_QUEUE_SIZE
Summary	response queue size for cluster server
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	30
MAX	32768
Default value	30

Description

It sets the maximum queue size to receive the response from the remote server.

ALIAS

Item	Description
Original name	CLUSTER_GSERVER_RESPONSE_QUEUE_SIZE
ALIAS	CLUSTER_SERVER_RESPONSE_QUEUE_SIZE

10.57 CLUSTER_HEARTBEAT_INTERVAL

Basic Information

Item	Description
Name	CLUSTER_HEARTBEAT_INTERVAL
Summary	interval seconds for health checking of cluster
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	86400
Default value	3

Description

It is the interval seconds for health checking of cluster. 0 means that it is disabled.

10.58 CLUSTER_HEARTBEAT_RETRY_COUNT

Basic Information

Item	Description
Name	CLUSTER_HEARTBEAT_RETRY_COUNT
Summary	retry count for health checking of cluster
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	65536
Default value	5

Description

It is the retry count for health checking of cluster.

10.59 CLUSTER_IGNORE_INACTIVE_MEMBER

Basic Information

Item	Description
Name	CLUSTER_IGNORE_INACTIVE_MEMBER
Summary	ignore in-active member for cluster
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	NO

Description

It ignores in-active member for cluster.

10.60 CLUSTER_KEEPALIVE_IDLE_TIME

Basic Information

Item	Description
Name	CLUSTER_KEEPALIVE_IDLE_TIME
Summary	The number of seconds a cluster connection needs to be idle
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	16383
Default value	0

Description

It is the idle time which is the duration without sending or receiving TCP packets between a cluster sessio n and a cdispatcher before sending a keep alive packet. In other words, if TCP packets are not exchanged during the seconds set in CLUSTER_KEEPALIVE_IDLE_TIME, then the keep alive mechanism is performed on cdispatcher side to detect the dead connection.

The default value is 0, in which case the keep alive feature is disabled.

10.61 CLUSTER_LOCKABLE_CSERVERS

Basic Information

Item	Description
Name	CLUSTER_LOCKABLE_CSERVERS
Summary	number of lockable cserver processes
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	2048
Default value	5

Description

It sets the number of cluster server processes performing the operation which acquires lock. However, th e number of cluster server processes performing the operation which does not acquire lock is set by using **CLUSTER_LOCKLESS_CSERVERS**.

ALIAS

Item	Description
Original name	CLUSTER_LOCKABLE_CSERVERS
ALIAS	CSERVERS

10.62 CLUSTER_LOCKLESS_CSERVERS

Basic Information

Item	Description
Name	CLUSTER_LOCKLESS_CSERVERS
Summary	number of lockless cserver processes
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	2048
Default value	5

Description

It sets the number of cluster server processes performing the operation which does not acquire lock. How ever, the number of cluster server processes performing the operation which acquires lock is set by using **CLUSTER_LOCKABLE_CSERVERS**.

ALIAS

Item	Description
Original name	CLUSTER_LOCKLESS_CSERVERS
ALIAS	LOCKLESS_CSERVERS

10.63 CLUSTER_MAX_PACKET_SIZE

Basic Information

Item	Description
Name	CLUSTER_MAX_PACKET_SIZE
Summary	maximum packet size for cluster session
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10 Mega
MAX	32 Giga
Default value	100 Mega

Description

It sets the maximum packet size of which the remote protocol can transfer at a time. If the column size to be remotely transferred exceeds the property size, then the property size should be set biggerthen the col umn size.

10.64 CLUSTER_MAX_PAYLOAD_SIZE

Basic Information

Item	Description
Name	CLUSTER_MAX_PAYLOAD_SIZE
Summary	maximum packet payload size for cluster session (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	524288
MAX	33554432
Default value	524288

Description

The cluster packet which is remotely transferred may be delivered in pieces, and this property sets the ma
ximum size of data to be stored in a piece.

10.65 CLUSTER_PACKET_ALLOCATION_TIMEOUT

Basic Information

Item	Description
Name	CLUSTER_PACKET_ALLOCATION_TIMEOUT
Summary	a time limit (sec) for how long statemets will wait to allocate packet memory
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	100000000
Default value	3

Description

It sets the maximum time (second) of waiting when allocating memory required for cluster packet config uration.

10.66 CLUSTER_PROTOCOL_FAILOVER_POLICY_TIMEOUT

Basic Information

Item	Description
Name	CLUSTER_PROTOCOL_FAILOVER_POLICY_TIMEOUT
Summary	a time limit of failover policy to wait for a response from the cluster protocol
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	0

Description

It is the maximum time of when waiting for the response after transferring the protocol in cluster. If it does not responds within the specified time, then GOLDILOCKS, depending on the protocol, may terminate the protocol or make the remote cluster member which does not responds to be failover. Specify the time limit by using *CLUSTER_PROTOCOL_FAILOVER_POLICY_TIMEOUT* property to use the failover policy. However, specify the time limit by using **CLUSTER_PROTOCOL_SESSION_FATAL_POLICY_TIMEOUT** property to use the policy terminating the session.

10.67 CLUSTER_PROTOCOL_SESSION_FATAL_POLICY_TIMEOUT

Basic Information

Item	Description
Name	CLUSTER_PROTOCOL_SESSION_FATAL_POLICY_TIMEOUT
Summary	a time limit of session fatal policy to wait for a response from the cluster protocol
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	0

Description

It is the maximum time of when waiting for the response after transferring the protocol in cluster. If it does not responds within the specified time, then GOLDILOCKS, depending on the protocol, may terminate the protocol or make the remote cluster member which does not responds to be failover. Specify the time limit by using *CLUSTER_PROTOCOL_SESSION_FATAL_POLICY_TIMEOUT* property to use the policy terminating the session. However, specify the time limit by using **CLUSTER_PROTOCOL_FAILOVER_POLICY_TIMEOUT** property to use the failover policy.

10.68 CLUSTER_SESSION_HASH_BUCKETS

Basic Information

Item	Description
Name	CLUSTER_SESSION_HASH_BUCKETS
Summary	Number of hash buckets for cluster sessions
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	127
MAX	1073741824
Default value	127

Description

It sets the number of hash buckets to control the cluster session.

10.69 CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY

Basic Information

Item	Description
Name	CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY
Summary	split brain resolution policy for cluster system
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	2
Default value	0

Description

It sets the policy to resolve split-brain situation in the cluster system. If the value is set to 1 or over, it enquires the solution of a locator.

If the query for a locator is timed out, it tries to enquire as many times as CLUSTER_SPLIT_BRAIN_RETRY_COUNT. If the property value after the retry failure is 1, then it forcibly proceeds the fail over. If it is 2, then it terminates the fatal.

10.70 CLUSTER_SPLIT_BRAIN_RETRY_COUNT

Basic Information

Item	Description
Name	CLUSTER_SPLIT_BRAIN_RETRY_COUNT
Summary	retry count for split brain resolution policy(1 ~ 65536)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	65536
Default value	1

Description

It is used when CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY is set to 1 or over in cluster system. It sets t he times of retrying to enquire when the query to a locator does not respond.

10.71 COMMITTER_HOT_POLICY_INTERVAL

Basic Information

Item	Description
Name	COMMITTER_HOT_POLICY_INTERVAL
Summary	committer deque interval for busy waiting
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	86400000000 (1 day)
Default value	0 (cold policy)

Description

It sets the timezone interval of busy waiting when the commit cserver is dequeing to read the commit pro tocol message. If it is set to 1,000,000 (1 second), and the time is not passed over 1 second from the last deque success to another deque retry, then it sets the timeout in deque to 0 and performs the busy waiti ng.

10.72 CONTROL_FILE_0 ~ CONTROL_FILE_7

Basic Information

Item	Description
Name	CONTROL_FILE_0
Summary	control file name
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/wal/control_0.ctl

Description

If a control file is corrupted, database can not be used. Therefore, the control file is multiplexed for stabili ty of database. It specifies the directory and file name of which stores each control file.

10.73 CONTROL_FILE_COUNT

Basic Information

Item	Description
Name	CONTROL_FILE_COUNT
Summary	control file count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	2
MAX	8
Default value	2

Description

If a control file is corruped, database can not be used. The control file is multiplexed for stability of datab ase. CONTROL_FILE_COUNT specifies the multiplexing number of control files. A control file is multiplexe d at least 2 up to 8.

10.74 CONTROL_FILE_TEMP_NAME

Basic Information

Item	Description
Name	CONTROL_FILE_TEMP_NAME
Summary	temporary file name for control file
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/backup/control.tmp

Description

During database operation, a control file is frequently changed, and its temporary copy can be made if ne cessary. CONTROL_FILE_TEMP_NAME specifies the directory and its file name to temporarily store the co ntrol file.

10.75 COORDINATOR_COMMIT_WRITE_MODE

Basic Information

Item	Description
Name	COORDINATOR_COMMIT_WRITE_MODE
Summary	coordinator commit write mode(0:disable, 1:wait mode)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It is a commit write mode applied to a coordinator. If TRANSACTION_COMMIT_WRITE_MODE is *no wait*, and its property is *wait*, then the coordinator node is operated as *wait*, and other nodes are operated as *no wait*.

10.76 DA_CLIENT_NUMA_NODE

Basic Information

Item	Description
Name	DA_CLIENT_NUMA_NODE
Summary	numa node for DA clients
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	-1
MAX	63
Default value	-1

Description

It sets the NUMA node ID to which the direct access (D/A) session is to be bound. This property is operate d when NUMA property is set to ON.

10.77 DATA_STORE_MODE

Basic Information

Item	Description
Name	DATA_STORE_MODE
Summary	data store mode(cds:1,tds:2)
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	2
Default value	2

Description

It sets the storing method of database.

- 1: CDS mode supports the concurrency for multiple users but it does not guarantee the durability. It d oes not record logs for all update operations such as insert/ delete/ update data, consequentially a fai lure can not be recovered.
- 2: TDS mode guarantee s the concurrency for multiple users and the durability using logs.

10.78 DATABASE_INSTANCE_NAME

Basic Information

Item	Description
Name	DATABASE_INSTANCE_NAME
Summary	database instance name
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	GOLDILOCKS

Description

It is the database instance name.

10.79 DDL_AUTOCOMMIT

Basic Information

Item	Description
Name	DDL_AUTOCOMMIT
Summary	DDL auto commit
Data type	BOOL
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to autocommit DDL operations which are not autocommitted yet. For example, autocommit is not applied to the operations such as creating/altering a table, so if DDL_AUTOCOMMIT is 0, a table creation and alteration can be undone by the rollback. On the other hand, if DDL_AUTOCOMMIT is 1, DDL to which autocommit is not applied is committed immediately.

10.80 DDL_LOCK_TIMEOUT

Basic Information

Item	Description
Name	DDL_LOCK_TIMEOUT
Summary	a time limit (sec) for how long DDL statemets will wait
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	0

Description

It means the lock wait time when DDL operations occur to the same object at the same time.
The default value is 0 second, and it does not wait for a lock when the DDL operation occurs.

When operations of altering a table structure simultaneously occur, they wait for the time specified in DD L_LOCK_TIMEOUT, without waiting for other transactions termination as follows.

- Transaction A

```
ALTER TABLE t1 ADD COLUMN ( new_column NUMBER );
```

- Transaction B

```
TRUNCATE TABLE t1;
```

If the waiting time exceeds DDL_LOCK_TIMEOUT, an error occurs as follows.

```
gSQL> TRUNCATE TABLE t1;
ERR-HYT00(14026): resource busy or timeout expired
```

10.81 DEADLOCK_PRIORITY

Basic Information

Item	Description
Name	DEADLOCK_PRIORITY
Summary	importance to choose deadlock victim
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	0
MAX	9
Default value	5

Description

When a deadlock occurs while simultaneously processing multiple transactions, a specific transaction wit h the low weight is selected as a victim among transactions which caused the deadlock, to solve the prob lem. If a deadlock occurs between a transaction started in sessions which have higher value for this prope rty and a transaction started in sessions which have lower value for this property, then latter is selected as a deadlock victim. Therefore, set this property according to the priority of each transaction.

Start the transaction after setting this property value so that this value is applied as a weight of that trans action. The transaction weight is not altered if this value is changed after the transaction already has bee n started.

10.82 DEFAULT_GLOBAL_SECONDARY_INDEX_CREATION

Basic Information

Item	Description
Name	DEFAULT_GLOBAL_SECONDARY_INDEX_CREATION
Summary	specifies whether or not create global secondary index at table creation
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	YES

Description

It sets whether to create the global secondary index when creating a table in cluster system. A non-deterministic query for the table which did not created the global secondary index fails. The global secondary index can be separately created after creating the table when the property is set to NO.

10.83 DEFAULT_INDEX_LOGGING

It is not supported after 3.2.

Basic Information

Item	Description
Name	DEFAULT_INDEX_LOGGING
Summary	default logging flag of indexes
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

If LOGGING property is not explicitly set by a user when an index is created, then it is set to DEFAULT_INDEX_LOGGING value. If an index is created in LOGGING tablespace, the LOGGING property should be set.

10.84 DEFAULT_INDEX_PCTFREE

Basic Information

Item	Description
Name	DEFAULT_INDEX_PCTFREE
Summary	default pctfree value of indexes (%)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	99
Default value	10

Description

If a user does not explicitly specify PCTFREE syntax when creating an index. The PCTFREE is set to DEFAUL T_INDEX_PCTFREE property value.

10.85 DEFAULT_INITRANS

Basic Information

Item	Description
Name	DEFAULT_INITRANS
Summary	default initrans value of tables
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	32
Default value	4

Description

If a user does not explicitly set INITRANS syntax when creating a table or an index, then it is set to DEFAULT_INITRANS property value.

10.86 DEFAULT_MAXTRANS

Basic Information

Item	Description
Name	DEFAULT_MAXTRANS
Summary	default maxtrans value of tables
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	32
Default value	32

Description

If a user does not explicitly set the MAXTRANS syntax when creating a table or an index, then it is set to DEFAULT_MAXTRANS property value.

10.87 DEFAULT_PCTFREE

Basic Information

Item	Description
Name	DEFAULT_PCTFREE
Summary	default pctfree value of tables (%)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	99
Default value	10

Description

If a user does not explicitly set the PCTFREE property when creating a table, it is set to DEFAULT_PCTFREE property value.

10.88 DEFAULT_PCTUSED

Basic Information

Item	Description
Name	DEFAULT_PCTUSED
Summary	default pctused value of tables (%)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	99
Default value	60

Description

If a user does not explicitly set the PCTUSED property when creating a table, it is set to DEFAULT_PCTUSED value.

10.89 DEFAULT_REMOVAL_BACKUP_FILE

Basic Information

Item	Description
Name	DEFAULT_REMOVAL_BACKUP_FILE
Summary	default removal flag of incremental backup files
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It specifies whether to delete the backup file when deleting the backup list.

10.90 DEFAULT_REMOVAL_OBSOLETE_BACKUP_LIST

Basic Information

Item	Description
Name	DEFAULT_REMOVAL_OBSOLETE_BACKUP_LIST
Summary	default removal flag of obsolete incremental backup lists
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It specifies whether to delete the previous obsoleted backup list when executing INCREMENTAL BACKUP.

10.91 DEFAULT_SHARDING

Basic Information

Item	Description
Name	DEFAULT_SHARDING
Summary	default sharding strategy (0: cloned, 1: hash sharding)
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It sets the default sharding strategy to be used if the sharding strategy is not determined when creating a table.

The following is an example of executing CREATE TABLE statement.

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
);
```

If DEFAULT_SHARDING value is 0 (cloned), the table is created as a cloned table as follows.

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
)
CLONED
```

```
AT CLUSTER WIDE
;
```

If DEFAULT_SHARDING value is 1 (hash sharding), the table is created as a hash-sharded table as follows.

```
CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128)
)
SHARDING BY HASH (id)
    SHARD COUNT 24
    AT CLUSTER WIDE
;
```

If DEFAULT_SHARDING is 1 (hash sharding) and <table sharding strategy> is not described, then the hash sharding key is determined based on the following order.

1. If PRIMARY KEY constraint is defined, primary key is used as a sharding key.

- The original message

```
CREATE TABLE t1 ( id INTEGER PRIMARY KEY, name VARCHAR(128) );
```

- Translation

```
CREATE TABLE t1 ( id INTEGER PRIMARY KEY, name VARCHAR(128) )
    SHARDING BY HASH(id)
    SHARD COUNT 24
    AT CLUSTER WIDE;
```

2. If UNIQUE constraint is defined, the firstly described UNIQUE constraint is used as the sharding key.

- The original message

```
CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) UNIQUE );
```

- Translation

```
CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) UNIQUE )
    SHARDING BY HASH(name)
    SHARD COUNT 24
    AT CLUSTER WIDE;
```

3. If key constraint is not defined, the first column except for the following excluded data type is used a s a sharding key.
    - The excluded data type: LONG VARCHAR, LONG VARBINARY, BOOLEAN

- The original message

```
CREATE TABLE t1 ( is_man BOOLEAN, id INTEGER, name VARCHAR(128) );
```

- Translation

```
CREATE TABLE t1 ( is_man BOOLEAN, id INTEGER, name VARCHAR(128) )
    SHARDING BY HASH(id)
    SHARD COUNT 24
    AT CLUSTER WIDE;
```

10.92 DISABLE_DDL

Basic Information

Item	Description
Name	DISABLE_DDL
Summary	disable All DDL
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It prevents all DDL execution.

The SQL statements which are affected by DISABLE_DDL are queried as follows.

```
gSQL>
SELECT command
  FROM v$sql_command
 WHERE is_ddl = 'YES'
 ORDER BY 1
;

10.93 DISABLE_DDL_CDC_GIVEUP

Basic Information

Item	Description
Name	DISABLE_DDL_CDC_GIVEUP
Summary	disable DDL which causing CDC give-up
Data type	BOOLEAN
Applicable phase	OPEN
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	TRUE
MIN	0
MAX	1
Default value	NO

Description

It prohibits DDL operation on the table of supplemental log, because it affects CDC's give up.
For more information, refer to **The occurrence of give up and whether to allow DDL statement according to DDL category**.

10.94 DISABLE_SERIAL_DDL

Basic Information

Item	Description
Name	DISABLE_SERIAL_DDL
Summary	disable Serial DDL
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

DDL is executed for all cluster members after sequentially acquiring locks in cluster environment as described in **Processing DDL in Cluster**.
The DDL which is performed in the serial lock method is called as the serial DDL.

DDL statements which are affected by DISABLE_SERIAL_DDL are queried as follows, and most of schema DDLs are affected.

```
gSQL>
SELECT command
     , is_ddl
     , cluster_lock_mode
  FROM v$sql_command
 WHERE is_ddl = 'YES'
   AND cluster_lock_mode = 'SERIAL'
 ORDER BY 1
;
SELECT command
     , is_ddl
     , cluster_lock_mode
```

```
  FROM v$sql_command
 WHERE is_ddl = 'YES'
   AND cluster_lock_mode = 'SERIAL'
 ORDER BY 1
;
COMMAND                                          IS_DDL CLUSTER_LOCK_MODE
------------------------------------------------ ------ -----------------
ALTER AUDIT POLICY                               YES    SERIAL
ALTER DATABASE CLEAR PASSWORD HISTORY            YES    SERIAL
ALTER DATABASE DATAFILE AUTOEXTEND ..            YES    SERIAL
ALTER FUNCTION                                   YES    SERIAL

10.95 DISABLE_UPDATE_PK_CDC_GIVEUP

Basic Information

Item	Description
Name	DISABLE_UPDATE_PK_CDC_GIVEUP
Summary	disable UPDATE primary key which caused CDC give-up
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It disables UPDATE primary key which caused CDC give up.

10.96 DISALLOWED_PROTOCOL_TARGETTYPE

Basic Information

Item	Description
Name	DISALLOWED_PROTOCOL_TARGETTYPE
Summary	disallowed TARGETTYPE protocol
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It disallows TARGETTYPE protocol.

10.97 DISALLOWED_PROTOCOL_TARGETTYPE_WITH_ALL

Basic Information

Item	Description
Name	DISALLOWED_PROTOCOL_TARGETTYPE_WITH_ALL
Summary	disallowed TARGETTYPE_WITH_ALL protocol
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It disallows TARGETTYPE_WITH_ALL protocol.

10.98 DISALLOWED_PROTOCOL_TARGETTYPE_WITH_NAME

Basic Information

Item	Description
Name	DISALLOWED_PROTOCOL_TARGETTYPE_WITH_NAME
Summary	disallowed TARGETTYPE_WITH_NAME protocol
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It disallows TARGETTYPE_WITH_NAME protocol.

10.99 DISPATCHER_CM_BUFFER_SIZE

Basic Information

Item	Description
Name	DISPATCHER_CM_BUFFER_SIZE
Summary	communication buffer size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	10485760
MAX	34359738368
Default value	31457280

Description

It is the size of entire communication buffer used in shared mode. It is allocated to and used in Shared Sta tic Area (SSA).

10.100 DISPATCHER_CM_UNIT_SIZE

Basic Information

Item	Description
Name	DISPATCHER_CM_UNIT_SIZE
Summary	communication unit size
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1024
MAX	10485760
Default value	1024

Description

It is the unit size managed by dispatcher in shared mode. If the size is large, the memory is wasted. If it is small, the performance is degraded. It is set to the maximum communication packet size in the shared m ode.

10.101 DISPATCHER_CONNECTIONS

Basic Information

Item	Description
Name	DISPATCHER_CONNECTIONS
Summary	maximum number of connections for each dispatcher
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10
MAX	32768
Default value	950

Description

It is the maximum number of connection (client) which a dispatcher can manage in shared mode.
If the system- supported maximum value is smaller than the set value, it is internally set to the system max imum.

10.102 DISPATCHER_HOT_POLICY_INTERVAL

Basic Information

Item	Description
Name	DISPATCHER_HOT_POLICY_INTERVAL
Summary	dispatcher dequeue interval for busy waiting
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	86400000000: 1 day
Default value	100000: 0.1 second

Description

It is the dispatcher dequeue interval for busy waiting. (micro second)

10.103 DISPATCHER_LOAD_BALANCING

Basic Information

Item	Description
Name	DISPATCHER_LOAD_BALANCING
Summary	load balancing algorithm for shared mode (0: number of clients, 1: round robin)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It is an algorithm allocating a dispatcher when connecting to a client in the shared mode.

- 0: It is allocated to a dispatcher of which the number of currently attached clients are small.
- 1: It is sequentially allocated to a dispatcher.

10.104 DISPATCHER_NUMA_STREAM_MAP

Basic Information

Item	Description
Name	DISPATCHER_NUMA_STREAM_MAP
Summary	numa stream map for dispatcher
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	'x' : no binding

Description

It determines NUMA node to whcih dispatchers are to be connected. This property is operated when NU MA property is set to on.
The following is an example of three dispatchers. It connects number 0 stream to number 0 NUMA node, connects number 1 stream to number 1 NUMA node, and number 2 stream to number 2 NUMA node.

```
DISPATCHER_NUMA_STREAM_MAP = '0:1:2'
```

10.105 DISPATCHER_QUEUE_SIZE

Basic Information

Item	Description
Name	DISPATCHER_QUEUE_SIZE
Summary	dispatcher queue size
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1024
MAX	32768
Default value	1024

Description

In shared mode, it sets the queue size for the communication between the dispatcher and the shared-ser ver.

10.106 DISPATCHER_REQUEST_MINI_QUEUE_COUNT

Basic Information

Item	Description
Name	DISPATCHER_REQUEST_MINI_QUEUE_COUNT
Summary	count of mini queue per request queue
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	16
Default value	4

Description

It is the count of mini queue per request queue.

10.107 DISPATCHER_RESPONSE_MINI_QUEUE_COUNT

Basic Information

Item	Description
Name	DISPATCHER_RESPONSE_MINI_QUEUE_COUNT
Summary	count of mini queue per response queue
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	16
Default value	4

Description

It is the count of mini queue per response queue.

10.108 DISPATCHERS

Basic Information

Item	Description
Name	DISPATCHERS
Summary	number of dispatcher processes
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	256
Default value	2

Description

It sets the number of dispatcher processes when using the shared mode.
It can not reduce the value by using alter system on open phase.

10.109 EXECUTE_INST_HASH_TABLE_USING_AVAILABLE_MEMORY

Basic Information

Item	Description
Name	EXECUTE_INST_HASH_TABLE_USING_AVAILABLE_MEMORY
Summary	execute instant hash table using available memory even if not enough
Data type	BOOLEAN
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

If the memory is not sufficient to expand the hash bucket in the query using an instant hash table, then it determines whether to fail the query or to perform the query without expanding the hash bucket.

10.110 FETCH_FAILOVER

Basic Information

Item	Description
Name	FETCH_FAILOVER
Summary	enable fetch failover
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	NO

Description

It enables the fetch failover.

10.111 FULL_TABLE_SCAN_CACHING_THRESHOLD

Basic Information

Item	Description
Name	FULL_TABLE_SCAN_CACHING_THRESHOLD
Summary	upper threshold of table size for buffer caching while full scan
Data type	BIGINT
Applicable phase	NO MOUNT above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1000
Default value	20

Description

The threshold of the table size determines whether to cache the tables created in the disk tablespace to buffer cache when performing a full scan. FULL_TABLE_SCAN_CACHING_THRESHOLD sets this threshold value. The default value is 20. In this case, it caches only the tables which are using the number of pages equal to or less than 2.0% of **BUFFER_CACHE_SIZE**. If this value is 1000 (100%), then all tables are cached to the buffer when performing the full scan.

For example, if BUFFER_CACHE_SIZE is 8192 and FULL_TABLE_SCAN_CACHING_THRESHOLD is 509 (50.9%), then only the tables which are using the number of pages equal to or less than 4169 (50.9% of 8192) are cached to the buffer when performing the full scan.

10.112 GLOBAL_CONNECTION_ALLOW_SESSION_DEPENDENCY

Basic Information

Item	Description
Name	GLOBAL_CONNECTION_ALLOW_SESSION_DEPENDENCY
Summary	allowed session dependent features in global connection
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	TRUE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to support the query execution including the session dependent information in the global connection.

10.113 GLOBAL_JOURNAL_BUFFER_SIZE

Basic Information

Item	Description
Name	GLOBAL_JOURNAL_BUFFER_SIZE
Summary	global journal buffer size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1024
MAX	10 Giga
Default value	1 Mega

Description

It is the size of global journal buffer.

10.114 GLOBAL_JOURNAL_BUFFER_TOTAL_MAX_SIZE

Basic Information

Item	Description
Name	GLOBAL_JOURNAL_BUFFER_TOTAL_MAX_SIZE
Summary	global journal buffer total max size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1 Mega
MAX	100 Giga
Default value	64 Mega

Description

It is the total max size of global journal buffer.

10.115 GLOBAL_PROPERTY_LOCK_TIMEOUT

Basic Information

Item	Description
Name	GLOBAL_PROPERTY_LOCK_TIMEOUT
Summary	a time limit(second) for how long global property lock statements will wait
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0 (infinite)
MAX	100000000
Default value	0

Description

When changing the global property, it performs the lock to control the concurrency. In this case, the wait ing time to perform the lock is set.

10.116 GLOBAL_TRANSACTION_COMMIT_WRITE_MODE

Basic Information

Item	Description
Name	GLOBAL_TRANSACTION_COMMIT_WRITE_MODE
Summary	global transaction commit write mode (0: no_wait, 1: wait, 2: disable)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	2
Default value	2

Description

It is a property to change the commit write mode of the global transaction. TRANSACTION_COMMIT_ WRITE_MODE property is applied to all transactions, but GLOBAL_TRANSACTION_COMMIT_WRITE_MODE property is applied only to a global transaction. If the property is set to 2, then it follows the TRANSACTIO N_COMMIT_WRITE_MODE.

- 0: It does not wait.
- 1: It waits.
- 2: It follows the value of TRANSACTION_COMMIT_WRITE_MODE.

10.117 GLOBAL_TRANSACTION_ISOLATION_SCOPE

Basic Information

Item	Description
Name	GLOBAL_TRANSACTION_ISOLATION_SCOPE
Summary	isolation scope for global transaction(0: system, 1: group)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It determines whether to process the data with a global transaction or with multiple domain transactions when the transaction changed the data through two cluster groups.

- 0: It processes with a global transaction.
- 1: It processes with multiple domain transactions.

If this property is set to 1, it commits each cluster group with a separate transaction, so it does n ot guarantees the transaction atomicity.

10.118 GLOBAL_TRANSACTION_LOG_DIR

Basic Information

Item	Description
Name	GLOBAL_TRANSACTION_LOG_DIR
Summary	default global transaction log directory
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/wal

Description

It is the default directory of global transaction log.

10.119 GLOBAL_TRANSACTION_LOG_FILE_SIZE

Basic Information

Item	Description
Name	GLOBAL_TRANSACTION_LOG_FILE_SIZE
Summary	global transaction log file size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	20 Mega
MAX	10 Giga
Default value	100 Mega

Description

It is the file size of global transaction log.

10.120 GMASTER_NUMA_NODE

Basic Information

Item	Description
Name	GMASTER_NUMA_NODE
Summary	numa node for gmaster process
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	-1
MAX	63
Default value	-1

Description

It sets the ID of NUMA node to be used by gmaster daemon. This property is operated when NUMA property is set to on.

10.121 GMON_AUTOSTART

Basic Information

Item	Description
Name	GMON_AUTOSTART
Summary	Indicate whether gmon process automatically starts or not (0 | 1)
Data type	BOOLEAN
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	1

Description

It sets whether to start gmon process automatically.

10.122 HINT_ERROR

Basic Information

Item	Description
Name	HINT_ERROR
Summary	enable hint error
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It sets whether to check syntax error and validation error for hint syntax.

10.123 IDLE_TIMEOUT

Basic Information

Item	Description
Name	IDLE_TIMEOUT
Summary	idle timeout(s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

It sets the maximum IDLE time possible to wait in C/S session. If it exceeds the specified idle time, TIMEO UT error occurs.

- 0: It means infinite waiting, and TIMEOUT error does not occur.

10.124 IN_DOUBT_DECISION

Basic Information

Item	Description
Name	IN_DOUBT_DECISION
Summary	decision for in-doubt transaction
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	2
Default value	2

Description

It determines whether to commit or to rollback the in-doubt transaction of distributed transactions.

- 1: Commit
- 2: Rollback

10.125 IN_KEY_RANGE_ARRAY_COUNT

Basic Information

Item	Description
Name	IN_KEY_RANGE_ARRAY_COUNT
Summary	array count for in key range scan
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	65536
Default value	20

Description

It is the maximum number of values which are targets of *in key range* performing the *in key range scan* b ased on array.

- IN_KEY_RANGE_ARRAY_COUNT should be 3 or bigger to perform the *in key range scan* based on arr ay for the statement below.

```
gSQL> SELECT * FROM T1 WHERE C1 IN ( 1, 2, 3 )
```

If the maximum number of in key range target values are bigger than IN_KEY_RANGE_ARRAY_COUNT v alue, then in key range in key range scan is performed based on instant table.

10.126 INCREMENTAL_BACKUP_SCAN_BUFFER_SIZE

Basic Information

Item	Description
Name	INCREMENTAL_BACKUP_SCAN_BUFFER_SIZE
Summary	number of pages read in one I/O operation during an incremental backup
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	8192
Default value	32

Description

It sets the number of pages to read by one time disk IO for performing incremental backup of the disk tablespace.

10.127 INCREMENTAL_DATAFILE_HEADER_UPDATE_CRITERIA

Basic Information

Item	Description
Name	INCREMENTAL_DATAFILE_HEADER_UPDATE_CRITERIA
Summary	criteria for the number of flush page count to update datafile header
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	134217728
Default value	134217728

Description

It sets the criteria of updating the data file header in the disk tablespace. It sets the LSN to start recovery in the datafile header when the pages updated as many as the set value is applied while IO slave applies the pages updated in the buffer cache to the disk. In this way, disk IO is decreased at restart recovery.

10.128 INDEX_BUILD_PARALLEL_FACTOR

Basic Information

Item	Description
Name	INDEX_BUILD_PARALLEL_FACTOR
Summary	index build parallel factor
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	64
Default value	0

Description

When creating an index, it specifies the number of parallel factor.

- 0: It is specified as the number of the core factor in the system.

10.129 INDEX_MERGE_RUN_COUNT

Basic Information

Item	Description
Name	INDEX_MERGE_RUN_COUNT
Summary	merge run count for memory index
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	2
MAX	64
Default value	32

Description

Memory B-tree index of bottom-up approach is created by extracting all keys from a table, sorting them i n certain block size (INDEX_SORT_RUN_SIZE) units, merging the sorted blocks, and generating the intern al node. INDEX_MERGE_RUN_COUNT sets the number of the sorted blocks to be merged at a time.

ALIAS

Item	Description
Original name	INDEX_MERGE_RUN_COUNT
ALIAS	MEMORY_MERGE_RUN_COUNT

10.130 INDEX_REBUILD_BLOCK_READ_COUNT

Basic Information

Item	Description
Name	INDEX_REBUILD_BLOCK_READ_COUNT
Summary	value count for a block read for index rebuild
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	65536
Default value	100

Description

When DML is performed while rebuilding the index on ONLINE mode, the journal data is stored. The index is rebuilt based on the data at the time of beginning of the rebuilding, then the updated data during the rebuilding is applied to the index through the journal data. INDEX_REBUILD_BLOCK_READ_COUNT sets how much journal data to be read and applied to the index during this process.

10.131 INDEX_SORT_RUN_SIZE

Basic Information

Item	Description
Name	INDEX_SORT_RUN_SIZE
Summary	sort run size for memory index (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	8192
MAX	32768
Default value	8192

Description

Memory B-tree index of bottom-up approach is created by extracting all keys from a table, sorting them i n a certain block size (INDEX_SORT_RUN_SIZE) unit, merging the sorted blocks, and generating the inter nal node. INDEX_SORT_RUN_SIZE sets the size of a single block to be sorted.

ALIAS

Item	Description
Original name	INDEX_SORT_RUN_SIZE
ALIAS	MEMORY_SORT_RUN_SIZE

10.132 INDEX_TREE_MERGE_PARALLEL_FACTOR

Basic Information

Item	Description
Name	INDEX_TREE_MERGE_PARALLEL_FACTOR
Summary	parallel factor for merging sub-trees
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	64
Default value	0

Description

When creating an index, it specifies the number of parallel factor to merge the sub-tree.
If that value is bigger than INDEX_BUILD_PARALLEL_FACTOR, then INDEX_BUILD_PARALLEL_FACTOR is used.

- 0: It follows INDEX_BUILD_PARALLEL_FACTOR.

10.133 INST_ALLOCATOR_COUNT

Basic Information

Item	Description
Name	INST_ALLOCATOR_COUNT
Summary	memory allocator count for instant tables or indexes
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	3
MAX	128
Default value	3

Description

This property increases the parallel property of operation allocating or deleting an instant block.

10.134 INST_HASH_TABLE_BUCKET_MAX_COUNT

Basic Information

Item	Description
Name	INST_HASH_TABLE_BUCKET_MAX_COUNT
Summary	instant hash table bucket max count
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	4294967295
Default value	0

Description

It sets the maximum expected bucket counts of the hash instant table.

10.135 INST_TABLE_BLOCK_SIZE

Basic Information

Item	Description
Name	INST_TABLE_BLOCK_SIZE
Summary	a block size of instant tables or indexes
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	8192
MAX	1048576
Default value	16384

Description

It determines the size of an instant block. If the anchor area of an instant record is bigger than an instant block, then the following error occurs.

```
gSQL> SELECT DISTINCT * FROM T1, T1, T1, T1, T1, T1, T1, T1, T1, T1;
ERR-HY000(14098): maximum record length(16360) exceeds
```

10.136 IPC_CHANNEL_COUNT

Basic Information

Item	Description
Name	IPC_CHANNEL_COUNT
Summary	IPC Channel Count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	2048
Default value	0

Description

It sets the number of channels for IPC communication.

10.137 JOURNAL_TEMP_DIR

Basic Information

Item	Description
Name	JOURNAL_TEMP_DIR
Summary	journaling temporary directory
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/journal

Description

It is the temporary directory of journaling.

10.138 KEEPALIVE_IDLE_TIME

Basic Information

Item	Description
Name	KEEPALIVE_IDLE_TIME
Summary	tcp keepalive idle time for checking dead client session (sec)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	16383
Default value	300

Description

It means the idle duration between the server and client without tcp packet exchange before sending kee p alive packet. If there is not tcp packet exchange for seconds (KEEPALIVE_IDLE_TIME), keep alive mecha nism starts execution to detect the dead connection on the server side.

10.139 LOCAL_CLUSTER_MEMBER

Basic Information

Item	Description
Name	LOCAL_CLUSTER_MEMBER
Summary	local cluster member name
Data type	VARCHAR
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	N/A
MAX	N/A
Default value	'G1N1'

Description

It is the local cluster member name.

10.140 LOCAL_CLUSTER_MEMBER_HOST

Basic Information

Item	Description
Name	LOCAL_CLUSTER_MEMBER_HOST
Summary	host name of local cluster member
Data type	VARCHAR
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	N/A
MAX	N/A
Default value	'127.0.0.1'

Description

It is host name of local cluster member.

10.141 LOCAL_CLUSTER_MEMBER_PORT

Basic Information

Item	Description
Name	LOCAL_CLUSTER_MEMBER_PORT
Summary	listen port of local cluster member
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	1024
MAX	49151
Default value	10101

Description

It is listen port of local cluster member.

10.142 LOCAL_JOURNAL_BUFFER_SIZE

Basic Information

Item	Description
Name	LOCAL_JOURNAL_BUFFER_SIZE
Summary	local journal buffer size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1024
MAX	10737418240 (10 Giga)
Default value	65536

Description

It is the local journal buffer size.

10.143 LOCATION_FILE

Basic Information

Item	Description
Name	LOCATION_FILE
Summary	location file name
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/wal/location.ctl

Description

It is the location file name.

10.144 LOCATOR_QUERY_TIMEOUT

Basic Information

Item	Description
Name	LOCATOR_QUERY_TIMEOUT
Summary	timeout for waiting locator response (sec)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	3

Description

It sets the time (second) waiting for the response after the cluster system enquires of a locator about the solution of split-brain situation. This property is used only when CLUSTER_SPLIT_BRAIN_RESOLUTION_POLICY is set to 1 or more.

10.145 LOCK_HASH_TABLE_SIZE

Basic Information

Item	Description
Name	LOCK_HASH_TABLE_SIZE
Summary	lock manager hash table size (The number of buckets)
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	2
MAX	1000000
Default value	65519

Description

It specifies the maximum hash table size managed by a lock manager.

10.146 LOCKABLE_DISPATCHER_CM_BUFFER_COUNT

Basic Information

Item	Description
Name	LOCKABLE_DISPATCHER_CM_BUFFER_COUNT
Summary	communication buffer count for lockable dispatcher
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	128
Default value	1

Description

It specifies the number of cluster lockable dispatcher's communication buffers.

10.147 LOCKLESS_DISPATCHER_CM_BUFFER_COUNT

Basic Information

Item	Description
Name	LOCKLESS_DISPATCHER_CM_BUFFER_COUNT
Summary	communication buffer count for lockless dispatcher
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	128
Default value	1

Description

It specifies the number of cluster lockless dispatcher's communication buffers.

10.148 LOG_BLOCK_SIZE

Basic Information

Item	Description
Name	LOG_BLOCK_SIZE
Summary	log block size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	512
MAX	4096
Default value	512

Description

It means the minimum size of what log buffer is flushed to the log file of the disk. Its value should be set t
o one of 512, 1024, 2048, 4096.

10.149 LOG_BUFFER_SIZE

Basic Information

Item	Description
Name	LOG_BUFFER_SIZE
Summary	default log buffer size (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1048576
MAX	10737418240
Default value	10485760

Description

A log buffer is the shared memory space in which the redo logs generated in database by the DML/DDL operations are stored. LOG_BUFFER_SIZE is referenced to set the memory size for the log buffer.

10.150 LOG_DIR

Basic Information

Item	Description
Name	LOG_DIR
Summary	default log direcotry
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/wal

Description

The log recorded in the log buffer is flushed to the logfile which exists in a non-volatile storage device to ensure the database durability. LOG_DIR sets the path to the log file.

10.151 LOG_FILE_SIZE

Basic Information

Item	Description
Name	LOG_FILE_SIZE
Summary	log file size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	20 Mbytes
MAX	120 Gbytes
Default value	100 Mbytes

Description

It sets the size of the logfile used in database. It is referenced only when creating the database, then log file size can not be updated after then.

10.152 LOG_GROUP_COUNT

Basic Information

Item	Description
Name	LOG_GROUP_COUNT
Summary	initial count of log group
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	4
MAX	254
Default value	4

Description

It sets the number of log group used in database. It is referenced only when creating the database, but af ter that, it does not affect any operations. After creating database, the operation to add or remove a log group is supported by a separate syntax.

10.153 LOG_MIRROR_MODE

Basic Information

Item	Description
Name	LOG_MIRROR_MODE
Summary	LogMirror Mode (1:Enable, 0:Disable)
Data type	BOOLEAN
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It is the property to configure the required shared memory when operating LogMirror, the redo log replic ation tool, at database startup.
It should be enabled to execute the LogMirror.
The size of the shared Memory can be changed using LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE.

10.154 LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE

Basic Information

Item	Description
Name	LOG_MIRROR_SHARED_MEMORY_STATIC_SIZE
Summary	shared memory size for LogMirror (byte)
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10485760 (10 M)
MAX	1073741824 (1 G)
Default value	104857600 (100 M)

Description

It sets the size of the shared memory used in LogMirror, the redo log replication tool.
It is applied in the state which LOG_MIRROR_MODE is enabled.

10.155 LOG_MIRROR_TIMEOUT

Basic Information

Item	Description
Name	LOG_MIRROR_TIMEOUT
Summary	logmirror retry timeout (sec)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	0

Description

It is the response waiting time of the LogMirror.
If its value is o, it waits indefinitely. Otherwise, it waits as long as the value set, then TIMEOUT occurs, an d it stops LogMirror service. Later, the server is operated normally.
It is applied in the state which LOG_MIRROR_MODE is enabled.

10.156 LOG_SYNC_INTERVAL

Basic Information

Item	Description
Name	LOG_SYNC_INTERVAL
Summary	interval for synchronize log (s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	10000
Default value	3

Description

Log flusher of GOLDILOCKS is a system thread which flushes the log buffer contents to disk logfile. When log flusher wakes up in the idle phase, it checks if log to flush exists. Then it flushes the log if any.
If the log flusher did not flush within the time set in LOG_SYNC_INTERVAL, it synchronizes the log buffer and the log file by performing a flush until the last block of the current log buffer.

10.157 LOG_SYNC_INTERVAL_MSEC

Basic Information

Item	Description
Name	LOG_SYNC_INTERVAL_MSEC
Summary	milli-second interval for synchronize log
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

It is the millisecond interval for synchronize log.

10.158 MAX_GROUP_COUNT

Basic Information

Item	Description
Name	MAX_GROUP_COUNT
Summary	maximum group count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	8192
Default value	32

Description

It is the maximum group count in the cluster system.

10.159 MAX_JOURNAL_FILE_SIZE

Basic Information

Item	Description
Name	MAX_JOURNAL_FILE_SIZE
Summary	maximum journal file size
Data type	BIGINT
Applicable phase	MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1099511627776 (1 Terabytes)
Default value	0 (no limit)

Description

It sets the maximum size (quota) of the global journaling file which internally stores journaling data when a journaling occurs in cluster system.

10.160 MAX_NODE_COUNT

Basic Information

Item	Description
Name	MAX_NODE_COUNT
Summary	maximum node count
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	1
MAX	8192
Default value	64

Description

It is the maximum node (instance) count which can join the cluster system.

10.161 MAXIMUM_CONCURRENT_ACTIVITIES

Basic Information

Item	Description
Name	MAXIMUM_CONCURRENT_ACTIVITIES
Summary	maximum number of active statements that the driver can support for a connection
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	65535
Default value	1024

Description

It sets the number of statements which can be executed simultaneously.

10.162 MAXIMUM_FILE_CACHE_SIZE

Basic Information

Item	Description
Name	MAXIMUM_FILE_CACHE_SIZE
Summary	the limit of file descriptor cache
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	16
MAX	32768
Default value	128

Description

It sets the maximum number of file caches which is being used in the session.

10.163 MAXIMUM_FLUSH_BUFFER_PAGE_COUNT

Basic Information

Item	Description
Name	MAXIMUM_FLUSH_BUFFER_PAGE_COUNT
Summary	maximum number of buffer page count to be flushing
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	8192
Default value	64

Description

It sets the maximum number of pages which can be recorded per disk writing operation. If the pages in the disk tablespace are updated in the buffer, then IO thread records them on the disk. If recording nearby pages together when performing disk writing operation, then it increases the efficiency of the system resource by decreasing the number of disk recording.

10.164 MAXIMUM_FLUSH_LOG_BLOCK_COUNT

Basic Information

Item	Description
Name	MAXIMUM_FLUSH_LOG_BLOCK_COUNT
Summary	maximum number of log block count to be flushing
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1000
MAX	2000000
Default value	100000

Description

When flushing the contents of the log buffer to disk log file, it sets the maximum number of log blocks to be flushed with a single writing operation.

10.165 MAXIMUM_FLUSH_PAGE_COUNT

Basic Information

Item	Description
Name	MAXIMUM_FLUSH_PAGE_COUNT
Summary	maximum number of page count to be flushing
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	8192
Default value	1024

Description

GOLDILOCKS datafiles are flushed to the disk by the checkpoint and certain DDL statements. For flushing datafiles, it sets the maximum number of data pages to be flushed with a single writing operation.

10.166 MAXIMUM_INDEX_REBUILD_JOURNAL_REPLAY_COUNT

Basic Information

Item	Description
Name	MAXIMUM_INDEX_REBUILD_JOURNAL_REPLAY_COUNT
Summary	maximum number of replaying journals for rebuild index
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	2
MAX	1024
Default value	2

Description

When rebuilding the index on ONLINE mode, it can be performed together with DML, and DML records the updates on the journal log. The index is rebuilt based on the data at the time of beginning of the rebuilding, then the updated data during the rebuilding is applied to the index through the journal log. The journal logs are initially applied, then journal logs which were accumulated while applying the journal logs are applied. This property sets how may times the journal logs are applied in this way.

10.167 MAXIMUM_JOURNAL_REPLAY_COUNT

Basic Information

Item	Description
Name	MAXIMUM_JOURNAL_REPLAY_COUNT
Summary	maximum number of replaying journals for rebalance table
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	2
MAX	1024
Default value	2

Description

The table rebalancing online can be performed together with DML in the cluster environment, and DML r ecords the updates on the journal log at that moment. The table rebalancing initially applies the journal l ogs which occurred during synchronizing tables, then applies journal logs which were accumulated while applying the journal logs. This property sets how may times the journal logs are applied in this way.

10.168 MAXIMUM_NAMED_CURSOR_COUNT

Basic Information

Item	Description
Name	MAXIMUM_NAMED_CURSOR_COUNT
Summary	maximum number of named cursor that the driver can support for a connection
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	100000
Default value	128

Description

It is the maximum number of named cursor which can be used within a single session.
A named curor is created in the following cases.

- When a named cursor is declared using functions like SQLSetCursorName(), SQLGetCursorName().

```
{
    ...
    SQLSetCursorName( stmt,
                      "my_cursor",
                      SQL_NTS );
    ...
}
```

- When the DECLARE cursor syntax is used by a function such as SQLExecDirect (), SQLPrepare ().

```
{
    ...
    SQLExecDirect( stmt,
                   "DECLARE my_cursor CURSOR FOR SELECT col_name FROM tab_name",
```

```
                    SQL_NTS );
    ...
}
```

- When DECLARE cursor FOR UPDATE syntax is used in an embedded SQL.

```
{
    ...
    EXEC SQL DECLARE my_cursor CURSOR FOR SELECT col_name FROM tab_name FOR UPDATE;
    ...
    EXEC SQL OPEN my_cursor;
    ...
    EXEC SQL FETCH my_cursor INTO :data;
    EXEC SQL DELETE FROM tab_name WHERE CURRENT OF my_cursor;
    ...
    EXEC SQL CLOSE my_cursor;
}
```

In an embedded SQL, DECLARE CURSOR syntax without FOR UPDATE as follows does not creat e a named cursor on the session.

```
{
    ...
    EXEC SQL DECLARE my_cursor CURSOR FOR SELECT col_name FROM tab_name;
    ...
}
```

10.169 MAXIMUM_PACKAGE_INSTANCE_COUNT

Basic Information

Item	Description
Name	MAXIMUM_PACKAGE_INSTANCE_COUNT
Summary	maximum number of package instance that the driver can support for a connection
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	100000
Default value	128

Description

It is the maximum number of package instances which are available in a single session.
A package instance is created when using the stateful package in the session.

10.170 MAXIMUM_SESSION_CM_BUFFER_SIZE

Basic Information

Item	Description
Name	MAXIMUM_SESSION_CM_BUFFER_SIZE
Summary	maximum communication bytes per shared mode session
Data type	BIGINT
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1048576
MAX	1073741824
Default value	20971520

Description

It sets the maximum buffer size available in a single session which is connected to shared mode.
For more information, refer to **DISPATCHER_CM_BUFFER_SIZE**.

10.171 MEASURE_CLUSTER_LATENCY

Basic Information

Item	Description
Name	MEASURE_CLUSTER_LATENCY
Summary	measure cluster latency
Data type	BOOL
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It is the measure cluster latency.

10.172 MIN_SAMPLE_ROW_COUNT

Basic Information

Item	Description
Name	MIN_SAMPLE_ROW_COUNT
Summary	minimum sampling row count for analyze table
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	9223372036854775807 (INT64_MAX)
Default value	100000

Description

It is the minimum number of sampling rows when executing **ANALYZE TABLE** by using the sampling.

10.173 MINIMUM_UNDO_PAGE_COUNT

Basic Information

Item	Description
Name	MINIMUM_UNDO_PAGE_COUNT
Summary	minimum undo page count
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	16
MAX	1048576
Default value	16

Description

DML uses the undo page to store the previous image. Undo page is consumed by using a single undo seg ment per DML. If all allocated pages of undo segments are consumed, the page of another undo segmen t can be used. MINIMUM UNDO PAGE_COUNT is the minimum number of undo page to specify the und o segment to import page when undo pages are insufficient. If the undo pages are insufficient, the pages can be imported only from the undo segment having more pages than MINIMUM UNDO PAGE_COUNT.

10.174 NET_BUFFER_SIZE

Basic Information

Item	Description
Name	NET_BUFFER_SIZE
Summary	TCP network buffer size (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1024
MAX	1073741824
Default value	32768

Description

It sets the TCP communications buffer size.
In the dedicated mode, it is set to the maximum communication packet size.
In the shared mode, it is set to **DISPATCHER_CM_UNIT_SIZE**.

10.175 NLS_DATE_FORMAT

Basic Information

Item	Description
Name	NLS_DATE_FORMAT
Summary	nls date format
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	YYYY-MM-DD

Description

NLS_DATE_FORMAT specifies the default date format of TO_CHAR and TO_DATE functions.

10.176 NLS_TIME_FORMAT

Basic Information

Item	Description
Name	NLS_TIME_FORMAT
Summary	nls time format
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	HH24:MI:SS.FF6

Description

NLS_DATE_FORMAT specifies the default time format of TO_CHAR and TO_DATE functions.

10.177 NLS_TIME_WITH_TIME_ZONE_FORMAT

Basic Information

Item	Description
Name	NLS_TIME_WITH_TIME_ZONE_FORMAT
Summary	nls time with time zone format
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	HH24:MI:SS.FF6 TZH:TZM

Description

NLS_TIME_WITH_TIME_ZONE FORMAT specifies the default time with time zone format of TO_CHAR an d TO_TIME_WITH_TIME_ZONE functions.

10.178 NLS_TIMESTAMP_FORMAT

Basic Information

Item	Description
Name	NLS_TIMESTAMP_FORMAT
Summary	nls timestamp format
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	YYYY-MM-DD HH24:MI:SS.FF6

Description

NLS_TIMESTAMP_FORMAT specifies the default timestamp format of TO_CHAR and TO_TIMESTAMP fun
ctions.

10.179 NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT

Basic Information

Item	Description
Name	NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT
Summary	nls timestamp with time zone format
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM

Description

NLS_TIMESTAMP_WITH_TIME_ZONE FORMAT specifies the default timestamp with time zone format of TO_CHAR and TO_TIMESTAMP WITH TIMEZONE functions.

10.180 NUMA

Basic Information

Item	Description
Name	NUMA
Summary	enable numa
Data type	BOOLEAN
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1
Default value	NO

Description

It enables NUMA.

To use the NUMA property in AIX, the user account should be modified. Execute the following command as a root user.

```
# chuser "capabilities=CAP_NUMA_ATTACH,CAP_PROPAGATE" <username>
```

<username> is not a root byt it is a user account of AIX.
Logout then login again to apply the modifications.

10.181 NUMA_MAP

Basic Information

Item	Description
Name	NUMA_MAP
Summary	numa node map
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	'x' : no binding

Description

It sets the map to connect cores of the system to NUMA node. This property is operated when NUMA pro perty is set to on.

The following is an example of the system having four cores.

- Connect core 0 and 1 to number 0 NUMA node, and core 2 and 3 to number 1 NUMA node.

```
NUMA_MAP = '0:0:1:1' # core
```

- Connect core 0 and 1 to number 0 NUMA node, and core 2 and 3 to number 1 NUMA node, and cor e 1 and 3 to number 2 NUMA node.

```
NUMA_MAP = '0:0,2:1:1,2' # core
```

10.182 OFFLINE_MEMBER_AFTER_FAILOVER

Basic Information

Item	Description
Name	OFFLINE_MEMBER_AFTER_FAILOVER
Summary	Automatically offline member after failover
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

The background process automatically takes the errored member offline after completing the failover cau sed by the node error.
If it is not possible to take the errored member offline because it is set to *NO*, then execute the following syntax before the errored member joins the system again.

```
gSQL> ALTER DATABASE OFFLINE INACTIVE CLUSTER MEMBERS;
Database altered.
```

10.183 ONLINE_INDEX_REBUILD_JOURNAL_REPLAY_THRESHOLD

Basic Information

Item	Description
Name	ONLINE_INDEX_REBUILD_JOURNAL_REPLAY_THRESHOLD
Summary	threshold bytes for replaying journals without table lock
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10737418240
Default value	1048576

Description

DML performed during rebuilding the index on ONLINE mode records the journal log. The journals are applied to the index multiple times when finishing rebuilding the index. **MAXIMUM_INDEX_REBUILD_JOURNAL_REPLAY_COUNT** sets how many times to apply the journal logs. However, if the amount of journal logs to be applied are small, then it is not repeated as many as it is set to be, but instantly set the table the EXCLUSIVE lock, and uses it as the threshold value to apply the last journal log.

10.184 ONLINE_JOURNAL_REPLAY_THRESHOLD

Basic Information

Item	Description
Name	ONLINE_JOURNAL_REPLAY_THRESHOLD
Summary	threshold bytes for replaying journals without table lock
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10737418240 (10G)
Default value	1048576 (1M)

Description

The table rebalancing online applies journal logs several times which were recorded by dml occurred duri ng the performance in the cluster environment. MAXIMUM_JOURNAL_REPLAY_COUNT sets how many ti mes to apply the journal logs. However, if the amount of journal logs to be applied are small, then it is no t repeated as many as it is set to be, but instantly set the table the EXCLUSIVE lock, and uses it as the thre shold value to apply the last journal log.

10.185 OS_GROUP_ACCESS

Basic Information

Item	Description
Name	OS_GROUP_ACCESS
Summary	enable access database with OS group permission
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

To connect to DA with another user of the same group, this property should be set to *YES*. Also, the uma sk of the system should be modified to *0002*.

10.186 PACKET_COMPRESSION_THRESHOLD

Basic Information

Item	Description
Name	PACKET_COMPRESSION_THRESHOLD
Summary	The size limit at which packets are compressed(bytes)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	32
MAX	2113929216
Default value	2113929216

Description

If the data size to be sent to the client is bigger than PACKET_COMPRESSION_THRESHOLD, it compresses the communication data.

10.187 PAGE_CHECKSUM_TYPE

Basic Information

Item	Description
Name	PAGE_CHECKSUM_TYPE
Summary	page checksum type (0:LSN, 1:CRC)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

A checksum is used to guarantee the physical consistency for each page of the datafile. GOLDILOCKS sup ports a page checksum of LSN, CRC scheme.

- 0: LSN
- 1: CRC

10.188 PARALLEL_IO_FACTOR

Basic Information

Item	Information
Name	PARALLEL_IO_FACTOR
Summary	parallel load factor
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	16
Default value	1

Description

It sets the number of threads for the parallel loading of data file when starting database and the number of threads for parallel recording of data file at checkpoint.

10.189 PARALLEL_IO_GROUP_1 ~ PARALLEL_IO_GROUP_16

Basic Information

Item	Description
Name	PARALLEL_IO_GROUP_1
Summary	parallel load group 1
Data type	VARCHAR
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/db

Description

It sets the group directory for parallel I/O of data file. It sets the number of group as many as PARALLEL_IO_FACTOR, then parallel I/O is performed in data file unit which belongs to each group.

10.190 PARALLEL_LOAD_FACTOR

Basic Information

Item	Description
Name	PARALLEL_LOAD_FACTOR
Summary	parallel load factor
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	64
Default value	1

Description

When starting database, it sets the number of threads for parallel operation after loading the memory of a data file.

10.191 PENDING_LOG_BUFFER_COUNT

Basic Information

Item	Description
Name	PENDING_LOG_BUFFER_COUNT
Summary	default pending log buffer count
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	32
Default value	4

Description

When multiple transactions are simultaneously running, the pending log buffer is used to reduce the com petition for the log buffer. PENDING LOG_BUFFER COUNT sets the number of pending log buffer which can be used simultaneously.

10.192 PLAN_CACHE

Basic Information

Item	Description
Name	PLAN_CACHE
Summary	caching sql plan
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	YES

Description

It determines whether to use the plan cache.

10.193 PLAN_CACHE_SIZE

Basic Information

Item	Description
Name	PLAN_CACHE_SIZE
Summary	sql plan cache size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	20971520
MAX	1099511627776
Default value	104857600

Description

It sets the memory size to be used for the plan cache.

10.194 PLAN_HISTORY

Basic Information

Item	Description
Name	PLAN_HISTORY
Summary	plan history for SQLs
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to use the plan history.

10.195 PLAN_HISTORY_SIZE

Basic Information

Item	Description
Name	PLAN_HISTORY_SIZE
Summary	plan history size
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	100000
Default value	0

Description

It sets the number of plans to be stored in the plan history.

10.196 PRIVATE_STATIC_AREA_INIT_SIZE

Basic Information

Item	Description
Name	PRIVATE_STATIC_AREA_INIT_SIZE
Summary	Initial size of Private Static Area (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1048576
MAX	34359738368
Default value	10485760

Description

It sets the initial size of the heap memory to use in the session. Even when there are memories which are not used in the session, the memories are not returned to operating system.

10.197 PRIVATE_STATIC_AREA_NEXT_SIZE

Basic Information

Item	Description
Name	PRIVATE_STATIC_AREA_NEXT_SIZE
Summary	Next size of Private Static Area (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1024
MAX	34359738368
Default value	10485760

Description

It sets the size of memory to extend when the session allocates additional heap memory.

10.198 PRIVATE_STATIC_AREA_SHRINK_THRESHOLD

Basic Information

Item	Description
Name	PRIVATE_STATIC_AREA_SHRINK_THRESHOLD
Summary	Threshold bytes to attempt to shrink private static area(byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1048576
MAX	34359738368
Default value	10485760

Description

The memory size is preserved as big as this property even when there are unused heap memories in the session, and those memories are not returned to the system but are reused in the session.

Even when it is set to smaller than PRIVATE_STATIC_AREA_INIT_SIZE, it is not decreased to smaller than the size.

10.199 PRIVATE_STATIC_AREA_SIZE

Basic Information

Item	Description
Name	PRIVATE_STATIC_AREA_SIZE
Summary	Shared Static Area Size (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	104857600
MAX	34359738368
Default value	104857600

Description

It specifies the maximum heap memory size to be allocated by the session.

10.200 PROCESS_MAX_COUNT

Basic Information

Item	Description
Name	PROCESS_MAX_COUNT
Summary	Process Max Count
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	12
MAX	65535
Default value	128

Description

It specifies the maximum number of processes (threads) available on the system.

Creating system process

- The process is created each time of connection to D/A mode or C/S dedicated mode.
- In C/S shared mode, processes are basic balancer, dispatcher and shared-server. A process is not created when connecting from client.

10.201 QUERY_TIMEOUT

Basic Information

Item	Description
Name	QUERY_TIMEOUT
Summary	query timeout (s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

It specifies the maximum time which a command received from the session can be executed. If the execution time exceeds, the TIMEOUT error occurs.

- 0: It means infinite waiting, and TIMEOUT error does not occur.

10.202 READABLE_ARCHIVELOG_DIR_COUNT

Basic Information

Item	Description
Name	READABLE_ARCHIVELOG_DIR_COUNT
Summary	readable archive log directory count
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	10
Default value	1

Description

It sets the number of directories in which archive redo logs exist when executing media recovery.

10.203 READABLE_BACKUP_DIR_COUNT

Basic Information

Item	Description
Name	READABLE_BACKUP_DIR_COUNT
Summary	readable backup directory count
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	10
Default value	1

Description

It sets the number of directories in which incremental backups exist when restoring files using incrementa l backups.

10.204 REBALANCE_BLOCK_READ_COUNT

Basic Information

Item	Description
Name	REBALANCE_BLOCK_READ_COUNT
Summary	block read count for rebalance
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	1
MAX	65536
Default value	1

Description

It is the block read count for rebalance.

10.205 REBALANCE_SHARD_DIVISOR

Basic Information

Item	Description
Name	REBALANCE_SHARD_DIVISOR
Summary	partition factor of shard upon rebalance
Data type	BIGINT
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	1000
Default value	1

Description

It sets the number of shards to divide which are used to rebalance and synchronize the table.
For more information, refer to **ALTER TABLE name REBALANCE**.

10.206 RECOMPILE_CHECK_MINIMUM_PAGE_COUNT

It is not supported after 3.1.

Basic Information

Item	Description
Name	RECOMPILE_CHECK_MINIMUM_PAGE_COUNT
Summary	minimum page count for recompile check
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	10000
Default value	64

Description

It sets the minimum page count to check if the plan is recompiled due to the page count modification.

10.207 RECOMPILE_PAGE_PERCENT

It is not supported after 3.1.

Basic Information

Item	Description
Name	RECOMPILE_PAGE_PERCENT
Summary	recompile page percent
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1000
Default value	30

Description

It sets the page percent when recompiles the plan due to the page count modification. If its value is 0, it does not recompile due to the page count modification.

10.208 RECOVERY_LOG_BUFFER_SIZE

Basic Information

Item	Description
Name	RECOVERY_LOG_BUFFER_SIZE
Summary	default log buffer size for recovery
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	786432
MAX	32 Mega
Default value	10 Mega

Description

It is the default log buffer size for recovery

10.209 RECYCLEBIN

Basic Information

Item	Description
Name	RECYCLEBIN
Summary	enable or disable recyclebin feature
Data type	BOOLEAN
Applicable phase	NO_MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	NO

Description

It sets whether to activate the recyclebin feature.

10.210 REDO_LOG_COMPRESSION_THRESHOLD

Basic Information

Item	Description
Name	REDO_LOG_COMPRESSION_THRESHOLD
Summary	The size limit at which redo log are compressed(bytes)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	32
MAX	2113929216
Default value	256

Description

If the size of the created REDO LOG is bigger than REDO_LOG_COMPRESSION_THRESHOLD value, it compresses REDO LOG.

10.211 REFINE_RELATION

Basic Information

Item	Description
Name	REFINE_RELATION
Summary	refine aged relations
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

If this property is set to NO, then REFINE RELATION process is not performed when restarting the server.

This property can be used when an error occurs during the REFINE RELATION process. However, segments of RELATIONs (tables or indexes) which were dropped but not REFINEd can not be reused. When resolving the error then setting this property to YES and restarting, it tries to REFINE Relations which were not dropped.

10.212 SESSION_FATAL_BEHAVIOR

Basic Information

Item	Description
Name	SESSION_FATAL_BEHAVIOR
Summary	session fatal behavior
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

When session fatal occurs, it determines whether to terminate only the thread which caused the fatal or to terminate the process.

- 0: It terminates only the thread which caused fatal.
- 1: It terminates the process.
  If multiple sessions are simultaneously performed in the process, the process is terminated after all sessions finish using database.

10.213 SESSION_MEMORY_INIT_SIZE

Basic Information

Item	Description
Name	SESSION_MEMORY_INIT_SIZE
Summary	initial memory size for session
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	131072 (128K)
MAX	1073741824 (1G)
Default value	131072 (128K)

Description

It sets the shared memory size to be allocated in advance so that it can be used in the session.

10.214 SESSION_MEMORY_SHRINK_THRESHOLD

Basic Information

Item	Description
Name	SESSION_MEMORY_SHRINK_THRESHOLD
Summary	threshold bytes to attempt to shrink session memory allocator (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	131072 (128K)
MAX	1073741824 (1G)
Default value	131072 (128K)

Description

It sets the threshold value to determine whether to return the dynamic shared memory which is not used by the session to the system when releasing the dynamic shared memory used in the session. In other wo rds, if the memory chunk which is bigger than the set value among unused memory exists, then it is retur ned to the system.

10.215 SESSION_POOL_INIT_SIZE

Basic Information

Item	Description
Name	SESSION_POOL_INIT_SIZE
Summary	initial memory size for session pool
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	0
MAX	1099511627776 (1T)
Default value	0

Description

It sets the initial memory size of the session pool.

If each session needs a memory, then the space is allocated from the session pool. If the space in the sessi on pool is insufficient, then the space is allocated from SSA.
The session pool is used to prevent the session from frequently accessing to SSA, and if it is set to "0", the n the session pool feature is inactivated.

10.216 SESSION_POOL_NEXT_SIZE

Basic Information

Item	Description
Name	SESSION_POOL_NEXT_SIZE
Summary	memory size to be expanded in session pool
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	131072 (128K)
MAX	1073741824 (1G)
Default value	1048576 (1M)

Description

It sets how much to extend the memory size in the session pool when expanding the session pool space.
It is valid only when SESSION_POOL_INIT_SIZE is bigger than 0.

10.217 SHARED_MEMORY_ADDRESS

Basic Information

Item	Description
Name	SHARED_MEMORY_ADDRESS
Summary	shared memory address
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	1610612736

Description

It specifies the address of Shared Static Area (SSA).

10.218 SHARED_MEMORY_STATIC_KEY

Basic Information

Item	Description
Name	SHARED_MEMORY_STATIC_KEY
Summary	Shared Memory Static KEY
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	542353

Description

When running server, it specifies the shared memory key values which are used to allocate Static Shared Area (SSA) space.

10.219 SHARED_MEMORY_STATIC_NAME

Basic Information

Item	Description
Name	SHARED_MEMORY_STATIC_NAME
Summary	Shared Memory Static Name
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	_STATIC

Description

When running server, it specifies the shared memory name which is used to allocate Static Shared Area (SA) space.

10.220 SHARED_MEMORY_STATIC_SIZE

Basic Information

Item	Description
Name	SHARED_MEMORY_STATIC_SIZE
Summary	Shared Memory Static Size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	104857600
MAX	1099511627776
Default value	629145600

Description

It specifies the size of the Shared Static Area (SSA).

10.221 SHARED_REQUEST_QUEUE_COUNT

Basic Information

Item	Description
Name	SHARED_REQUEST_QUEUE_COUNT
Summary	count of global request queue
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	16
Default value	1

Description

In shared mode, it sets the number of queues of which the dispatcher requests to the shared-server. A queue is used when multiple dispatchers allocate user's requests to the shared-server. Generally, a single queue is used for the load-balance.
However, SHARED_REQUEST_QUEUE_COUNT value is increased because if the number of dispatcher and shared-server increase, then a conflict to the queue causes performance degradation.
If the the value becomes bigger, the load-balance can be inefficient and the possibility of deadlock increases.

10.222 SHARED_SERVERS

Basic Information

Item	Description
Name	SHARED_SERVERS
Summary	number of shared-server processes
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	2048
Default value	10

Description

It sets the number of shared-server processes on shared mode.
At open phase, the value can not be decreased by using alter system.

10.223 SHARED_SESSION

Basic Information

Item	Description
Name	SHARED_SESSION
Summary	to enable shared session
Data type	BOOL
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

It sets whether to activate shared mode. If the value is set to *NO*, load-balancer (gbalancer), dispatcher (g dispatcher), shared-server (gserver) are not executed.

10.224 SNAPSHOT_STATEMENT_TIMEOUT

Basic Information

Item	Description
Name	SNAPSHOT_STATEMENT_TIMEOUT
Summary	snapshot statement timeout (s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	22118400 (1 year)
Default value	22118400 (1 year)

Description

It sets the maximum holding time of the statement required for the snapshot read. TIMEOUT error occurs for a snapshot statement which exceeds the time.

10.225 SQL_HISTORY_SIZE

Basic Information

Item	Description
Name	SQL_HISTORY_SIZE
Summary	history size for SQLs
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	100000
Default value	0

Description

It is the history size for SQLs.

10.226 SQL_HISTORY_TYPE

Basic Information

Item	Description
Name	SQL_HISTORY_TYPE
Summary	history type for SQLs
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	2
Default value	0

Description

It is the history type for SQLs.

- 0: Direct-execute
- 1: Prepare-execute
- 2: All

10.227 SUPPLEMENTAL_LOG_DATA_PRIMARY_KEY

Basic Information

Item	Description
Name	SUPPLEMENTAL_LOG_DATA_PRIMARY_KEY
Summary	supplemental log data of primary key columns be logged in redo log files
Data type	BOOLEAN
Applicable phase	MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It records supplemental log for all changes in the database.

10.228 SYNC_DISPATCHER_CM_BUFFER_COUNT

Basic Information

Item	Description
Name	SYNC_DISPATCHER_CM_BUFFER_COUNT
Summary	communication buffer count for synchronization dispatcher
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	1
MAX	128
Default value	1

Description

It specifies the number of cluster synchronization dispatcher's communication buffers.

10.229 SYSTEM_DISK_DATA_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_DISK_DATA_TABLESPACE_SIZE
Summary	default system disk data tablespace size(byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	32 Mega
MAX	30 Giga
Default value	200 Mega

Description

It sets the initial DISK_DATA_TBS tablespace size when creating the database.

10.230 SYSTEM_FILE_IO

Basic Information

Item	Description
Name	SYSTEM_FILE_IO
Summary	i/o type for system file (0: direct io, 1: buffered io)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It sets IO type of when using the database file except for the data file and the log file.

10.231 SYSTEM_MEMORY_AUX_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_MEMORY_AUX_TABLESPACE_SIZE
Summary	default system memory auxiliary tablespace size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	32 Mega
MAX	30 Giga
Default value	200 Mega

Description

It determines the size of initial MEM_AUX_TBS tablespace when creating the database.

10.232 SYSTEM_MEMORY_DATA_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_MEMORY_DATA_TABLESPACE_SIZE
Summary	default system memory data tablespace size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	32 Mega
MAX	30 Giga
Default value	200 Mega

Description

It determines the initial tablespace size of MEM_DATA_TBS when creating database.

10.233 SYSTEM_MEMORY_DICT_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_MEMORY_DICT_TABLESPACE_SIZE
Summary	default dictionary tablespace size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	256 Mega
MAX	30 Giga
Default value	256 Mega

Description

It determines the initial tablespace size of DICTIONARY_TBS when creating database.

10.234 SYSTEM_MEMORY_TEMP_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_MEMORY_TEMP_TABLESPACE_SIZE
Summary	default system memory temporary tablespace size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	32 Mega
MAX	30 Giga
Default value	200 Mega

Description

It determines the initial tablespace size of MEM_TEMP_TBS when creating database.

10.235 SYSTEM_MEMORY_UNDO_TABLESPACE_SIZE

Basic Information

Item	Description
Name	SYSTEM_MEMORY_UNDO_TABLESPACE_SIZE
Summary	default system memory undo tablespace size (byte)
Data type	BIGINT
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	NONE
MIN	32 Mega
MAX	30 Giga
Default value	32 Mega

Description

It determines the initial tablespace size of MEM_UNDO_TBS when creating database.

10.236 SYSTEM_TABLESPACE_DIR

Basic Information

Item	Description
Name	SYSTEM_TABLESPACE_DIR
Summary	system tablespace directory
Data type	VARCHAR
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/db

Description

It sets the path to which the initial system tablespaces are stored when creating database.

10.237 SYSTEM_UDS_DIR

Basic Information

Item	Description
Name	SYSTEM_UDS_DIR
Summary	system unix domain socket directory
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	'/tmp'

Description

It sets a directory on which the unix domain socket file is created.
Setting the directory for the unix domain socket except for DB system, such asglsnr, is managed by a sepa rate configuration file.
The maximum setting value is 60 bytes. (The maximum size of the absolute path (directory + file name) f or the unix domain socket file varies according to OS, but generally it is around 100 bytes.)

10.238 TCP_CLIENT_NUMA_NODE

Basic Information

Item	Description
Name	TCP_CLIENT_NUMA_NODE
Summary	numa node for TCP clients
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	-1
MAX	63
Default value	-1

Description

It sets the NUMA node ID to which the client server session is bound. This property is operated when NU MA property is set to on.

10.239 TCP_NODELAY

Basic Information

Item	Description
Name	TCP_NODELAY
Summary	no delays in buffer flushing within the TCP/IP protocol stack
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	1
Default value	YES

Description

It sets TCP_NODELAY option of the socket when transferring the data to a client in C/S method (TCP sock et).
Set it to *NO* when fast latency is not required and reducing the network load is needed.

10.240 TEMP_SEGMENT_CACHE_SIZE

Basic Information

Item	Description
Name	TEMP_SEGMENT_CACHE_SIZE
Summary	the number of segments to be cached for global temporary tables and indexes in each session
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	DEFERRED
MIN	0
MAX	4294967295
Default value	3

Description

It sets the number of segments to catch in a session instead of returning to a tablespace when dropping a global temporary table or a global temporary index segment. Segments in a segment cach is reused later in a global temporary tableor a global temporary index.

- 0: It does not use a segment cache of a global temporary table or of a global temporary index in a session.
- 1 ~ 4294967295: It keeps the specific number of segment caches of a global temporary table or of a global temporary index in a session.

10.241 TEMP_UNDO_ENABLED

Basic Information

Item	Description
Name	TEMP_UNDO_ENABLED
Summary	enables writing undo records of global temporary tables to the temp tablespace
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It defines the location of logging undo records for a global temporary table.

- 0 (FALSE): It records the undo records in the default undo tablespace of database.
- 1 (TRUE): It records the undo records in the default temporary tablespace of database.

10.242 TIMED_STATISTICS

Basic Information

Item	Description
Name	TIMED_STATISTICS
Summary	timed statistics
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	2
Default value	0

Description

It is whether to check the wait event.
To record the statistics related to wait event on v$system_event, v$session_event and v$session_wait tabl e, set this property.

- 0: It does not record the statistics.
- 1: It records the statistics.
- 2: It records the statistics by using the high precision timer.

10.243 TIMER_INTERVAL

Basic Information

Item	Description
Name	TIMER_INTERVAL
Summary	timer interval time(us)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	10
MAX	100000
Default value	10000

Description

It sets the time interval which is required when the timer thread sets the system time.

10.244 TIMEZONE

Basic Information

Item	Description
Name	TIMEZONE
Summary	timezone
Data type	VARCHAR
Applicable phase	NONE
Updatable	FALSE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	+09:00

Description

It is a time zone value of database.
It is applied when creating database, and it uses the value of the range from '-14:00' to '+14:00'.

10.245 TRACE_ALTER_SYSTEM

Basic Information

Item	Description
Name	TRACE_ALTER_SYSTEM
Summary	write trace messages forALTER SYSTEM
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

It records the SQL statements in trace file ($GOLDILOCKS_DATA/trc/system.trc) when executing ALTER SYSTEM syntax.

Set TRACE_ALTER_SYSTEM property to *ON* to record system changes.

SELECT inquiry, and execution of INSERT, UPDATE, DELETE syntax have nothing to do with TRACE_ALTER_SYSTEM property, so they do not affect the performance of TRACE_ALTER_SYSTEM.

10.246 TRACE_DDL

Basic Information

Item	Description
Name	TRACE_DDL
Summary	write trace messages for DDL
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	YES

Description

When executing DDL, it records the executed SQL statements in trace file ($GOLDILOCKS_DATA/trc/system.trc).

Set *TRACE_ALTER_SYSTEM* property to *ON* to record SQL statements execution such as CREATE/DROP/ALTER table.

TRACE_DDL property affects only to DDL statements. However, it has nothing to do with SELECT inquiry, and execution of INSERT, UPDATE, DELETE syntax. Therefore, it does not affect the performance.

10.247 TRACE_LOG_ID

Basic Information

Item	Description
Name	TRACE_LOG_ID
Summary	trace log ID
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	0

Description

The execution plan for the query, and other related information are recorded in the trace file (opt_p[process ID_s [session ID].trc) under the trace directory ($GOLDILOCKS_DATA/trc/) when processing queries. To record SQL statement for the query, the execution plan and the execution time, refer to the following flag information.

Table 10-1 Flag information for TRACE_LOG_ID

Information	Flag(on)	Flag(off)
Whether to output the PSM call flow (procedure/function)	1000000	0
Whether to output the successful SQL query	100000	0
Whether to output the failed SQL query	10000	0
Whether to output the execution plan	1000	0
Whether to output the execution type (direct/prepare)	100	0
Whether to output the bind value	10	0
Whether to output the execution time per section	1	0

To set it in a form of "output the successful SQL query" + "output the execution plan" + "output the bind value", set the TRACE_LOG_ID value to 101010.

10.248 TRACE_LOG_MSGBUF_SIZE

Basic Information

Item	Description
Name	TRACE_LOG_MSGBUF_SIZE
Summary	memory buffer size for trace log message
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	8192
MAX	10485760
Default value	24576

Description

It sets the size of the heap memory buffer which is used to configure the log message to be recorded in t he trace logfile.

10.249 TRACE_LOG_TIME_DETAIL

Basic Information

Item	Description
Name	TRACE_LOG_TIME_DETAIL
Summary	detail trace log time
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It sets whether to increase the time accuracy when recording trace log.
If the value is ON, it has an accuracy of 1 us.
If the value is OFF, it has an accuracy of 10 ms.

10.250 TRACE_LOGGER

Basic Information

Item	Description
Name	TRACE_LOGGER
Summary	trace log type (1:file, 2:file & remote)
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	2
Default value	1

Description

It sets the target on which the trace log is written.
If it is 1, then it is recorded in a file, and if it is 2, then it is remotely recorded in a file.
When it is remotely written, then it remotely collects trace logs from gtrclogger and records in a file.

10.251 TRACE_LOGGER_REMOTE_HOST

Basic Information

Item	Description
Name	TRACE_LOGGER_REMOTE_HOST
Summary	remote host for trace logger
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	255255255255
Default value	127000000001

Description

It sets the host to which the trace log is remotely transferred by setting TRACE_LOGGER to 2.

10.252 TRACE_LOGGER_REMOTE_PORT

Basic Information

Item	Description
Name	TRACE_LOGGER_REMOTE_PORT
Summary	remote port for trace logger
Data type	BIGINT
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1024
MAX	49151
Default value	21470

Description

It sets the port to which the trace log is remotely transferred by setting TRACE_LOGGER to 2.

10.253 TRACE_LOGIN

Basic Information

Item	Description
Name	TRACE_LOGIN
Summary	write login trace messages for user
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It records the related access information in trace file ($GOLDILOCKS_DATA/trc/login.trc) on login.
Set TRACE_LOGIN property to *ON* to record the related information on login.

10.254 TRACE_LONG_RUN_CURSOR

Basic Information

Item	Description
Name	TRACE_LONG_RUN_CURSOR
Summary	write trace SQL for cursor life-time over specific time (mili-sec. 0 ~ 10000000)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

When cursor life-time is longer than the specified property time, then it records the SQL statement of the cursor in the trace file ($GOLDILOCKS_DATA/trc/system.trc).

- Description of value
  - Unit: millisecond
  - Value 0: It does not record information.
  - Recommended value: 20 (millisecond) or longer
  - The value of 20 or longer is recommended because the execution time is measured using the tim e tic in 10 ms period.
  - Use **TRACE_LONG_RUN_TIMER** property to increase the precision.

- The following is an example of recording the SQL statement whose cursor life-time is longer than 1 s econd.

```
gSQL> ALTER SYSTEM SET TRACE_LONG_RUN_CURSOR = 1000;
```

- The following is an example of restoring to the default value.

```
gSQL> ALTER SYSTEM SET TRACE_LONG_RUN_CURSOR TO DEFAULT;
```

It is used to trace the user program maintaining the cursor for a long time as follows.

```
int main()
{
   ...
   EXEC SQL DECLARE cur1 CURSOR FOR SELECT name FROM t1 WHERE pk = :s_id;
   EXEC SQL OPEN cur1
   EXEC SQL FETCH cur1 INTO :s_name;
   ...
   long_run_user_logic( s_name ); ❶ Due to the user logic, ager fails to clean up resources
for a long time.
   ...
   EXEC SQL CLOSE cur1;
   ...
}
```

10.255 TRACE_LONG_RUN_SQL

Basic Information

Item	Description
Name	TRACE_LONG_RUN_SQL
Summary	write trace for long-run SQL over specific execution time (mili-sec. 0 ~ 10000000)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

It records the SQL statement whose execution time is longer than the specified property time in the trace file ($GOLDILOCKS_DATA/trc/system.trc).

- Description of value
  - Unit: millisecond
  - Value 0: It does not record information.
  - Recommended value: 20 (millisecond) or longer
  - The value of 20 or longer is recommended because the execution time is measured using the tim e tic in 10 ms period.
  - Use **TRACE_LONG_RUN_TIMER** property to increase the precision.

The following is an example of recording the SQL statement whose execution time is longer than 1 secon d.

```
gSQL> ALTER SYSTEM SET TRACE_LONG_RUN_SQL = 1000;
```

The following is an example of restoring to the default value.

```
gSQL> ALTER SYSTEM SET TRACE_LONG_RUN_SQL TO DEFAULT;
```

10.256 TRACE_LONG_RUN_TIMER

Basic Information

Item	Description
Name	TRACE_LONG_RUN_TIMER
Summary	trace long-run timer resolution (0: timer thread(10 ms interval), 1: gettimeofday())
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

It controls the measurement precision when measuring the execution time of the SQL statement by using the following properties.

- **TRACE_LONG_RUN_CURSOR**
- **TRACE_LONG_RUN_SQL**

- Value
  - 0: It uses the timer thread whose interval is 10 milliseconds.
  - 1: It measures the time by using gettimeofday() function. In this case, the precision is higher but t he system call causes the work load.

10.257 TRACE_SYSTEM_DIR

Basic Information

Item	Description
Name	TRACE_SYSTEM_DIR
Summary	system logger directory
Data type	VARCHAR
Applicable phase	NONE
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	FALSE
MIN	N/A
MAX	N/A
Default value	$GOLDILOCKS_DATA/trc

Description

It sets the disk path where the trace log message is recorded.

ALIAS

Item	Description
Original name	TRACE_SYSTEM_DIR
ALIAS	SYSTEM_LOGGER_DIR

10.258 TRACE_XA

Basic Information

Item	Description
Name	TRACE_XA
Summary	logging trace log for xa interfaces
Data type	BOOLEAN
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	NO

Description

It specifies whether to output trace messages when using XA interface. Message is output to the 'SYSTEM_LOGGER_DIR / xa.trc'.

10.259 TRANSACTION_ALLOCATION_TIMEOUT

Basic Information

Item	Description
Name	TRANSACTION_ALLOCATION_TIMEOUT
Summary	a time limit (sec) for allocating transaction slot
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	3

Description

It is the maximum waiting time when allocating transaction slots.

The following error occurs when the waiting time exceeds TRANSACTION_ALLOCATION_TIMEOUT.

```
gSQL> insert into t1 values(1);
ERR-HYT00(14129): transaction allocation time exceeded
```

10.260 TRANSACTION_COMMIT_WRITE_MODE

Basic Information

Item	Description
Name	TRANSACTION_COMMIT_WRITE_MODE
Summary	transaction commit write mode (0: no_wait, 1: wait)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	1
Default value	0

Description

TRANSACTION_COMMIT_WRITE_MODE specifies whether a log generated by the transaction is flushed to the disk log file, when the transaction is committed. If TRANSACTION_COMMIT_WRITE_MODE is '1', the log should be flushed to the disk log file at the time of the transaction commit. Otherwise the transaction is committed regardless of log flush.

If the system is operated when TRANSACTION_COMMIT_WRITE_MODE is set to '0', the latest data will be lost when GOLDILOCKS is abnormally terminated without log flush after COMMIT transaction. It is because the logs are not recorded in this case.

Therefore, if all committed transactions should be remained (stored) in database, the system should be operated after setting TRANSACTION_COMMIT_WRITE_MODE to '1'. Or, 'ALTER SYSTEM FLUSH LOGS' statement should be explicitly performed at the time of transaction commit in order to flush log after TRANSACTION_COMMIT_WRITE_MODE is set to '0'.

- 0: no wait
- 1: wait

10.261 TRANSACTION_MAXIMUM_UNDO_PAGE_COUNT

Basic Information

Item	Description
Name	TRANSACTION_MAXIMUM_UNDO_PAGE_COUNT
Summary	The maximum number of undo pages that a transaction can write.
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	1
MAX	13107200
Default value	13107200

Description

It means the maximum number of undo pages which the transaction can record. The minimum value is 1 (8 Kbytes) and the maximum value is 13107200 (100 Gbytes).

10.262 TRANSACTION_TABLE_SIZE

Basic Information

Item	Description
Name	TRANSACTION_TABLE_SIZE
Summary	transaction table size
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	64
MAX	10240
Default value	1024

Description

It sets the maximum number of transaction tables which are executed in database. The database should r estart to modify the number of transaction tables, and the number can be modified as long as the numbe r is bigger than the previously specified number. However, if it is modified to the smaller number, then th e restart fails when it is same or smaller than the maximum value of the transaction slot identifier used by the transactions prepared after the restart recovery.

For example, if the value set as 1,024 is modified to 512 and the maximum value of the transaction slot i dentifier used by the transactions prepared at the restart is also 512, then the restart fails as follows. In th is case, modify it to the number bigger than 512, then the restart succeeds.

```
gSQL> ALTER SYSTEM SET TRANSACTION_TABLE_SIZE = 512 SCOPE = FILE;
System altered.
gSQL> \CONNECT sys gliese as sysdba
gSQL> \SHUTDOWN
Shutdown success
```

- The restart fails.

```
gSQL> \STARTUP
ERR-HY000(14118): TRANSACTION_TABLE_SIZE property value must be equal to or greater than '513'
gSQL> ALTER SYSTEM SET TRANSACTION_TABLE_SIZE = 513 SCOPE = FILE;
System altered.
gSQL> \SHUTDOWN
Shutdown success
gSQL> \STARTUP
Startup success
```

TRANSACTION_TABLE_SIZE of all cluster members should be same in cluster environment, so it is required to restart all cluster members to modify TRANSACTION_TABLE_SIZE.

10.263 TRANSACTION_TIMEOUT

Basic Information

Item	Description
Name	TRANSACTION_TIMEOUT
Summary	transaction timeout (s)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	10000000
Default value	0

Description

It sets the duration of when the transaction is activated. It is used to prevent the side effects of when the transaction is activated for a long time. If a transaction exceeds the specified time, then gmaster daemon automatically terminates the session owned by that transaction.

10.264 UNDO_RELATION_ALLOCATION_TIMEOUT

Basic Information

Item	Description
Name	UNDO_RELATION_ALLOCATION_TIMEOUT
Summary	a time limit (sec) for allocating undo relation
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	100000000
Default value	3

Description

It is the maximum waiting time when allocating undo relations.

The following error occurs when the waiting time exceeds UNDO_RELATION_ALLOCATION_TIMEOUT.

```
gSQL> insert into t1 values(1);
ERR-HYT00(14130): undo relation allocation time exceeded
```

10.265 UNDO_RELATION_COUNT

Basic Information

Item	Description
Name	UNDO_RELATION_COUNT
Summary	undo relation count
Data type	BIGINT
Applicable phase	NO MOUNT or below
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	8
MAX	10240
Default value	128

Description

It sets the number of undo relation to be used in database. Undo relation is allocated for the purpose tha t the transaction executing DML uses undo segment. The database should restart to modify the number of undo relations, and the number can be modified only to the number bigger than the previously specifi ed number.

If it is modified to a smaller number, then the restart fails. For example, if the value set as 128 is modified to 64, then the restart fails as follows. In this case, modify it to 128 or bigger, then the restart succeeds.

```
gSQL> ALTER SYSTEM SET UNDO_RELATION_COUNT = 64 SCOPE = FILE;
System altered.
gSQL> \CONNECT sys gliese as sysdba
gSQL> \SHUTDOWN
Shutdown success
```

- The restart fails.

```
gSQL> \STARTUP
ERR-HY000(14119): UNDO_RELATION_COUNT property value must be equal to or greater than '128'
gSQL> ALTER SYSTEM SET UNDO_RELATION_COUNT = 128 SCOPE = FILE;
```

```
System altered.
gSQL> \SHUTDOWN
Shutdown success
gSQL> \STARTUP
Startup success
```

10.266 UNDO_SHRINK_THRESHOLD

Basic Information

Item	Description
Name	UNDO_SHRINK_THRESHOLD
Summary	threshold bytes to attempt to shrink undo segment (byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	1048576
MAX	107374182400
Default value	10485760

Description

Ager thread periodically (10 seconds) checks the undo segment space. If it occupies more space than this property value, then the reusable space is returned to the tablespace. The attempt to return is made until the undo segment space remains as big as this property (byte), and the return is finished when the amou nt of the remaining undo page becomes smaller than MINIMUM_UNDO_PAGE_COUNT.

10.267 USE_LARGE_PAGES

Basic Information

Item	Description
Name	USE_LARGE_PAGES
Summary	use large pages
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0
MAX	2
Default value	0

Description

It uses HugePage. HugePage should first be set in the device to use USE_LARGE_PAGES property.

- 0: It does not use the large page.
- 1: It uses the large page. When it fails to allocate the shared memory, then an error occurs.
- 2: It tries to allocate the shared memory by using the large page. When it fails to allocate the shared memory, then it allocates the memory by using the regular page.

It can be used in Linux kernel 2.6.32-573 or higher.

10.268 USER_DATA_TABLESPACE_MEDIA_TYPE

Basic Information

Item	Description
Name	USER_DATA_TABLESPACE_MEDIA_TYPE
Summary	default media type of user data tablespace
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	0 (Memory)
MAX	1 (Disk)
Default value	0 (Memory)

Description

It sets the default media type if the media type of the tablespace is omitted when creating the user data t ablespace. 0 is memory and 1 is the disk.

10.269 USER_DATA_TABLESPACE_SIZE

Basic Information

Item	Description
Name	USER_DATA_TABLESPACE_SIZE
Summary	default user data tablespace size(byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	32 Mega
MAX	30 Giga
Default value	32 Mega

Description

It sets the default size if the data file size is omitted when creating the user data tablespace or adding the data file.

10.270 USER_DISK_DATA_TABLESPACE_NEXTSIZE

Basic Information

Item	Description
Name	USER_DISK_DATA_TABLESPACE_NEXTSIZE
Summary	default next size of user data tablespace
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	3554432 Byte
MAX	30 Giga
Default value	10 Mega

Description

It sets the default size if the size to be extended is not set when it is required to extend the data file of th e user disk data tablespace.

10.271 USER_TEMP_TABLESPACE_SIZE

Basic Information

Item	Description
Name	USER_TEMP_TABLESPACE_SIZE
Summary	default user temp tablespace size(byte)
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	TRUE
ALTER SYSTEM	IMMEDIATE
MIN	32 Mega
MAX	30 Giga
Default value	32 Mega

Description

It sets the default size if the data file size is omitted when creating the user temp tablespace or adding th e data file.

10.272 XA_TRANSACTION_IDLE_TIMEOUT

Basic Information

Item	Description
Name	XA_TRANSACTION_IDLE_TIMEOUT
Summary	idle timeout for xa transaction
Data type	BIGINT
Applicable phase	NO MOUNT or above
Updatable	TRUE
ALTER SESSION	FALSE
ALTER SYSTEM	IMMEDIATE
MIN	0 (no limit)
MAX	10000000
Default value	60

Description

It is the maximum waiting time of xa transaction in idle (The duration between the beginning of XA and t he next transaction). If it remains in Idle exceeding this time, then xa transaction is rolled back.

If it is set to 0, then XA infinitely waits even in idle.

Part III.

SQL Manual

11.

SQL Elements

11.1 Syntax Elements

Identifiers

Identifier is divided into an ordinary identifier and a delimited identifier.
An ordinary identifier consists of a letter or letters and numbers and it is used by internally substituting all characters to uppercase letters. Therefore, an ordinary identifier is not case-sensitive.

The following is an example of an ordinary identifier.

```
GOLDILOCKS
GoldiLocks
```

A delimited identifier consists of a letter or letters and numbers and they are enclosed with double quotes ("). All the characters are used literally as internally described. Therefore, a delimited identifier is case-sens itive.

The following is an example of a delimited identifier.

```
"GOLDILOCKS"
"GoldiLocks"
```

Literals

Literals mean representation of non-null value.

Text Literals

Text literals mean representation of strings and binary strings.

Use single quote (') at the beginning and end of a string to write string of text literals.
Not only the double quotes (") string but also all strings except for the single quote (') string can be writt en within a single quote (').
Use a single quote twice without white spaces in between to write a single quote (') in a string.
A maximum of 4000 characters can be written in a string.

The followings are examples of text literals for a string.

```
'GOLDILOCKS'
'Sunje''s DBMS'
```

A binary string of text literals is a string of hexadecimal numbers which starts with x'(X') and ends with '. Only the characters corresponding to 0 ~ 9, A (a) ~ F (f) can be written in each position of a hexadecimal string. The length of a hexadecimal string should always be a even number because its two digits mean o ne byte. A maximum of 4,000 characters can be written in a binary string.

The followings are examples of text literals for a binary string.

```
x'001f'
X'FF0A'
x'aF37BBc013'
```

Numeric Literals

Numeric literals mean literals of numeric type, and integers or the number with decimal point can be writ ten. The syntax for numeric literals is as follows.

```
[ + ¦ - ] <digits> [ . <digits> ] [ E ¦ e [ + ¦ - ] <digits> ] [ f ¦ F ¦ d ¦ D ]
```

- The first +/- means a positive or negative value of the entire number, and it can be omitted. If omitte d, the default value is a positive value.
- In <digits>, numbers from 0 to 9 can be listed without white space, the number with decimal point ca n be written by using decimal point (.).
- An exponent form can be written after the first <digits>, and E or e is written, and it stands for expon ent. Then +/- is written according to exponent sign, and <digits> is written. +/- of exponent can be o mitted. If omitted, the default value is a positive value.
- Lastly, character such as f, F, d, D can be written after numbers. It means that it is a number of BINAR Y_FLOAT, BINARY_DOUBLE. If the corresponding character is omitted, the number is considered as N UMBER type.

The followings are examples of numeric literals.

```
20
+123.45
0.03
+1.23E-02
-1.5
10f
+123.45F
1.2E-3F
-22d
```

```
123.45D
-1.23E+05D
```

Datetime Literals

Datetime literals are representation of date/time type.
Datetime value is specified using string literal, or by converting character or numeric value to datetime val ue using TO_*function (TO_DATE, etc).

Datetime data types are DATE, TIME, TIME WITH TIME ZONE, TIMESTAMP, TIMESTAMP WITH TIME ZON E.

Date Literals

Date literals are written in a form of DATE'string literal' or TO_DATE(string_literal [, format]).

- DATE'string literal'
  - The format of date type is ' SYYYY-MM-DD'.
  - DATE'2002-07-15'
- TO_DATE(string_literal [, format])
  - If the format is not specified, the format of date type is NLS_DATE_FORMAT by default.
  - If the format is specified, the specified format is applied.

- The date type includes year, month, day, hour, minute, second (except for fractional seconds).
- If the date is omitted, the default value is the first day of the current month.
- If the hour, minute, second are omitted, the default value is midnight.
  - HH24 format: '00:00:00'
  - HH12 format: '12:00:00'
- To set the hour, minute, second to the default value (midnight) when the date value includes hour, minute, second, then use the TRUNC(date) function.
  - For example, in TRUNC(SYSDATE), SYSDATE includes the values of the year, month, day, hour, minute, second.
- To compare only the values of the year, month, day among date values, then set the values of the ho ur, minute, second are set to midnight using the TRUNC function.

For more information, refer to **TO_DATE**, **Datetime Format String**, **NLS_DATE_FORMAT**.

- The following is an example of date literals.

```
DATE'2002-07-15'
```

- The following is an example of when the format is not specified, so NLS_DATE_FORMAT is 'YYYY-M M-DD'.

```
TO_DATE( '2002-07-15' )
```

- The followings are examples of when the format is specified.

```
TO_DATE( '15-JUL-02', 'DD-MON-RR' )
TO_DATE( '2002-07-15 00:00:00', 'YYYY-MM-DD HH24:MI:SS' )
TO_DATE( '2002-07-15 13:25:30', 'YYYY-MM-DD HH24:MI:SS' )
```

- The following is an example of when the date is omitted. (It is set to the first day of the current mont h).

```
gSQL> SELECT TO_DATE( '2000-07', 'YYYY-MM' ) FROM DUAL;
TO_DATE( '2000-07', 'YYYY-MM' )
------------------------------
2000-07-01
```

- The following is an example of when the hour, minute, second are omitted. (It is set to the midnight).

```
gSQL> SELECT
      TO_CHAR( DATE'2002-07-15', 'YYYY-MM-DD HH24:MI:SS' ) AS RESULT
      FROM DUAL;
RESULT
-------------------
2002-07-15 00:00:00
```

- The following is an example of setting the hour, minute, second of DATE value (SYSDATE) to the def ault value (midnight).

```
gSQL> SELECT
      TO_CHAR( SYSDATE,
               'YYYY-MM-DD HH24:MI:SS' ) AS RESULT_SYSDATE,
      TO_CHAR( TRUNC( SYSDATE ),
               'YYYY-MM-DD HH24:MI:SS' ) AS RESULT_TRUNC_SYSDATE
      FROM DUAL;
RESULT_SYSDATE      RESULT_TRUNC_SYSDATE
  ------------------- --------------------
  2014-08-19 10:06:49 2014-08-19 00:00:00
```

- The following is an example of comparing only the values of the year, month, day among date values.

```
gSQL> SELECT
      TO_DATE( '2002-08-12' ) =
```

```
      TRUNC( TO_DATE( '2002-08-12 23:59:59', 'YYYY-MM-DD HH24:MI:SS' ) )
      AS RESULT FROM DUAL;
RESULT
------
TRUE
```

Time Literals

Time literals are written in a form of TIME'string literal' or TO_TIME(string_literal [, format]).

- TIME'string literal'
  - The format of time type is 'HH24:MI:SS[.[FF6]]'.
  - TIME'15:30:59.999999'
- TO_TIME(string_literal [, format])
  - If the format is not specified, the format of time type is NLS_TIME_FORMAT by default.
  - If the format is specified, the specified format is applied.

The time type includes hour, minute, second (fractional seconds).
Fractional seconds can be specified to maximum six digits numbers format.

For more information, refer to **TO_TIME**, **Datetime Format String**, **NLS_TIME_FORMAT**.

- The following is an example of time literals.

```
TIME'15:30:59.999999'
```

- The following is an example of when the format is not specified, so NLS_TIME_FORMAT is 'HH24:MI:SS.FF6'.

```
TO_TIME( '15:30:59.999999' )
```

- The following is an example of when the format is specified.

```
TO_TIME( '09.45.03.546873 AM', 'HH12.MI.SS.FF6 AM' )
TO_TIME( '09:45:03', 'HH12:MI:SS' )
```

Time with Time Zone Literals

Time with time zone literals is written in a form of TIME'string literal', TIME WITH TIME ZONE'string literal' , TO_TIME_WITH_TIME_ZONE(string_literal [, format]), or TO_TIME_TZ(string_literal [, format]).

- TIME'string literal' or TIME WITH TIME ZONE'string literal'
  - The format of time with time zone type is 'HH24:MI:SS[.[FF6]] TZH:TZM'.

    - TIME'15:30:59.999999 +09:00'
    - TIME WITH TIME ZONE'15:30:59.999999 +09:00'
- TO_TIME_WITH_TIME_ZONE(string_literal [, format])
    - If the format is not specified, the format of time with time zone type is NLS_TIME_WITH_TIME_ZONE_FORMAT by default.
    - If the format is specified, the specified format is applied.

Time with time zone type includes hour, minute, second (fractional seconds), and time zone offset (time zone hour, time zone minute).
Fractional seconds can be specified to maximum six digits numbers format.

For more information, refer to **TO_TIME_WITH_TIME_ZONE**, **Datetime Format String**, **NLS_TIME_WITH_TIME_ZONE_FORMAT**.

- The followings are examples of time with time zone literals.

```
TIME'15:30:59.999999 +09:00'
TIME WITH TIME ZONE'15:30:59.999999 +09:00'
```

- The following is an example of when the format is not specified, so NLS_TIME_WITH_TIME_ZONE_FORMAT is 'HH24:MI:SS.FF6 TZH:TZM'.

```
TO_TIME_WITH_TIME_ZONE( '15:30:59.999999 +09:00' )
TO_TIME_TZ( '15:30:59.999999 +09:00' )
```

- The following is an example of when the format is specified.

```
TO_TIME_WITH_TIME_ZONE( '09.45.03.546873 +09:00 AM',
                        'HH12.MI.SS.FF6 TZH:TZM AM' )
```

Timestamp Literals

Timestamp literals are written in a form of TIMESTAMP'string literal' or TO_TIMESTAMP(string_literal [, format]).

- TIMESTAMP'string literal'
    - The format of timestamp type is 'SYYYY-MM-DD HH24:MI:SS[.[FF6]]'.
    - TIMESTAMP'2002-07-15 15:39:59.999999'
- TO_TIMESTAMP(string_literal [, format])
    - If the format is not specified, the format of timestamp type is NLS_TIMESTAMP_FORMAT by default.
    - If the format is specified, the specified format is applied.

Timestamp type includes year, month, day, hour, minute, second (fractional seconds).
Fractional seconds can be specified to maximum six digits numbers format.

For more information, refer to **TO_TIMESTAMP**, **Datetime Format String**, **NLS_TIMESTAMP_FORMAT**.

- The following is an example of timestamp literals.

```
TIMESTAMP'2002-07-15 15:39:59.999999'
```

- The following is an example of when the format is not specified, so NLS_TIMESTAMP_FORMAT is 'YYYY-MM-DD HH24:MI:SS.FF6'.

```
TO_TIMESTAMP( '2002-07-15 15:39:59.999999' )
```

- The following is an example of when the format is specified.

```
TO_TIMESTAMP( '15-JUL-02 11.06.30.123456 AM',
              'DD-MON-RR HH12.MI.SS.FF6 AM' )
```

Timestamp with Time Zone Literals

Timestamp with time zone literals is written in a form of TIMESTAMP'string literal', TIMESTAMP WITH TIME ZONE'string literal', TO_TIMESTAMP_WITH_TIME_ZONE(string_literal [, formt]), or TO_TIMESTAMP_TZ(string_literal [, format]).

- TIMESTAMP'string literal' or TIMESTAMP WITH TIME ZONE'string literal'
  - The format of timestamp with time zone type is 'SYYYY-MM-DD HH24:MI:SS[.[FF6]] TZH:TZM'.
  - TIMESTAMP'2002-07-15 15:39:59.999999 +09:00'
  - TIMESTAMP WITH TIME ZONE'2002-07-15 15:39:59.999999 +09:00'
- TO_TIMESTAMP_WITH_TIME_ZONE(string_literal [, formt])
  - If the format is not specified, the format of timestamp with time zone type is NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT by default.
  - If the format is specified, the specified format is applied.

Timestamp with time zone type includes year, month, day, hour, minute, second (fractional seconds), time zone offset (time zone hour, time zone minute).
Fractional seconds can be specified to maximum six digits numbers format.

For more information, refer to **TO_TIMESTAMP_WITH_TIME_ZONE**, **Datetime Format String** , **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**.

- The following is an example of timestamp with time zone literals.

```
TIMESTAMP'2002-07-15 15:39:59.999999 +09:00'
TIMESTAMP WITH TIME ZONE'2002-07-15 15:39:59.999999 +09:00'
```

- The following is an example of when the format is not specified, so NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT is 'YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM'.

```
TO_TIMESTAMP_WITH_TIME_ZONE( '2002-07-15 15:39:59.999999 +09:00' )
TO_TIMESTAMP_TZ( '2002-07-15 15:39:59.999999 +09:00' )
```

- The following is an example of when the format is specified.

```
TO_TIMESTAMP_WITH_TIME_ZONE( '15-JUL-02 11.06.30.123456 +09:00 AM',
                             'DD-MON-RR HH12.MI.SS.FF6 TZH:TZM AM' )
TO_TIMESTAMP_TZ( '15-JUL-02 11.06.30.123456 +09:00 AM',
                 'DD-MON-RR HH12.MI.SS.FF6 TZH:TZM AM' )
```

Interval Literals

The interval literals specify the time interval.

Intervals are classified and expressed as follows.

- Year-month INTERVAL values
  - It includes YEAR and MONTH.
  - Display string expression: 'year-month'
  - It can be written in a form as *INTERVAL 'string literal' YEAR[leading precision] TO MONTH* or *NUMTOYMINTERVAL(num, interval_indicator)*
- Day-time INTERVAL values
  - It includes DAY, HOUR, MINUTE, SECOND (fractional seconds).
  - Display string expression: 'day hour:minute:second.fractional_seconds'
  - It can be written in a form as *INTERVAL 'string literal' DAY[leading precision] TO SECOND[fractional seconds precision]* or *NUMTODSINTERVAL(num, interval_indicator)*.
- The interval value's sign is specified only once at the beginning of the string representation.
  e.g. INTERVAL'+3 11:22:33.999999'DAY TO SECOND (O)
  INTERVAL'-3 +11:22:33.999999'DAY TO SECOND (X)

The followings are the list of interval types.

- INTERVAL YEAR (leading precision)
- INTERVAL MONTH (leading precision)
- INTERVAL YEAR (leading precision) TO MONTH
- INTERVAL DAY (leading precision)

- INTERVAL HOUR (leading precision)
- INTERVAL MINUTE (leading precision)
- INTERVAL SECOND (leading precision[, fractional seconds precision])
- INTERVAL DAY (leading precision) TO HOUR
- INTERVAL DAY (leading precision) TO MINUTE
- INTERVAL DAY (leading precision) TO SECOND (fractional seconds precision)
- INTERVAL HOUR (leading precision) TO MINUTE
- INTERVAL HOUR (leading precision) TO SECOND (fractional seconds precision)
- INTERVAL MINUTE (leading precision) TO SECOND (fractional seconds precision)

Leading precision
- It is the digit number of the field, it can be specified from 2 to 6. If it is not specified, the default value is set to 2.
- If the leading field value exceeds the leading precision, then an error is returned.

Fractional seconds precision
- It is the digit number of fractional seconds, and it can be specified from 0 to 6. If it is not specified, the default value is set to 6.
- If the fractional second field value exceeds the fractional seconds precision, then it is rounded off.

For more information, refer to **INTERVAL**, **Precisions and value range of the second or later field in INTERVAL * TO * , NUMTODSINTERVAL**, **NUMTOYMINTERVAL**.

Examples of Using Interval Literals.

The followings are examples of using interval literals.

Interval YEAR

The followings are examples of using interval YEAR literals.

Example	Description	Display string
INTERVAL'1'YEAR INTERVAL'01-00'YEAR	1 year	+01-00
INTERVAL'100'YEAR	It exceeds the leading precision 2, so it returns the error.	-
INTERVAL'100'YEAR(3)	100 year	+100-00
INTERVAL'+999999'YEAR(6)	999999 year	+999999-00
INTERVAL'-999999'YEAR(6)	-(999999 year)	-999999-00

Interval MONTH

The followings are examples of using interval MONTH literals.

Example	Description	Display string
INTERVAL'1'MONTH INTERVAL'00-01'MONTH	1 month	+00-01
INTERVAL'100'MONTH	It exceeds the leading precision 2, so it returns the error.	-
INTERVAL'100'MONTH(3)	8 year 4 month	+008-04
INTERVAL'+999999'MONTH(6)	83333 year 3 month	+083333-03
INTERVAL'-999999'MONTH(6)	-(83333 year 3 month)	-083333-03

Interval YEAR TO MONTH

The followings are examples of using interval YEAR TO MONTH literals.

Example	Description	Display string
INTERVAL'1-06'YEAR TO MONTH	1 year 6 month	+01-06
INTERVAL'1-12'YEAR TO MONTH	The month value exceeded 11, so it returns the error.	-
INTERVAL'100-11'YEAR TO MONTH	It exceeds the leading precision 2, so it returns the er ror.	-
INTERVAL'100-11'YEAR(3) TO MONTH	100 year 11 month	+100-11
INTERVAL'+999999-11'YEAR(6) TO MO NTH	999999 year 11 month	+999999-11
INTERVAL'-999999-11'YEAR(6) TO MO NTH	-(999999 year 11 month)	-999999-11

Interval DAY

The followings are examples of using interval DAY literals.

Example	Description	Display string
INTERVAL'1'DAY INTERVAL'01 00:00:00'DAY	1 day	+01 00:00:00
INTERVAL'100'DAY	It exceeds the leading precision 2, so it returns the error.	-
INTERVAL'100'DAY(3)	100 day	+100 00:00:00
INTERVAL'+999999'DAY(6)	999999 day	+999999 00:00:00
INTERVAL'-999999'DAY(6)	-(999999 day)	-999999 00:00:00

Interval HOUR

The followings are examples of using interval HOUR literals.

Example	Description	Display string
INTERVAL'1'HOUR INTERVAL'00 01:00:00'HOUR	1 hour	+00 01:00:00
INTERVAL'1000'HOUR(3)	It exceeds the leading precision 3, so it returns the error	-

Example	Description	Display string
INTERVAL'1000'HOUR(4)	41 day 16 hour	+0041 16:00:00
INTERVAL'+999999'HOUR(6)	41666 day 15 hour	+041666 15:00:00
INTERVAL'-999999'HOUR(6)	-(41666 day 15 hour)	-041666 15:00:00

Interval MINUTE

The following are examples of using interval MINUTE literals.

Example	Description	Display string
INTERVAL'1'MINUTE INTERVAL'00 00:01:00'MINUTE	1 minute	+00 00:01:00
INTERVAL'12345'MINUTE(4)	It exceeds the leading precision 4, so it returns the error	-
INTERVAL'12345'MINUTE(5)	8 day 13 hour 45 minute	+00008 13:45:00
INTERVAL'+999999'MINUTE(6)	694 day 10 hour 39 minute	+000694 10:39:00
INTERVAL'-999999'MINUTE(6)	-(694 day 10 hour 39 minute)	-000694 10:39:00

Interval SECOND

The followings are examples of using interval SECOND literals.

Example	Description	Display string
INTERVAL'1'SECOND INTERVAL'00 00:00:01.000000'SECOND	1 second	+00 00:00:01.000000
INTERVAL'100'SECOND	It exceeds the leading precision 2, so it returns the error.	-
INTERVAL'99.9999999'SECOND INTERVAL'99.9999999'SECOND(2,6)	The fractional seconds are rounded off to become 100 second, then it exceeds the leading precision 2, so it returns the error.	-
INTERVAL'99.9999999'SECOND(3)	1 minute 40 second	+000 00:01:40.000000
INTERVAL'29.506167'SECOND(2, 2)	29.51 second	+00 00:00:29.51
INTERVAL'999999.999999'SECOND(6,6)	11day 13 hour 46 minute 39.999999 second	+000011 13:46:39.999999
INTERVAL'-999999.999999'SECOND(6,6)	-(11day 13 hour 46 minute 39.999999 second)	-000011 13:46:39.999999

Interval DAY TO HOUR

The followings are examples of using interval DAY TO HOUR literals.

Example	Description	Display string
INTERVAL'1 23'DAY TO HOUR		

Example	Description	Display string
INTERVAL'01 23:00:00'DAY TO HOUR	1 day 23 hour	+01 23:00:00
INTERVAL'1 24'DAY TO HOUR	The hour value exceeds 23 (in valid), so it returns the error.	-
INTERVAL'100 23'DAY TO HOUR	It exceeds the leading precisio n 2, so it returns the error.	-
INTERVAL'100 23'DAY(3) TO HOUR	100 day 23 hour	+100 23:00:00
INTERVAL'+999999 23'DAY(6) TO HOUR	999999 day 23 hour	+999999 23:00:00
INTERVAL'-999999 23'DAY(6) TO HOUR	-(999999 day 23 hour)	-999999 23:00:00
INTERVAL'-999999 +23'DAY(6) TO HOUR	Invalid sign error	-

Interval DAY TO MINUTE

The followings are examples of using interval DAY TO MINUTE literals.

Example	Description	Display string
INTERVAL'1 23:59'DAY TO MINUTE INTERVAL'01 23:59:00'DAY TO MINUTE	1 day 23 hour 59 second	+01 23:59:00
INTERVAL'1 24:59'DAY TO MINUTE	The hour value exceeds 23 (in valid), so it returns the error.	-
INTERVAL'1 23:60'DAY TO MINUTE	The minute value exceeds 59 (invalid), so it returns the erro r.	-
INTERVAL'100 23:59'DAY TO MINUTE	It exceeds the leading precisio n 2, so it returns the error.	-
INTERVAL'100 23:59'DAY(3) TO MINUTE	100 day 23 hour 59 minute	+100 23:59:00
INTERVAL'+999999 23:59'DAY(6) TO MINUTE	999999 day 23 hour 59 minut e	+999999 23:59:00
INTERVAL'-999999 23:59'DAY(6) TO MINUTE	-(999999 day 23 hour 59 min ute)	-999999 23:59:00

Interval DAY TO SECOND

The followings are examples of using interval DAY TO SECOND literals.

Example	Description	display string
INTERVAL '1 23:59:59.999999'DAY TO SECOND	1 day 23 hour 59 minute 59.9 99999 second	+01 23:59:59.999999
INTERVAL '1 24:59:59.999999'DAY TO SECOND	The hour value exceeds 23, so it returns the error.	-
INTERVAL '1 23:60:59.999999'DAY TO SECOND	The minute value exceeds 59, so it returns the error.	-
	The second value exceeds 60,	

Example	Description	display string
INTERVAL '1 23:59:60.999999'DAY TO SECOND	so it returns the error.	-
INTERVAL '99 23:59:59.9999999'DAY TO SECOND	The fractional seconds are rounded off to become 100 day, then it exceeds the leading precision 2, so it returns the error.	-
INTERVAL '99 23:59:59.9999999'DAY(3) TO SECOND	100 day	+100 00:00:00.000000
INTERVAL '1 11:22:33.567890'DAY(2) TO SECOND(2)	1 day 11 hour 22 minute 33.57 second	+01 11:22:33.57
INTERVAL '+999999 23:59:59.999999'DAY(6) TO SECOND(6)	999999 day 23 hour 59 minute 59.999999 hour	+999999 23:59:59.999999
INTERVAL '-999999 23:59:59.999999'DAY(6) TO SECOND(6)	-(999999 day 23 hour 59 minute 59.999999 hour)	-999999 23:59:59.999999

Interval HOUR TO MINUTE

The followings are examples of using interval HOUR TO MINUTE literals.

Example	Description	Display string
INTERVAL'23:59'HOUR TO MINUTE INTERVAL'00 23:59:00'HOUR TO MINUTE	23 hour 59 minute	+00 23:59:00
INTERVAL'23:60'HOUR TO MINUTE	The minute value exceeds 59, so it returns the error.	-
INTERVAL'100:59'HOUR TO MINUTE	It exceeds the leading precision 2, so it returns the error.	-
INTERVAL'100:59'HOUR(3) TO MINUTE	4 day 4 hour 59 minute	+004 04:59:00
INTERVAL'+999999:59'HOUR(6) TO MINUTE	41666 day 15 hour 59 minute	+041666 15:59:00
INTERVAL'-999999:59'HOUR(6) TO MINUTE	-(41666 day 15 hour 59 minute)	-041666 15:59:00

Interval HOUR TO SECOND

The followings are examples of using interval HOUR TO SECOND literals.

Example	Description	Display string
INTERVAL '23:59:59.999999'HOUR TO SECOND INTERVAL '00 23:59:59.999999'HOUR TO SECOND	23 hour 59 minute 59.999999 second	+00 23:59:59.999999
INTERVAL '23:60:59.999999'HOUR TO SECOND	The minute value exceeds 59, so it returns the error.	-
INTERVAL '23:59:60.999999'HOUR TO SECOND	The second value exceeds 59,	-

Example	Description	Display string
	so it returns the error.	
INTERVAL '99:59:59.9999999'HOUR TO SECOND	The fractional seconds are rounded off to become 100 hour, then it exceeds the leading precision 2, so it returns the error.	-
INTERVAL '99:59:59.9999999'HOUR(3) TO SECOND	4 day 4 hour	+004 04:00:00.000000
INTERVAL '11:22:29.569'HOUR(3) TO SECOND(1)	11 hour 22 minute 29.6 second	+000 11:22:29.6
INTERVAL '+999999:59:59.999999'HOUR(6) TO SECOND(6)	41666 day 15 hour 59 minute 59.999999 second	+041666 15:59:59.999999
INTERVAL '-999999:59:59.999999'HOUR(6) TO SECOND(6)	-(41666 day 15 hour 59 minute 59.999999 second)	-041666 15:59:59.999999

Interval MINUTE TO SECOND

The followings are examples of using interval MINUTE TO SECOND literals.

Example	Description	Display string
INTERVAL '15:23.123456'MINUTE TO SECOND INTERVAL '00 00:15:23.123456'MINUTE TO SECOND	15 minute 23.123456 second	+00 00:15:23.123456
INTERVAL '15:60.123456'MINUTE TO SECOND	The second value exceeds 59, so it returns the error.	-
INTERVAL '99:59.999999'MINUTE TO SECOND(2)	The fractional seconds are rounded off to become 100 minute, then it exceeds the leading precision 2, so it returns the error.	-
INTERVAL '99:59.999999'MINUTE(3) TO SECOND(2)	1 hour 40 minute	+000 01:40:00.00
INTERVAL '+999999:59.999999'MINUTE(6) TO SECOND(6)	694 day 10 hour 39 minute 59.999999 second	+000694 10:39:59.999999
INTERVAL '-999999:59.999999'MINUTE(6) TO SECOND(6)	-(694 day 10 hour 39 minute 59.999999 second)	-000694 10:39:59.999999

Null Value

Null value is an unknown value or an undefined value. NULL value can be a value of any data type. The u nknown value of the boolean type is represented as null value.
Null value is defined as a keyword and it is not case-sensitive.

The following is an example of null value representation.

```
NULL
Null
```

Comments

Single Line Comment

A single line comment is a comment which starts with -- or //. The single line comment processes a com ment from the behind of the comment's symbol to the end of the line.

The following is an example of using a single line comment.

```
gSQL> SELECT I1, -- I2, I3,
2 I4, I5
3 FROM T1;
I1        I4        I5
--------- --------- ---------
column i1 column i4 column i5
1 row selected.
gSQL> SELECT I1, // I2, I3,
2 I4, I5
3 FROM T1;
I1        I4        I5
--------- --------- ---------
column i1 column i4 column i5
1 row selected.
```

Multiple Line Comment

A multiple line comment is a comment which starts with /* and ends with */. Multiple line comments spe cify a comment from /* to */, and it can use multiple lines to represent comments.

The following is an example of using multiple line comment.

```
gSQL> SELECT I1, I2, I3, I4, I5
2  /* Output
3   all columns of TABLE T1 */
4 FROM T1;
I1        I2        I3        I4        I5
--------- --------- --------- --------- ---------
column i1 column i2 column i3 column i4 column i5
1 row selected.
```

Hint Comment

A hint comment is a comment which starts with /*+ and ends with */. Hint comment is similar to multipl e line comment, but the difference is that the hint comment has + at the beginning.
Do not use a space between * and +. If so, it will be treated as multiple line comment.

Unlike other comments, a hint comment is specified to be used only at the location which is right after th e SELECT keyword. The processing method which a user specified to GOLDILOCKS optimizer is described in the hint comment. For more information, refer to **SQL Hint**.

The following is an example of using hint comment.

```
gSQL> SELECT /*+ FULL(T1) */ * FROM T1;
I1        I2        I3        I4        I5
--------- --------- --------- --------- ---------
column i1 column i2 column i3 column i4 column i5
1 row selected.
```

SQL Reserved Words and Keywords

SQL Reserved Words

GOLDILOCKS supports reserved words which are specified as SQL reserved words. The SQL reserved word s can not be used other than specified location.

SQL reserved words can be used as identifiers by using double quotes ("), but it is not recommended to u se it as follows, because readability decreases.

```
gSQL> CREATE TABLE "SELECT" ( "FROM" INTEGER );
Table created.
gSQL> INSERT INTO "SELECT" ( "FROM" ) VALUES ( 1 );
1 row created.
gSQL> SELECT "FROM" FROM "SELECT";
FROM
----
   1
1 row selected.
```

The followings are SQL reserved words of GOLDILOCKS. * marked SQL reserved words are supported by t he SQL standard.
For more information about the list, refer to **V$RESERVED_WORDS**.

SQL Keywords

GOLDILOCKS SQL keywords are not reserved words. However, they are keywords which are internally use d by GOLDILOCKS. Therefore, it is not recommended to use GOLDILOCKS SQL keywords because it can d ecrease the readability of the results.

GOLDILOCKS SQL keywords list can be viewed through **V$KEYWORDS**.

Compatibility for Syntax Elements

The SQL standard compatibility for syntax element is as follows.

Table 11-1 SQL standard compatibility for syntax element

Feature ID	Description	Availability
E021-03	Character literals	O
E131	Null value support (nulls in lieu of values)	O
E161	SQL comments using leading double minus	O
F051-01	DATE data type (including support of DATE literal)	O
	TIME data type (including support of TIME literal) with fractional seconds pr	

Feature ID	Description	Availability
F051-02	ecision of at least 0	O
F051-03	TIMESTAMP data type (including support of TIMESTAMP literal) with fractio nal seconds precision of at least 0 and 6	O
F271	Compound character literals	X
F383	Set column not null clause	O
F391	Long identifiers	X
F392	Unicode escapes in identifiers	X
F393	Unicode escapes in literals	X
T023	Compound binary literals	X
T024	Spaces in binary literals	X
T101	Enhanced nullability determination	X
T351	Bracketed comments	X
T591	UNIQUE constraints of possibly null columns	O
X041	Basic table mapping: null absent	X
X042	Basic table mapping: null as nil	X
X051	Advanced table mapping: null absent	X
X052	Advanced table mapping: null as nil	X
X170	XML null handling options	X
X400	Name and identifier mapping	X

11.2 Data Type

Numeric Type

Numeric data types are classified according to the storage method and the fractional part representation.

- Classification by the storage method
  - Decimal numeric type
    - It stores decimal numbers in 100 digits basis.
    - Types: NUMBER, NUMERIC, FLOAT
  - Binary numeric type
    - It stores numbers of C language as it is.
    - Types: NATIVE_INTEGER, NATIVE_DOUBLE

- Classification by fractional part representation
  - Fixed point data type (exact numeric)
    - It is a numeric type whose scale is fixed.
    - Types: NUMERIC(precision, scale), NATIVE_INTEGER
  - Floating point data type (approximate numeric)
    - It is a numeric type whose scale is not fixed.
    - Types: FLOAT(precision), NATIVE_DOUBLE

Decimal Numeric Type

This type's precision and scale are based on decimal number. The precision indicates accuracy of the valid digits, and the scale indicates the range of fraction.

Decimal Fixed Point Number Type

The decimal fixed point number type is defined in SQL.

Table 11-2 Decimal fixed point number type

Type	Decimal precision	Decimal scale	Refer to
NUMBER(p)	p	0	**NUMBER**
NUMBER(p, s)	p	s	**NUMBER**
NUMERIC(p)	p	0	**NUMERIC**
NUMERIC(p, s)	p	s	**NUMERIC**
DECIMAL(p)	p	0	**NUMERIC** type alias
DECIMAL(p, s)	p	s	**NUMERIC** type alias

Type	Decimal precision	Decimal scale	Refer to
DEC(p)	p	0	**NUMERIC** type alias
DEC(p, s)	p	s	**NUMERIC** type alias
SMALLINT	5	0	**NUMBER** type alias
INTEGER	10	0	**NUMBER** type alias
BIGINT	19	0	**NUMBER** type alias
INT2	5	0	**NUMBER** type alias
INT4	10	0	**NUMBER** type alias
INT8	19	0	**NUMBER** type alias

Decimal Floating Point Number Type

The decimal floating point number type is defined in SQL.

Table 11-3 Decimal floating point number type

Type	Decimal precision	Decimal scale	Refer to
NUMBER	38	N/A	**NUMBER**
FLOAT(p)	ceil($\log_{10} 2^{p}$)	N/A	**FLOAT**
REAL	ceil($\log_{10} 2^{24}$) = 8	N/A	**FLOAT** type alias
DOUBLE	ceil($\log_{10} 2^{53}$) = 16	N/A	**FLOAT** type alias
FLOAT4	ceil($\log_{10} 2^{24}$) = 8	N/A	**FLOAT** type alias
FLOAT8	ceil($\log_{10} 2^{53}$) = 16	N/A	**FLOAT** type alias

Binary Number Type

This type's precision and scale are based on binary number. The precision indicates accuracy of the valid d igits, and the scale indicates the range of fraction.

Binary Fixed Point Number Type

The binary fixed point number type refers to the signed integer data type of C language.
1 bit is used to represent the sign bit, and other bits are used to represent the precision, but not any bit is used to represent the scale.

Table 11-4 Binary fixed point number type

Type	Binary precision	Binary scale	Refer to
NATIVE_SMALLINT	15	0	**NATIVE_SMALLINT**
NATIVE_INTEGER	31	0	**NATIVE_INTEGER**
NATIVE_BIGINT	63	0	**NATIVE_BIGINT**

Binary Floating Point Number Type

The binary floating point type refers to the float and double data type in C language.
1 bit is used to represent the sign bit, and other bits are used to represent the precision and scale.

Table 11-5 Binary floating point number type

Type	Binary precision	Binary scale	Refer to
NATIVE_REAL	23	8	**NATIVE_REAL**
NATIVE_DOUBLE	52	11	**NATIVE_DOUBLE**

The precision and scale of binary floating point type is subject to change depending on the influence of the compiler and OS.

CHARACTER STRING Type

CHARACTER STRING data types are classified according to whether it is a variable length string and the maximum length of string.

- Classification by whether it is a variable length string
  - Fixed length string
    - Refer to **CHARACTER**.
  - Variable length string
    - Refer to **CHARACTER VARYING**, **CHARACTER LONG VARYING**.
- Classification by the maximum length of a string
  - 2000 [characters or bytes]
    - Refer to **CHARACTER**.
  - 4000 [characters or bytes]
    - Refer to **CHARACTER VARYING**.
  - 100 megabytes
    - Refer to **CHARACTER LONG VARYING**.

BINARY STRING Type

BINARY STRING data types are classified according to whether it is a variable length binary string and the maximum length of binary string.

- Classification by whether it is a variable length binary string

    - Fixed length binary string
        - Refer to **BINARY**.
    - Variable length binary string
        - Refer to **BINARY VARYING**, **BINARY LONG VARYING**.
- Classification by the maximum length of binary string
    - 2000
        - Refer to **BINARY**.
    - 4000
        - Refer to **BINARY VARYING**.
    - 100 Mega Bytes
        - Refer to **BINARY LONG VARYING**.

Date/ Time Type

Date/ time data type specifies the year, month, day, hour, minute, second, time zone offset in accordanc e with their representation method.
Date/ time type has **DATE**, **TIME**, **TIMESTAMP** types.

INTERVAL Type

INTERVAL data type specifies the time interval.
It specifies the time interval of the year, month, day, hour, minute, second in accordance with their repres entation method.

INTERVAL data types are classified to the YEAR TO MONTH family type and the DAY TO SECOND family t ype, according to the range of value representation.

BOOLEAN Type

The BOOLEAN data type stores truth value of TRUE, FALSE, UNKNOWN. UNKNOWN value is represented as a null value. All expressions used as condition returns the BOOLEAN value and the column or the value defined as a BOOLEAN data type can be used as a condition.

The following literals can be stored in the boolean data type.

- TRUE
    - Keyword: TRUE

    - Literal: 't', 'true' , 'y', 'yes' , 'on' ,'1'
- FALSE
    - Keyword: FALSE
    - Literal: 'f', 'false', 'n', 'no', 'off', '0'
- UNKNOWN
    - Keyword: UNKNOWN, NULL

For more information, refer to **BOOLEAN**.

ROWID Type

All the records stored in the database has a unique location information. The record identifier (ROWID) is used to distinguish each record.

ROWID data type is used to store and manage the record identifier (ROWID).
Record identifier (ROWID) is obtained by the query using the ROWID pseudo column.

For more information, refer to **ROWID**.

Type Comparison

Comparing two types is executed on the basis of one representative type. If the comparison target type is different from the representative type, then the comparison can go through a type conversion.
The representative types for type comparison defines the representative type for comparing two types.

The following table describes target type conversion for comparison per each representative type.

- **Type conversion for the VC comparison**
- **Type conversion for the LC comparison**
- **Type conversion for the VB comparison**
- **Type conversion for the LB comparison**
- **Type conversion for the NB comparison**
- **Type conversion for the ND comparison**
- **Type conversion for the NU comparison**
- **Type conversion for the DA comparison**
- **Type conversion for the TI comparison**
- **Type conversion for the TZ comparison**
- **Type conversion for the TS comparison**
- **Type conversion for the SZ comparison**

- **Type conversion for the YM comparison**
- **Type conversion for the DS comparison**
- **Type conversion for the BO comparison**
- **Type conversion for the RI comparison**

The followings are abbreviations which are used for the type comparison.

- "VC": CHARACTER VARYING
- "LC": CHARACTER LONG VARYING
- "VB": BINARY VARYING
- "LB": BINARY LONG VARYING
- "NB": NATIVE_BIGINT
- "ND": NATIVE_DOUBLE
- "NU": NUMBER
- "DA": DATE
- "TI": TIME
- "TZ": TIME WITH TIMEZONE
- "TS": TIMESTAMP
- "SZ": TIMESTAMP WITH TIMEZONE
- "YM": INTERVAL YEAR TO MONTH
- "DS": INTERVAL DAY TO SECOND
- "BO": BOOLEAN
- "RI": ROWID

In the type comparison table, the built-in data types are represented by an abbreviated word en closed in double quotes ("").

- "CHAR": CHARACTER
- "VARCHAR": CHARACTER VARYING
- "LONG VARCHAR": CHARACTER LONG VARYING
- "VARBINARY": BINARY VARYING
- "LONG VARBINARY": BINARY LONG VARYING
- "TIME_TZ": TIME WITH TIMEZONE
- "TIMESTAMP_TZ": TIMESTAMP WITH TIMEZONE
- "INTERVAL_YM": INTERVAL YEAR TO MONTH
- "INTERVAL_DS": INTERVAL DAY TO SECOND

Table 11-6 The representative types for type comparison

Data type	CHAR	VARCHAR	LONG VARCHAR	BINARY	VARBINARY	LONG VARBINARY	NATIVE SMALLINT	NATIVE INTEGER	NATIVE BIGINT	NATIVE REAL	NATIVE DOUBLE	NUMBER	NUMERIC	FLOAT	DATE	TIME	TIME TZ	TIMESTAMP	TIMESTAMP TZ	INTERVAL YM	INTERVAL DS	BOOLEAN	ROWID

Type Conversion

Type conversions are classified into implicit type conversion and explicit type conversion.

- Implicit type conversion occurs in an expression, an operator, a function, a condition for select, insert, delete, update.
- Explicit type conversion occurs through the CAST operator.

The availability of type conversion describes the availability of data type conversion from a type to another type.

In the type conversion table, the built-in data types are represented by an abbreviated string enc losed in double quotes ("").

- "CHAR": CHARACTER
- "VARCHAR": CHARACTER VARYING
- "LONG VARCHAR": CHARACTER LONG VARYING
- "VARBINARY": BINARY VARYING
- "LONG VARBINARY": BINARY LONG VARYING
- "TIME_TZ": TIME WITH TIMEZONE
- "TIMESTAMP_TZ": TIMESTAMP WITH TIMEZONE

- "INTERVAL_YM": INTERVAL YEAR TO MONTH
- "INTERVAL_DS": INTERVAL DAY TO SECOND

Table 11-23 The availability of type conversion

Data type	CHAR	VARCHAR	LONG VARCHAR	BINARY	VARBINARY	LONG VARBINARY	NATIVE SMALLINT	NATIVE INTEGER	NATIVE BIGINT	NATIVE REAL	NATIVE DOUBLE	NUMBER	NUMERIC	FLOAT	DATE	TIME	TIME TZ	TIMESTAMP	TIMESTAMP TZ	INTERVAL YM	INTERVAL DS	BOOLEAN	ROWID

- Conversion to CHARACTER type
  - When the source type is CHARACTER type:
    - If the source type precision is bigger than the CHARACTER type precision, then an error occu rs.
    - If the source type precision is equal to the CHARACTER type precision, then the string is not c hanged.
    - If the source type precision is smaller than the CHARACTER type precision, then space charac ters are added to the string as many as the precision difference.
  - When the source type is CHARACTER VARYING type or CHARACTER LONG VARYING type:
    - If the source type string length is bigger than the CHARACTER type precision, then an error o ccurs.
    - If the source type string length is equal to the CHARACTER type precision, then the string is n ot changed.
    - If the source type string length is smaller than the CHARACTER type precision, then space ch aracters are added to the string as many as precision difference.
  - When the source type is numeric type, date/time type, INTERVAL type, BOOLEAN type or ROWID type:
    - If the converted string length of the source type is bigger than the CHARACTER type precisio n, then an error occurs.
    - If the converted string length of the source type is equal to the CHARACTER type precision, t he string is not changed.
    - If the converted string length of the source type is smaller than the CHARACTER type precisio n, then space characters are added to the string as many as precision difference.

- Conversion to CHARACTER VARYING type
  - When the source type is CHARACTER type:
    - If the source type precision is bigger than the CHARACTER VARYING type precision, then an error occurs.
    - If the source type precision is equal or smaller than the CHARACTER VARYING type precision, then the string is not changed.
  - When the source type is CHARACTER VARYING type or CHARACTER LONG VARYING type:
    - If the source type string length is bigger than the CHARACTER VARYING type precision, then an error occurs.
    - If the source type string length is equal or smaller than the CHARACTER VARYING type precis ion, then the string is not changed.
  - When the source type is numeric type, date/time type, INTERVAL type, BOOLEAN type or ROWID type:
    - If the converted string length of the source type is bigger than the CHARACTER VARYING typ e precision, then an error occurs.
    - If the converted string length of the source type is equal or smaller than the CHARACTER VA RYING type precision, then the string is not changed.

- Conversion to CHARACTER LONG VARYING type
  - When the source type is CHARACTER STRING type:

        - The source type string is not changed.
    - When the source type is numeric type, date/time type, INTERVAL type, BOOLEAN type or ROWID type:
        - The converted string of the source type is not changed.

- Conversion to BINARY type
    - When the source type is BINARY type:
        - If the source type precision is bigger than the BINARY type precision, then an error occurs.
        - If the source type precision is equal to the BINARY type precision, then the binary string is not changed.
        - If the source type precision is smaller than the BINARY type precision, the X'00' characters ar e added to the binary string as many as the precision difference.
    - When the source type is BINARY VARYING type or BINARY LONG VARYING type:
        - If the source type binary string length is bigger than the BINARY type precision, then an error occurs.
        - If the source type binary string length is equal to the BINARY type precision, then the binary s tring is not changed.
        - If the source type binary string length is smaller than the BINARY type precision, the X'00' ch aracters are added to a binary string as many as precision difference.

- Conversion to BINARY VARYING type
    - When the source type is BINARY type:
        - If the source type precision is bigger than the BINARY VARYING type precision, then an error occurs.
        - If the source type precision is equal or smaller than the BINARY VARYING type precision, the n the binary string is not changed.
    - When the source type is BINARY VARYING type, BINARY LONG VARYING type:
        - If the source type binary string length is bigger than the BINARY VARYING type precision, the n an error occurs.
        - If the source type binary string length is equal or smaller than the BINARY VARYING type pre cision, the binary string is not changed.

- Conversion to BINARY LONG VARYING type
    - If the source type is BINARY STRING type, the source type binary string is not changed.

- Conversion to numeric type
    - When the source type is CHARACTER STRING type:
        - If the string does not comply with the numeric format, then an error occurs.
        - An overflow or rounding can occur due to the precision and scale which is defined in the con verted type.
    - When the source type is numeric type:
        - An overflow or rounding can occur due to the precision and scale which is defined in the con verted type.

  - When the source type is INTERVAL type:
    - It can be converted to the numeric type only when the source type is the single field (YEAR, MONTH, DAY, HOUR, MINUTE, SECOND).
    - An overflow or rounding can occur due to the precision and scale which is defined in the converted type.

- Conversion to DATE type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the DATE type format, then an error occurs.
    - An overflow can occur due to a value range which is defined in the converted type.
  - When the source type is DATE type or TIMESTAMP type:
    - The error does not occur.
  - When the source type is TIMESTAMP WITH TIME ZONE type:
    - It is converted to the DATE type value upon consideration of the time zone offset.

- Conversion to TIME type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the TIME type format, then an error occurs.
    - A rounding can occur due to a value range which is defined in the converted type.
  - When the source type is TIME type or TIMESTAMP type:
    - The error does not occur.
  - When the source type is TIME WITH TIME ZONE type or TIMESTAMP WITH TIME ZONE type:
    - It is converted to the value of TIME type upon consideration of the time zone offset.

- Conversion to TIME WITH TIME ZONE type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the TIME WITH TIME ZONE type format, then an error occurs.
    - A rounding can occur due to a value range which is defined in the converted type.
  - When the source type is TIME type, TIME WITH TIME ZONE type or TIMESTAMP WITH TIME ZONE type:
    - It is converted to the value of TIME WITH TIME ZONE type upon consideration of the time zone offset.

- Conversion to TIMESTAMP type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the TIMESTAMP type format, then an error occurs.
    - An overflow or rounding can occur due to a value range which is defined in the converted type.
  - When the source type is DATE type or TIMESTAMP type:
    - The error does not occur.
  - When the source type is TIMESTAMP WITH TIME ZONE type:
    - It is converted to the TIMESTAMP type value upon consideration of the time zone offset.

- Conversion to TIMESTAMP WITH TIME ZONE type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the TIMESTAMP WITH TIME ZONE type format, then an error occurs.
    - An overflow or rounding can occur due to a value range which is defined in the converted type.
  - When the source type is DATE type, TIMESTAMP type or TIMESTAMP WITH TIME ZONE type:
    - It is converted to the value of TIMESTAMP WITH TIME ZONE type upon consideration of the time zone offset.

- Conversion to INTERVAL YEAR TO MONTH family type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the year-month interval literal format, then an error occurs.
    - For more information, refer to **Interval Literals**.
    - An overflow can occur due to a precision which is defined in the converted type.
  - When the source type is NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT, NUMBER, NUMERIC or FLOAT type:
    - The converted type should be a single field (YEAR, MONTH).
    - An overflow can occur due to a precision which is defined in the converted type.
  - When the source type is INTERVAL YEAR TO MONTH family type:
    - An overflow can occur due to a precision which is defined in the converted type.

- Conversion to INTERVAL DAY TO SECOND family type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the day-time interval literal format, then an error occurs.
    - For more information, refer to **Interval Literals**.
    - An overflow or rounding can occur due to the precision which is defined in the converted type.
  - When the source type is NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT, NUMBER, NUMERIC, or FLOAT type:
    - The converted type should be a single field (DAY, HOUR, MINUTE, SECOND)
    - An overflow or rounding can occur due to the precision which is defined in the converted type.
  - When the source type is INTERVAL DAY TO SECOND family type:
    - An overflow or rounding can occur due to the precision which is defined in the converted type.

- Conversion to BOOLEAN type
  - When the source type is CHARACTER STRING type:
    - The conversion is available when the string is "TRUE" or "FALSE", and it is case-insensitive. (It is convertible even when the string includes a space before and after it.)
  - When the source type is BOOLEAN type:
    - The error does not occur.

- Conversion to ROWID type
  - When the source type is CHARACTER STRING type:
    - If the string does not comply with the ROWID type format, then an error occurs.
  - When the source type is ROWID type:
    - The error does not occur.

Type Combination

When Type Combination Is Required

A CASE operator and a **set operator** have many expressions as a result of operation.
Each expression can have different types each other as follows. In this case, the result type should be dete rmined.

- The following describes an excution result of a CASE operator.

```
SELECT CASE expr WHEN expr THEN char(3)
                 WHEN expr THEN char(5)
                 ELSE char(1)
       END
  FROM t1;
```

- The following describes an excution result of a set operator.

```
SELECT float_column
  FROM t1
UNION ALL
SELECT number_precision_column
  FROM t2
UNION ALL
SELECT native_integer_column
  FROM t3;
```

A rule is applied to determine the result type according to the type combination. The following is an exa mple of applying the rule.

- Result type combination rule
  - **set operator**
  - CASE operator
    - **CASE Expression**

        - **COALESCE**
        - **NULLIF**

Result Type Combination Rule

Each expression's data type should be the same family type which is available to combine.

- Examples of applying result type combination rule
    - **set operator**
    - CASE operator
        - **CASE Expression**
        - **COALESCE**
        - **NULLIF**

The result types determined by result type combination rule are described in the following table.

The following abbreviations are used to describe the result type combination rule.

- "VC": CHARACTER VARYING
- "LC": CHARACTER LONG VARYING
- "VB": BINARY VARYING
- "LB": BINARY LONG VARYING
- "NS": NATIVE_SMALLINT
- "NI": NATIVE_INTEGER
- "NB": NATIVE_BIGINT
- "NR": NATIVE_REAL
- "ND": NATIVE_DOUBLE
- "FL": FLOAT
- "NU": NUMBER
- "DA": DATE
- "TI": TIME
- "TZ": TIME WITH TIMEZONE
- "TS": TIMESTAMP
- "SZ": TIMESTAMP WITH TIMEZONE
- "YM": INTERVAL YEAR TO MONTH
- "DS": INTERVAL DAY TO SECOND
- "BO": BOOLEAN
- "RI": ROWID

In result type combination table, the built-in data types are represented by an abbreviated word enclosed in double quotes ("").

- "CHAR": CHARACTER
- "VARCHAR": CHARACTER VARYING
- "LONG VARCHAR": CHARACTER LONG VARYING
- "BINARY": BINARY
- "VARBINARY": BINARY VARYING

- The result type of when all is CHAR type
  - If the lengths are different, then it is VARCHAR type.
  - If the lengths are equal, then it is CHAR type.
- The result type of when all is BINARY type
  - If the lengths are different, then it is VARBINARY type.
  - If the lengths are equal, then it is BINARY type.
- The result type of INTERVAL YEAR TO MONTH type
  - If YEAR type and MONTH type are mixed, then it is INTERVAL YEAR TO MONTH type.
  - If there is only YEAR type, then it is INTERVAL YEAR type.
  - If there is only MONTH type, then it is INTERVAL MONTH type.
- The result type of INTERVAL DAY TO SECOND type
  - The start field is the biggest range field of each target expression.
  - The end field is the smallest range field of each target expression.
  - e.g. {INTERVAL DAY, INTERVAL HOUR} => INTERVAL DAY TO HOUR
- The precision, scale of the result type
  - CHARACTER STRING type
    - The maximum character length of the target expression

    - BINARY STRING type
        - The maximum character length of the target expression
    - NUMERIC type
        - It specifies an acceptable maximum range of the type's value.
    - TIME/TIMESTAMP type
        - The maximum fractional seconds precision of the target expression
    - INTERVAL YEAR TO MONTH
        - The maximum leading precision of the target expression
    - INTERVAL DAY TO SECOND
        - Leading precision is the maximum leading precision of the start field
        - Fractional seconds precision is the maximum fractional seconds precision.
- For more information, refer to **Type Comparison**.

Compatibility for Data Type

The SQL standard compatibility for data type is as follows.

Table 11-25 SQL standard compatibility for data type

Feature ID	Description	Availability
B033	Untyped SQL-invoked function arguments	X
E011-01	INTEGER and SMALLINT data types	O
E011-02	REAL, DOUBLE PRECISION, and FLOAT data types	O
E011-03	DECIMAL and NUMERIC data types	X
E011-04	Arithmetic operators	O
E011-05	Numeric comparison	O
E011-06	Implicit casting among the numeric data types	O

11.3 Format String

Format string defines the format which is used when a numeric type or date/time type is converted to a c haracter string or when a character string is converted to a numeric types or date/time type.

- When a numeric type or date/time type is converted to a character string type, the representation for mat of the string is as follows.
  - Refer to **TO_CHAR(number)**, **TO_CHAR(datetime)**.
  - Numeric type: TO_CHAR(1234.56, 'S9,999.99') → '+1,234.56'
  - Date/time type: TO_CHAR(SYSDATE, 'YYYY-MM-DD') → '2012-07-15'
- When a character string is converted to the numeric type or date/time type, the representation forma t of the string is as follows.
  - Refer to **TO_NUMBER**, **TO_NATIVE_REAL**, **TO_NATIVE_DOUBLE**.
  - Refer to **TO_DATE**.
  - Refer to **TO_TIMESTAMP**, **TO_TIMESTAMP_WITH_TIME_ZONE**.
  - Refer to **TO_TIME**, **TO_TIME_WITH_TIME_ZONE** .
  - Numeric type: TO_NUMBER('+1,234.56', 'S9,999.99') → NUMBER TYPE
  - Date/time type: TO_DATE('2012-07-15', 'YYYY-MM-DD') → DATE TYPE

Format strings are classified according to the type.
- Numeric data type: Refer to **Number Format String**.
- Date/time type: Refer to **Datetime Format String**.

Number Format String

Number format string defines the format which is used when a numeric type is converted to a character s tring type, or when a character string type is converted to a numeric type.

Number format string is used as an argument of the functions such as **TO_CHAR(number)**, **TO_NATIVE_ SMALLINT**, **TO_NATIVE_INTEGER**, **TO_NATIVE_BIGINT**, **TO_NUMBER**, **TO_NATIVE_REAL**, **TO_NATIVE_DO UBLE**.

Number format string can specify multiple format elements according to the desired format.

All number format elements are rounded off to fit the format.
If the number of digits before the decimal point of the value to be converted is bigger than the number o f digits specified in the format string, then they are replaced with '#' character.
If the format element representing the sign of MI, S, PR is not specified, a negative number returns - sign and a positive number returns a white space to the front of the number.

Table 11-26 Number format elements

Format element	Example	Description
, (comma)	9,999	It returns a comma to the specified position. Multiple commas can be specified. Format string can not begin with a comma, and it can not come after the decimal point (.).
. (period)	99.99	It returns a decimal point (.) to the specified position. The decimal point in the format string can be specified only once.
$	$9999	It returns the $ sign to the front of the number.
0	0999 9990	It returns zero (0) to the front of or to the end of the number. If the number of digit of the value to be converted is smaller than the number of digit to the zero position of the format string, then the gap is filled with zero (0)s and is returned.
9	9999	It returns a white space and numbers according to the sign and the number of specified 9. If the number of digit of the value to be converted is smaller than the number of the specified 9, then the gap is filled with white spaces and is returned. For a positive number, a white space is returned to the front of the number. For a negative number, '-' symbol is returned to the front of the number. If the value before the format string's decimal point is 0, then 0 is returned as a white space. e.g. TO_CHAR(0.123, '9.999') → .123 e.g. TO_CHAR(0, '9') → 0
B	B9999	If the value is zero, it returns a white space.
EEEE	9.9EEEE	It returns in exponential notation. It can be at the end of format string or it can be in front of S, MI, PR. It can not be specified together with a comma (,).
MI	9999MI	For a positive number, a white space is returned to the end of the number. For a negative number, '-' symbol is returned to the end of the number. It can be specified only at the end of format string and it can not be specified together with S, PR.
PR	9999PR	For a positive number, white spaces are returned to the beginning and end of the number. For a negative number, it returns the number into the inside of angle brackets. <number> It can be specified only at the end of format string, and it can not be specified together with S, MI.
RN rn	RN rn	Roman numerals are converted to uppercase and returned. (RN) Roman numerals are converted to lowercase and returned. (rn) Only the numbers between 1 ~ 3999 are returned. It can be specified together only with FM format element, but it can not be specified with any other format elements. It can not be used in TO_NUMBER function.

Format element	Example	Description
S	S9999 9999S	For a positive number, '+' symbol is returned to the front of the number. For a negative number '-' symbol is returned to the front of the number. (S9999) For a positive number, '+' symbol is returned to the end of the number. For a negative number '-' symbol is returned to the end of the number. (9999S) It can be specified only at the beginning of format string or at the end of format string. It can not be specified together with MI, PR.
V	999V99	10^n(n: the digit number of 9 after V format element) multiplied by the value is returned. It can not specified together with the decimal point (.). It can not be used in TO_NUMBER function.
X	XXXX xxxx	It returns the white space and hexadecimal number according to the digit number of the specified X. It converts an integer value to the hexadecimal number, and returns it. (A non-integer value is rounded off to make it to an integer value.) XXX returns hexadecimal uppercase letters and xxxx returns hexadecimal lowercase letters. If the number of the converted hexadecimal digit is smaller than the number of the specified X, then the gap is filled with white spaces and is returned. Only 0 and positive integers are processed, and negative numbers are replaced with '#'. It can be specified together only with format element 0 and FM, but it can not be specified with any other format elements.
FM	FM	It removes the front and end white spaces, and returns left aligned effect. It removes the front and end white spaces of the number. It removes zero(0)s under the decimal point which are added by 9 format element.

Followings are examples of using number format string.

```
TO_CHAR( 12345, '99,999' )          : ' 12,345'
TO_CHAR( 123456789, '999,999,999' ) : ' 123,456,789'

Datetime Format String

Datetime format string defines the format which is used when a date/time type is converted to a characte r string type, or when a character string type is converted to a date/time type.

Datetime format string is used as an argument of the functions such as **TO_CHAR(datetime)**, **TO_DATE**, **TO_TIMESTAMP**, **TO_TIMESTAMP_WITH_TIME_ZONE**, **TO_TIME**, **TO_TIME_WITH_TIME_ZONE**.

For datetime format string, if the format string is not specified, then the default value is used. The default value of each type is specified in the session property (NLS _ * _ FORMAT).

- DATE: Refer to **NLS_DATE_FORMAT**.
- TIMESTAMP: Refer to **NLS_TIMESTAMP_FORMAT**.

- TIMESTAMP WITH TIME ZONE: Refer to **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**.
- TIME: Refer to **NLS_TIME_FORMAT**.
- TIME WITH TIME ZONE: Refer to **NLS_TIME_WITH_TIME_ZONE_FORMAT**.

NLS * _FORMAT values can be changed by using **ALTER SESSION SET property_name**.

In datetime format string, multiple format elements can be specified upon the desired representation.

Table 11-27 Datetime format elements

Format element	Whether to use TO_* datetime	Description
- / , . ; : "text" Special characters	Y	It returns the format element character to the specified location.
AD A.D.	Y	AD with or without periods.
AM A.M.	Y	AM with or without periods.
BC B.C.	Y	BC with or without periods.
CC	N	Century If the last two digits of the four digits year is 01~ 99, the value which is added by one to the first two digits is returned. (e.g. If the year is 2005, 21 is returned.) If the last two digits of the four digits year is 00, The first two digits value is returned. (e.g. If the year is 2000, 20 is returned.)
D	Y	It returns the sequence of the day in a week. (1 ~ 7) Sunday is 1, saturday is 7, and so on.
DAY Day day	Y	It returns the day of the week. (e.g. SUNDAY) • DAY: The day which is all in uppercase is returned. • Day: The day whose first character is uppercase and others are lowercase is returned. • day: The day which is all in lowercase is returned.
DD	Y	It returns the sequence of the day in a month. (1 ~ 31)
DDD	Y	It returns the sequence of the day in a year. (1 ~ 366)
DY		It returns the abbreviated word for the day of the week. (e.g. SUN) • DY: The day which is all in uppercase is returned.

Format element	Whether to use TO_* datetime	Description
Dy dy	Y	• Dy: The day whose first character is uppercase and others are lowercase is returned. • dy: The day which is all in lowercase is returned.
FF[1..6]	Y	It returns fractional seconds as many as the number of the specified digits (1-6) after FF. If the number is not specified, the default value is 6. (FF is equal to FF6.) If the number of fractional seconds digit is bigger than the number specified after FF, then it is rounded down. If the number of fractional seconds digit is smaller than the number specified after FF, then zero(0) is added according to the specified number. It can not be used in DATE type.
HH HH12	Y	The hour (1 ~ 12)
HH24	Y	The hour (0 ~ 23)
IW	N	The week containing the first thursday of the year designated as the calendar week by ISO 8601 standards (1 ~ 52 week or 1 ~ 53 weeks) becomes the first week. • The calendar week starts from monday. • The first calendar week includes January 4th. • The first calendar week may includes December 29th, 30th, and 31st. • The last calendar week may include January 1st, 2nd, and 3rd.
IYYY	N	The 4 digits year embracing the calendar week defined by ISO 8601 standards
IYY IY I	N	The 3 digits year embracing the calendar week defined by ISO 8601 standards The 2 digits year embracing the calendar week defined by ISO 8601 standards The single digit year embracing the calendar week defined by ISO 8601 standards
J	Y	Julian day: The number of days since BC 4714-11-24
MI	Y	Minute (0 ~ 59)
MM	Y	Month (01 ~ 12), January(01)~December(12)
MON Mon mon	Y	The abbreviated word for the month. (e.g. JAN) • MON: The month which is all in uppercase is returned. • Mon: The month whose first character is uppercase and others are lowercase is returned. • mon: The month which is all in lowercase is returned.
MONTH Month	Y	The month name (e.g. JANUARY) • MONTH: All uppercase month name is returned. • Month: The month name that only the first letter is uppercase and oth

Format element	Whether to use TO_* datetime	Description
month		ers are lowercase is returned. • month: The month of which is all in lowercase is returned.
PM P.M.	Y	PM with or without periods.
Q	N	The quarter of the year (1 ~ 4) January to March is 1 and October to December is 4.
RM Rm rm	Y	It returns the roman numeral month. (e.g. I) • RM: The month which is all in uppercase is returned. • Rm: The month whose first character is uppercase and others are lowercase is returned. • rm: The month which is all in lowercase is returned.
RR	Y	Adjusted two digit year The two digit year represented by RR can be converted to four digit year as follows. • When the two digit year represented by RR is 00~49: ◦ If the last two digits of the current year is 00~50, ▪ the four digit year is represented using the first two digits of the current year and the two digits which is represented by RR. ◦ If the last two digits of the current year is 51~99, ▪ the four digit year is represented using "the first two digits of the current year+1" and the two digits which is represented by RR. • When the two digit year represented by RR is 50~99: ◦ If the last two digits of the current year is 00~50, ▪ the four digit year is represented using "the first two digit of the current year - 1" and the two digits which is represented by RR. ◦ If the last two digit of the current year is 51~99, ▪ the four digit year is expressed using the first two digit of the current year and the two digits which is represented by RR.
RRRR	Y	Adjusted four digit year Two digit or four digit can be input. Two digit input is processed in the same way as RR.
SS	Y	Second (0 ~ 59)
SSSSS	Y	Seconds since last midnight (0 ~ 86399)
TZH	Y	Time Zone Hour It can not be used in DATE, TIMESTAMP, TIME types. It is available in TIMESTAMP WITH TIME ZONE, TIME WITH TIME ZONE types.
TZM	Y	Time Zone Minute It can not be used in DATE, TIMESTAMP, TIME types. It can be used only in

Format element	Whether to use TO_* datetime	Description
		TIMESTAMP WITH TIME ZONE, TIME WITH TIME ZONE types.
WW	N	The sequence of the week in a year. (1~ 53) The first week 1 starts on the first day of the year and continues to the seven th day of the year.
W	N	The sequence of the week in a month. (1 ~ 5) The first week 1 starts on the first day of the month and ends on the seventh day.
Y,YYY	Y	It returns the year with comma in the Y,YYY form.
YYYY SYYYY	Y	Four digit year. SYYYY displays the sign of year. • If it is BC, it displays '-'. If it is AD, it displays ' '.
YYY YY Y	Y	• YYY: The last three digit year of the current year • YY: The last two digit year of the current year • Y: The last one digit year of the current year

The followings are examples of using datetime format string.

```
* - / , . ; : "text" Special character
   • TO_CHAR( TO_DATE( '2012-07-15 03:30:30', 'YYYY-MM-DD HH12:MI:SS' ),
              'YYYY/MM/DD HH12:MI:SS' )
     ==> '2012/07/15 03:30:30'
   • TO_CHAR( TO_DATE( '2012-07-15', 'YYYY-MM-DD' ),
              'YYYY"year" DDD"th day"' )
     ==> '2012year 197th day'
```

```
* AD
   • TO_CHAR( TO_DATE( '2012-07-15 AD', 'YYYY-MM-DD AD' ), 'YYYY AD' )
     ==> '2012 AD'
   • TO_CHAR( TO_DATE( '0001-01-01 BC', 'YYYY-MM-DD AD'), 'YYYY AD' )
     ==> '0001 BC'
* BC
   • TO_CHAR( TO_DATE( '0001-01-01 BC', 'YYYY-MM-DD BC'), 'YYYY BC' )
     ==> '0001 BC'
   • TO_CHAR( TO_DATE( '2012-07-15', 'YYYY-MM-DD' ), 'YYYY BC' )
     ==> '2012 AD'
```

```
* AM
   • TO_CHAR( TO_DATE( '2012-07-15 03:30:30 AM',

     ==> '2052' ( (Current year / 10 years) is 205 )
```

11.4 Expressions

Expression is a combination of value, operator and function for getting data values.

The following is the position of the SQL commands in which expression can be used.
- Target clause in SELECT
- GROUP BY clause in SELECT
- ORDER BY clause in SELECT
- WHERE clause and HAVING clause in SELECT
- INSERT VALUES clause
- UPDATE SET clause
- RETURN clause in INSERT, DELETE, UPDATE

Expression types are various as follows.
- Simple expression
- Compound expression
- Boolean value expression
- Case expression
- Datetime expression
- Scalar subquery expression
- Sequence manipulation expression

Simple expressions are column, pseudo columns, literals, and null value.
Compound expressions are combination of multiple expressions.

For more information, refer to the followings.
- **Null Value**
- **Literals**
- **Pseudo Columns**
- **Operators**
- **Functions**

Boolean Value Expression

Syntax

```
<boolean value expression> ::=
        <boolean term>
      | <boolean value expression> OR <boolean term>
```

```
<boolean term> ::=
        <boolean factor>
      ¦ <boolean term> AND <boolean factor>
<boolean factor> ::=
        [ NOT ] <boolean test>
<boolean test> ::=
        <boolean primary> [ IS [ NOT ] <truth value> ]
<truth value> ::=
        TRUE
      ¦ FALSE
      ¦ UNKNOWN
<boolean primary> ::=
        <column>
        <condition>
      ¦ <boolean predicand>
<boolean predicand> ::=
        <parenthesized boolean value expression>
      ¦ <nonparenthesized value expression primary>
<parenthesized boolean value expression> ::=
        <left paren> <boolean value expression> <right paren>
```

Description

<boolean value expression> describes a boolean value. <boolean primary> with boolean value are <column>, <condition>, and <boolean predicand>. <column> should be declared as BOOLEAN type, and it is allowed to return a boolean value using CAST.

<boolean value expression> can use logical operators such as AND, OR, NOT, and the dedicated operators of boolean value such as IS, IS NOT are also supported.

IS operator and IS NOT operator which are described in <boolean test> determine whether the boolean value described in <boolean primary> matches with one of the <truth value> (TRUE, FALSE, UNKNOWN).

For more information, refer to **Conditions**.

Example

```
gSQL> SELECT * FROM T1 WHERE CAST('TRUE' AS BOOLEAN);
I1
-----
TRUE
```

```
FALSE
null
3 rows selected.
gSQL> SELECT * FROM T1 WHERE I1;
I1
----
TRUE
1 row selected.
gSQL> SELECT * FROM T1 WHERE I1 IS TRUE;
I1
----
TRUE
1 row selected.
gSQL> SELECT * FROM T1 WHERE I1 IS NOT FALSE;
I1
----
TRUE
null
2 rows selected.
gSQL> SELECT * FROM T1 WHERE I1 IS UNKNOWN;
I1
----
null
1 row selected.
```

CASE Expression

Syntax

```
<case expression> ::=
        <simple case>
      ¦ <searched case>
<simple case> ::=
        CASE expr WHEN comparison_expr THEN result
                 [ WHEN comparison_expr THEN result ... ]
                 [ ELSE result ]
        END
<searched case> ::=
        CASE WHEN condition THEN result
```

```
            [ WHEN condition THEN result ... ]
            [ ELSE result ]
        END
```

Description

WHEN ... THEN clause is evaluated in the order of which is described in the CASE statement.
If a comparison result is FALSE, the subsequent WHEN ... THEN clauses are evaluated until TRUE comes up.
If a comparison result is TRUE, the result is returned, and the evaluation is not executed any more.

- Simple case
  The comparison_expr of CASE expr and WHEN ... THEN clause is evaluated as the equal operation. (expr = comparison_expr).
- Searched case
  The condition of WHEN ... THEN clause is evaluated.

If all evaluation results of the WHEN clause are FALSE, then result of ELSE clause is returned.
If ELSE clause is omitted, NULL is returned as a result.

If there are multiple types of THEN or ELSE clause results, the result type is determined by **Result Type Combination Rule**.

For more information, refer to the followings.
- **COALESCE**
- **NULLIF**

Example

- Simple case

```
gSQL> SELECT I1,
            CASE I1 WHEN 1 THEN 'ONE'
                    WHEN 2 THEN 'TWO'
                    ELSE 'NUMBER'
            END AS CASE_RESULT1,
            CASE I1 WHEN 1 THEN 'ONE'
                    WHEN 2 THEN 'TWO'
            END AS CASE_RESULT2
        FROM T1;
I1 CASE_RESULT1 CASE_RESULT2
```

```
-- ------------ -----------
 1 ONE          ONE
 2 TWO          TWO
 3 NUMBER       null
3 rows selected.
```

- Searched case

```
gSQL> SELECT I1,
             CASE WHEN I1 = 1 THEN 'ONE'
                  WHEN I1 = 2 THEN 'TWO'
                  ELSE 'NUMBER'
             END AS CASE_RESULT1,
             CASE WHEN I1 = 1 THEN 'ONE'
                  WHEN I1 = 2 THEN 'TWO'
             END AS CASE_RESULT2
        FROM T1;
I1 CASE_RESULT1 CASE_RESULT2
-- ------------ ------------
 1 ONE          ONE
 2 TWO          TWO
 3 NUMBER       null
3 rows selected.
```

CAST Specification

Syntax

```
CAST( expression AS data_type )
```

Description

CAST converts the expression data type to the data type of the specified data_type.

Example

```
gSQL> SELECT CAST( '1-2' AS INTERVAL YEAR TO MONTH ) AS RESULT FROM DUAL;
RESULT
------
```

```
+01-02
1 row selected.
```

Scalar Subquery Expression

Scalar subquery expression is a subquery which returns a single row with one column as a result. The scal ar subquery expression result is the values described in select list of the subquery.

If the subquery does not return any row, then the result value is NULL, and if it returns two or more rows, then an error occurs.

Scalar subquery expression can be described on most position which describes expression. The subquery s hould be enclosed in parentheses. Even when scalar subquery expression is used as a function argument and the scalar subquery expression is enclosed in parentheses, other parentheses for the subquery is requ ired regardless of the function parentheses. Otherwise, an error occurs.

The following is an example of using scalar subquery expression.

```
gSQL> select * from dual where dummy = (select * from dual);
DUMMY
-----
X
1 row selected.
gSQL> select sum(select 1 from dual) from dual;
ERR-42000(40000): syntax error
select sum(select 1 from dual) from dual
...........^    ^
Error at line 1
gSQL> select sum((select 1 from dual)) from dual;
SUM((SELECT 1 FROM DUAL))
-------------------------
                        1
1 row selected.
```

Compatibility

The SQL standard compatibility for expression is as follows.

Table 11-28 SQL standard compatibility for expression

Feature ID	Description	Availability
E121-03	Value expressions in ORDER BY clause	O
F051-05	Basic date and time Explicit CAST between datetime types and character string types	O
F201	CAST function	O
F261-01	Simple CASE	O
F261-02	Searched CASE	O
F261-03	NULLIF	O
F261-04	COALESCE	O
F263	Comma-separated predicates in simple CASE expression	X
F301	CORRESPONDING in query expressions	X
F385	Drop column generation expression clause	X
F561	Full value expressions	X
F846	Octet support in regular expression operators	X
F847	Nonconstant regular expressions	X
F850	Top-level <order by clause> in <query expression>	O
F855	Nested <order by clause> in <query expression>	O
F856	Nested <fetch first clause> in <query expression>	O
F857	Top-level <fetch first clause> in <query expression>	O
F861	Top-level <result offset clause> in <query expression>	O
F863	Nested <result offset clause> in <query expression>	O
S091-03	Arrays expressions	X
S111	ONLY in query expressions	X
T121	WITH (excluding RECURSIVE) in query expression	O
T581	Regular expression substring function	X

11.5 Pseudo Columns

Pseudo column is not only similar to function, but also it is similar to table column because it can return di fferent value in row unit every time the pseudo column is executed.

Table 11-29 Supported pseudo column

Name	Description	Refer to
CURRVAL	It is a pseudo column which is related to a sequenc e.	**CURRVAL**
NEXTVAL	It is a pseudo column which is related to a sequenc e.	**ROWID Pseudo Column**
ROWNUM	It is the row number which satisfies the condition.	**ROWNUM**
ROWID	It returns the record identifier in database.	**ROWID Pseudo Column**
CLUSTER_GROUP_ID	It returns the record identifier in database.	**CLUSTER_GROUP_ID Pseudo Colum n**
CLUSTER_MEMBER_ID	It returns the member identifier in which the recor d is stored.	**CLUSTER_MEMBER_ID Pseudo Colu mn**
CLUSTER_GROUP_NA ME	It returns the group name in which the record is st ored.	**CLUSTER_GROUP_NAME Pseudo Co lumn**
CLUSTER_MEMBER_N AME	It returns the member name in which the record is stored.	**CLUSTER_MEMBER_NAME Pseudo Column**
CLUSTER_SHARD_ID	It returns the shard identifier in which the record is stored.	**CLUSTER_SHARD_ID Pseudo Colum n**

ROWID Pseudo Column

ROWID pseudo column is a record identifier, and it returns the identification information of each databas e record.

ROWID has the following information to identify the location within the database depending on the syste m.

Standalone system
- OBJECT_ID
- TABLESPACE_ID
- PAGE_ID
- OFFSET in PAGE

Cluster system
- GRID_BLOCK_SEQUENCE
- GRID_BLOCK_ID
- MEMBER_ID
- SHARD_ID

The information stored inside in base 64 encoding is converted into the value such as A-Z, a-z, 0-9, +, / th en output when querying ROWID.

Each information to identify the address within database stored in ROWID can be obtained using the RO WID-related functions.

The address of the deleted record can be newly reassigned to the record to be inserted.

ROWID pseudo column can be used only in SELECT operation, but it can not be used in INSERT, UPDATE, DELETE operations.

For more information, refer to **ROWID**, **ROWID-related Functions**.

The following is an example of querying ROWID pseudo column.

```
gSQL> SELECT ROWID FROM T1;
                  ROWID
----------------------
AAAAAAAAFpEAACAAAEAkAAA
AAAAAAAAFpEAACAAAEAkAAB
AAAAAAAAFpEAACAAAEAkAAC
AAAAAAAAFpEAACAAAEAkAAD
AAAAAAAAFpEAACAAAEAkAAE
5 rows selected.
```

CLUSTER_GROUP_ID Pseudo Column

CLUSTER_GROUP_ID pseudo column returns the group identifier of a server in which the record is stored.

CLUSTER_GROUP_ID pseudo column can perform the SELECT, but it can not perform the INSERT, UPDAT E, or DELETE.

This information in valid in the cluster system.

The following is an example of retrieving CLUSTER_GROUP_ID pseudo column.

```
gSQL> SELECT T1.C1, T1.CLUSTER_GROUP_ID FROM T1;
C1 T1.CLUSTER_GROUP_ID
-- --------------------
A                     1
B                     2
C                     3
3 rows selected.
```

CLUSTER_MEMBER_ID Pseudo Column

CLUSTER_MEMBER_ID pseudo column returns the member identifier of a server in which the record is st ored.

CLUSTER_MEMBER_ID pseudo column can perform the SELECT, but it can not perform the INSERT, UPD ATE, or DELETE.

This information in valid in the cluster system.

The following is an example of retrieving CLUSTER_MEMBER_ID pseudo column.

```
gSQL> SELECT T1.C1, T1.CLUSTER_MEMBER_ID FROM T1;
C1 T1.CLUSTER_MEMBER_ID
-- --------------------
A                     1
B                     3
C                     5
3 rows selected.
```

CLUSTER_GROUP_NAME Pseudo Column

CLUSTER_GROUP_NAME pseudo column returns the group name of a server in which the record is store d.

CLUSTER_GROUP_NAME pseudo column can perform the SELECT, but it can not perform the INSERT, UP DATE, or DELETE.

This information in valid in the cluster system.

The following is an example of retrieving CLUSTER_GROUP_NAME pseudo column.

```
gSQL> SELECT T1.C1, T1.CLUSTER_GROUP_NAME FROM T1;
C1 T1.CLUSTER_GROUP_NAME
-- --------------------
A  G1
B  G2
C  G3
3 rows selected.
```

CLUSTER_MEMBER_NAME Pseudo Column

CLUSTER_MEMBER_NAME pseudo column returns the member name of a server in which the record is st ored.

CLUSTER_MEMBER_NAME pseudo column can perform the SELECT, but it can not perform the INSERT, UPDATE, or DELETE.

This information in valid in the cluster system.

The following is an example of retrieving CLUSTER_MEMBER_NAME pseudo column.

```
gSQL> SELECT T1.C1, T1.CLUSTER_MEMBER_NAME FROM T1;
C1 T1.CLUSTER_MEMBER_NAME
-- ----------------------
A  G1N1
B  G2N1
C  G3N1
3 rows selected.
```

CLUSTER_SHARD_ID Pseudo Column

CLUSTER_SHARD_ID pseudo column returns the shard identifier in which the record is stored.

CLUSTER_SHARD_ID pseudo column is allowed for SELECT only, but it is not allowed for INSERT, UPDATE, or DELETE.

This information in valid in the cluster system.

The following is an example of retrieving CLUSTER_SHARD_ID pseudo column.

```
gSQL> SELECT T1.C1, T1.CLUSTER_SHARD_ID FROM T1;
C1 CLUSTER_SHARD_ID
-- ----------------
A                14
B                17
C                 4
3 rows selected.
```

Compatibility

The SQL standard compatibility for pseudo column is as follows.

Table 11-30 SQL standard compatibility for pseudo column

Feature ID	Description	Availability
T176	Sequence generator support	O
T177	Sequence generator support: simple restart option	O

11.6 Operators

An operator is represented by one or more specific symbols or keywords, and it performs an operation using one or more arguments.

The operator types are various as follows.

- Arithmetic operator
- Concatenation operator
- Set operator

Arithmetic Operator

Syntax

```
<arithmetic operator> ::=
        <value term>
      ¦ <expression> + <value term>
      ¦ <expression> - <value term>
<value term> ::=
        <value factor>
      ¦ <value term> * <value factor>
      ¦ <value term> / <value factor>
<value factor> ::=
        <expression>
      ¦ + <expression>
      ¦ - <expression>
```

Description

An arithmetic operator performs an arithmetic operation of the numeric types, date/time types or interval types.

The arithmetic operator precedence is as follows.

1. **+ (POSITIVE), - (NEGATIVE)**
2. *** (MULTIPLICATION), / (DIVISION)**
3. **+ (ADDITION), - (SUBTRACTION)**

Concatenation Operator

Syntax

```
<concatenation operator> ::=
        <expression> || <expression>
```

Description

A concatenation operator returns strings which connect between values of CHARACTER STRING type or BINARY STRING type.
For more information, refer to **|| (CONCATENATE)**, **CONCATENATE**.

Set Operator

Syntax

```
<set operator> ::=
        <set operator term>
      | <subquery> UNION [ ALL | DISTINCT ] <set operator term>
      | <subquery> EXCEPT [ ALL | DISTINCT ] <set operator term>
      | <subquery> MINUS [ ALL | DISTINCT ] <set operator term>
<set operator term> ::=
        <subquery>
      | <subquery> INTERSECT [ ALL | DISTINCT ] <set operator term>
```

Description

set operator performs a set operation of the subquery results.

INTERSECT ALL/DISTINCT has a higher precedence than other set operators.

Table 11-31 Set operators

Operator	Description
UNION ALL	It is the union which does not exclude duplicated rows of the subquery result.
UNION DISTINCT	It is the union which excludes duplicated rows of the subquery result.
EXCEPT ALL	It is the difference set which does not exclude duplicated rows of the subquery result.
EXCEPT DISTINCT	It is the difference set which excludes duplicated rows of the subquery result.

Operator	Description
MINUS ALL	It is as same as EXCEPT ALL.
MINUS DISTINCT	It is as same as EXCEPT DISTINCT.
INTERSECT ALL	It is the intersection which does not exclude duplicated rows of the subquery result.
INTERSECT DISTINCT	It is the intersection which excludes duplicated rows of the subquery result.

Compatibility

The SQL standard compatibility for operator is as follows.

Table 11-32 SQL standard compatibility for operator

Feature ID	Description	Availability
E011-04	Arithmetic operators	O
E021-07	Character concatenation	O
E071-01	UNION DISTINCT table operator	O
E071-02	UNION ALL table operator	O
E071-03	EXCEPT DISTINCT table operator	O
E071-05	Columns combined via table operators need not have exactly the same data type	O
E071-06	Table operators in subqueries	O
F041-08	All comparison operators are supported (rather than just =)	O
F302-01	INTERSECT DISTINCT table operator	O
F302-02	INTERSECT ALL table operator	O
F304	EXCEPT ALL table operator	O
F846	Octet support in regular expression operators	X
J571	NEW operator	X

11.7 Functions

Functions and operators are similar in features. However, to represent arguments, functions use parentheses after its name. A function can have zero or more arguments.

The function has two types as follows.
. • Single row function
• Aggregate function

Single Row Function

Single row function creates a single result row for each row in the table or view.

The single row functions are as follows.

- Numeric function
- Character string function returning character values
- Character string function returning number values
- Datetime function
- General comparison function
- Conversion function
- Conditional function
- NULL-related function
- ROWID-related function
- Encryption function
- System information function

Numeric Functions

A numeric value is input in numeric function, and the numeric function returns a numeric result.

For more information about the numeric function types, refer to the followings.

- **ABS**
- **ACOS**
- **ASIN**
- **ATAN**
- **ATAN2**
- **BITAND**

- BITNOT
- BITOR
- BITXOR
- CBRT
- CEIL
- COS
- COT
- DEGREES
- EXP
- FACTORIAL
- FLOOR
- LN
- LOG
- MOD
- PI
- POWER
- RADIANS
- RANDOM
- ROUND(number)
- SHARD_ID
- SHIFT_LEFT
- SHIFT_RIGHT
- SIGN
- SIN
- SQRT
- TAN
- TRUNC(number)
- WIDTH_BUCKET

Character String Functions Returning Character Values

A character string type value is input in character string functions returning character values, and the func tion returns the result of character string type.

For more information about character string functions returning character values types, refer to the follo wings.

- CHR
- CONCAT
- CONCATENATE
- INITCAP
- LOWER

- LPAD
- LTRIM
- OVERLAY
- REPEAT
- REPLACE
- REVERSE
- RPAD
- RTRIM
- SPLIT_PART
- SUBSTR
- SUBSTRB
- TRANSLATE
- TRIM
- UPPER

Character String Functions Returning Number Values

A character string type value is input in character string functions returning number values the value, and the function returns the result of number type.

For more information about character string functions returning number values types, refer to the followi ngs.

- ASCII
- BIT_LENGTH
- BYTE_LENGTH
- CHAR_LENGTH
- INSTR
- LENGTH
- LENGTHB
- OCTET_LENGTH
- POSITION

Datetime Functions

The value of date/time/timestamp/interval type is input in datetime function, and the function returns the result of date/time/timestamp/interval type.

For more information about datetime functions types, refer to the followings.

- ADDDATE
- ADDTIME

- ADD_MONTHS
- DATEADD
- DATEDIFF
- DATE_ADD
- DATE_PART
- EXTRACT
- FROM_TZ
- LAST_DAY
- MONTHS_BETWEEN

General Comparison Functions

General comparison function returns a minimum value or a maximum value for the value set.

For more information about general comparison function types, refer to the followings.

- GREATEST
- LEAST

Conversion Functions

Conversion function sets the value of a particular data type.

For more information about conversion function types, refer to the followings.

- NUMTODSINTERVAL
- NUMTOYMINTERVAL
- TO_CHAR(datetime)
- TO_CHAR(number)
- TO_DATE
- TO_NATIVE_BIGINT
- TO_NATIVE_DOUBLE
- TO_NATIVE_INTEGER
- TO_NATIVE_REAL
- TO_NATIVE_SMALLINT
- TO_NUMBER
- TO_TIME
- TO_TIME_TZ
- TO_TIME_WITH_TIME_ZONE
- TO_TIMESTAMP
- TO_TIMESTAMP_TZ
- TO_TIMESTAMP_WITH_TIME_ZONE

Conditional Functions

Conditional function returns a result of specific value depending on a condition.

For more information about conditional function types, refer to the followings.

- CASE2
- DECODE

NULL-related Functions

NULL-related function returns a result of specific value depending on whether the input value is a NULL v alue.

For more information about null-related function types, refer to the followings.

- COALESCE
- NULLIF
- NVL
- NVL2

ROWID-related Functions

ROWID-related function is used to obtain information about the ROWID.

For more information about ROWID-related function types, refer to the followings.

- Valid functions in stand-alone
  - ROWID_OBJECT_ID
  - ROWID_TABLESPACE_ID
  - ROWID_PAGE_ID
  - ROWID_ROW_NUMBER

- Valid functions in cluster
  - ROWID_GRID_BLOCK_ID
  - ROWID_GRID_BLOCK_SEQ
  - ROWID_MEMBER_ID
  - ROWID_SHARD_ID

Encryption Functions

Encryption function encrypt, decrypts, or hashes the given plain text by using the specific algorithm, then returns the result.

For more information about the encryption function, refer to **DIGEST**.

System Information Functions

System information function is used to obtain information about sessions and the system.

For more information about system information function type, refer to the followings.

- CLOCK_DATE
- CLOCK_LOCALTIME
- CLOCK_LOCALTIMESTAMP
- CURRENT_CATALOG
- CURRENT_DATE
- CURRENT_SCHEMA
- CURRENT_TIME
- CURRENT_TIMESTAMP
- CURRENT_USER
- LAST_IDENTITY_VALUE
- LOCALTIME
- LOCALTIMESTAMP
- LOGON_USER
- SESSION_ID
- SESSION_SERIAL
- SESSION_USER
- SESSIONTIMEZONE
- STATEMENT_DATE
- STATEMENT_LOCALTIME
- STATEMENT_LOCALTIMESTAMP
- STATEMENT_TIME
- STATEMENT_TIMESTAMP
- STATEMENT_VIEW_SCN
- SYSDATE
- SYSTIME
- SYSTIMESTAMP
- TRANSACTION_DATE
- TRANSACTION_LOCALTIME
- TRANSACTION_LOCALTIMESTAMP
- TRANSACTION_TIME
- TRANSACTION_TIMESTAMP
- USER_ID
- VERSION

Aggregate Function

Aggregate function creates a single result row for multiple rows.

For more information about aggregate function types, refer to the followings.

- COUNT
- COUNT(*)
- SUM
- AVG
- MIN
- MAX
- STDDEV
- STDDEV_POP
- STDDEV_SAMP
- VAR_POP
- VAR_SAMP
- VARIANCE

Window Function

It returns the result of the function for the defined record range.

The defined record range is called as a window, and the execution range is defined in OVER <window name or specification>.

For more information about the window, refer to **window clause**.

Each record within the group has the result of executing the window function for the window (defined range). Therefore, unlike aggregate function, the window function returns multiple records for each group.

The window function is available in *select list* and *order by* clause.

Window functions are as follows.

- AVG() OVER
- CORR() OVER
- COUNT() OVER
- COUNT(*) OVER
- COVAR_POP() OVER
- COVAR_SAMP() OVER

- CUME_DIST() OVER
- DENSE_RANK() OVER
- FIRST() OVER
- FIRST_VALUE() OVER
- LAG() OVER
- LAST() OVER
- LAST_VALUE() OVER
- LEAD() OVER
- LISTAGG() OVER
- MAX() OVER
- MEDIAN() OVER
- MIN() OVER
- NTH_VALUE() OVER
- NTILE() OVER
- PERCENT_RANK() OVER
- PERCENTILE_CONT() OVER
- PERCENTILE_DISC() OVER
- RANK() OVER
- RATIO_TO_REPORT() OVER
- REGR_AVGX() OVER
- REGR_AVGY() OVER
- REGR_COUNT() OVER
- REGR_INTERCEPT() OVER
- REGR_R2() OVER
- REGR_SLOPE() OVER
- REGR_SXX() OVER
- REGR_SXY() OVER
- REGR_SYY() OVER
- ROW_NUMBER() OVER
- STDDEV() OVER
- STDDEV_POP() OVER
- STDDEV_SAMP() OVER
- STRING_AGG() OVER
- SUM() OVER
- VAR_POP() OVER
- VAR_SAMP() OVER
- VARIANCE() OVER

Compatibility

The SQL standard compatibility for function is as follows.

Table 11-33 SQL standard compatibility for function

Feature ID	Description	Availability
B033	Untyped SQL-invoked function arguments	X
E021-04	CHARACTER_LENGTH function	O
E021-05	OCTET_LENGTH function	O
E021-06	SUBSTRING function	O
E021-08	UPPER and LOWER functions	O
E021-09	TRIM function	O

Feature ID	Description	Availability
T572	Multiset-returning external SQL-invoked functions	X
T581	Regular expression substring function	X
T614	NTILE function	O
T615	LEAD and LAG functions	O
T616	Null treatment option for LEAD and LAG functions	O
T617	FIRST_VALUE and LAST_VALUE functions	O
T618	NTH_VALUE function	O
T619	Nested window functions	X
T621	Enhanced numeric functions	O

11.8 Conditions

Condition

Condition is an expression which is evaluated as TRUE, FALSE, UNKNOWN.

Condition can be used in the following SQL statements.
- WHERE clauses in DELETE, UPDATE statements
- WHERE and HAVING clauses in SELECT statement
- Where the BOOLEAN TYPE can be used

The condition types are as follows.
- Comparison condition
- Logical condition
- Null condition
- Compound condition
- Pattern-matching condition
- Between condition
- In condition
- Exists condition
- Distinct condition

Table 11-34 Condition precedence

Precedence	Condition type
1	Operators in condition clauses
2	=, !=, <, >, <=, >=
3	IS [NOT] NULL, [NOT] BETWEEN, [NOT] IN, LIKE, EXISTS, IS [NOT] DISTINCT FROM
4	NOT
5	AND
6	OR

Comparison Conditions

It compares both conditional expressions, and returns the boolean type of TRUE, FALSE, UNKNOWN valu es.

Table 11-35 Comparison conditions

Condition	Description
=	It checks if both conditions are equal.
!=, <>	It checks if both conditions are not equal.
>	It compares which one of both conditions is bigger.
<	It compares which one of both conditions is smaller.
>=	It compares which one of both conditions is bigger or equal.
<=	It compares which one of both conditions is smaller or equal.
ANY, SOME	If there is a condition whose left expr satisfies at least one of right expr_list (or subque ry results), then it returns TRUE. If there is not right subquery result, then it returns FALSE.
ALL	If there is a condition whose left expr satisfies all right expr_list (or subquery results), t hen it returns TRUE. If there is not right subquery result, then it returns TRUE.

For more information, refer to **Type Comparison**.

< Simple Comparison Conditions >

Syntax

```
<simple_comparison_condition> ::=
        <expr>          <comparison_operator> <expr>
      ¦ <expr>          <comparison_operator> ( <subquery> )
      ¦ ( <subquery> )  <comparison_operator> <expr>
      ¦ ( <subquery> )  <comparison_operator> ( <subquery> )
      ¦ ( <expr_list> ) <comparison_operator> ( <expr_list> )
      ¦ ( <expr_list> ) <comparison_operator> ( <subquery> )
      ¦ ( <subquery> )  <comparison_operator> ( <expr_list> )
      ¦ ( <subquery> )  <comparison_operator> ( <subquery> )
<comparison_operator> ::=
        <  =   >
      ¦ <  !=  >
      ¦ <  <   >
      ¦ <  >   >
```

```
      ¦ <  <=  >
      ¦ <  >=  >
<expr_list> ::=
        <expr>
      ¦ <expr>, ... , <expr>
      ¦ ( <expr> )
      ¦ ( <expr> , ... , <expr> )
```

For more information, refer to **Scalar Subquery Expression**.

Description

If the expr list or subquery comes to both left and right of comparison_operator, then the number of expr or subquery target to be compared should be same.
If there is a subquery, the number of result record should be one.

Example

Table 11-36 Example of simple comparison conditions

Conditional expression	Result
'abc' = 'abc'	TRUE
'abc' != 'abc'	FALSE
'abc' < 'abc'	FALSE
'abc' <= 'abc'	TRUE
'abc' > 'abc'	FALSE
'abc' >= 'abc'	TRUE
(1, 2, 3) = (1, 2, 3)	TRUE
(1, 2, 3) = (1, 2, 4)	FALSE
(1, 2, 3) != (4, 5, 6)	TRUE
(1, 2, 3) != (1, 2, 3)	FALSE
(1, 2, 3) < (1, 2, 4)	TRUE
(1, 2, 3) < (1, 2, 3)	FALSE
(1, 2, 3) <= (1, 2, 4)	TRUE
(1, 2, 3) <= (1, 2, 2)	FALSE
(1, 2, 3) > (1, 2, 2)	TRUE
(1, 2, 3) > (1, 2, 4)	FALSE
(1, 2, 3) >= (1, 2, 2)	TRUE
(1, 2, 3) >= (1, 2, 4)	FALSE

〈Group Comparison Conditions〉

Syntax

```
〈group_comparison_condition〉 ::=
   〈expr〉          〈comparison_operator〉 〈quantifier〉 ( 〈expr_list〉 )
 ¦ 〈expr〉          〈comparison_operator〉 〈quantifier〉 ( 〈subquery〉 )
 ¦ ( 〈expr_list〉 ) 〈comparison_operator〉 〈quantifier〉 ( 〈expr_list_list〉 )
 ¦ ( 〈expr_list〉 ) 〈comparison_operator〉 〈quantifier〉 ( 〈subquery〉 )
 ¦ ( 〈subquery〉 )  〈comparison_operator〉 〈quantifier〉 ( 〈expr_list〉 )
 ¦ ( 〈subquery〉 )  〈comparison_operator〉 〈quantifier〉 ( 〈expr_list_list〉 )
 ¦ ( 〈subquery〉 )  〈comparison_operator〉 〈quantifier〉 ( 〈subquery〉 )
〈comparison_operator〉 ::=
        〈 =  〉
      ¦ 〈 !=  〉
      ¦ 〈 〈  〉
      ¦ 〈 〉  〉
      ¦ 〈 〈=  〉
      ¦ 〈 〉=  〉
〈quantifier〉 ::=
        ALL
      ¦ ANY
      ¦ SOME
〈expr_list〉 ::=
        〈expr〉
      ¦ 〈expr〉, ... , 〈expr〉
      ¦ ( 〈expr〉 )
      ¦ ( 〈expr〉 , ... , 〈expr〉 )
〈expr_list_list〉 ::=
        〈expr_list〉
      ¦ 〈expr_list〉, ... , 〈expr_list〉
```

For more information, refer to **Scalar Subquery Expression**.

Description

If the expr list or subquery comes to both left and right of comparison_operator, then the number of expr or subquery target to be compared should be same.
If a subquery comes to the left of comparison_operator, the number of result record should be one.
If a subquery comes to the right of comparison_operator, the number of result record can be multiple.

Example

Table 11-37 Example of group comparison conditions

Conditional expression	Result
1 =any (1, 2, 3, 4, 5)	TRUE
1 =any (1, 2, null, 4, 5)	TRUE
1 =any (2, null, 4, 5)	NULL
1 =any (100, 2, 3, 4, 5)	FALSE
1 =all (1, +1, 1E+0)	TRUE
1 =all (1, +1, 1E+0, null)	NULL
1 =all (1, 2, 3, 4, 5)	FALSE
(1, 2) =any ((0, 1), (1, 2), (3, 4))	TRUE
(1, 2) =any ((0, 1), (1, 2), (null, null))	TRUE
(1, 2) =any ((0, 1), (2, 3), (3, 4))	FALSE
(1, 2) =all ((1, 2), (+1, +2), (1E+0, 2E+0))	TRUE
(1, 2) =all ((1, 2), (+1, +2), (null, null))	NULL
(1, 2) =all ((0, 1), (2, 3), (3, 4))	FALSE
When the result record of comparison_operator's right subquery is 0	
('X') =any (select dummy from dual where dummy = 'Y')	FALSE
('X') =all (select dummy from dual where dummy = 'Y')	TRUE

Logical Conditions

Logical conditions are such as AND, OR, NOT.

AND

Syntax

```
<boolean value expression> AND <boolean value expression>
```

Description

Table 11-38 Truth table of AND boolean operator

AND	True	False	Unknown
True	True	False	Unknown
False	False	False	False
Unknown	Unknown	False	Unknown

OR

Syntax

```
<boolean value expression> OR <boolean value expression>
```

Description

Table 11-39 Truth table of OR boolean operator

OR	True	False	Unknown
True	True	True	True
False	True	False	Unknown
Unknown	True	Unknown	Unknown

NOT

Syntax

```
NOT <boolean value expression>
```

Description

Table 11-40 Truth table of NOT boolean operator

expr	NOT
True	False
False	True
Unknown	Unknown

Null Condition

Syntax

```
<expr> IS [NOT] NULL
```

Description

It checks whether the result value of expr is NULL.

Table 11-41 Result table of IS NULL condition

expr	IS NULL	IS NOT NULL
NULL	True	False
NOT NULL	False	True

Compound Conditions

It is a conditional expression in which multiple conditions are combined.

```
compound_condition ::=
        ( condition )
      ¦ NOT condition
      ¦ condition < AND ¦ OR > condition
```

Pattern-matching Conditions

Like Condition

Syntax

```
like_condition ::=
        string [NOT] LIKE pattern [ ESCAPE escape_character ]
```

Description

It checks if a string matches the specified pattern.

Arguments such as string, pattern, escape_character can be of a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, or of the type which is available to be converted to a character type.
If string, pattern, escape_character are NULL, it returns NULL.

If escape_character is omitted, there is not a default value.
If escape_character is specified, the escape_character should be one character.

If pattern does not include '_' nor '%', it is processed in the same way as equal operation(string = pattern)
.
If pattern includes '_' or '%', the string checks if it matches as follows.

- '_': If it corresponds to one arbitrary character.
- '%': If it corresponds to the arbitrary character string which has zero or more characters.

Use ESCAPE syntax to compare '_' or '%' included in the pattern with characters.
Specify escape_character, and describe the specified escape_character before the pattern's '_' or '%'.

Example

```
gSQL> SELECT 'hello%' LIKE 'h%o!%' ESCAPE '!' AS RESULT FROM DUAL;
RESULT
------
TRUE
```

- 'represent' LIKE 'represent'   => TRUE
- 'represent' LIKE ' represent ' => FALSE
- 'represent' LIKE 'REPRESENT'   => FALSE
- 'represent' LIKE 'r_pr_s_nt'   => TRUE
- 'represent' LIKE 're%t'   => TRUE
- 'represent' LIKE 'rep'   => FALSE
- 'summer_vacation' LIKE 'summer_vacation' ESCAPE '\' => TRUE
- NULL LIKE 'summer_vacation' ESCAPE '\'   => NULL
- 'summer_vacation' LIKE NULL ESCAPE '\'   => NULL
- 'summer_vacation' LIKE 'summer_vacation' ESCAPE NULL => NULL

BETWEEN Condition

Syntax

```
<between condition> ::=
   <expr1> [ NOT ] BETWEEN [ ASYMMETRIC ¦ SYMMETRIC ] <expr2> AND <expr3>
```

Description

It checks whether expr1 is within the range between expr2 and expr3.

If ASYMMETRIC or SYMMETRIC is omitted, the default is ASYMMETRIC.
If data types among expr1, expr2, expr3 are different, they are converted.

For more information, refer to **Type Comparison**, **Type Conversion**.

Table 11-42 Equivalence of between conditions

A	B
X BETWEEN ASYMMETRIC Y AND Z	X BETWEEN Y AND Z
X BETWEEN Y AND Z	X >= Y AND X <= Z
X NOT BETWEEN Y AND Z	NOT(X BETWEEN Y AND Z)
X BETWEEN SYMMETRIC Y AND Z	((X BETWEEN Y AND Z) OR (X BETWEEN Z AND Y)
X NOT BETWEEN SYMMETRIC Y AND Z	NOT(X BETWEEN SYMMETRIC Y AND Z)

Example

Table 11-43 Example of between condition

Conditional expression		Result
BETWEEN [ASYMMETRIC]	3 BETWEEN 1 AND 5	TRUE
	NULL BETWEEN 1 AND 5 3 BETWEEN NULL AND 5 3 BETWEEN 1 AND NULL	NULL
	3 BETWEEN 5 AND 1	FALSE
BETWEEN SYMMETRIC	3 BETWEEN SYMMETRIC 1 AND 5	TRUE
	NULL BETWEEN SYMMETRIC 1 AND 5 3 BETWEEN SYMMETRIC NULL AND 5 3 BETWEEN SYMMETRIC 1 AND NULL	NULL
	3 BETWEEN SYMMETRIC 5 AND 1	TRUE

IN Condition

Syntax

```
<in_condition> ::=
        <expr>          [NOT] IN ( <expr_list> )
      ¦ <expr>          [NOT] IN ( <subquery> )
      ¦ ( <expr_list> ) [NOT] IN ( <expr_list_list> )
      ¦ ( <expr_list> ) [NOT] IN ( <subquery> )
      ¦ ( <subquery> )  [NOT] IN ( <expr_list> )
      ¦ ( <subquery> )  [NOT] IN ( <expr_list_list> )
      ¦ ( <subquery> )  [NOT] IN ( <subquery> )
<expr_list> ::=
        <expr>
```

```
      ¦ <expr>, ... , <expr>
      ¦ ( <expr> )
      ¦ ( <expr> , ... , <expr> )
<expr_list_list> ::=
        <expr_list>
      ¦ <expr_list>, ... , <expr_list>
```

Description

In condition returns the same result as = ANY.
NOT IN condition returns the same result as !=ALL.

For more information, refer to **Comparison Conditions**.

Example

Table 11-44 Example of IN condition

Conditional expression	Result
1 IN (1, 2, 3, 4, 5)	TRUE
1 IN (1, 2, null, 4, 5)	TRUE
1 IN (2, null, 4, 5)	NULL
1 IN (100, 2, 3, 4, 5)	FALSE
NULL IN (1, 2, 3)	NULL
1 NOT IN (2, 3, 4, 5)	TRUE
1 NOT IN (2, null, 4, 5)	NULL
1 NOT IN (1, 2, null, 4, 5)	FALSE
1 NOT IN (100, 2, 3, 4, 5)	TRUE
NULL NOT IN (1, 2, 3)	NULL

EXISTS Condition

Syntax

```
exists_conditions ::=
        EXISTS ( subquery )
```

Description

It checks whether the result record of subquery exists.
If the result record of subquery exists, it returns TRUE. Otherwise, it returns FALSE.

Example

```
gSQL> SELECT * FROM DUAL WHERE EXISTS ( SELECT * FROM DUAL );
      DUMMY
      -----
      X
      1 row selected.
gSQL> SELECT * FROM DUAL
       WHERE EXISTS ( SELECT * FROM DUAL WHERE DUMMY = 'Y' );
      no rows selected.
```

DISTINCT Condition

Syntax

```
distinct_conditions ::=
        <expr> IS [NOT] DISTINCT FROM <expr>
      | ( <expr_list> ) IS [NOT] DISTINCT FROM ( <expr_list> )
```

Description

The operand type of distinct condition should be comparable one another.
If the operand is <expr_list>, then the data in the same position becomes the comparison target.

If all operands of distinct condition is not null value,
is distinct from is as same as *not equal(!=)*,
is not distinct from returns the same result of when it is *eqaul(=)*.

DISTINCT condition processes NULL value as a general data instead of unknown, and this is what is differ ent from other comparing operators.

- IS DISTINCT FROM
  - If all operands are NULL
    - NULL is distinct from NULL => FALSE

    - If one of the operand is NULL
        - NULL is distinct from 1 => TRUE
        - 1 is distinct from NULL => TRUE
    - If all operands are not NULL
        - 1 is distinct from 1 => FALSE
        - 1 is distinct from 2 => TRUE
    - If the operand is <expr_list>
        - (1, 2, 3) is distinct from (1, 2, 3) => FALSE
        - (1, 2, 3) is distinct from (1, 3, 3) => TRUE
        - (1, 2, 3) is distinct from (4, 5, 6) => TRUE

- IS NOT DISTINCT FROM
    - If all operands are NULL
        - NULL is not distinct from NULL => TRUE
    - If one of the operand is NULL
        - NULL is not distinct from 1 => FALSE
        - 1 is not distinct from NULL => FALSE
    - If all operands are not NULL
        - 1 is not distinct from 1 => TRUE
        - 1 is not distinct from 2 => FALSE
    - If the operand is <expr_list>
        - (1, 2, 3) is not distinct from (1, 2, 3) => TRUE
        - (1, 2, 3) is not distinct from (1, 3, 3) => FALSE
        - (1, 2, 3) is not distinct from (4, 5, 6) => FALSE

Example

```
* IS DISTINCT FROM
gSQL>
SELECT i1,
       i2,
       i1 IS DISTINCT FROM i2 AS IsDistinct
  FROM t1;
  I1   I2 ISDISTINCT
---- ---- ----------
   1 null TRUE
   1    1 FALSE
   1    2 TRUE
null null FALSE
null    1 TRUE
null    2 TRUE
```

```
6 rows selected.
gSQL>
SELECT i1,
       i2,
       i3,
       ( I1, I2, I3 ) IS DISTINCT FROM ( 1, 1, 1 ) AS RESULT
  FROM t1;
  I1   I2   I3 RESULT
---- ---- ---- ------
   1    1    1 FALSE
   2 null    3 TRUE
null null null TRUE
3 rows selected.
* IS NOT DISTINCT FROM
gSQL>
SELECT i1,
       i2,
       i1 IS NOT DISTINCT FROM i2 AS IsNotDistinct
  FROM t1;
  I1   I2 ISNOTDISTINCT
---- ---- -------------
   1 null FALSE
   1    1 TRUE
   1    2 FALSE
null null TRUE
null    1 FALSE
null    2 FALSE
6 rows selected.
gSQL>
SELECT i1,
       i2,
       i3,
       ( I1, I2, I3 ) IS NOT DISTINCT FROM ( 1, 1, 1 ) AS RESULT
 FROM t1;
  I1   I2   I3 RESULT
---- ---- ---- ------
   1    1    1 TRUE
   2 null    3 FALSE
null null null FALSE
3 rows selected.
```

Compatibility

The SQL standard compatibility for condition is as follows.

Table 11-45 SQL standard compatibility for condition

Feature ID	Description	Availability
E061-01	Comparison predicate	O
E061-02	BETWEEN predicate	O
E061-03	IN predicate with list of values	O
E061-04	LIKE predicate	O
E061-05	LIKE predicate: ESCAPE clause	O
E061-06	NULL predicate	O
E061-07	Quantified comparison predicate	O
E061-08	EXISTS predicate	O
E061-09	Subqueries in comparison predicate	O
E061-11	Subqueries in IN predicate	O
E061-12	Subqueries in quantified comparison predicate	O
E061-13	Correlated subqueries	O
E061-14	Search condition	O
F051-04	Comparison predicate on DATE, TIME, and TIMESTAMP data types	X
F053	OVERLAPS predicate	X
F263	Comma-separated predicates in simple CASE expression	X
F291	UNIQUE predicate	X
F481	Expanded NULL predicate	O
F841	LIKE_REGEX predicate	X
P008	Comma-separated predicates in a CASE statement Extended CASE	X
S151	Type predicate	X
T141	SIMILAR predicate	X
T151	DISTINCT predicate	X
T152	DISTINCT predicate with negation	X
T461	Symmetric BETWEEN predicate	O
T501	Enhanced EXISTS predicate	O
T631	IN predicate with one list element	X
X090	XML document predicate	X
X091	XML content predicate	X
X141	IS VALID predicate: data-driven case	X
X142	IS VALID predicate: ACCORDING TO clause	X
X143	IS VALID predicate: ELEMENT clause	X
X144	IS VALID predicate: schema location	X
X145	IS VALID predicate outside check constraints	X

Feature ID	Description	Availability
X151	IS VALID predicate with DOCUMENT option	X
X152	IS VALID predicate with CONTENT option	X
X153	IS VALID predicate with SEQUENCE option	X
X155	IS VALID predicate: NAMESPACE without ELEMENT clause	X
X157	IS VALID predicate: NO NAMESPACE with ELEMENT clause	X

12.

SQL Languages

Structured Query Languages (SQL) are classified as follows.

- Data Definition Language
- Data Manipulation Language
- Data Query Language
- Control Language

12.1 Data Definition Language

DDL Related Statements

For more information, refer to the followings.

- Non-schema object DDL
  - **Database Related Statements**
  - **Profile Related Statements**
  - **Audit Policy Related Statement**
  - **Authorization Related Statements**
  - **Schema Related Statements**
  - **Tablespace Related Statements**

- SQL schema object DDL
  - **Table Related Statements**
  - **Index Related Statements**
  - **View Related Statements**
  - **Sequence Related Statements**
  - **Synonym Related Statements**

- Cluster object DDL
  - **Cluster System Related Statements**
  - **Cluster Group Related Statements**
  - **Cluster Member Related Statements**
  - **Cluster Location Related Statements**
  - **Global Secondary Index Related Statements**

Concepts of DDL

Data Definition Language (DDL) is an SQL language which creates, drops and alters SQL objects.

SQL objects of a database are listed in the following table. For more information, refer to the links in the f ollowing table.

Table 12-1 SQL objects types

Object type	Object	Description	Refer to
		It is an object which defines a password man	

Object type	Object	Description	Refer to
Non-schema object	Profile	agement policy.	**Profile**
	Audit policy	It is an object which defines the SQL audit p olicy.	**Audit Policy**
	User	It is a user object which consists of a set of p rivileges.	**Authorization**
	Schema	It is a logical position including SQL schema objects such as tables.	**Schema**
	Tablespace	It is a physical storage of objects such as tabl es, indexes, etc.	**Tablespace**
	Public synonym	It is a public synonym.	**Public Synonym**
SQL schema object	Table	It is a physical relation where the data is stor ed.	**Table**
	View	It is a logical relation which consists of querie s.	**View**
	Index	It is an index objects to improve query perfor mance.	**Index**
	Sequence	It is an object which generate sequence num ber.	**Sequence**
	Synonym	It is an object which declares an alias for an object.	**Synonym**
	Stored procedure	It is an user defined procedure object.	**Stored Procedure**
	Stored function	It is an user defined function object.	**Stored Function**
Cluster object	Cluster group	It is a cluster member set.	**Cluster Group**
	Cluster member	It is a data server which configures a cluster s ystem.	**Cluster Member**
	Cluster location	It is a location object of a cluster member.	**Cluster Location**
	Shard	It is a set of rows which horizontally divides a cluster table.	**Cluster Table and Shard**
	Global secondary index	It is an index for the row identifier of a cluste r.	**Global Secondary Index**

DDL and Transaction

A transaction of GOLDILOCKS includes not only DML statements such as INSERT, DELETE, UPDATE data, but also DDL statement such as CREATE, DROP, ALTER objects. Many DBMS performs implicit transaction s of DDL. On the other hand, GOLDILOCKS includes a DDL statement in the transaction, and it guarantee s the atomicity and consistency of transaction.

This features is useful when a user needs to atomically perform batch DDL such as database migration or tool installation, or to recover a mistake through ROLLBACK when statement such as DROP TABLE or TRU

NCATE TABLE is executed by user mistake.

If the property of DDL statement is auto-commit, then it automatically commits when executing the state ment. On the other hand, if it is not auto-commit, then it can rollback the transaction even after the state ment was executed. Whether the DDL is auto-commit or not is queried by using **V$SQL_COMMAND** view as follows.

```
gSQL>
SELECT command, auto_commit
  FROM V$SQL_COMMAND
 WHERE is_ddl = 'YES';
COMMAND                                                  AUTO_COMMIT
-------------------------------------------------------- -----------
ALTER AUDIT POLICY                                       YES
ALTER CLUSTER GROUP .. ADD CLUSTER MEMBER                YES
ALTER CLUSTER GROUP .. OFFLINE CLUSTER MEMBER            YES
ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS             YES
ALTER DATABASE OFFLINE INACTIVE CLUSTER MEMBERS          YES
ALTER DATABASE RESET LOCAL CLUSTER MEMBER                YES
ALTER DATABASE ADD LOGFILE GROUP                         YES
ALTER DATABASE ADD LOGFILE MEMBER                        YES
ALTER DATABASE DROP LOGFILE GROUP                        YES
ALTER DATABASE DROP LOGFILE MEMBER                       YES
ALTER DATABASE RENAME GLOBAL TRANSACTION LOGFILE         YES
ALTER DATABASE RENAME LOGFILE                            YES
ALTER DATABASE ARCHIVELOG                                YES
ALTER DATABASE NOARCHIVELOG                              YES
ALTER DATABASE DATAFILE AUTOEXTEND ..                    YES
ALTER DATABASE CLEAR PASSWORD HISTORY                    NO

FLASHBACK TABLE                                  YES
128 rows selected.
```

The followings are examples of COMMIT and ROLLBACK when table-related DDL statements are included in the transactions, and examples of its effects on other transactions. The example shows that the transac tion including DDL guarantees the transaction atomicity. In addition, it ensures the reading consistency of the transaction, which is not affected by other transactions before transaction's commitment or when th e transaction is rolled back.

Creating Object and Transaction

- Before committing or rolling back a transaction of creating table

When a table is created, and transaction is not committed, the table data can be manipulated on the DDL transaction as follows. However, other transactions are not allowed to enquire the table until the creating table transaction is committed. CREATE TABLE statement, like as INSERT statement, can not be queried b y any other transaction until the transaction is committed.

  - Transaction A: Table t1 is created but the transaction is not committed.

```
gSQL> CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) );
Table created.
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
gSQL> SELECT * FROM t1;
```

```
ID NAME
-- ------
 1 leekmo
1 row selected.
```

As above, if table t1 is created on the transaction A and the transaction is not yet committed, the transact ion B in another session can not enquire the table t1 and can not create the table named as t1.

- Transaction B: Table t1 can not be enquired until committing the transaction A.

```
gSQL> SELECT * FROM t1;
ERR-42000(16040): table or view does not exist :
SELECT * FROM t1
              *
ERROR at line 1:
```

- Table t1 can not be created until the transaction A is rolled back.

```
gSQL> CREATE TABLE t1 ( emp_no INTEGER );
ERR-HYT00(14026): resource busy or timeout expired
```

- After committing a transaction of creating table

If the transaction A is committed, table t1 can be enquired by the transaction B and CREATE TABLE state ment returns a validation error to notify that the table t1 exists as follows.

- Transaction B: After committing the transaction A, the table can be enquired as follows.

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
```

- After the transaction A is committed, a validation error is returned.

```
gSQL> CREATE TABLE t1 ( emp_no INTEGER );
ERR-42000(16005): name 'PUBLIC.T1' is already used by an existing object :
CREATE TABLE t1 ( emp_no INTEGER )
             *
ERROR at line 1:
```

- After rolling back a transaction of creating table

If the transaction A is rolled back, creating table t1 is also rolled back, and table t1 can be created by the t ransaction B.

- Transaction B: The transaction A is rolled back and its state becomes as same as before creating t able t1.

```
gSQL> SELECT * FROM t1;
ERR-42000(16040): table or view does not exist :
SELECT * FROM t1
              *
ERROR at line 1:
```

- The transaction A is rolled back and it can create the table t1.

```
gSQL> CREATE TABLE t1 ( emp_no INTEGER );
Table created.
```

Dropping Object and Transaction

- Before committing or rolling back a transaction of dropping table

When a table is dropped, and transaction is not committed, other transactions can enquire the dropped t able until the DROP TABLE transaction is committed. DROP TABLE statement, like as DELETE statement, r etrieves the state of before deleting the table when other transaction enquires it until the transaction is c ommitted.

The following example describes the state which the transaction A drops the table t1, then it creates new table t1, and the transaction is not committed.

- Transaction A: There is a row having two columns in the table t1 before dropping the table.

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
```

- Dropping the existing table t1

```
gSQL> DROP TABLE t1;
Table dropped.
```

    - Creating the new table t1

```
gSQL> CREATE TABLE t1 ( addr VARCHAR(128) );
Table created.
```

    - Creating a new row in the newly created table t1

```
gSQL> INSERT INTO t1 VALUES ( 'Seoul, Korea' );
1 row created.
gSQL> SELECT * FROM t1;
ADDR
------------
Seoul, Korea
1 row selected.
```

If the transaction B enquires when the transaction A is not committed, the information which is before th e transaction A is executed is obtained as follows. DROP TABLE statement, like as DELETE statement, doe s not affect any other transaction until the transaction is committed.

    - Transaction B: The transaction B retrieves the table which is before the execution of the transacti on A.

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
```

- After committing a transaction of dropping table

If the transaction A is committed, then the transaction B enquires the newly created table t1 as follows.

    - Transaction B: After committing the transaction A, the transaction B enquires the newly created t able t1.

```
gSQL> SELECT * FROM t1;
ADDR
------------
Seoul, Korea
1 row selected.
```

- After rolling back a transaction of dropping table

If the transaction A is rolled back, the transaction B enquires the table t1 which is before the execution of the transaction A as follows. Namely, if the transaction A is rolled back, the rollback transaction does not affect the data of which the transaction B enquires.

- Transaction B: If the transaction A is rolled back, the transaction B enquires the information whic h is before the execution of the transaction A.

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
```

Altering Object and Transaction

ALTER TABLE statement is used to alter the table structure. ALTER TABLE statement also ensures atomicit y and consistency of the transaction like as CREATING TABLE or DROPPING TABLE statements. Before co mmitting a transaction in which a column is added to a table, other transactions retrieve the information of the existing table as follows. Namely, ALTER TABLE statement, like as UPDATE statement, retrieves inf ormation which is before DDL transaction in other transaction until the transaction is committed.

- Transaction A: It adds a new UPDATE_TIME column.

```
gSQL> ALTER TABLE t1 ADD COLUMN ( update_time TIMESTAMP DEFAULT CURRENT_TIMESTAMP );
Table altered.
```

- The table t1 including the added column is retrieved.

```
gSQL> select * from t1;
ID NAME   UPDATE_TIME
-- ------ --------------------------
 1 leekmo 2014-07-10 12:50:33.540495
1 row selected.
```

If the transaction B is executed before committing the transaction A as follows, then the table t1 which is before adding a column is retrieved.

- Transaction B: The added column UPDATE_TIME is not retrieve, because the transaction A is not com mitted.

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
```

```
 1 leekmo
1 row selected.
```

12.2 Data Manipulation Language

DML Related Statements

For more information, refer to the followings.

- INSERT related statements
  - **INSERT INTO**
  - **INSERT INTO name RETURNING**
  - **INSERT INTO name RETURNING .. INTO**

- UPDATE related statements
  - **UPDATE**
  - **UPDATE name RETURNING**
  - **UPDATE name RETURNING .. INTO**
  - **UPDATE name WHERE CURRENT OF cursor_name**

- DELETE related statements
  - **DELETE FROM**
  - **DELETE FROM name RETURNING**
  - **DELETE FROM name RETURNING .. INTO**
  - **DELETE FROM name WHERE CURRENT OF cursor_name**

- SELECT related statements: **SELECT .. INTO**

- Dynamic SQL related statements
  - **EXECUTE IMMEDIATE 'sql_string'**
  - **PREPARE statement_name**
  - **EXECUTE statement_name**

Concepts of DML

Data Manipulation Language (DML) is an SQL language which manipulates and enquires data in existing tables such as INSERT, DELETE, UPDATE.

This chapter describes only DML statements which change data. For more information about queries, refe r to **Data Query Language**.

The DDL statements change the SQL object structure, but DML statements manipulate the objects conten ts. For example, ALTER TABLE statement alters the table structure, but INSERT statement adds one or mo re rows in the table.

DML statements such as inserting, deleting, updating data in table are classified as follows.

Table 12-2 Data manipulation statements

Category	Statements	Description
INSERT	INSERT .. VALUES	It adds a single row to the table.
	INSERT .. SELECT	It adds the query results to the table.
	INSERT .. RETURN .. INTO	It sets the value of the added row as a variable.
	INSERT .. RETURN	It retrieves the added row as the query result.
DELETE	DELETE .. WHERE	It deletes the row which satisfies the condition.
	DELETE .. WHERE CURRENT OF	It deletes the row which is at the cursor's position.
	DELETE .. RETURN .. INTO	It sets the value of the removed row as a variable.
	DELETE .. RETURN	It retrieves the removed row as the query result.
UPDATE	UPDATE .. WHERE	It updates the row which satisfies the condition.
	UPDATE .. WHERE CURRENT OF	It updates the row which is at the cursor's position.
	UPDATE .. RETURN .. INTO	It sets the value of the updated row as a variable.
	UPDATE .. RETURN	It retrieves the updated row as the query result.

Inserting Data

It adds data in a row unit when adding data to a table. The INSERT statement cad add one or more rows to a table. Even when the data in some columns are omitted, all rows are added with completed columns to the table.

The following is an example of a table.

```
CREATE TABLE t1
(
    id   NUMBER(10,0),
    name VARCHAR(128),
    addr VARCHAR(1024) DEFAULT 'n/a'
);
```

The most basic way to add a row is as follows.

```
INSERT INTO t1 VALUES ( 1, 'leekmo', 'Seoul, Korea' );
```

The values listed in the VALUES clause are inserted in accordance with the sequence of the listed column when the table is created.
However, the example above can cause an unexpected failure when inserting or deleting columns, so it is recommended to explicitly specify the column name as follows.

```
INSERT INTO t1 (id, name, addr) VALUES ( 1, 'leekmo', 'Seoul, Korea' );
INSERT INTO t1 (name, addr, id) VALUES ( 'leekmo', 'Seoul, Korea', 1 );
```

The two INSERT statements above are listed in different order from the columns, but the added row of th e table t1 has the same data.

If the table does not list all the columns, unspecified column is set to the default value to complete the ro w. The addr column which was not used in the statement stores the default value (n/a) which was specifi ed when creating table as follows.

```
INSERT INTO t1 ( id, name ) VALUES ( 1, 'leekmo' );
INSERT INTO t1 ( id, name ) SELECT id, name FROM emp;
```

Use DEFAULT to explicitly specify the default value for the column as follows.

```
INSERT INTO t1 ( id, name, addr ) VALUES ( 1, 'leekmo', DEFAULT );
```

Use either of the following two statements to set all the columns to the default value.

```
INSERT INTO t1 ( id, name, addr ) VALUES ( DEFAULT, DEFAULT, DEFAULT );
INSERT INTO t1 DEFAULT VALUES;
```

Use a single INSERT statement to add multiple rows. The following is an example of adding three new ro ws using a single INSERT statement.

```
INSERT INTO t1 (id, name, addr) VALUES
  ( 1, 'leekmo', 'Seoul, Korea' ),
  ( 2, 'mkkim', 'Seoul, Korea' ),
  ( 3, 'xcom', 'Inchon, Korea' );
```

Use the SELECT query results to add multiple rows. The following is an example of adding rows to the tab le t1 by retrieving employees who joined the company more than three years ago.

```
INSERT INTO t1 ( id, name, addr )
SELECT id, name, addr
  FROM emp
 WHERE DATEDIFF( YEAR, SYSDATE, join_date ) >= 3;
```

Deleting Data

DELETE statement deletes data from the table in a row unit like when inserting data. Rows can be delete d by using WHERE condition or by using row's ID(ROWID).

The following is an example of deleting rows which satisfy WHERE condition.

```
DELETE FROM t1 WHERE id = 1;
```

The following is an example of deleting the row using ROWID.

```
gSQL> SELECT rowid FROM t1 WHERE id = 1;
                  ROWID
----------------------
AAAAAAAAFNHAACAAAAAiAAA
1 row selected.
gSQL> DELETE FROM t1 WHERE ROWID = 'AAAAAAAAFNHAACAAAAAiAAA';
1 row deleted.
```

DELETE statement without a WHERE clause deletes the entire row in a table. DELETE statement without a WHERE clause is similar to TRUNCATE TABLE statement in terms of deleting entire row, but it is recom mended to use the TRUNCATE TABLE statement.

```
DELETE FROM t1;
TRUNCATE TABLE t1;
```

Updating Data

Update data by using UPDATE statement. One or more rows and columns can be updated. Other column s which is not specified in the UPDATE statement is not affected.

The following is an example of updating a column in rows which satisfy the condition.

```
UPDATE t1 SET page_view = page_view + 1 WHERE id = 1;
```

The followings are examples of updating multiple columns, and the two UPDATE statements mean the sa me.

```
UPDATE t1 SET page_view = page_view + 1, status = 'F' WHERE id = 1;
UPDATE t1 SET (page_view, status) = (page_view + 1, 'F') WHERE id = 1;
```

Use DEFAULT as follows to set the column value to a default value.

```
UPDATE t1 SET addr = DEFAULT WHERE id = 1;
```

Manipulating Data Using Cursor

Cursor is a session object to execute queries and to manipulate the query result. Use cursor to update or delete the query result set.

The following is an example of declaring updatable cursor, and updating or deleting the row at the positi on of the current cursor using the updatable cursor.

```
gSQL> DECLARE cur1 CURSOR FOR SELECT id, data FROM t1 FOR UPDATE;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> \var v_id INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> DELETE FROM t1 WHERE CURRENT OF cur1;
1 row deleted.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> UPDATE t1 SET id = id + :v_id WHERE CURRENT OF cur1;
1 row updated.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT * FROM t1 ORDER BY 1;
```

```
ID DATA
-- ------
 1 data_1
 6 data_3
2 rows selected.
```

The examples above describe the followings.
Use **DECLARE cursor_name** to declare FOR UPDATE cursor, and use **OPEN cursor_name** to open the curs
or.
Use **FETCH cursor_name** to move the cursor to the specified position.
Use **DELETE FROM name WHERE CURRENT OF cursor_name** to delete the row in the specified position.
Use **UPDATE name WHERE CURRENT OF cursor_name** to update the row in the specified position.

FOR UPDATE cursor is closed using **CLOSE cursor_name**, or it is closed when committing transaction.

DML Query

When executing DML statements changing the data, use RETURNING clause to retrieve the changed data.
The RETURNING clause of DML statements, like as SELECT, can retrieve data, so the execution of the DM
L statement and the SELECT statement can be replaced with the DML query.

The following is an example of using **INSERT INTO name RETURNING** syntax to insert data and retrieve th
e result. The join_date value which was input by using SYSDATE function can be retrieved by a single DM
L query.

```
gSQL> INSERT INTO t1 ( id, join_date )  VALUES ( 1, SYSDATE ) RETURNING id, join_date;
ID JOIN_DATE
-- ----------
 1 2014-07-18
1 row created.
```

The following is an example of using **DELETE FROM name RETURNING** syntax to delete data and retrieve
the result. The result data can be manipulated by using operation in RETURNING clause.

```
gSQL> DELETE FROM t1 RETURNING ( id || ': ' || join_date ) AS id_and_join_date;
ID_AND_JOIN_DATE
----------------
1: 2014-07-18
1 row deleted.
```

The following is an example of using **UPDATE name RETURNING** syntax to update rows and retrieve the

updated values. The value which is before updating can be retrieved by using OLD clause.

- It updates the row and retrieves the updated value.

```
gSQL> UPDATE t1 SET page_view = page_view + 1 WHERE id = 1 RETURNING page_view;
PAGE_VIEW
---------
      102
1 row updated.
```

- It updates the row and retrieves the value which is before the updating.

```
gSQL> UPDATE t1 SET page_view = page_view + 1 WHERE id = 1 RETURNING OLD page_view;
PAGE_VIEW
---------
      102
1 row updated.
```

RETURNING clause of DML statements, like as SELECT query, can retrieve multiple query results. However, if the DML is executed only for a single row, then the host variable can be obtained by using RETURNING INTO clause. In this case, the number of changed rows should be one or less, like **SELECT .. INTO** clause .

The following is an example of setting the value to the host variable using RETURNING .. INTO clause of e ach DML statement.

- It declares the host variable.

```
gSQL> \var v_id        INTEGER
gSQL> \var v_page_view BIGINT
gSQL> \var v_date      DATE
```

- After inserting the row, a value is set to the host variable.

```
gSQL> INSERT INTO t1 ( id, join_date ) VALUES ( 1, SYSDATE ) RETURNING join_date INTO :v_date;
V_DATE
--------------------------
2014-07-18 16:57:11.000000
1 row created.
```

- After updating the row, a value is set to the host variable.

```
gSQL> UPDATE t1 SET page_view = page_view + 1 WHERE id = 1 RETURN page_view INTO :v_page_view;
V_PAGE_VIEW
```

```
------------
         101
1 row updated.
```

- After deleting the row, a value is set to the host variable.

```
gSQL> DELETE FROM t1 WHERE id = 1 RETURN id, page_view INTO :v_id, :v_page_view;
V_ID V_PAGE_VIEW
---- ------------
   1          101
1 row deleted.
```

For more information about DML query, refer to the followings.

- **INSERT INTO name RETURNING**
- **INSERT INTO name RETURNING .. INTO**
- **DELETE FROM name RETURNING**
- **DELETE FROM name RETURNING .. INTO**
- **UPDATE name RETURNING**
- **UPDATE name RETURNING .. INTO**

12.3 Data Query Language

Query Related Statements

For more information, refer to the followings.

- SELECT query related statements
  - SELECT
  - SELECT .. FOR UPDATE

- DML query related statements
  - INSERT INTO name RETURNING
  - UPDATE name RETURNING
  - DELETE FROM name RETURNING

- Cursor related statements
  - DECLARE cursor_name
  - OPEN cursor_name
  - FETCH cursor_name
  - CLOSE cursor_name
  - DELETE FROM name WHERE CURRENT OF cursor_name
  - UPDATE name WHERE CURRENT OF cursor_name

Concepts of Query

Query means a series of operations to retrieve data for one or more of the table or view. By using the que ry, a user can get the result data which satisfies the specific condition in the desired form from the stored data.

Query is a SELECT statement which is at the top in the entire SQL statement separated by ';'. Top-level SE LECT statement can include another SELECT statement in it. In this case, the subordinate SELECT stateme nt is called as a subquery.

In GOLDILOCKS, query is divided into SELECT query, DML query, and cursor. SELECT query returns the res ult by using the SELECT statement. DML query returns the result by using the RETURNING phrase in INSE RT, DELETE, UPDATE statements. Cursor temporarily saves the result sets when it is enquired once, and ra ndomly accesses to a row of the saved result set, then brings the result.
A user can get the results at once by using SELECT query and DML query. On the other hand, by using th

e cursor, SELECT statement specified with DECLARE cursor is executed in OPEN cursor, and then it holds t he result set until CLOSE cursor is called. Then it repeatedly brings the result by randomly accessing to a r ow of the result set using FETCH cursor.

This chapter describes SELECT query, DML query and cursor.

Basic Query

The basic form of a query is *SELECT <select list> FROM <table expression>*. *<select list>* which is between SELECT and FROM keywords, specifies one or more columns or expressions to be included in rows which are the result for the table or view described in *<table expression>*.

```
SELECT n_name
     , INITCAP( n_name )
  FROM nation
 WHERE n_regionkey = 1;
N_NAME                    INITCAP( N_NAME )
------------------------- -------------------------
ARGENTINA                 Argentina
BRAZIL                    Brazil
CANADA                    Canada
PERU                      Peru
UNITED STATES             United States
5 rows selected.
```

One or more tables or views can be described in <table expression>, and same column can be included in two tables or views. In this case, the name of table or view should be specified together when describing that column in <select list>. When describing a table or a column, it is recommended to clearly describe t he schema names and table names, etc.

- A wrong example

```
SELECT n_name
  FROM nation   AS n
     , v_nation AS v
 WHERE n.n_nationkey = v.n_nationkey
   AND v.n_regionkey = 1;
ERR-42000(16142): column ambiguously defined :
SELECT n_name
       *
```

```
ERROR at line 1:
```

- A correct example

```
SELECT n.n_name
  FROM nation   AS n
     , v_nation AS v
 WHERE n.n_nationkey = v.n_nationkey
   AND v.n_regionkey = 1;
N_NAME
-------------------------
ARGENTINA
BRAZIL
CANADA
PERU
UNITED STATES
5 rows selected.
```

<select list> supports the alias name. It changes output column names in each columns which are separated by comma (,). Alias name can be used only in the <order by clause>, and it can not to be used in other phrases.

```
SELECT p_type
     , p_retailprice * 0.9 AS discount_price
  FROM part
 ORDER BY discount_price
 FETCH 5;
    2     3     4     5
P_TYPE                 DISCOUNT_PRICE
---------------------- --------------
PROMO BURNISHED COPPER           810.9
ECONOMY BRUSHED NICKEL           810.9
LARGE BRUSHED BRASS              811.8
LARGE BRUSHED NICKEL             811.8
PROMO ANODIZED STEEL             811.8
5 rows selected.
```

In addition to <select list>, <hint clause> and <set quantifier> can also be used between SELECT and FROM keywords. <hint clause> allows a user to directly adjust the query execution plan. For more information, refer to **SQL Hint**. <set quantifier> removes the duplicate data of the row which is returned as the result. For more information, refer to **query specification**.

- An example of using hint

```
SELECT
       /*+ INDEX( part ) */
       p_type
     , p_retailprice
  FROM part
 WHERE p_partkey = 100;
P_TYPE               P_RETAILPRICE
-------------------- -------------
ECONOMY ANODIZED TIN        1000.1
1 row selected.
```

- An example of using <set quantifier>

```
SELECT DISTINCT
       o_orderpriority
  FROM orders;
O_ORDERPRIORITY
---------------
5-LOW
2-HIGH
3-MEDIUM
1-URGENT
4-NOT SPECIFIED
5 rows selected.
```

SET Operator

SET operators combine the result set of two or more queries into a single result set. SET operators are UN ION, EXCEPT, INTERSECT, and MINUS. MINUS operates as same as EXCEPT. Each SET operator has additi onal options such as ALL and DISTINCT. If the option is omitted, DISTINCT is used by default.

When using the SET operators to describe two or more queries, generally the queries are processed sequ entially from the left. When parentheses are used to explicitly specify the processing order of the queries, then those queries are processed first.

```
SELECT n_name

```

Each query of the SET operators should have the same number of the target, and the target at the same positions of each query should have a data type which belongs to the same group.

<order by clause> of SET operator sorts the final result set. Each query of SET operators can have its own <order by clause> to sort themselves.

For more information about SET operators, refer to **set operator**.

Common Table Expression (CTE)

The temporary result set configured through <with clause> is called as Common Table Expression (CTE). CTE defined in the syntax can be referenced within the execution range. One or more CTE are configured in <with clause>, and each CTE can be configured by referencing CTE including itself. Repeatedly executin g the query to configure the temporary result set is called as recursive subquery factoring.

CTE is classified into recursive CTE and non-recursive CTE.

Referring to CTE which is currently defined within CTE (self-reference CTE) is called as recursive CTE. CTE other than recursive CTE is called as non-recursive CTE.

```
* recursive CTE
WITH RECURSIVE_CTE ( c1 ) AS
     (
          SELECT 1
            FROM dual
```

```
          UNION ALL
          SELECT c1 + 1
            FROM RECURSIVE_CTE      ❶ Self reference
           WHERE c1 < 10
     )
SELECT c1 FROM RECURSIVE_CTE;
```

```
* non-recursive CTE
WITH NON_RECURSIVE_CTE ( c1 ) AS
     (
          SELECT i1
            FROM t1
          UNION ALL
          SELECT i1
            FROM t2
     )
SELECT c1 FROM NON_RECURSIVE_CTE;
```

Recursive CTE

Recursive CTE is always consists of two query block sets using UNION ALL. The query block including Self-reference CTE is called as a recursive member query, and other query blocks are called as anchor member queries.

```
WITH CTE_RECURSIVE( c1, c2 ) AS
    (
         SELECT i1, i2                      ❶ Anchor member query
           FROM t1
          WHERE i2 IS NULL
         UNION ALL
         SELECT i1, i2                      ❷ Recursive member query
           FROM CTE_RECURSIVE, t1
          WHERE CTE_RECURSIVE.c1 = t1.i2
    )
SELECT c1, c2 FROM CTE_RECURSIVE;
```

Recursive CTE configures records acquired from an anchor member query into the temporary result set, a nd acquires those records through CTE reference in the recursive member query. Recursive CTE also confi gures results acquired from the recursive member query into the temporary result set, and tries to execut e the recursive member query again. This process is repeated until it is unable to configure the temporary result set.

〈search clause〉 is used to specify the sequence of the record configuration configured in the current step. 〈search clause〉 supports DEPTH FIRST BY and BREADTH FIRST BY. 〈search clause〉 can be described only within recursive CTE.

For more information, refer to **〈search clause〉**.

```

When configuring the results configured in the previous step into the current temporary result set, then r ecursive CTE is infinitely executed. In this case, the system determines that the cycle occurs, so it causes cy cle detected error.

The comparing target is selected through <cycle clause> to determine whether cycle occurs, and whether cycle occurred is also ca be seen. If using <cycle clause>, it does not cause an error for cycle detected whe n cycle occurred.

When <cycle clause> is not specified, then all columns used when defining CTE are selected as targets of determining whether cycle occurred.

```
gSQL> SELECT * FROM t1;

Join

Join is a query that combines rows from more than one table or view in <from clause>. If there is not a join condition, the result is obtained by combining each result row of the left table or view with each result row of the right table or view.

If tables or views have a column name in common when joining two or more tables or views in <from clause>, a user should distinguish these columns by using the table or view name in <select list>, <where clause>. Otherwise, a validation error occurs.

Join queries either contain the join condition or do not contain the join condition. Join condition is for comparing columns from two different tables or views. If the join condition is not specified, each row of a table or view is combined with each row of another table or view, and the combined row is returned. If the join condition is specified, rows from each table or view which satisfies the join condition, are returned in the combined form.

Equi-join is a join whose join condition contains an equality operator(=). Equi-join condition is an important factor in optimizing the join operation by the optimizer.

Self-join is a join operation which has only the same tables in <from clause>. To describe column in <select list>, the alias name in each table is described and table alias in column is used.

CROSS JOIN

CROSS JOIN is a join operation whose join condition does not exist, and it is also called as Cartesian Product. CROSS JOIN combines each row of one table or view with each row of the other, and the combined row is returned as a result.

```
SELECT a.r_name
     , b.r_name
  FROM region AS a
     , region AS b
 FETCH 5;
R_NAME                    R_NAME
------------------------- -------------------------
AFRICA                    AFRICA
AFRICA                    AMERICA
```

```
AFRICA                    ASIA
AFRICA                    EUROPE
AFRICA                    MIDDLE EAST
5 rows selected.
```

INNER JOIN

INNER JOIN returns the rows which satisfy the join condition for two or more tables or views. INNER JOIN is when *inner join* is explicitly specified in <from clause>. Or, when tables or views are listed with comma (,) in <from clause> and its join condition is specified in <where clause>.
If there are explicit *inner join* in <from clause>, and the join condition in <where clause>, then they are pr ocessed as one inner join condition.

- An example of using an INNER JOIN statement

```
SELECT n_name
  FROM region INNER JOIN nation ON r_regionkey = n_regionkey
 WHERE r_name = 'AFRICA';
N_NAME
-------------------------
ALGERIA
ETHIOPIA
KENYA
MOROCCO
MOZAMBIQUE
5 rows selected.
```

- An example of a list using a comma (,)

```
SELECT n_name
  FROM region
     , nation
 WHERE r_regionkey = n_regionkey
   AND r_name = 'AFRICA';
N_NAME
-------------------------
ALGERIA
ETHIOPIA
KENYA
MOROCCO
MOZAMBIQUE
```

```
5 rows selected.
```

OUTER JOIN

OUTER JOIN returns all rows which satisfy the join condition for two or more tables or views. It also retur ns rows which do not satisfy the join condition for one or both side of table or view depending on the dir ection of OUTER JOIN.

OUTER JOIN can be classified as LEFT OUTER JOIN , RIGHT OUTER JOIN, FULL OUTER JOIN. All three OUT ER JOIN returns rows which satisfy the join condition, but they are distinguished by the additional results. LEFT OUTER JOIN returns all rows of the left table which do not satisfy the join condition by filling NULL f or all of its right rows. RIGHT OUTER JOIN returns all rows of the right table which do not satisfy the join condition by filling NULL for all of its left rows. FULL OUTER JOIN returns all additional return results of LE FT OUTER JOIN and RIGHT OUTER JOIN.

```
SELECT r_name
     , n_name
  FROM region LEFT OUTER JOIN nation
       ON r_regionkey = n_regionkey AND r_name = 'AFRICA';
R_NAME                    N_NAME
------------------------- -------------------------
AFRICA                    ALGERIA
AFRICA                    ETHIOPIA
AFRICA                    KENYA
AFRICA                    MOROCCO
AFRICA                    MOZAMBIQUE
AMERICA                   null
ASIA                      null
EUROPE                    null
MIDDLE EAST               null
9 rows selected.
```

GOLDILOCKS supports the outer join operator(+) for compatibility with Oracle, and which is not supporte d in the SQL standard. The outer join operator(+) lists tables by using a comma(,) in <from clause> and it adds a (+) to a node column which is operated as the outer node in the join condition of <where clause>.

When using the outer join operator (+), the sign(+) should be specified on the right side of the column as follows.

```
select * from t1, t2 where t1.i1 = t2.i1(+);
```

The syntax rules of the outer join operator (+) are as follows.

- <Join outer operator> can be used only for <where clause>.
- <Join outer operator> can be used only for <column reference> of <table reference> which is a target of <joined table>.
- <value expression> including <join outer operator>, can not be combined with other conditions whic h use <OR logical operator>.
- <column reference> including <join outer operator> can not be used as the argument of IN function.
- A <table reference> can not be used as null generated table of many outer joins (constraints on the o uter join)
- When executing the outer join of two or more tables, they are listed according to the left outer join s equence, and executes the outer join from the very left of them.
- When executing Out Join of two or more tables and multiple tables are combined into a table by the outer join, then the outer join is executed according to the sequence of calculation by an optimizer.

Even when the outer join operator (+) is specified, it is ignored in the following cases.

- <join outer operator> can be used for <value expression> which can be used as the join condition bet ween the two tables, if it can not be used as the join condition, then it is ignored and an error or war ning does not occur.
- <join outer operator> which is specified in <column reference> of the outer query is ignored, and an error or warning does not occur.
- If two <table refernce> are outer joined using <join outer operator>, then <join outer operator> shoul d be specified in all <column reference> which belong to null generated tables. Otherwise, join of tw o <table reference> is processed as an inner join, an error or warning does not occur.

Differences between Oracle and GOLDILOCKS for the outer join operator (+) are as follows.

- Quantified comparison (in, = any, = all = row, etc.)
  - GOLDILOCKS: It processes the operation as a validation error.
  - Oracle: The and/or operation is applied, and performs the validation check.
- *Or* sub-clause in an *and* clause
  - GOLDILOCKS: Validation is applied on the columns of an *or* sub-clause.
  - Oracle: Validation is ignored on the columns of an *or* sub-clause.
- When the condition clause includes a subquery
  - GOLDILOCKS: The outer join is applied and the condition is processed as a join condition.
  - Oracle: The outer join is applied but the condition is processed as a where filter.

GOLDILOCKS supports the outer join operator (+) for compatibility with Oracle. It is recommend ed to specify OUTER JOIN in <from clause>. (Oracle also recommends to specify OUTER JOIN in <from clause>.)

NATURAL JOIN

NATURAL JOIN uses the join condition of an equality operator(=) for columns of same name when joinin g two or more tables or views. It is as same as INNER JOIN except that NATURLAL JOIN has the implicit joi n condition for columns of the same name.

```
SELECT r_name
  FROM region a NATURAL JOIN region b;
R_NAME
-------------------------
AFRICA
AMERICA
ASIA
EUROPE
MIDDLE EAST
5 rows selected.
```

SEMI JOIN

SEMI JOIN returns the corresponding left rows if there exist right rows which satisfy the join condition. U nlike other join operations to return the rows which combine the left and right rows, SEMI JOIN returns o nly the left rows as the result.

- An example of using the semi join

```
SELECT r_name
  FROM region
 WHERE r_regionkey IN ( SELECT n_regionkey
                          FROM nation
                         WHERE n_nationkey < 5 );
R_NAME
-------------------------
AFRICA
AMERICA
MIDDLE EAST
3 rows selected.
```

ANTI-SEMI JOIN

ANTI-SEMI JOIN returns the corresponding left rows if there does not exist any right rows which satisfy th e join condition. It returns only the left rows as the result like as SEMI JOIN.

- An example of using the anti-semi join

```
SELECT r_name
  FROM region
 WHERE r_regionkey NOT IN ( SELECT n_regionkey
                              FROM nation
                             WHERE n_nationkey < 5 );
R_NAME
-------------------------
ASIA
EUROPE
2 rows selected.
```

For more information about the join operation, refer to **joined table**.

Hierarchical Query

A hierarchical query can process the hierarchical model data. The hierarchical model data consists of the hierarchical relationship with the connecting condition.

Recursive CTE is used to express the hierarchical query. For more information, refer to **Recursive CTE**.

The other way to configure a hierarchical query is using <hierarchical query clause>.

<hierarchical query clause> creates a hierarchy by using the given starting condition (<start with clause>) and child connecting condition (<connect by clause>), and configures the result record with depth-first m ethod. <hierarchical query clause> should include <connect by clause>.

```
SELECT *
  FROM r_region
 WHERE r_population > 10000000
 START WITH r_name = 'EARTH'              ❶ Starting condition
CONNECT BY r_domain = PRIOR r_name        ❷ Connecting condition
```

All expressions used as an argument of PRIOR operator among expressions described in <connect by> are configured into the result for the current hierarchy. Only the expressions configured into the result are us ed as targets to check whether cycle occurs. The results configured in this way can be referenced through **<hierarchy expression>**.

Whether cycle occurs in a hierarchical query is checked by repeatedly searching along the parent hierarch y based on currently configured result and checking whether the same result exists. When it is determine d that cycle occurred based on the current result, then the information is set that the parent record of the

current result record includes the record where cycle occurred.

If searching for the record including cycle occurrence information, then the system determines that the cy cle occurs, so it causes cycle detected error. If describing NOCYCLE in <connect by> statement, then it do es not cause cycle detected error, and whether cycle occurs is known through CONNECT_BY_ISCYCLE wh ich is one of <hierarchical expression>.

```
gSQL>
SELECT * FROM t1;
I1 I2
-- ----
A  null
AA A
AB A
AC A
AA AA
AB AA
6 rows selected.
gSQL>
SELECT i1, i2, CONNECT_BY_ISCYCLE
  FROM t1
START WITH i1 = 'A'
CONNECT BY NOCYCLE i2 = prior i1;
I1 I2   CONNECT_BY_ISCYCLE
-- ---- ------------------
A  null                  0
AA A                     1
AB AA                    0
AB A                     0
AC A                     0
5 rows selected.
```

Sibling records of the same parent records are sorted through <order sibling by clause>. <order sibling by clause> is applied when configuring the result record per each hierarchy.
However, <order by clause> which has a similar form sorts all records acquired from the query block. Ther efore, <order sibling by clause> and <order by clause> does not affect each other, and constraints do not exist between them.

```
gSQL>
SELECT * FROM t1;
I1  I2
--- ----
```

```
A   null
AA  A
AB  A
fAA AA
eAA AA
bAA AA
dAB AB
cAB AB
aAB AB
9 rows selected.
```

- The following is an example of defining the order of fetching sibling records of the same parent recor ds.

```
gSQL>
SELECT LEVEL, i1, i2
  FROM t1
START WITH i1 = 'A'
CONNECT BY i2 = PRIOR i1
ORDER SIBLINGS BY i1;
LEVEL I1  I2
----- --- ----
    1 A   null
    2 AA  A
    3 bAA AA
    3 eAA AA
    3 fAA AA
    2 AB  A
    3 aAB AB
    3 cAB AB
    3 dAB AB
9 rows selected.
```

- The following is an example of sorting all results retrieved in a hierarchy by using ORDER BY clause in an order of LEVEL.

```
gSQL>
SELECT LEVEL, i1, i2
  FROM t1
START WITH i1 = 'A'
CONNECT BY i2 = PRIOR i1
ORDER SIBLINGS BY i1
```

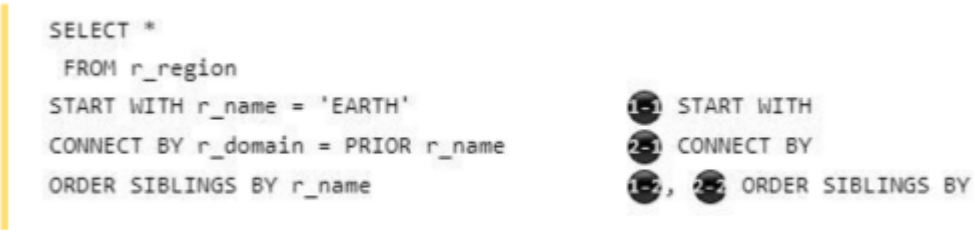
```
ORDER BY LEVEL;
LEVEL I1  I2
----- --- ----
    1 A   null
    2 AA  A
    2 AB  A
    3 bAA AA
    3 eAA AA
    3 fAA AA
    3 aAB AB
    3 cAB AB
    3 dAB AB
9 rows selected.
```

Order of evaluating hierarchical query

<hierarchical query clause> consists of <start with connect by clause> and <order siblings by clause>.

Statements in <hierarchical query clause> are executed in the following order.

Results acquired through <start with connect by clause> from each hierarchy are sorted through <order siblings by clause>. <start with clause> is evaluated for the root hierarchy and <order siblings by clause> is applied. Then, the result is configured by using <connect by clause> and <order siblings by clause> for child hierarchy which is configured later.



<hierarchical query clause> in the query block is executed in the following order.

<hierarchical query clause> is described between <where clause> and <group by clause> after <from clause>. Unlike the describing order for <hierarchical query clause>, <hierarchical query clause> is evaluated after <from clause> and before <where clause>.

Conditions described in <where clause> does not affect the evaluation of <hierarchical query clause>.

The followings are the evaluating order of <hierarchical query clause> according to the configuration of

〈from clause〉 and 〈where clause〉.

- When only a single table exists in *from* clause

```
SELECT *
 FROM r_region
WHERE r_population > 10000000          ❸ Condition in WHERE clause
START WITH r_name = 'EARTH'            ❶ START WITH
CONNECT BY r_domain = PRIOR r_name     ❷ CONNECT BY
```

- When join condition configured with multiple tables exists in *from* clause
  - When join condition is described in ON clause of FROM clause

```
SELECT *
  FROM r_region INNER JOIN s_region
       ON r_id = s_id                  ❶ Join condition in ON clause
 WHERE r_population > 10000000         ❹ Condition in WHERE clause
START WITH r_name = 'EARTH'            ❷ START WITH
CONNECT BY r_domain = PRIOR r_name     ❸ CONNECT BY
```

- When join condition is described in WHERE clause

```
SELECT *
  FROM r_region, s_region
 WHERE r_population > 10000000         ❸ Condition in WHERE clause
   AND r_id = s_id                     ❸ Join condition in WHERE clause
START WITH r_name = 'EARTH'            ❶ START WITH
CONNECT BY r_domain = PRIOR r_name     ❷ CONNECT BY
```

  - When join condition is described in both ON clause of FROM and in WHERE clause

```
SELECT *
  FROM r_region INNER JOIN s_region
       ON r_name = s_name              ❶ Join condition in ON clause
 WHERE r_population > 10000000         ❹ Condition in WHERE clause
   AND r_id = s_id                     ❹ Join condition in WHERE clause
START WITH r_name = 'EARTH'            ❷ START WITH
CONNECT BY r_domain = PRIOR r_name     ❸ CONNECT BY
```

If 〈group by clause〉 is used in a query block including 〈hierarchical query clause〉, then it is able to config ure the result set group by using 〈hierarchical expression〉.

```
SELECT COUNT(*)
  FROM r_region
 START WITH r_name = 'EARTH'
CONNECT BY r_domain = PRIOR r_name
 GROUP BY PROIR r_domain
```

Grouping Result Set (group by)

<group by clause> is used in order to group the rows which have the same column into one. <group by clause> lists and delimiters columns by using the comma (,), and GOLDILOCKS supports the group operation based on it.

```
SELECT
       o_orderpriority
     , MIN( o_totalprice ) AS min_price
     , MAX( o_totalprice ) AS max_price
  FROM orders
 GROUP BY
       o_orderpriority;
O_ORDERPRIORITY MIN_PRICE MAX_PRICE
--------------- --------- ---------
5-LOW              857.71 530604.44
2-HIGH              896.8 522720.61
3-MEDIUM           875.52 508668.52
1-URGENT            866.9 544089.09
4-NOT SPECIFIED    884.82 555285.16
5 rows selected.
```

If <group by clause> is specified, only the columns and the aggregate functions described in <group by clause> can be included in <select list>.

If only constants or parentheses instead of columns are specified in <group by clause>, it is assumed to be empty grouping set which includes the imaginary columns of the same value in each row. Then, the grouping in column base is performed. It is same when specifying <having clause> without <group by clause>.

<having clause> can be used to get the specified rows from grouped results by <group by clause>. <having clause> describes the conditions for each group, and it can describes the condition using the aggregate operation.

```
SELECT
       o_orderpriority
     , MIN( o_totalprice ) AS min_price
     , MAX( o_totalprice ) AS max_price
  FROM orders
 GROUP BY
       o_orderpriority
 HAVING
       MIN( o_totalprice ) < 870;
O_ORDERPRIORITY MIN_PRICE MAX_PRICE
--------------- --------- ---------
5-LOW              857.71 530604.44
1-URGENT            866.9 544089.09
2 rows selected.
```

For more information about the grouping, refer to **group by clause**.

Window Query

The window function returns the execution result of the function for the defined record range. The defined record range is called as a window and the record range is defined in OVER <window name or specification>. Unlike a general function or an aggregate function, the window function has OVER clause.

```
SUM( sales ) OVER ()
SUM( sales ) OVER window_name
SUM( sales ) OVER ( PARTITION BY item_no
                    ORDER BY sales
                    ROWS BETWEEN UNBOUNDED PRECEDING
                             AND CURRENT ROW )
```

The window function, like as an aggregate function, returns the execution result of function for multiple records. However, the aggregate function returns a single record per each group, but the window function returns multiple records per each group.

Each record in the group of the window function has the execution result of the function for the window (the defined record range). Therefore, unlike an aggregate function, the window function returns all records of each group.

The following is an example of executing the aggregate function and the window function.

- The following is a sample table.

```
gSQL>
SELECT * FROM store;
ITEM_NO SALES_DATE SALES
------- ---------- -----
    100 2001-01-01   150
    100 2001-01-02   100
    100 2001-01-03   170
    100 2001-01-04    90
    100 2001-01-05   200
    235 2001-01-01    70
    235 2001-01-02   130
    235 2001-01-03   190
    235 2001-01-04   150
    235 2001-01-05    50
10 rows selected.
```

- Executing result of aggregate function

```
gSQL>
SELECT SUM( sales ) AS aggrfunc_sum
  FROM store;
AGGRFUNC_SUM
------------
        1300
1 row selected.
```

- Executing result of window function

```
gSQL>
SELECT item_no,
       sales,
       SUM( sales ) OVER () as windowfunc_sum
  FROM store;
ITEM_NO SALES WINDOWFUNC_SUM
------- ----- --------------
    100   150           1300
    100   100           1300
    100   170           1300
    100    90           1300
    100   200           1300
    235    70           1300
```

```
    235   130           1300
    235   190           1300
    235   150           1300
    235    50           1300
10 rows selected.
```

The window function defines the window (the execution range of the function) in OVER <window name or specification> clause.

It is divided into groups as described in <window partition clause> PARTITION BY.
Then, the records in the group are sorted as described in <window order clause> ORDER BY.
Then, the record range, the window function target, is defined among records sorted within the group as described in <window frame clause>.

For more information about the definition for the window, refer to **window clause**.

The window function is executed per partition defined in <window partition clause> PARTITION BY, and i f PARTITION BY is omitted, then the entire result record become a single partition.

If <window order clause> ORDER BY is described, then the window frame (the execution range of the wi ndow function) is applied to each record (current row) within the partition.

The window frame is defined by describing <window frame clause>, and it defines the application unit (R OWS/ RANGE/ GROUPS), starting point, ending point and the excluded records.

If <window frame clause> is omitted, then RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT R OW is applied by default. In this case, the execution range is from the record at the beginning of the parti tion to all peer records of the current record.

For more information about <window frame clause>, refer to **<window frame clause>**.

The following examples describe the difference in results between the case when <window order clause> ORDER BY is omitted and the case when the window frame is applied by describing <window order claus e> ORDER BY.

- When <window order clause> ORDER BY is omitted
    - If PARTITION BY is described, then it calculates the sum(sales) per the specified partition.

```
gSQL>
SELECT item_no,
       sales,
       SUM( sales ) OVER ( PARTITION BY item_no ) as windowfunc_sum
  FROM store;
ITEM_NO SALES WINDOWFUNC_SUM
```

```
------- ----- --------------
    100   150            710
    100   100            710
    100   170            710
    100    90            710
    100   200            710
    235    70            590
    235   130            590
    235   190            590
    235   150            590
    235    50            590
10 rows selected.
```

    - If PARTITION BY is omitted, then the entire record is considered as a single partition, so it calculates the sum(sales) of all records.

```
gSQL>
SELECT item_no,
       sales,
       SUM( sales ) OVER ( ) as windowfunc_sum
  FROM store;
ITEM_NO SALES WINDOWFUNC_SUM
------- ----- --------------
    100   150           1300
    100   100           1300
    100   170           1300
    100    90           1300
    100   200           1300
    235    70           1300
    235   130           1300
    235   190           1300
    235   150           1300
    235    50           1300
10 rows selected.
```

- When <window order clause> ORDER BY is described

    - If PARTITION BY is described: <window frame clause> is omitted, so RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW is applied by default, and it calculates the sum(sales) from the record at the beginning of the partition to all peer records of the current record.

```
gSQL>
SELECT item_no,
       sales,
       SUM( sales ) OVER ( PARTITION BY item_no
                           ORDER BY sales ) as windowfunc_sum
  FROM store;
ITEM_NO SALES WINDOWFUNC_SUM
------- ----- --------------
    100    90             90
    100   100            190
    100   150            340
    100   170            510
    100   200            710
    235    50             50
    235    70            120
    235   130            250
    235   150            400
    235   190            590
10 rows selected.
```

- If PARTITION BY is omitted: The entire record is considered as a single partition. In this case, <window frame clause> is omitted, and RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW is applied by default, so it calculates the sum(sales) from the record at the beginning of the partition to all peer records of the current record.

```
gSQL>
SELECT item_no,
       sales,
       SUM( sales ) OVER ( ORDER BY sales ) as windowfunc_sum
  FROM store;
ITEM_NO SALES WINDOWFUNC_SUM
------- ----- --------------
    235    50             50
    235    70            120
    100    90            210
    100   100            310
    235   130            440
    100   150            740
    235   150            740
    100   170            910
    235   190           1100
    100   200           1300
```

```
10 rows selected.
```

When executing multiple window functions for the same window (the defined record range), then defin e the window name in WINDOW clause and refer to it.

```
gSQL>
SELECT item_no,
       sales_date,
       sales,
       SUM( sales ) OVER W1 cumulative_sales,
       AVG( sales ) OVER w1 avg_sales
  FROM store
WINDOW w1 AS ( PARTITION BY item_no
               ORDER BY sales_date
               ROWS BETWEEN UNBOUNDED PRECEDING
                        AND CURRENT ROW );
ITEM_NO SALES_DATE SALES CUMULATIVE_SALES AVG_SALES
------- ---------- ----- ---------------- ---------
    100 2001-01-01   150              150       150
    100 2001-01-02   100              250       125
    100 2001-01-03   170              420       140
    100 2001-01-04    90              510     127.5
    100 2001-01-05   200              710       142
    235 2001-01-01    70               70        70
    235 2001-01-02   130              200       100
    235 2001-01-03   190              390       130
    235 2001-01-04   150              540       135
    235 2001-01-05    50              590       118
10 rows selected.
```

The window function can be described in *select list* and *order by* clause.

The window function is executed for the result set after FROM, WHERE, GROUP BY and HAVING clause i s executed. If aggregate, GROUP BY and HAVING clause is used in a query, then describe the group colu mn instead of the original table's column in the window function.

For more information, refer to **Window Function** and **window clause**.

Sorting Result Set (order by)

<Order by clause> sorts the result set based on the specific columns. <order by clause> can sort based on all types of column except the LONG type.

When a positive integer value is in <order by clause>, it means the column which is located in the corresponding to an integer value for the targets in the <select list>. The range of positive integer value which can be described in <order by clause> is from 1 and to the number of the targets in <select list>.

```
SELECT
       o_orderpriority
     , MIN( o_totalprice ) AS min_price
     , MAX( o_totalprice ) AS max_price
  FROM orders
 GROUP BY
       o_orderpriority
 ORDER BY 1;
O_ORDERPRIORITY MIN_PRICE MAX_PRICE
--------------- --------- ---------
1-URGENT            866.9 544089.09
2-HIGH              896.8 522720.61
3-MEDIUM           875.52 508668.52
4-NOT SPECIFIED    884.82 555285.16
5-LOW              857.71 530604.44
5 rows selected.
```

If the column data type in <order by clause> is numeric, it is sorted by numeric comparison. If the column data type is a character type, it is sorted by character comparison.

Each column in <order by clause> can be described by using the sorting direction option such as ASC, DESC. If it is omitted, it is regarded as ASC.

For more information about sorting, refer to **order by clause**.

Subquery

Subquery supports a multi-level search request. The multi-level search request means that the result of the current query depends on the result of the subquery.
For example, the query to get people who is older than the average age of the people in a specific group is written in multi-step. The first query is to obtain the average age of people in a specific group, then the

second query is to retrieve the number of people who is older than the average using the first query.

```
SELECT e_name
  FROM emp
 WHERE e_age > ( SELECT AVG(e_age)
                   FROM emp
                  WHERE e_dept = 'RND' );
```

A subquery can be used in <from clause>, <where clause>. The subquery in <from clause> is "inline view" and the subquery in <where clause>is "nested subquery".

The column name of a table or view in nested subquery can be same as the column name of a table or view in the query including the nested subquery when using the nested subquery. If only the column name exists in <select list> of the nested subquery, then it refer to the column of the table or view in the nested subquery. If the column name in <select list> of the nested subquery does not exist in the nested subquery's table or view, then it refers to the column name of the table or view in the query which includes the nested subquery, if exists.

```
SELECT r_name
  FROM region
 WHERE EXISTS ( SELECT *
                  FROM nation
                 WHERE n_nationkey < 5             /* nation.n_nationkey */
                   AND n_regionkey = r_regionkey ) /* nation.n_regionkey = region.r_regionkey
*/
;
```

The optimizer unnests the nested subquery of <where clause> in the query which includes the nested subquery. Then it processes it as SEMI JOIN or ANTI-SEMI JOIN operation.
This is an optimization of the nested subquery, and the optimizer determines it by calculating the cost of unnesting if the subquery exists in IN, NOT IN, EXISTS, NOT EXISTS, quantify operator.
If a user wants to forcibly unnest the nested subquery, the user can use <hint clause> of nested subquery.

For more information about unnesting the nested subquery, refer to **SQL Hint**.

```
SELECT r_name
  FROM region
 WHERE r_regionkey IN ( SELECT /*+ UNNEST */
                               n_regionkey
                          FROM nation
                         WHERE n_nationkey < 5 );
```

For more information about subquery, refer to **subquery**.

12.4 Control Language

Control Language Related Statements

For more information, refer to the followings.

- Transaction control related statements
  - **COMMIT**
  - **ROLLBACK**
  - **LOCK TABLE**
  - **SAVEPOINT savepoint_specifier**
  - **RELEASE SAVEPOINT savepoint_specifier**

- Session control related statements: Refer to the followings.
  - **ALTER SESSION SET property_name**
  - **SET SESSION AUTHORIZATION user_identifier**
  - **SET SESSION CHARACTERISTICS AS transaction_mode**
  - **SET TIME ZONE**
  - **SET TRANSACTION transaction_mode**

- System control related statements: Refer to the followings.
  - **ALTER SYSTEM CHECKPOINT**
  - **ALTER SYSTEM {MOUNT | OPEN} DATABASE**
  - **ALTER SYSTEM [KILL | DISCONNECT] SESSION**
  - **ALTER SYSTEM SET property_name**
  - **ALTER SYSTEM RESET property_name**
  - **ALTER SYSTEM SWITCH LOGFILE**

Transaction Control

Transaction control statements are used to manage the changes caused by executing DML or DDL statem ents in the transactions. Transaction control statements can be committed to keep the changes permane ntly, or rolled back to undo the changes.

Transaction control statements are classified as follows.

Table 12-3 Transaction control statements

Statement	Description	Refer to
COMMIT	It terminates the transaction normally.	**COMMIT**
ROLLBACK	It undoes the transaction.	**ROLLBACK**
SAVEPOINT	It creates the savepoint.	**SAVEPOINT savepoint_specifier**
RELEASE SAVEPOINT	It removes the savepoint.	**RELEASE SAVEPOINT savepoint_specifier**
LOCK TABLE	It sets the table-level lock.	**LOCK TABLE**
SET TRANSACTION	It controls the transaction properties. (Read/write, isolation level)	**20.25 SET TRANSACTION transaction_mode**
SET CONSTRAINTS	It controls the checkpoint of the deferrable constraints.	**SET CONSTRAINTS**

A transaction is automatically created when the DML statements or DDL statements are executed for the first time. DML statements change the data and DDL statements change the SQL objects. However, the SELECT statements or the control statement do not generate a transaction.

The transaction rollbacks are classified as total rollback and partial rollback. The partial rollback is executed either in an explicit method or an implicit method. The total rollback is executed by ROLLBACK statement, and it undoes any changes performed by DML, DDL within the transaction.

The explicit partial rollback is a method which a user executes ROLLBACK statement using the savepoint as follows.
The following example describes that savepoints sp1, sp2 are declared, and then the partial rollback is explicitly executed.

```
gSQL> CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
gSQL> SAVEPOINT sp1;
Savepoint created.
gSQL> INSERT INTO t1 VALUES ( 2, 'mkkim' );
1 row created.
gSQL> SAVEPOINT sp2;
Savepoint created.
gSQL> INSERT INTO t1 VALUES ( 3, 'xcom' );
1 row created.
gSQL> ROLLBACK TO SAVEPOINT sp2;
Rollback complete.
```

```
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
 2 mkkim
2 rows selected.
gSQL> ROLLBACK TO SAVEPOINT sp1;
Rollback complete.
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
gSQL> ROLLBACK WORK;
Rollback complete.
gSQL> SELECT * FROM t1;
no rows selected.
```

The implicit partial rollback is undoing only the changes of the corresponding statement when an error oc curs while executing the statement.
The following example describes the implicit partial rollback.
If a unique constraint is violated, only the INSERT statement is rolled back and the previous changes of th e transaction are retained.

```
gSQL> ALTER TABLE t1 ADD CONSTRAINT t1_uk UNIQUE(id);
Table altered.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO t1 VALUES ( 4, 'egonspace' );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 1, 'jhkim' );
ERR-40002(16057): unique constraint (PUBLIC.T1_UK) violated
gSQL> SELECT * FROM t1;
ID NAME
-- ---------
 1 leekmo
 2 mkkim
 3 xcom
 4 egonspace
4 rows selected.
```

Session Control

Session is a logical object to manage the user's state information who accesses the database. Session control statement changes the session properties.

Session control statements are classified as follows.

Table 12-4 Session control statements

Statement	Description	Refer to
SET SESSION CHARACTERISTICS	It controls the transaction properties in the session.	**SET SESSION CHARACTERISTICS AS transaction_mode**
SET TIME ZONE	It alters the time zone of the session.	**SET TIME ZONE**
SET SESSION AUTHORIZATION	It alters the user of the session.	**SET SESSION AUTHORIZATION user_identifier**
SET SCHEMA	It alters the session schema.	**SET SCHEMA schema_name**
ALTER SESSION SET	It alters the session property.	**ALTER SESSION SET property_name**

SET TRANSACTION statement is the transaction controlling statement and SET SESSION CHARACTERISTICS statement is session controlling statement. Both SET TRANSACTION statement and SET SESSION CHARACTERISTICS statement control the transaction properties.
The difference between SET TRANSACTION statement and SET SESSION CHARACTERISTICS statement is that SET TRANSACTION statement is applied only to a transaction which will be executed next. On the other hand, SET SESSION CHARACTERISTICS statement is applied for all transactions which occur in the session afterwards.

The following is a result of CURRENT_TIMESTAMP statement which obtains the current date and time after changing the time zone by using SET TIME ZONE statement.

```
gSQL> SELECT CURRENT_TIMESTAMP FROM DUAL;
CURRENT_TIMESTAMP
---------------------------------
2014-07-21 11:42:49.828276 +09:00
1 row selected.
gSQL> SET TIME ZONE '+00:00';
Session set.
gSQL> SELECT CURRENT_TIMESTAMP FROM DUAL;
CURRENT_TIMESTAMP
---------------------------------
2014-07-21 02:43:03.437940 +00:00
1 row selected.
```

System Control

System control statements manage the database system, and they are classified as follows.

Table 12-5 System control statements

Statement	Description	Refer to
ALTER SYSTEM {OPEN|MOUNT} DATABASE	It starts up the database.	**ALTER SYSTEM {MOUNT | OPEN} DATABASE**
ALTER SYSTEM CHECKPOINT	It performs the checkpoint.	**ALTER SYSTEM CHECKPOINT**
ALTER SYSTEM KILL SESSION	It forcibly terminates the specific session.	**ALTER SYSTEM [KILL | DISCONNECT] SESSION**
ALTER SYSTEM SWITCH LOGFILE	It switches the log file.	**ALTER SYSTEM SWITCH LOGFILE**
ALTER SYSTEM SET	It sets the system properties.	**ALTER SYSTEM SET property_name**
ALTER SYSTEM RESET	It removes the system properties.	**ALTER SYSTEM RESET property_name**

The following is an example of enquiring sessions connected to the database, and terminating the specific session.

```
gSQL> SELECT USER_NAME, SESSION_ID, SERIAL_NO, SESSION_STATUS, PROGRAM_NAME FROM V$SESSION
WHERE USER_NAME = 'TEST';
USER_NAME SESSION_ID SERIAL_NO SESSION_STATUS PROGRAM_NAME
--------- ---------- --------- -------------- ------------
TEST              62        49 CONNECTED      gsql
TEST              65       109 CONNECTED      gsqlnet
TEST              66       130 CONNECTED      gsql
3 rows selected.
gSQL> ALTER SYSTEM DISCONNECT SESSION 65, 109;
System altered.
```

12.5 Processing SQL in Cluster

This chapter describes how to process various SQL statements in a cluster environment.

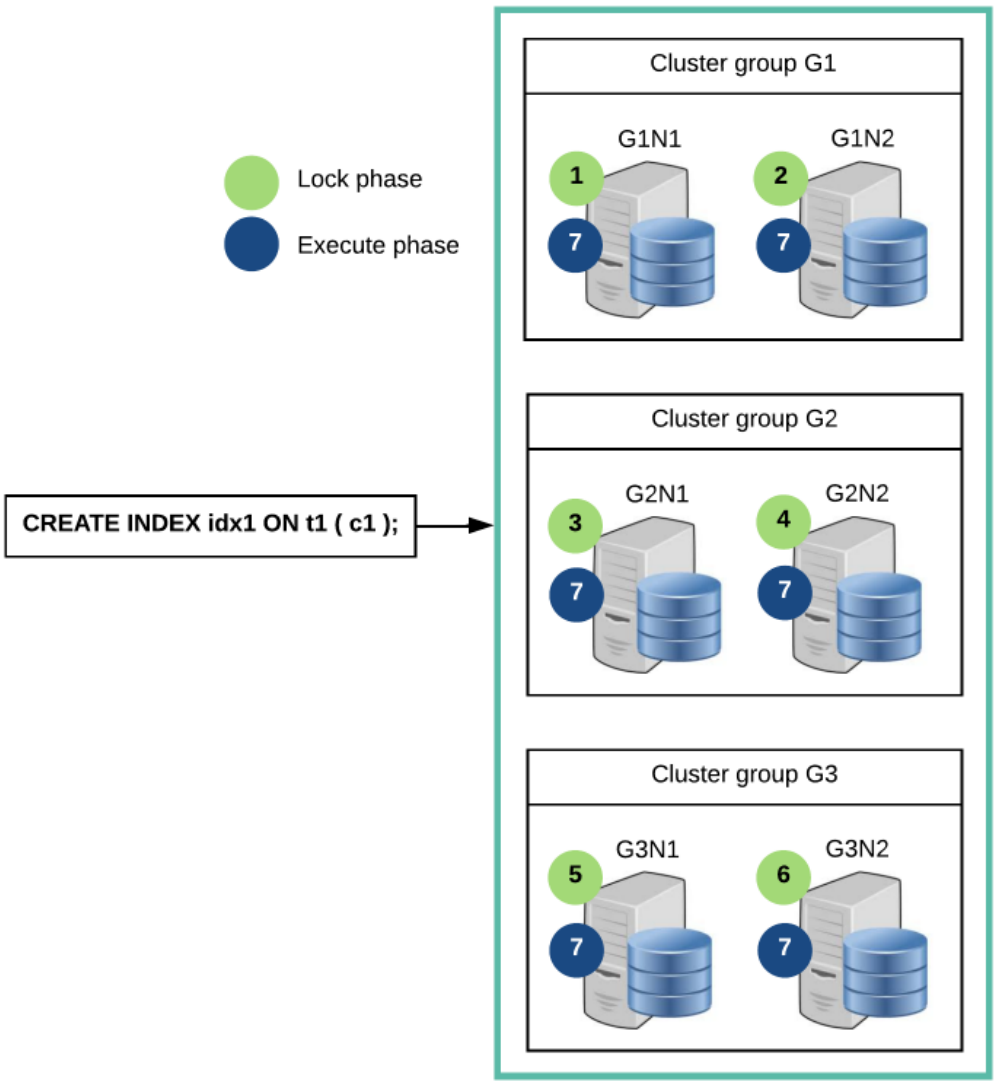
Processing DDL in Cluster

DDL Processing Procedure in Cluster

GOLDILOCKS cluster does not have a separate meta server, and a user can perform DDL in any cluster me mber configuring the cluster system.

DDL is executed following the procedure below in a cluster environment.

Figure 1 Processing DDL in cluster



DDL is performed through two phases, which are a lock phase and and execution phase. On the lock pha se, a lock which is required for performing DDL is acquired and DDL is sequentially performed on every cl uster member. On the execute phase, DDL is simultaneously performed for every cluster member.

DDL is completed when DDL is successfully performed on every cluster members. If DDL fails on a specific cluster member, then DDL operations on every cluster members are cancelled. DDL can not be performed if an error occurred in any cluster member. All cluster member synchronize meta information for objects t hrough this process.

Simultaneous DDL Execution

The cluster object DDL which changes the cluster system configuration and the SQL object DDL can not b e simultaneously performed. The availability of simultaneously performing the cluster object DDL and the SQL object DDL are as follows.

Table 12-6 Availability of simultaneously performing DDL

DDL	Cluster object DDL	SQL object DDL
Cluster object DDL	X	X
SQL object DDL	X	O

The following DDL can not be simultaneously performed as given above.

- Cluster object DDL and cluster object DDL
  - (X) CREATE CLUSTER GROUP g2 CLUSTER MEMBER g2n1 HOST '192.168.0.21' PORT 10210;
  - (X) ALTER CLUSTER GROUP g1 ADD CLUSTER MEMBER g1n2 HOST '192.168.0.12' PORT 10120;
- Cluster object DDL and SQL object DDL
  - (X) CREATE CLUSTER GROUP g2 CLUSTER MEMBER g2n1 HOST '192.168.0.21' PORT 10210;
  - (X) CREATE TABLE t1 (c1 INTEGER);
- SQL object DDL and SQL object DDL
  - (O) CREATE TABLE t1 (c1 INTEGER);
  - (O) CREATE TABLE t2 (a1 INTEGER);

Processing SELECT in Cluster

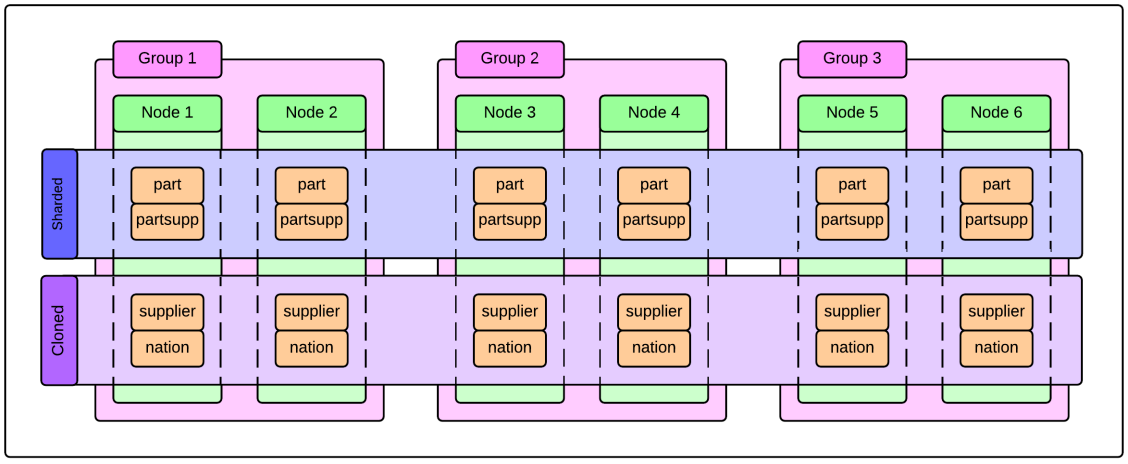
Generally, a query processing of the cluster is similar to that of the stand alone. However, when the data exist on both a local server and a remote server, it is different that the cluster requests the query processi ng to a remote server and receives the result from it.

There are a sharded table and a cloned table (refer to **Cluster Table and Shard**) in a cluster environment, and each table data is stored in a local server and a remote server. The sharded table data is dividedly stor ed in a group, and its duplicated data is stored in members of the same group. The data is duplicated and

stored in every group and member of a cloned table.

The following figure describes a 3 x 2 GOLDILOCKS cluster and tables stored in that cluster.

Figure 2 3 x 2 cluster configuration and tables



The following DDL creates the tables given above.

```
CREATE TABLE part
(
    p_partkey     INTEGER
  , p_name        VARCHAR(55)
  , p_brand       CHAR(10)
  , p_type        VARCHAR(25)
  , p_size        INTEGER
  , p_retailprice NUMERIC(12,2)
  , CONSTRAINT part_pk PRIMARY KEY( p_partkey ) INDEX part_pk_index
)
    SHARDING BY HASH(p_partkey)
    SHARD COUNT 3;
CREATE TABLE partsupp
(
    ps_partkey    INTEGER
  , ps_suppkey    INTEGER
  , ps_availqty   INTEGER
  , ps_supplycost NUMERIC(12,2)
  , CONSTRAINT partsupp_pk PRIMARY KEY( ps_partkey, ps_suppkey ) INDEX partsupp_pk_index
)
   SHARDING BY HASH(ps_partkey)
   SHARD COUNT 3;
CREATE TABLE supplier
(
```

```
    s_suppkey     INTEGER
  , s_name        CHAR(25)
  , s_nationkey   INTEGER
  , s_phone       CHAR(15)
  , CONSTRAINT supplier_pk PRIMARY KEY( s_suppkey ) INDEX supplier_pk_index
)  CLONED;
CREATE TABLE nation
(
    n_nationkey   INTEGER
  , n_name        CHAR(25)
)  CLONED;
```

In the figure above, the part table and the partsupp table is a sharded table, and their data are dividedly s tored per a group. The supplier table is a cloned table and its data is duplicated and stored in every node.

GOLDILOCKS in a cluster environment processes a query depending on the table type and the location of search target data. Cluster processes the query according to the method to collect the data and the meth od to manipulate the fetched data.

Query Processing Method in a Cluster

A cluster should collect data from both a local server and a remote server to process a query. It creates SQ L statement, delivers it to a local server and a remote server, then collects the results of query processing t o collect the data.

The data is manipulated according to the statement type of the collected data. For example, the cluster q uery for *group by* statement is processed by grouping after collecting the data.

Collecting and manipulating data is performed by the plan node called as a cluster puller.

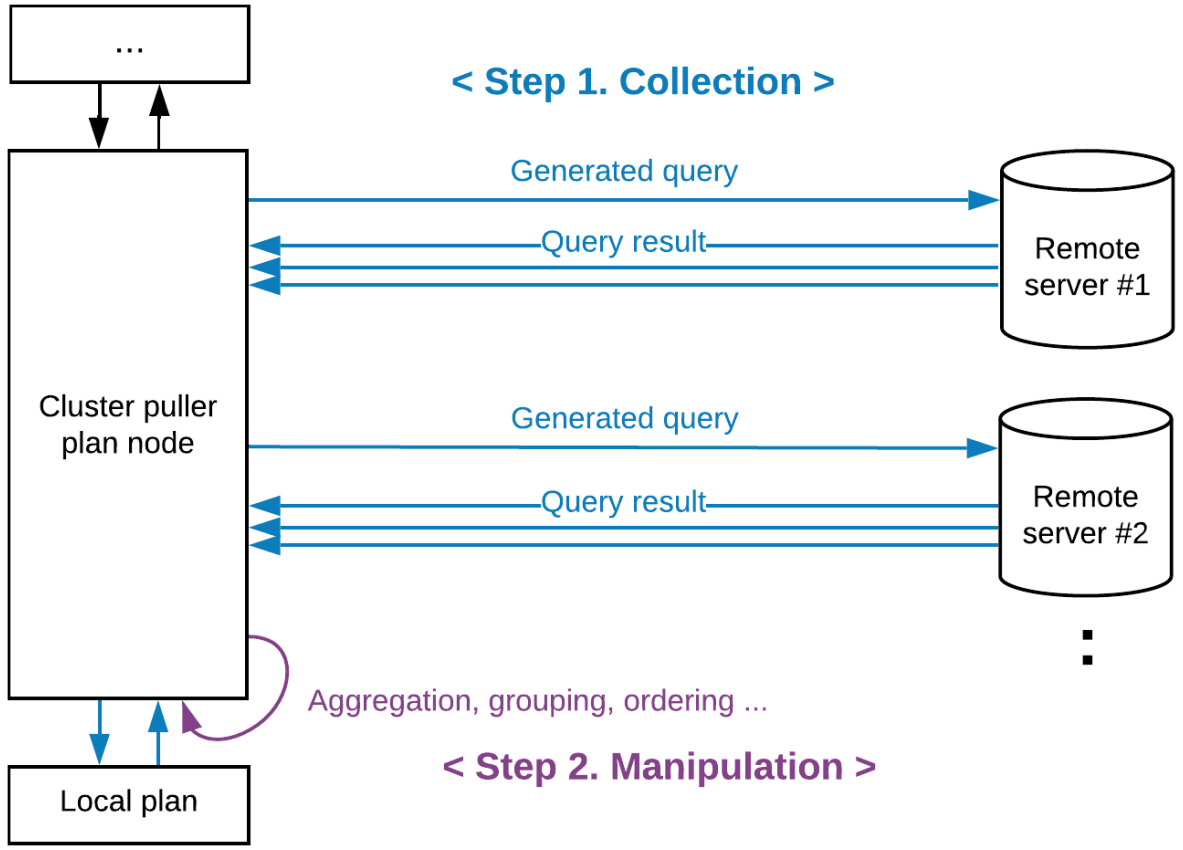
Cluster Puller

Cluster puller node collects and manipulates the data.

- The data collection is a process to collect the data from multiple servers.
- The data manipulation is a process to create a new data based on the collected data.

The following is a process to perform the cluster puller.

Figure 3 Performing cluster puller



A cluster puller is classified according to the data fetching method from a local server and whether to dist inguish a remote delivering server when fetching data from a remote server.

A cluster puller is divided into the following three plan nodes.

Table 12-7 Cluster puller node

Cluster puller node	How to collect the local data	How to collect the remote data
Plan based cluster	It performs a plan configured in t he local.	It performs a generated query. (It collects the result without distinguishing the re mote server)
Single cluster	It performs a generated query.	It performs a generated query. (It collects the result without distinguishing the re mote server)
Multiple cluster	It performs a generated query.	It perform a generated query. (It collects the result by distinguishing the remote s erver)

A generated query is configured to collect or update the data while performing a query provided by a use r. For more information, refer to **Generated Query**.

Those paragraphs below describes how to collect the data per each feature in available in each cluster pul ler node and how to manipulate the data.

How to Collect Data

- By pass: It collects the processed results in the delivered sequence.
- Merge sort: It sequentially collects the processed results according to the given order of sorting.

How to Manipulate the Collected Data

- No manipulation: It does not manipulate the data.
- Aggregation: It aggregate the collected data.
- Grouping: It groups the collected data.
- Ordering: It orders for the collected data.
- Intersect key group: It classifies the collected data based on the delivering server, and groups each ser ver data by a given key, then intersects them in group unit.
- Distinct key group: It classifies the collected data based on the delivering server, and groups each serv er data by a given key, then performs distinct on them in group unit.

Cluster Puller Feature

The cluster puller node collects data from a local server or a remote server. It determines the server from which to collect he data, then fetches data by transferring a generated query.

The following is an example of retrieving a single table without *where* condition.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1;
C1
--
 1
 2
 3
3 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |              ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                          |                 3 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |                 3 |
```

```
┆    2  ┆      PLAN BASED CLUSTER                    ┆ LOCAL/REMOTE     3 ┆
┆    3  ┆        INDEX ACCESS ("T_SHARD_1", "IDX")   ┆ (         1)     1 ┆
================================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."IDX" ) */ "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
     3  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : T_SHARD_1.C1
<<<  end print plan
```

After performing the query, a plan based cluster is used as cluster puller. The plan based cluster in the ex ecution plan above is a plan whose idx is 2 in <Execution Plan>.

The following information is output on ROWS field of the cluster puller.

- LOCAL ONLY n: The number of data fetched from a local server.
- REMOTE ONLY n: The number of data fetched from a remote server.
- LOCAL/REMOTE n: The total number of data fetched from a local server and a remote server.

The following is the detailed information about PLAN BASED CLUSTER.

- SQL: Generated query
- TARGET DOMAIN: The target group and the target member to transfer a generated query and the n umber of data fetched from the group

Selecting Target Server to Perform in Cluster Puller

It analyzes the following information and selects the target to perform a generated query.

- Table replication placement strategy
- **Cluster Domain**
- **Reducing Target Domain of Cluster Puller**

It analyzes the information listed above for each tables included in a generated query, and find a server in common, then selects it as a target server to perform the generated query. They are classified as target d omains on the cluster puller node.

The following is a summary of the replication placement strategy of defined tables to describe **Generated Query**.

```
t_shard_1 (shard table)  : at cluster group G1, G2, G3
t_shard_2 (shard table)  : at cluster group G1, G3
t_clone_1 (cloned table) : at cluster group G1, G2, G3 (cluster wide)
```

```
t_clone_2 (cloned table) : at cluster group G2, G3
```

The following is an example of selecting the execution target server according to the table replication pla cement strategy.

- Execution target server: All servers in G1, G3

```
gSQL> SELECT c1 FROM t_shard_2;
```

- Execution target server: All servers in G1, G2, G3

```
gSQL> SELECT c1 FROM t_clone_1;
```

- Execution target server: All servers in G1, G3 (Commonly included cluster group)

```
gSQL> SELECT c1 FROM t_shard_2, t_clone_1;
```

The following is an example of selecting the execution target server according the description of the clust er domain.

- Execution target server: All servers in G1, G2, G3

```
gSQL> SELECT c1 FROM t_shard_1@GLOBAL;
```

- Execution target server: The server to which the user query was requested

```
gSQL> SELECT c1 FROM t_shard_1@LOCAL;
```

- Execution target server: All servers in G2

```
gSQL> SELECT c1 FROM t_shard_1@G2;
```

- Execution target server: G3N1 server

```
gSQL> SELECT c1 FROM t_shard_1@G3N1;
```

- Execution target server: Target server does not exist

```
gSQL> SELECT c1 FROM t_shard_1@G4;
```

The following is an example of selecting the execution target server according the sharding key search co ndition.

- Execution target server: All servers in G1, G2, G3

```
gSQL> SELECT c1 FROM t_shard_1;
```

- Execution target server: All servers in G1, G2, G3

```
gSQL> SELECT c1 FROM t_shard_1 WHERE c1 = 1;
```

- Execution target server: All servers in G3

```
gSQL> SELECT c1 FROM t_shard_1 WHERE shard_key = 500;
```

- Execution target server: Target server does not exist

```
gSQL> SELECT c1 FROM t_shard_1 WHERE shard_key = 100 AND shard_key = 500;
```

It looks for servers in common through the table replication placement strategy and cluster domain, shard ing key searching strategy when performing the generated query searching for the data. If multiple server s in the same cluster group are targets to perform, then the generated query is performed for only one ac cessible server per each cluster group considering the network condition of when it is performed.

The following is an example of selecting a target server to perform.

- Table replication placement strategy: All servers in G1, G2, G3

- Cluster domain
- t_shard_1: All servers in G2
- t_clone_1: All servers in G1, G2, G3
- join: All servers in G1, G2, G3

- Sharding key searching strategy: All servers in G2

- Target servers to perform the generated query: A single server in G2

```
gSQL> \EXPLAIN PLAN ONLY SELECT * FROM t_shard_1@G2, t_clone_1 WHERE t_shard_1.shard_key =
300;
>>>  start print plan
< Execution Plan >
=================================================================
|  IDX  |  NODE DESCRIPTION                      |           ROWS |

             PHYSICAL FILTER : T_SHARD_1.SHARD_KEY = 300
     5  -  CLONED
           READ COLUMN : T_CLONE_1.C1
<<<  end print plan
```

Utilizing Cluster Puller

It selects a cluster puller node according to the data manipulation method. If the data manipulation is not required, then it can use a plan based cluster or a single cluster. If the ordering for the results are required, then it uses multiple clusters. The data collection method is determined according to the data manipulati on method.

Table 12-8 Features supported by cluster puller node

Cluster	How to collect the data	How to manipulate the data
Plan based cluster	By pass	No manipulation
Single cluster	By pass	No manipulation Aggregation Grouping
Multiple cluster	Merge sort	Ordering Grouping Intersect key group Distinct key group

Cluster Puller Plan Node

The cluster puller plan node is classified according to the data collection method from a local server and a remote server. For more information about the classification of cluster puller plan nodes according to the data collection, refer to **Cluster Puller Plan Node**.

Plan Based Cluster

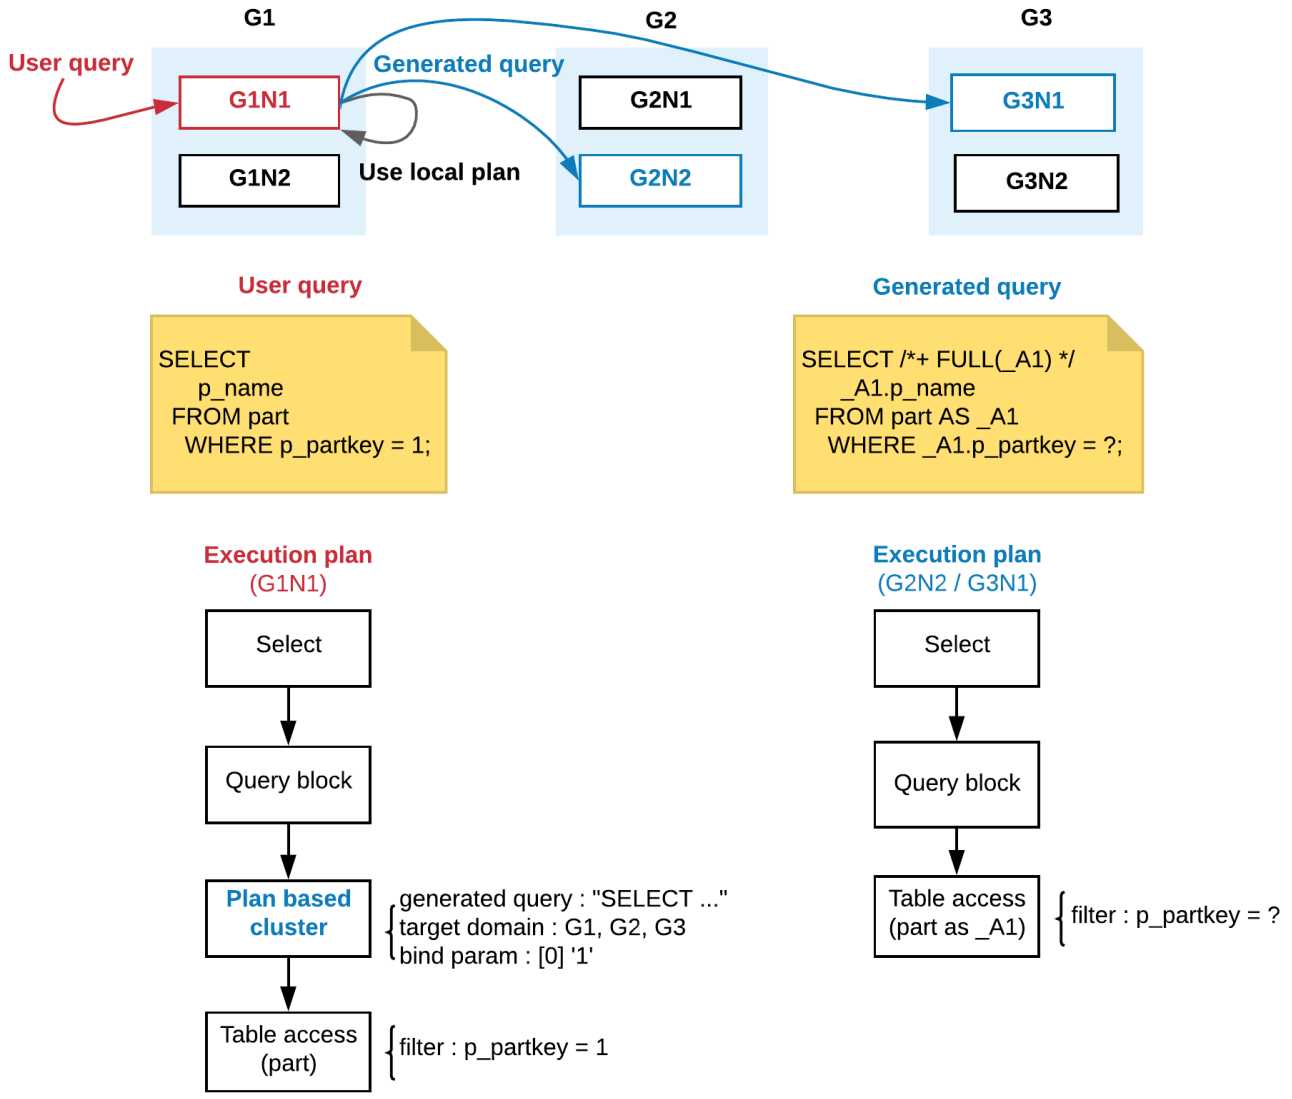
It collects the execution results in an order received from the data collection phase.

- Collecting local data: It performs the plan configured in local.
- Collecting remote data: It performs the generated query.

It does not manipulate anything except for applying a filter to the collected data. (No manipulation)

The following is an example of performing the plan based cluster.

Figure 4 Plan based cluster



Single Cluster

It collects the execution results in an order received from the data collection phase.

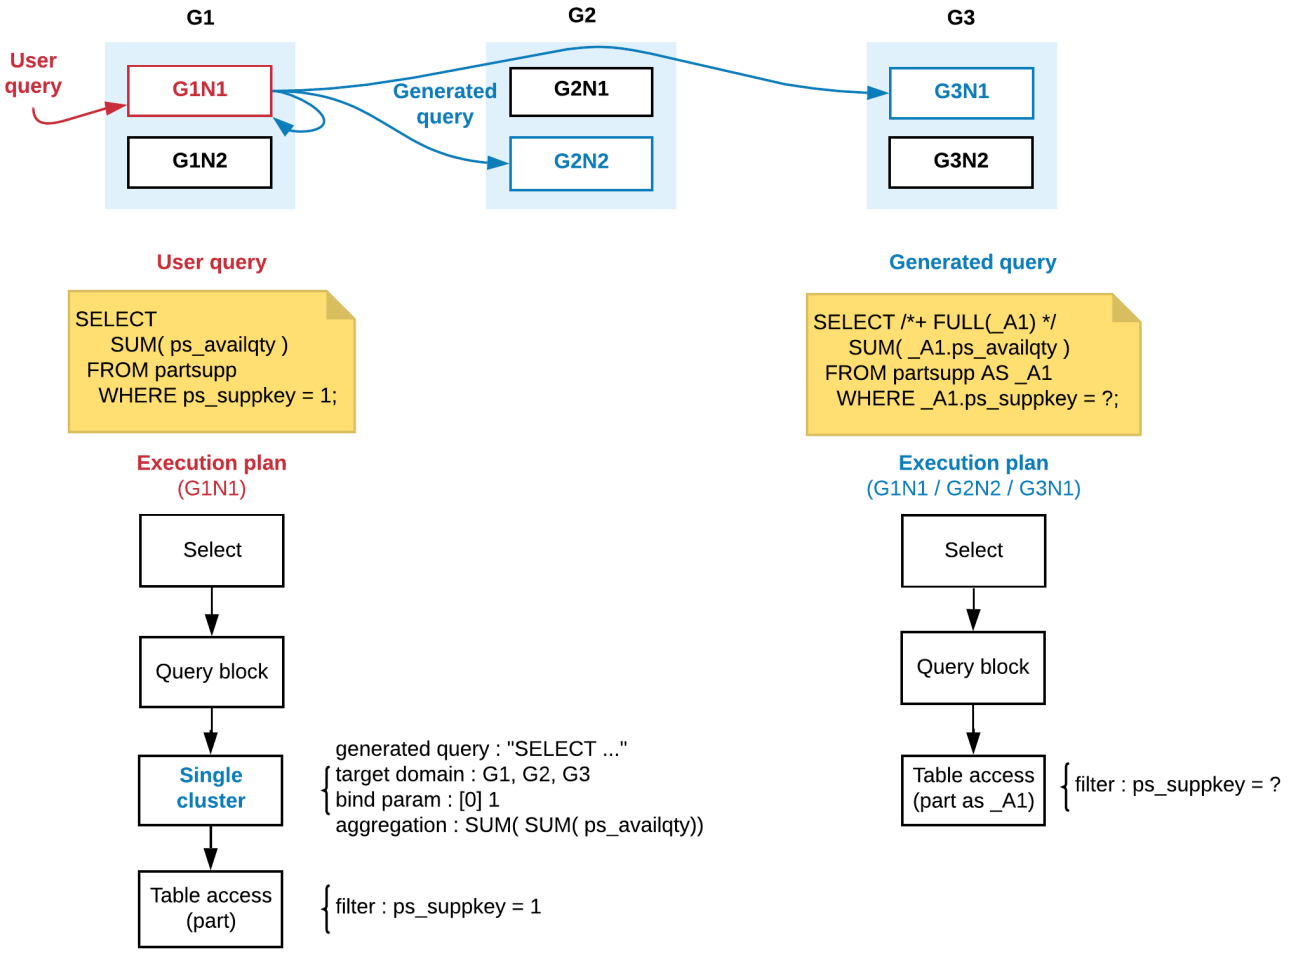
- Collecting local data: It performs the generated query.
- Collecting remote data: It performs the generated query.

A single cluster supports the following data manipulation methods.

- No manipulation
- Aggregation
- Grouping

The following is an example of performing a single cluster.

Figure 5 Single cluster



Multiple Clusters

Multiple clusters perform the generated query by using each different cluster executor per group. They co llect data by performing merge sort the data received with all cluster executors on the data collection pha se.

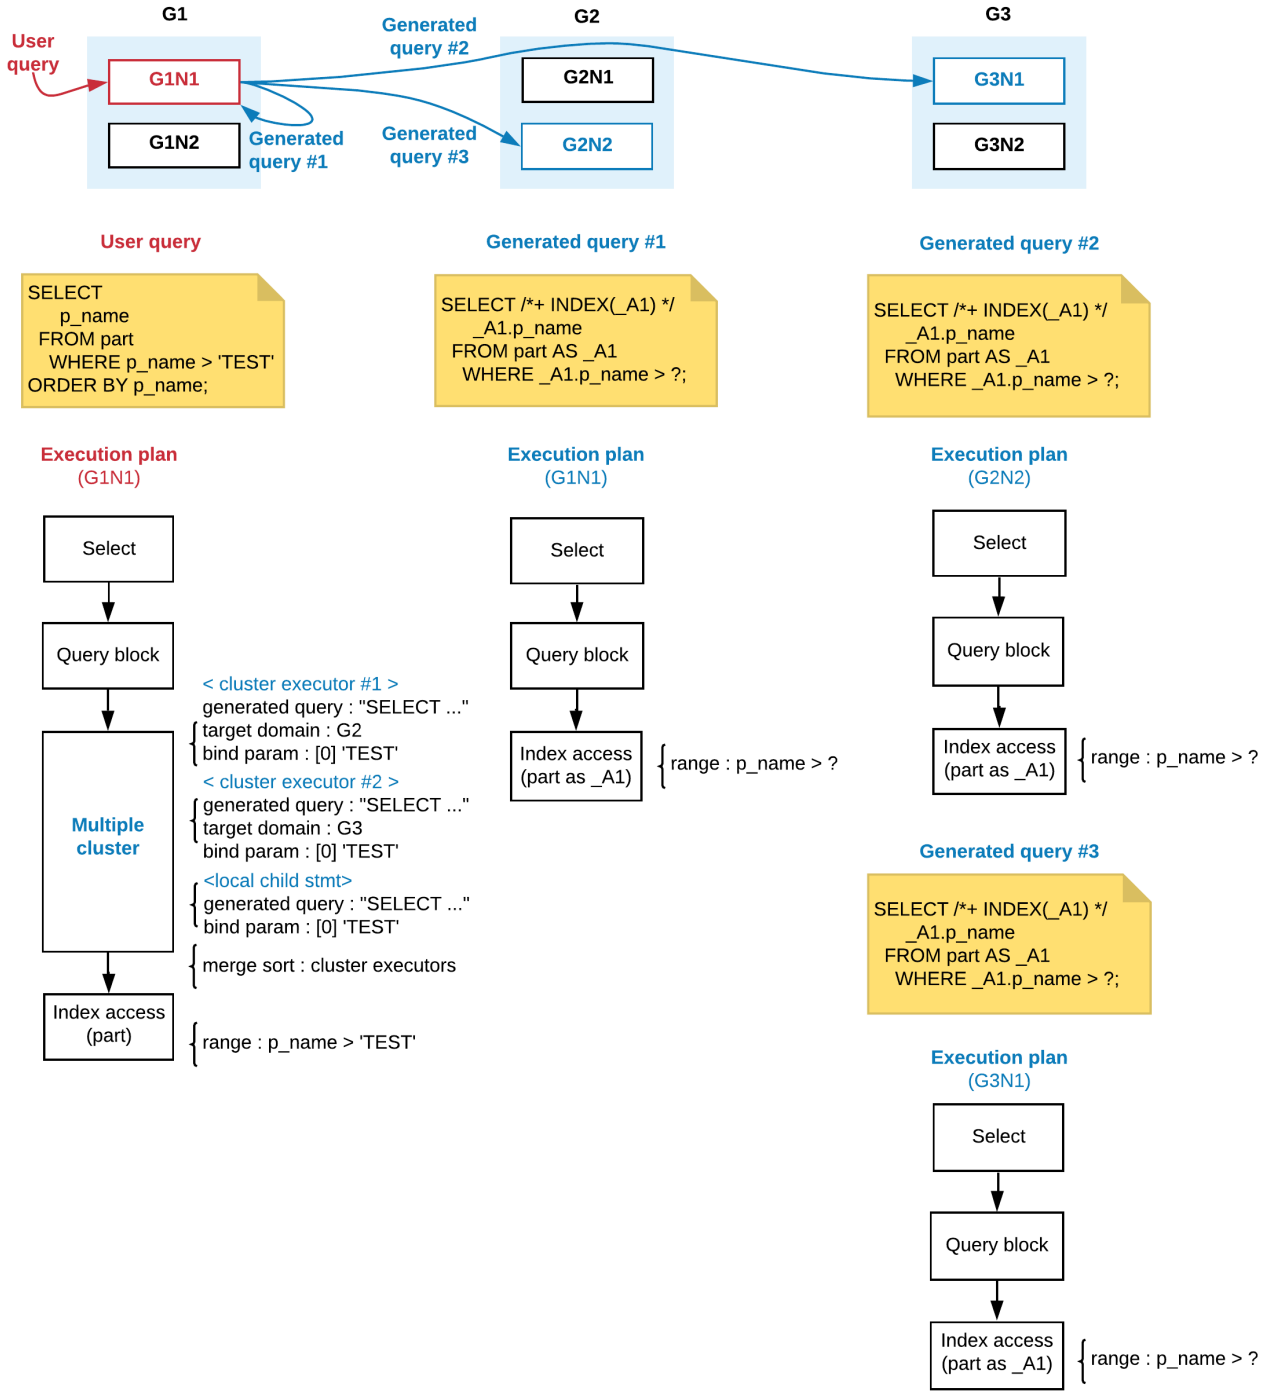
- Collecting local data: It performs the generated query.
- Collecting remote data: It performs the generated query.

Multiple clusters support the following data manipulation methods.

- Ordering
- Grouping
- Intersect key group
- Distinct key group

The following is an example of performing multiple clusters.

Figure 6 Multiple clusters



Cluster Domain

Cluster domain collects data only from limited servers in cluster environment. For example, if it queries as follows by setting the cluster group corresponding to employees in a specific range as a cluster domain, t hen it can find specific employees from the sharded table which consists of salary class.

- It configures a sharded table per a salary class.

```
gSQL> CREATE TABLE t1( name VARCHAR(128), salary INTEGER )
    SHARDING BY RANGE( salary )
        SHARD s1 VALUES LESS THAN ( 200 )       AT CLUSTER GROUP G1,
        SHARD s2 VALUES LESS THAN ( 400 )       AT CLUSTER GROUP G2,
        SHARD s3 VALUES LESS THAN ( MAXVALUE )  AT CLUSTER GROUP G3;
Table created.
gSQL> INSERT INTO t1 VALUES ( 'A', 500 );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 'B', 100 );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 'C', 300 );
1 row created.
```

- It searches for employees in a specific salary range.

```
gSQL> SELECT name, salary FROM t1@G2;
NAME SALARY
---- ------
C       300
1 row selected.
```

Cluster domain is defined by targeting a table or a view specified in **from clause** and referring to **〈cluster domain〉**, and one of the followings can be selected.

- Cluster member performing a user query
- Cluster member performing a user query targeting offline table
- All cluster groups
- A cluster group
- A cluster member

When a cluster member is selected as a cluster domain, then it access the corresponding server, then coll ects data. If the server does not have the data distribution for the target table, then the query result does not exist.

It supports *@LOCAL_OFFLINE* cluster domain to retrieve the offline table data from the server to which th

e user is connected. If the table is online, then an error occurs.

If a cluster group is selected as a cluster domain, then it has the data distribution for the corresponding ta ble in the group, and it collects data by accessing to a server which can communicate with. If an accessibl e server does not exist, then the query result does not exist.

If all cluster groups are selected as a cluster domain, then data from each cluster group are collected and transferred to a user.

A cluster domain can not be used to determine the data update target. In other words, <cluster domain> can not be applied to a target table of DML.

A cluster domain for a target table of DML causes a syntax error as follows.

```
gSQL> INSERT INTO t1@LOCAL VALUES ( 1 );
ERR-42000(16062): syntax error :
INSERT INTO t1@LOCAL VALUES ( 1 )
             *
ERROR at line 1:
gSQL> UPDATE t1@GLOBAL SET c1 = 1;
ERR-42000(16062): syntax error :
UPDATE t1@GLOBAL SET c1 = 1
         *
ERROR at line 1:
gSQL> DELETE FROM t1@G1;
ERR-42000(16062): syntax error :
DELETE FROM t1@G1
             *
ERROR at line 1:
```

A cluster domain for a target table of SELECT FOR UPDATE causes a syntax error as follows.

- Cluster domain for the data collection target

```
gSQL> SELECT c1 FROM t1@LOCAL;
I1
--
 1
1 row selected.
```

- Cluster domain for the data update target

```
gSQL> SELECT c1 FROM t1@LOCAL FOR UPDATE;
ERR-42000(16062): syntax error :
```

```
SELECT c1 FROM t1@LOCAL FOR UPDATE
                *
ERROR at line 1:
```

Reducing Target Domain of Cluster Puller

The methods to reduce the target domain to be processed by transferring a generated query are as follo ws.

- **Cluster Domain**: It reduces the target domain by specifying the domain.
- Shard key filter: It reduces the target domain by providing the sharding key condition.
- Rowinfo domain filter: It reduces the target domain by providing the pseudo column condition relate d to a table.

The combination of the shard key filter and the rowinfo domain filter are called as the domain filter.

The following is an example of retrieving a single table by specifying the retrieving target domain in the t able.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1@G2;
C1
--
 2
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |              ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                          |                 1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |                 1 |
|    2  |      PLAN BASED CLUSTER                    | REMOTE ONLY     1 |
|    3  |        INDEX ACCESS ("T_SHARD_1", "IDX")   | (         0)    0 |
================================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."IDX" ) */ "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
           TARGET DOMAIN : G2(G2N1,G2N2) 1 rows
     3  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : T_SHARD_1.C1
<<<  end print plan
```

When the retrieving target domain is specified, then TARGET DOMAIN is reduced to G2 as in the exampl

e above. For more information about domain, refer to **Cluster Domain**.

The following is an example of restricting TARGET DOMAIN by adding the shard key condition on where clause.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 WHERE shard_key = 555;
C1
--
 3
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                      ¦                ROWS ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                      ¦                   1 ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")          ¦                   1 ¦
¦    2  ¦      PLAN BASED CLUSTER               ¦ REMOTE ONLY       1 ¦
¦    3  ¦        TABLE ACCESS ("T_SHARD_1")     ¦                   0 ¦
================================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."C1" FROM "PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
WHERE "_A1"."SHARD_KEY" = :_V0
           TARGET DOMAIN : G3(G3N1,G3N2) 1 rows
     3  -  RANGE SHARD ( # 3 )
           READ COLUMN : T_SHARD_1.SHARD_KEY, T_SHARD_1.C1
             PHYSICAL FILTER : T_SHARD_1.SHARD_KEY = 555
<<<  end print plan
```

When the shard key condition which has a constant value is added, then TARGET DOMAIN is reduced as i n the example above.

The retrieving target group can be restricted by using the shard key condition. The shard key condition w hich has a constant value can determine the retrieving target while configuring the plan. The shard key c ondition which is not a constant value determines the retrieving target group at the time of executing the query.
In other words, adding the shard key condition which is not a constant value does not reduce TARGET D OMAIN. Instead, SHARD KEY FILTER condition which is the information to determine the domain is confi gured at the time of executing the query.

The following is an example of restricting TARGET DOMAIN by adding the shard key condition which is n ot a constant value to where clause.

```
gSQL> VAR V1 INTEGER
gSQL> EXEC :V1 := 555
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 WHERE shard_key = :V1;
C1
--
 3
1 row selected.
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                      ¦                ROWS ¦
-----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                      ¦                   1 ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")          ¦                   1 ¦
¦    2  ¦      PLAN BASED CLUSTER               ¦ REMOTE ONLY       1 ¦
¦    3  ¦        TABLE ACCESS ("T_SHARD_1")     ¦                   0 ¦
=============================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."C1" FROM "PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
WHERE "_A1"."SHARD_KEY" = :_V0
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G2(G2N1,G2N2) 0 rows, G3(G3N1,G3N2) 1 rows
             SHARD KEY FILTER : ( T_SHARD_1.SHARD_KEY = :V1 )
     3  -  RANGE SHARD ( # 3 )
           READ COLUMN : T_SHARD_1.SHARD_KEY, T_SHARD_1.C1
             PHYSICAL FILTER : T_SHARD_1.SHARD_KEY = :V1
<<<  end print plan
```

TARGET DOMAIN can also be reduced by providing the **Pseudo Columns** condition related to the table. It can be used as a domain filter only when using equal (=) condition for the pseudo column.

Table 12-9 Pseudo column which can be used as the domain filter

Pseudo column	Whether to use the pseudo column as the domain filter
CURRVAL	Not available
NEXTVAL	Not available
ROWNUM	Not available
ROWID	Available
CLUSTER_GROUP_ID	Available
CLUSTER_MEMBER_ID	Available
CLUSTER_GROUP_NAME	Available
CLUSTER_NAME_ID	Available
CLUSTER_SHARD_ID	Available

The following is an example of restricting TARGET DOMAIN by adding the pseudo column condition.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 WHERE cluster_group_name = 'G3';
C1
--
 3
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |                ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                          |                   1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |                   1 |
|    2  |      PLAN BASED CLUSTER                    | REMOTE ONLY       1 |
|    3  |        INDEX ACCESS ("T_SHARD_1", "IDX")   | (         0)      0 |
================================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."IDX" ) */ "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1" WHERE "_A1"."CLUSTER_GROUP_NAME" = :_V0
           TARGET DOMAIN : G3(G3N1,G3N2) 1 rows
     3  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : T_SHARD_1.C1
             LOGICAL KEY FILTER : T_SHARD_1.CLUSTER_GROUP_NAME = 'G3'
<<<  end print plan
```

The pseudo column condition using the constant value reduces TARGET DOMAIN.

The following is an example of using the pseudo column condition which is not a constant value.

```
gSQL> VAR V1 VARCHAR( 10 )
gSQL> EXEC :V1 := 'G3N1'
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 WHERE cluster_member_name = :V1;
C1
--
 3
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |                ROWS |
--------------------------------------------------------------------------------
```

```
┆    0  ┆  SELECT STATEMENT                          ┆                 1 ┆
┆    1  ┆    QUERY BLOCK ("$QB_IDX_2")               ┆                 1 ┆
┆    2  ┆      PLAN BASED CLUSTER                    ┆ REMOTE ONLY     1 ┆
┆    3  ┆        INDEX ACCESS ("T_SHARD_1", "IDX")   ┆ (       0)      0 ┆
=============================================================================
     1  -  TARGET : T_SHARD_1.C1
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."IDX" ) */ "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1" WHERE "_A1"."CLUSTER_MEMBER_NAME" = :_V0
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G2(G2N1,G2N2) 0 rows, G3(G3N1,G3N2) 1 rows
             ROWINFO DOMAIN FILTER : T_SHARD_1.CLUSTER_MEMBER_NAME = :V1
     3  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : T_SHARD_1.C1
             LOGICAL KEY FILTER : T_SHARD_1.CLUSTER_MEMBER_NAME = :V1
<<<  end print plan
```

Adding the pseudo column condition which is not a constant value does not reduce TARGET DOMAIN. In stead, ROWINFO DOMAIN FILTER condition which is the information to determine the domain is configur ed at the time of execution.

Generated Query

The generated query is generated to refer to or to update the data in another server when processing a q uery given by a user.

```
SELECT c1 FROM t1;
```

When the query is given by a user as above, then the server to which the query is given generates a simila r generated query to collects the t1 data from all related cluster groups as follows.

```
SELECT c1 FROM t1@LOCAL;
```

The following example table is configured to describe the generated query.

```
CREATE TABLE t_shard_1( shard_key INTEGER, c1 INTEGER )
    SHARDING BY RANGE( shard_key )
        SHARD s1 VALUES LESS THAN ( 200 )       AT CLUSTER GROUP G1,
        SHARD s2 VALUES LESS THAN ( 400 )       AT CLUSTER GROUP G2,
        SHARD s3 VALUES LESS THAN ( MAXVALUE )  AT CLUSTER GROUP G3;
CREATE TABLE t_shard_2( shard_key INTEGER, c1 INTEGER )
    SHARDING BY RANGE( shard_key )
        SHARD s1 VALUES LESS THAN ( 300 )       AT CLUSTER GROUP G1,
        SHARD s2 VALUES LESS THAN ( MAXVALUE )  AT CLUSTER GROUP G3;
```

```
CREATE TABLE t_clone_1( c1 INTEGER ) CLONED AT CLUSTER WIDE;
CREATE TABLE t_clone_2( c1 INTEGER ) CLONED AT CLUSTER GROUP G2, G3;
```

The generated query is a query which was configured again based on the cluster puller plan node.

Each cluster puller plan node configures the generated query for **data collection method** according to **Util izing Cluster Puller**.

Generated Query for No Manipulation

When the collected data is not manipulated, then the plan based cluster or the single cluster is used as th e cluster puller plan node.

The generated query is configured and output on the explain plan result for the cluster puller plan node which does not manipulate the data, but the information about manipulation is not output.

The following is an example of no manipulation using the plan based cluster.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1;
C1
--
 1
 3
 2
3 rows selected.
>>>  start print plan
< Execution Plan >

```

Generated Query for Aggregation

The generated query for aggregation supports aggregation per each group. It aggregates the data collect ed through the generated query again, then configures the final result.

Table 12-10 How to manipulate aggregation data

Aggregation in user query	Operation form included in the generated query	Operation for the aggregation result
COUNT()	COUNT()	SUM(COUNT())
SUM()	SUM()	SUM(SUM())
AVG()	COUNT(), SUM()	SUM(SUM()) / SUM(COUNT())
MIN()	MIN()	MIN(MIN())
MAX()	MAX()	MAX(MAX())

The generated query configures a query including COUNT operation to process COUNT operation of the user query. It gathers the data collected through the generated query, and accumulates COUNT results p er each group. The accumulated value of COUNT result for every group becomes the result of user COUN T operation.

The following is an example of an aggregation using a single cluster.

```
gSQL> \EXPLAIN PLAN SELECT COUNT( c1 ) FROM t_shard_1;
COUNT( C1 )
-----------
          3
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                              |            ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                              |               1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |               1 |
|    2  |      SINGLE CLUSTER                            | LOCAL/REMOTE  1 |
|    3  |        SELECT STATEMENT                        |               1 |
|    4  |          QUERY BLOCK ("$QB_IDX_2")             |               1 |
|    5  |            TABLE ACCESS ("T_SHARD_1" AS _A1)   |               1 |
================================================================================
```

```
     1  -  TARGET : COUNT( T_SHARD_1.C1 )
     2  -  SQL : SELECT /*+ FULL( _A1 ) */ COUNT( "_A1"."C1" ) FROM "PUBLIC"."T_SHARD_1"@LOCAL
AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
           RE-AGGREGATION
             AGGREGATION : SUM( COUNT( T_SHARD_1.C1 ) )
     4  -  TARGET : COUNT( _A1.C1 )
     5  -  RANGE SHARD ( # 3 )
           READ COLUMN : _A1.C1
           AGGREGATION : COUNT( _A1.C1 )
<<<  end print plan
```

When DISTINCT is specified in the aggregation operation as if COUNT(DISTINCT c1), then the generated query including the aggregation can not be configured, and the cluster puller plan node does not support the data manipulation related to the aggregation.

The following is an example of COUNT(DISTINCT) operation.

```
gSQL> \EXPLAIN PLAN SELECT COUNT( DISTINCT c1 ) FROM t_shard_1;
COUNT( DISTINCT C1 )
--------------------
                   3
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                              |            ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                              |               1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |               1 |
|    2  |      AGGREGATION BY HASH                       |               1 |
|    3  |        PLAN BASED CLUSTER                      | LOCAL/REMOTE  3 |
|    4  |          TABLE ACCESS ("T_SHARD_1")            |               1 |
================================================================================
     1  -  TARGET : COUNT( DISTINCT T_SHARD_1.C1 )
     2  -  DISTINCT AGGREGATION : COUNT( DISTINCT T_SHARD_1.C1 )
     3  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."C1" FROM "PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
     4  -  RANGE SHARD ( # 3 )
           READ COLUMN : T_SHARD_1.C1
<<<  end print plan
```

When the aggregation including DISTINCT is used, the generated query of the cluster puller does not include the aggregation. The data collected by the cluster puller performs the aggregation operation through separate plan node.

Generated Query for Grouping

The generated query for grouping performs grouping per each group. It groups the data collected through the generated query again.

HAVING condition is applied after the grouping is completed on the cluster puller plan node.

The following is an example of grouping on the cluster puller plan node.

```
gSQL> \EXPLAIN PLAN SELECT COUNT( c1 ) FROM t_shard_1 AS A GROUP BY c1 HAVING MIN( shard_key )
> 1;
COUNT( C1 )
-----------
          1
          1
          1
3 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                              |            ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                              |               3 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |               3 |
|    2  |      SINGLE CLUSTER                            | LOCAL/REMOTE  3 |
|    3  |        SELECT STATEMENT                        |               1 |
|    4  |          QUERY BLOCK ("$QB_IDX_2")             |               1 |
|    5  |            GROUP HASH INSTANT                  |               1 |
|    6  |              TABLE ACCESS ("T_SHARD_1" AS _A1) |               1 |
================================================================================
     1  -  TARGET : COUNT( A.C1 )
     2  -  SQL : SELECT /*+ USE_GROUP_HASH(100) FULL( _A1 ) */ "_A1"."C1", MIN(
"_A1"."SHARD_KEY" ), COUNT( "_A1"."C1" ) FROM "PUBLIC"."T_SHARD_1"@LOCAL AS "_A1" GROUP BY
"_A1"."C1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
           RE-GROUPING
             GROUP KEY : A.C1
             AGGREGATION : MIN( MIN( A.SHARD_KEY ) ), SUM( COUNT( A.C1 ) )
             PHYSICAL FILTER : MIN( A.SHARD_KEY ) > 1
```

```
     4  -  TARGET : _A1.C1, MIN( _A1.SHARD_KEY ), COUNT( _A1.C1 )
     5  -  GROUP KEY : _A1.C1
           RECORD COLUMN : MIN( _A1.SHARD_KEY ), COUNT( _A1.C1 )
           READ KEY COLUMN : _A1.C1
           READ RECORD COLUMN : MIN( _A1.SHARD_KEY ), COUNT( _A1.C1 )
     6  -  RANGE SHARD ( # 3 )
           READ COLUMN : _A1.SHARD_KEY, _A1.C1
<<<  end print plan
```

The cluster puller plan node is determined according to **data collection method** grouped per group. Whe n the data is collected in the way of by pass, a single cluster is used. When the data is collected in the way of merge sort, multiple clusters are used.

When using the preserved order of the subordinate node of the cluster puller plan node for grouping, the data is collected in the way of merge sort .

The following is an example of grouping which uses a single cluster.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 AS A GROUP BY c1;
C1
--
 1
 2
 3
3 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
| IDX | NODE DESCRIPTION                                |            ROWS |
--------------------------------------------------------------------------------
|   0 | SELECT STATEMENT                                |               3 |
|   1 |  QUERY BLOCK ("$QB_IDX_2")                      |               3 |
|   2 |   SINGLE CLUSTER                                | LOCAL/REMOTE  3 |
|   3 |    SELECT STATEMENT                             |               1 |
|   4 |     QUERY BLOCK ("$QB_IDX_2")                   |               1 |
|   5 |      GROUP                                      |               1 |
|   6 |       INDEX ACCESS ("T_SHARD_1" AS _A1, "IDX") | (      1)     1 |
================================================================================
     1  -  TARGET : A.C1
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."IDX" ) */ "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1" GROUP BY "_A1"."C1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
```

```
          RE-GROUPING
            GROUP KEY : A.C1
     4  -  TARGET : _A1.C1
     5  -  GROUP KEY : _A1.C1
     6  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : _A1.C1
<<<  end print plan
```

The grouping which uses a single cluster can get the grouping result after all data is collected.

The following is an example of grouping which uses multiple clusters.

```
gSQL> \EXPLAIN PLAN SELECT /*+ MERGE_GROUP */ c1 FROM t_shard_1 AS A GROUP BY c1;
C1
--
 1
 2
 3
3 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================

     6  -  RANGE SHARD ( # 3 )
```

```
           READ INDEX COLUMN : _A1.C1
<<<  end print plan
```

The grouping which uses multiple clusters can get the grouping result after the data collection per grouping key is completed.

However, if all sharding keys are used as a grouping condition, then the cluster puller using no manipulation is configured. The cluster puller configures the generated query including grouping, and transfers the result to the superordinate plan without manipulating the collected data.

The following is an example of grouping with no manipulation when a user query includes GROUP BY statement.

```
gSQL> \EXPLAIN PLAN SELECT shard_key FROM t_shard_1 AS A GROUP BY shard_key;
SHARD_KEY
---------
      111
      555

Generated Query for Ordering

The generated query for ordering performs ordering per each group. It orders the data collected through the generated query again, then configures the result.

The data collection for ordering is supported by the merge sort method. The merge sort method uses mul tiple clusters.

The following is an example of processing the ordering by using the preserved order in multiple clusters.

```
gSQL> \EXPLAIN PLAN SELECT c1 FROM t_shard_1 ORDER BY c1;
C1

Generated Query for Intersect Key Group

The intersect key group evaluation determines whether it received the same data from all groups.

It is not applied to all collected data. The intersect is applied only when key group values are same and all of nil expression values are null.

If nil expression value is not null, then the result is configured without evaluating the intersect key group.

If all nil expression values are null, then it configures the intersect key group result only when it received t

he same data from all groups.

The generated query for the intersect key group is ordered in an order of the key group. The data collecte d through the generated query is ordered again in an order of the key group. The intersect key group is a pplied to the sorted data according to the nil expression value.

The following is an example of processing the intersect key group in multiple clusters.

```
gSQL> \EXPLAIN PLAN
      SELECT /*+ REMOTE_JOIN( t_clone_1 ) */ t_clone_1.c1, t_shard_1.c1
        FROM t_clone_1
             LEFT OUTER JOIN
             t_shard_1
             ON t_clone_1.c1 = t_shard_1.c1;

Generated Query for Distinct Key Group

The distinct key group evaluation determines whether it received the same data from two or more groups.

Distinct is applied when the key group values are same and the data was received from each group. Disti nct is not applied to the data from the same group.

The generated query for the distinct key group is ordered in an order of the key group. The data collected through the generated query is ordered again in an order of the key group. The distinct key group is appli ed to the sorted data according to the received group.

The following is an example of processing the distinct key group in multiple clusters.

```
gSQL> \EXPLAIN PLAN
      SELECT t_clone_1.c1
        FROM t_clone_1
       WHERE t_clone_1.c1 IN ( SELECT /*+ REMOTE_UNNEST */ t_shard_1.c1 FROM t_shard_1 );

Constraints of Generated Query Configuration

The generated query configuration is constrained in the following cases.

- **Offset & limit**
- **Using non-deterministic expression**

- **When unable to unnest subquery**

Offset & limit

The information about **offset limit clause** is not included in a generated query.

- The generated query does not include the offset information.

```
gSQL> \EXPLAIN PLAN ONLY SELECT c1 FROM t_shard_1 OFFSET 1;

When unable to unnest subquery

A subquery which can be made into a constant is included in the generated query in a bind para meter form.
A subquery which can not be made into a constant is not included in the generated query.

For more information about unnesting a subquery, refer to **Subquery**.

- The generated query can not include the unnested subquery.
- The subquery is processed on the cluster puller node or the superordinate node.

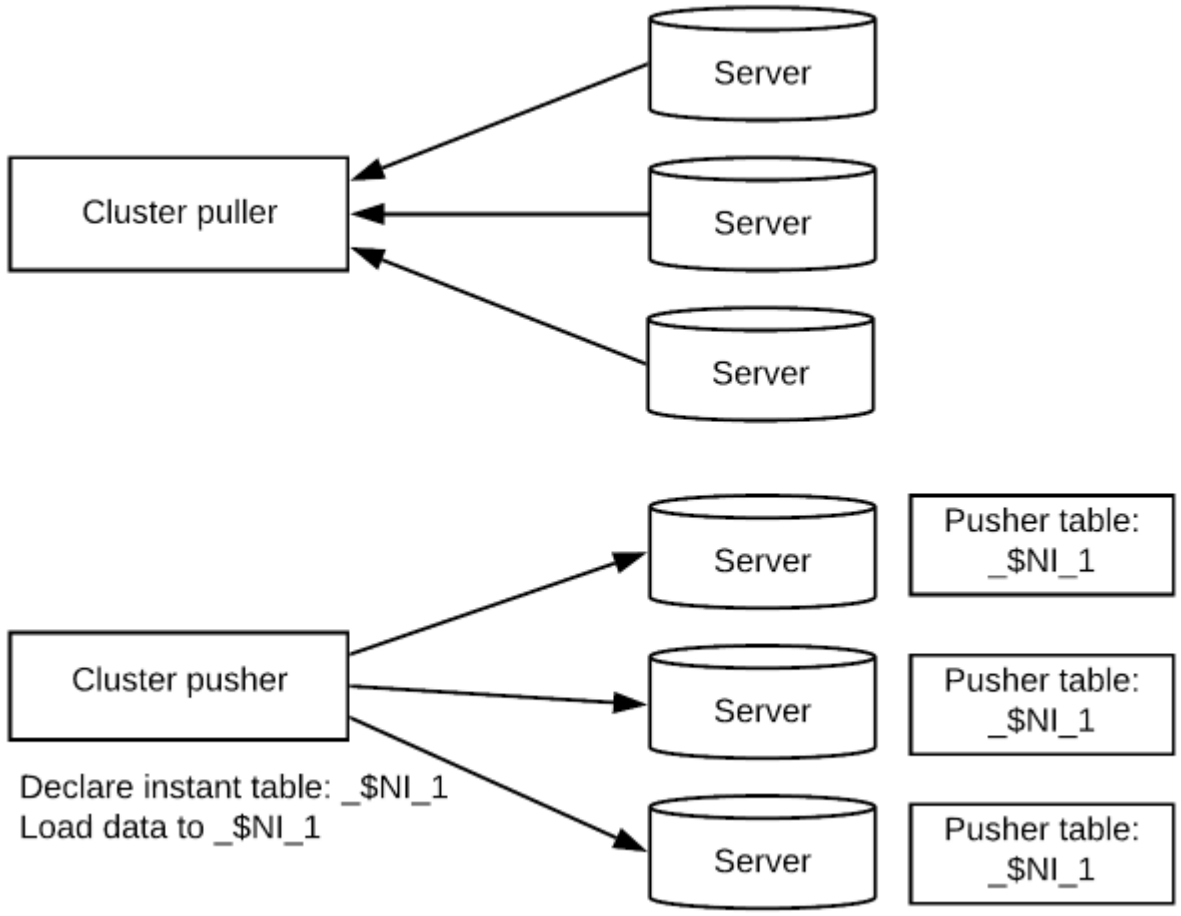
Cluster Pusher

The cluster pusher node creates and manages a virtual table for the efficient query process of the cluster puller node.

Figure 7 Cluster puller vs cluster pusher

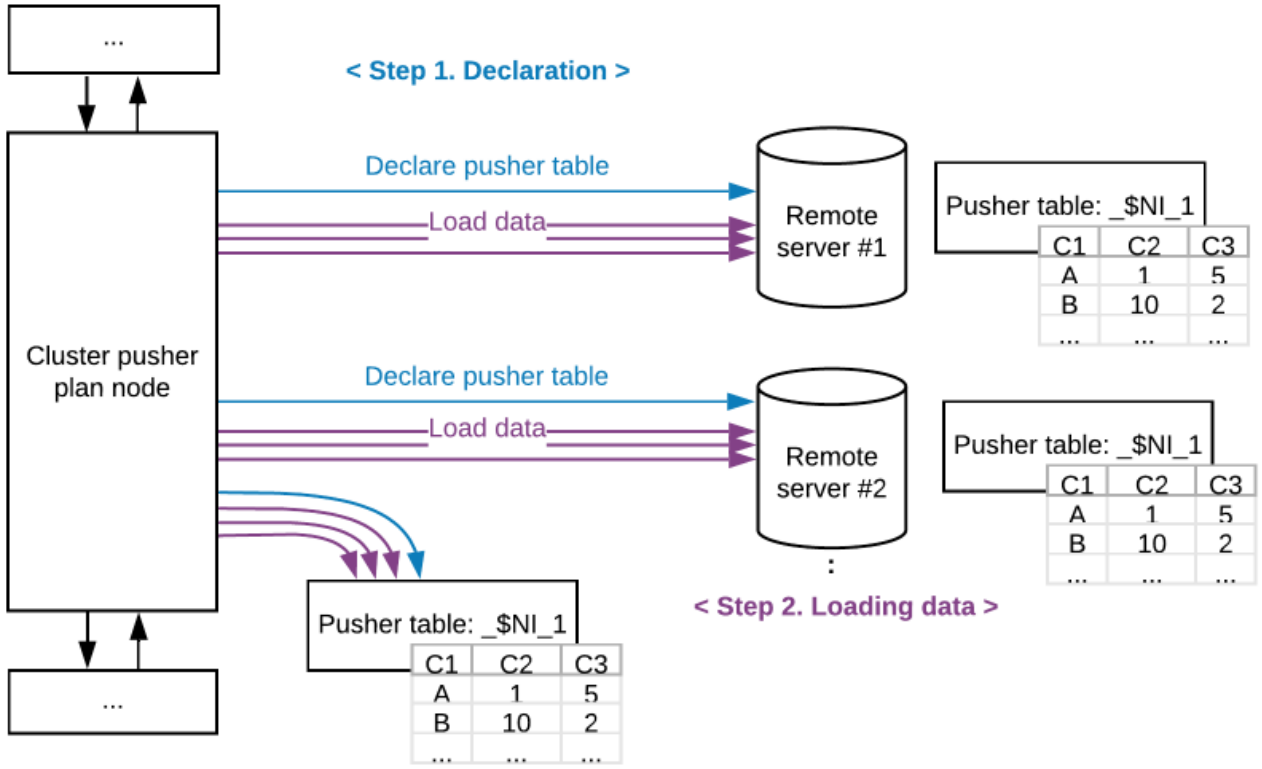


The cluster puller node collects the data. The cluster pusher node distributes the data in a new table form.

The cluster pusher node declares a pusher table and loads the data.

- Declaring pusher table: It creates an instant table in a local server and a remote server.
- Loading data: It loads the data received from the subordinate node of the cluster pusher node on the pusher table.

Figure 8 Performing cluster pusher



The following is an example of using the cluster pusher.

```
gSQL> \EXPLAIN PLAN ONLY
      SELECT A.c1
        FROM t_shard_1 AS A, t_shard_1 AS B
       WHERE A.shard_key = B.c1;
>>>  start print plan
< Execution Plan >

             HASH FILTER : _$NI_7.C1 = A.SHARD_KEY
<<<  end print plan
```

In the execution plan above, the plan whose idx of <Execution Plan> is 3 is the cluster pusher.

The pusher table name is output on NODE DESCRIPTION of the cluster pusher.

The detailed information about CLUSTER PUSHER is as follows.

- SQL: It is a query declaring a pusher table.
- COLUMN: It is an original expression per each column of the pusher table.
- SHARDED: They are columns of a pusher table used based on the pusher table data distribution.
- TARGET DOMAIN: It is the member and group to configure the pusher table, and the number of dat a transferred that group.

Pusher Table

The pusher table is an instant table in user query unit which is configured by the query processor to effici ently use the cluster puller. It is used to build the collected data in the driver server in a relation form.

The configured pusher table can be referred from the generated query like as a general table.

The following is an example of performing the join query which does not use the pusher table.

```
gSQL> \EXPLAIN PLAN
      SELECT /*+ LOCAL_JOIN( t_shard_1 ) */ t_shard_1.c1
        FROM t_shard_1, t_shard_2
       WHERE t_shard_1.shard_key = t_shard_2.shard_key;

     1  -  TARGET : T_SHARD_1.C1
     2  -  JOINED COLUMN : T_SHARD_1.C1
     3  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."SHARD_KEY", "_A1"."C1" FROM
"PUBLIC"."T_SHARD_1"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
     4  -  RANGE SHARD ( # 3 )
           READ COLUMN : T_SHARD_1.SHARD_KEY, T_SHARD_1.C1
     5  -  HASH KEY : T_SHARD_2.SHARD_KEY
           READ KEY COLUMN : T_SHARD_2.SHARD_KEY
             HASH FILTER : T_SHARD_2.SHARD_KEY = T_SHARD_1.SHARD_KEY
     6  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."SHARD_KEY" FROM "PUBLIC"."T_SHARD_2"@LOCAL
AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G3(G3N1,G3N2) 2 rows
     7  -  RANGE SHARD ( # 4 )
           READ COLUMN : T_SHARD_2.SHARD_KEY
<<<  end print plan
```

Two cluster puller plans are used when performing the join as given above. It is because a single generate d query can not process the join for two tables with each different sharding strategy.

The following is an example of performing the join query by using the pusher table.

```
gSQL> \EXPLAIN PLAN
SELECT /*+ REMOTE_JOIN( t_shard_1 ) */ t_shard_1.c1
  FROM t_shard_1, t_shard_2
 WHERE t_shard_1.shard_key = t_shard_2.shard_key;

<<<  end print plan
```

The generated query of the cluster puller configured in the execution result above includes the join.

CLUSTER PUSHER which is configured under SINGLE CLUSTER defines the pusher table "_$NI_7" through DECLARE statement.

The data collected from table t_shard_2 in CLUSTER PUSHER are distributed to the pusher table in a local server and a remote server by using the sharding strategy of t_shard_1. The join for those two tables can be processed by expressing them as a single generated query, because t_shard_1 and pusher table use th e same sharding strategy.

The pusher table has following features.

- It declares the pusher table on the cluster pusher plan node, and loads the data.
- It is configured as a table included in SESSION_SCHEMA.
- It can not configure an index.
- Multiple pusher tables can be configured in a single user query.
- Pusher tables are not shared among user queries.
- The performance cycle of the user query and the management cycle of the pusher table are same.
- The pusher table configured in each server has either a replicated data or a distributed data.

Pusher Table Configured with Replicated Data

The data configuration of the pusher table varies upon performing the cluster puller.

The pusher table configured to process the outer join as given below processes the generated query inclu ding the outer join with all servers having the same data for t_shard_2.

```
gSQL> \EXPLAIN PLAN ONLY
      SELECT A.c1
```

```
        FROM t_shard_1 AS A LEFT OUTER JOIN t_shard_2 AS B ON A.c1 = B.c1;
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                    |      ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                    |         0 |

|    6  |        HASH JOIN (INVERTED LEFT OUTER JOIN)          |         0 |
|    7  |          PUSHER TABLE ACCESS ("_$NI_5")              |         0 |
|    8  |          HASH JOIN INSTANT                           |         0 |
|    9  |            INDEX ACCESS ("T_SHARD_1" AS A, "IDX")    |         0 |
================================================================================
     1  -  TARGET : A.C1
     2  -  SQL : SELECT /*+ KEEP_JOINED_TABLE USE_HASH_IN( _A1, 100 ) FULL( _A2 ) INDEX( _A1,
"PUBLIC"."IDX" ) */ "_A1"."C1" FROM (
"PUBLIC"."T_SHARD_1"@"G1N1"¦"G1N2"¦"G2N1"¦"G2N2"¦"G3N1"¦"G3N2" AS "_A1" LEFT OUTER JOIN
"SESSION_SCHEMA"."_$NI_5"@LOCAL AS "_A2" ON "_A1"."C1" = "_A2"."C1") ALIAS "_A3"
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G2(G2N1,G2N2) 0 rows, G3(G3N1,G3N2) 0 rows
     3  -  SQL : DECLARE INSTANT TABLE "SESSION_SCHEMA"."_$NI_5" ( "C1" NUMBER(10, 0) )
           COLUMN : B.C1 AS C1
           CLONED
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G2(G2N1,G2N2) 0 rows, G3(G3N1,G3N2) 0 rows
     4  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."C1" FROM "PUBLIC"."T_SHARD_2"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G3(G3N1,G3N2) 0 rows
     5  -  RANGE SHARD ( # 4 )
           READ COLUMN : B.C1
     6  -  JOINED COLUMN : A.C1
     8  -  HASH KEY : A.C1
           READ KEY COLUMN : A.C1
             HASH FILTER : A.C1 = _$NI_5.C1
     9  -  RANGE SHARD ( # 3 )
           READ INDEX COLUMN : A.C1
<<<  end print plan
```

The pusher table configured with the replicated data is output as CLONED as the result above.

Pusher Table Configured with Distributed Data

The following is an example of processing outer join by using the sharding key of t_shard_1 as the join co ndition.

```
gSQL> \EXPLAIN PLAN ONLY
      SELECT A.c1
        FROM t_shard_1 AS A LEFT OUTER JOIN t_shard_2 AS B ON A.shard_key = B.c1;
>>>  start print plan
< Execution Plan >

<<<  end print plan
```

The pusher table divides the data for t_shard_2 per a group. The data is distributed based on C1 column of t_shard_2 according to the sharding strategy configured in the sharding key of t_shard_1.

The pusher table which consists of the distributed data is output SHARDED as the detailed result above.

Processing Cluster Query per SELECT Statement

The chapters above describes the **Cluster Puller** and **Cluster Pusher** plan node to process SELECT in cluster. This chapter describes how to process cluster query per SELECT statement by using them.

FROM Statement (Single Table)

Processing a query in a single table is divided into the processing in a sharded table and the processing in a cloned table. If it is processed in a sharded table, then it is divided into n groups and stored, so it reques ts the query to both a local server and a remote server, then collects them and makes them into a result. GOLDILOCKS uses the plan based cluster or the single cluster plan node to request the query to the remo te server and receive the result from it. Those cluster pullers simultaneously requests the query to both a l ocal server and a remote server, then collect the results in parallel to make them into a result set.

The following is an example of processing the query in *part* table which is a sharded table.

```
gSQL> \EXPLAIN PLAN
      SELECT p_name, p_brand, p_type, cluster_group_id
        FROM part;
P_NAME P_BRAND    P_TYPE CLUSTER_GROUP_ID
------ ---------- ------ ----------------
Part#3 Brand#2    STEEL                 1
Part#2 Brand#1    NICKEL                2
Part#5 Brand#3    STEEL                 2
Part#1 Brand#1    COPPER                3
Part#4 Brand#3    NICKEL                3
5 rows selected.
>>>  start print plan
< Execution Plan >
============================================================

```

```
┆    2  ┆      PLAN BASED CLUSTER        ┆ LOCAL/REMOTE     5 ┆
┆    3  ┆        TABLE ACCESS ("PART")   ┆                  1 ┆
============================================================
     1  -  TARGET : PART.P_NAME, PART.P_BRAND, PART.P_TYPE, PART.CLUSTER_GROUP_ID
     2  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."CLUSTER_GROUP_ID", "_A1"."P_NAME",
"_A1"."P_BRAND", "_A1"."P_TYPE" FROM "PUBLIC"."PART"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 2 rows, G3(G3N1,G3N2) 2 rows
     3  -  HASH SHARD ( # 3 )
           READ COLUMN : PART.P_NAME, PART.P_BRAND, PART.P_TYPE
<<<  end print plan
```

When the cloned table is created by using the cloned strategy as AT CLUSTER WIDE strategy, then all nod es have replications, so most of local servers can process the query about the cloned table. However, if a new group or a new member is added, then the group or the member dos not have data about the clone d table. Therefore, it should bring the data from the remote server, so it configures the cluster puller at th is moment. For more information about the cloned strategy, refer to **Cloned Strategy**.

The following is an example of processing the query in *supplier* table which is a cloned table.

```
gSQL> \EXPLAIN PLAN
      SELECT s_name, s_nationkey
        FROM supplier;
S_NAME                    S_NATIONKEY
------------------------- ---------------
Supplier#1                FRANCE
Supplier#2                KOREA
Supplier#3                GERMANY
Supplier#4                UNITED STATES

5 rows selected.
>>>  start print plan
< Execution Plan >
======================================================================
┆  IDX  ┆  NODE DESCRIPTION                        ┆           ROWS ┆
----------------------------------------------------------------------
┆    0  ┆  SELECT STATEMENT                        ┆              5 ┆
┆    1  ┆    QUERY BLOCK ("$QB_IDX_2")             ┆              5 ┆
┆    2  ┆      TABLE ACCESS ("SUPPLIER")           ┆              5 ┆
======================================================================
     1  -  TARGET : SUPPLIER.S_NAME, SUPPLIER.S_NATIONKEY
     2  -  CLONED
           READ COLUMN : SUPPLIER.S_NAME, SUPPLIER.S_NATIONKEY
```

```
<<<  end print plan
```

It can bring all data about *supplier* table from a local server as given above, so it does not configure the cl uster puller.

The following is an example of processing the query in *supplier* table which is a cloned table by using the domain.

```
gSQL> \EXPLAIN PLAN
      SELECT s_name, s_nationkey
        FROM supplier@G2;
S_NAME                    S_NATIONKEY
------------------------- ---------------
Supplier#1                FRANCE
Supplier#2                KOREA
Supplier#3                GERMANY

     2  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."S_NAME", "_A1"."S_NATIONKEY" FROM
"PUBLIC"."SUPPLIER"@LOCAL AS "_A1"
           TARGET DOMAIN : G2(G2N1,G2N2) 5 rows
     3  -  CLONED
           READ COLUMN : SUPPLIER.S_NAME, SUPPLIER.S_NATIONKEY
<<<  end print plan
```

It configures the cluster puller as given above to bring the data about supplier table from the remote serv er.

FROM Statement (Join)

The data collection for the cluster puller plan node are processed in one of the two following forms.

- Data collection from a single group: It is used for a query which consists of cloned tables only or whe n the cluster domain is limited to a single group.
- Data collection from multiple groups: It is used for a query which includes a sharded table.

Join using the cluster puller plan node are also performed in the two forms above.

When performing join by collecting data from a single group, then the join between two cloned tables co nfigures cluster puller by collecting the data.
If the common cluster domain does not exist between two cloned tables, then one of the two following methods can be selected to perform it.

First, it configures the cluster puller per each join target table, then performs the join.

```
gSQL> \EXPLAIN PLAN
      SELECT s_suppkey, n_name
        FROM supplier@g2, nation@g3
       WHERE s_nationkey = n_nationkey;
S_SUPPKEY N_NAME
--------- -------------------------
        1 FRANCE
        2 INDIA
        3 GERMANY
        4 CANADA
        5 UNITED STATES
5 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |               ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                          |                  5 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |                  5 |
|    2  |      HASH JOIN (INNER JOIN)                |                  5 |
|    3  |        PLAN BASED CLUSTER                  | REMOTE ONLY      5 |
|    4  |          TABLE ACCESS ("SUPPLIER")         |                  0 |
|    5  |        HASH JOIN INSTANT                   |                  5 |
|    6  |          PLAN BASED CLUSTER                | REMOTE ONLY     30 |
|    7  |            TABLE ACCESS ("NATION")         |                  0 |
================================================================================
```

```
     1  -  TARGET : SUPPLIER.S_SUPPKEY, NATION.N_NAME
     2  -  JOINED COLUMN : SUPPLIER.S_SUPPKEY, NATION.N_NAME
     3  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."S_SUPPKEY", "_A1"."S_NATIONKEY" FROM
"PUBLIC"."SUPPLIER"@LOCAL AS "_A1"
           TARGET DOMAIN : G2(G2N1,G2N2) 5 rows
     4  -  CLONED
           READ COLUMN : SUPPLIER.S_SUPPKEY, SUPPLIER.S_NATIONKEY
     5  -  HASH KEY : NATION.N_NATIONKEY
           RECORD COLUMN : NATION.N_NAME
           READ KEY COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
             HASH FILTER : NATION.N_NATIONKEY = SUPPLIER.S_NATIONKEY
     6  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."N_NATIONKEY", "_A1"."N_NAME" FROM
"PUBLIC"."NATION"@LOCAL AS "_A1"
           TARGET DOMAIN : G3(G3N1,G3N2) 30 rows
     7  -  CLONED
           READ COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
<<<  end print plan
```

However, if it is performed as given above, the problem is that it should bring all data from the two table s.

Second, it configures the pusher table for a table, then performs the join query including the pusher table. In this case, a single group collects the data as follows.

```
gSQL> \EXPLAIN PLAN
      SELECT /*+ REMOTE_JOIN( supplier ) */ s_suppkey, n_name
        FROM supplier@g2, nation@g3
       WHERE s_nationkey = n_nationkey;
S_SUPPKEY N_NAME

<<<  end print plan
```

When performing the join by collecting the data from multiple groups, then the data should be collected from multiple groups when processing the query because the data are distributed into multiple groups in the sharded table.

Joins including the sharded table are classified as follows.

- Case 1: Joining sharded table and cloned table

    - The cloned table data is distributed to all groups where sharded table data were distributed.
- Case 2: Joining sharded table and cloned table
    - The cloned table data is distributed not distributed to one or more groups where sharded table d ata were distributed.
- Case 3: Joining sharded table and sharded table
    - Equi-join condition between sharding keys of two sharded tables exists.
- Case 4: Joining sharded table and sharded table
    - Equi-join condition using the sharding key of a sharded table exists.
- Case 5: Joining sharded table and sharded table
    - Equi-join condition using the sharding key does not exist.

In case 1, if the cloned table data exists in all groups where the sharded table data is distributed, then the total sum of join results from each group becomes the entire join result.

FROM Statement (Outer Join)

The query process in outer join is divided into the data collection from a single group and the data collecti on from multiple groups like as **FROM Statement (Join)**.

Outer join which collects data from a single group is applied only to a query which consists of cloned tabl es only or when the cluster domain is limited to a single group. It configures the join result by performing the generated query including the outer join in a single group as follows.

```
gSQL> \EXPLAIN PLAN

```

Outer join which collects data from multiple groups is applied to following three cases.

- Case 1: Joining sharded table and cloned table
  - The cloned table data is distributed to all groups where sharded table data were distributed.
- Case 2: Joining sharded table and sharded table
  - Equi-join condition between sharding keys of two sharded tables exists.
- Case 3: It includes one or more sharded tables and equi-join condition does not exists between shardi ng keys.

In case 1, it configures the generated query including the outer join.
The total sum of outer join results from each group becomes the entire join result as follows.

```
gSQL> \EXPLAIN PLAN

```

The generated query includes the ordering for columns included in an equi-join condition as above. It collects data collected from each group in an order of the ordering, then applies the intersect key group only to the case whose nil expression value is null.

FROM Statement (Join Including Subquery)

The join including the subquery is classified according to whether the subquery is used as a join condition. When processing the cluster of the join which does not use the subquery as a join condition, it collects an d manipulates the data through the cluster puller, then applies the filter related to the subquery. The join which uses the subquery as a join condition processes the join according to the join operation.

The following is an example of processing the subquery which is not used as the join condition.

```
gSQL> \EXPLAIN PLAN

Joins which use the subquery as a join condition are classified according to the operator including the sub query as follows.

Table 12-11 Join including subquery

Join operation	Operator including the subquery
INNER JOIN	All operators except for **〈Group Comparison Conditions〉**
OUTER JOIN	All operators except for **〈Group Comparison Conditions〉**
SEMI JOIN	**〈Group Comparison Conditions〉** having EXISTS, IN, ANY quantifier
ANTI-SEMI JOIN	**〈Group Comparison Conditions〉** having NOT EXISTS, NOT IN, ALL quantifier

For more information about the join operation, refer to **Join**.

If a join condition or a filter, which includes a subquery is used in an inner join, then it collects the data an d applies the filter related to the subquery as follows.

```
gSQL> \EXPLAIN PLAN
      SELECT ps_partkey, s_name
        FROM supplier
```

```
            INNER JOIN
            partsupp

If a join condition including a subquery exists in an outer join, then it can not configure the generated qu ery including the outer join.
In this case, perform the join by configuring the cluster puller per each join target table as follows.

```
gSQL> \EXPLAIN PLAN
      SELECT ps_partkey, s_name
        FROM supplier
             LEFT OUTER JOIN
             partsupp
             ON ps_suppkey = ( SELECT s_suppkey FROM DUAL );

When a subquery specified in where statement is converted into a semi join by performing <subquery unnest>, then the generated query to process the semi join includes the semi join statement. The total sum of generated query results from multiple groups becomes the duplicate semi join result. Then, it manipulates the data in distinct key group method to delete the duplicate semi join results. For more information about distinct key group, refer to **Generated Query for Distinct Key Group**.

The following is an example of processing the distinct key group for the semi join.

```
gSQL> \EXPLAIN PLAN

WHERE Statement

Filter configured on plan node are classified as follows.

- Constant filter: This filter is processed by being made into a constant in plan node unit.
- Post filter: This filter includes a subquery or it consists of non-deterministic expressions.
- Filter: This filter is the rest of what is not classified as a constant filter or a post filter.

The generated query configures the cluster puller and the filter belonging to the subordinate node into a query. It configures the query in a bind parameter form by making a constant filter into a constant, and c onfigures the filter into a query without modification. However, it does not configure the generated quer y for a post filter.

The following is an example of the generated query including a constant filter.

```
gSQL> \VAR v1 INTEGER

GROUP BY Statement

The query process for the group by statement varies upon the sharding strategy which can be used by the subordinate plan node, and grouping configuration.

Table 12-12 Grouping according to the sharding strategy of subordinate node

Sharding strategy of subordinate node, and grouping	Data collection	Data manipulation	Processing *having* clause
When all sharding keys of subordinate node are included in the grouping key	It performs the generated query including *group by* statement in all groups.	no manipulation	It includes *having* clause in the generated query.
When subordinate node is a cloned node	It performs the generated query including *group by* statement in a single group.	no manipulation	It includes *having* clause in the generated query.
When it is unable to use the sharding strategy of the subordinate node	It performs the generated query excluding *group by* statement in all groups.	grouping	It applies *having* clause after manipulating the data.

If having clause includes the non-deterministic information, except when the subordinate node is a cloned node, then the generated query including grouping can not be configured. In conclusion, the cluster puller plan node is configured below *group by*.

The following is an example of grouping when all sharding keys on the subordinate node are included in the grouping key.

```
gSQL> \EXPLAIN PLAN
      SELECT p_partkey
        FROM part
       GROUP BY p_partkey
      HAVING SUM( p_size ) > 0;

When sharding strategy of the subordinate node is unable to use for grouping, it performs the grouping per group through the generated query. It collects the data, then performs the grouping again to creates the grouping result. The generated query configured at that moment does not include *having* clause. *having* clause is evaluated after creating the grouping result.

The following is an example of grouping which can not use the sharding strategy of the subordinate node.

```
gSQL> \EXPLAIN PLAN
      SELECT p_type
        FROM part
       GROUP BY p_type
      HAVING SUM( p_size ) > 0;

<<<  end print plan
```

In the result above, it collects the data by using the single cluster, then performs grouping.

When sharding strategy of the subordinate node is unable to use for grouping, it can be processed by usi ng ordering for the grouping key in the generated query. The data collected by processing the generated query from each group are sorted per grouping key by merge sorting. Then, it performs the grouping aga in based on the sorted data, and it is called as merge-grouping.

The following is an example of grouping by using the merge-grouping.

```
gSQL> \EXPLAIN PLAN

ORDER BY Statement

The cluster puller uses merge sorting to manipulate the data for *order by* statement. It configures the gen erated query including ordering, then collects the data per group. It merges the data while sorting the col lected data in an order of the ordering key. *Order by* node can not have a filter, so it transfers the merge s orting result to the superordinate node without modification.

It uses multiple clusters to perform merge sorting.

The following is an example of processing *order by* statement for the sharded table by using merge sortin g.

```
gSQL> \EXPLAIN PLAN
      SELECT p_type
        FROM part
       ORDER BY p_size;
P_TYPE

DISTINCT Statement

The generated query of the cluster puller to perform distinct statement includes distinct statement. When performing distinct for the sharded table, then it collects the data and configures the result through grou ping. Performing distinct for a cloned table configures the result without modifying the collected data.

The following is an example of processing distinct statement for the sharded table.

```
gSQL> \EXPLAIN PLAN
      SELECT DISTINCT p_name
        FROM part;
P_NAME
------
Part#2
Part#4
Part#3
Part#1
Part#5
5 rows selected.

```

Single Row Statement

Single row query processing in cluster is classified according to whether it is a cloned table or a sharded table. The generated query for process the single row query for the cloned table includes all aggregation functions. It configures the result by collecting the data performed the generated query only in a single group.

The following is an example of a single row statement for the cloned table in a remote server.

```
gSQL> \EXPLAIN PLAN
      SELECT COUNT( DISTINCT s_name ), SUM( s_suppkey )
        FROM supplier@G2;
COUNT( DISTINCT S_NAME ) SUM( S_SUPPKEY )
------------------------ ----------------
                       5               15
1 row selected.
>>>  start print plan
< Execution Plan >
=========================================================================
|  IDX  |  NODE DESCRIPTION                     |               ROWS |
-------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                     |                  1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")          |                  1 |
|    2  |      PLAN BASED CLUSTER               | REMOTE ONLY      1 |
|    3  |        AGGREGATION BY HASH            |                  0 |
|    4  |          TABLE ACCESS ("SUPPLIER")    |                  0 |
=========================================================================
```

```
     1  -  TARGET : COUNT( DISTINCT SUPPLIER.S_NAME ), SUM( SUPPLIER.S_SUPPKEY )
     2  -  SQL : SELECT /*+ FULL( _A1 ) */ COUNT( DISTINCT "_A1"."S_NAME" ), SUM(
"_A1"."S_SUPPKEY" ) FROM "PUBLIC"."SUPPLIER"@LOCAL AS "_A1"
           TARGET DOMAIN : G2(G2N1,G2N2) 1 rows
     3  -  AGGREGATION : SUM( SUPPLIER.S_SUPPKEY )
           DISTINCT AGGREGATION : COUNT( DISTINCT SUPPLIER.S_NAME )
     4  -  CLONED
           READ COLUMN : SUPPLIER.S_SUPPKEY, SUPPLIER.S_NAME
<<<  end print plan
```

Single row query processing in a sharded table is classified according to whether the aggregation functio n includes distinct or not.

When one or more aggregation function including distinct exists

- The cluster puller plan node is configured below the plan for a single row processing.
- The generated query does not include an aggregation function.

The following is an example of processing a single row for a sharded table which has an aggregation incl uding distinct.

```
gSQL> \EXPLAIN PLAN
      SELECT COUNT( DISTINCT p_name ), SUM( p_size )
        FROM part;
COUNT( DISTINCT P_NAME ) SUM( P_SIZE )
------------------------ -------------
                       5            58
1 row selected.
>>>  start print plan
< Execution Plan >
=====================================================================
|  IDX  |  NODE DESCRIPTION                  |               ROWS |
---------------------------------------------------------------------
|    0  |  SELECT STATEMENT                  |                  1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")       |                  1 |
|    2  |      AGGREGATION BY HASH           |                  1 |
|    3  |        PLAN BASED CLUSTER          | LOCAL/REMOTE     5 |
|    4  |          TABLE ACCESS ("PART")     |                  1 |
=====================================================================
     1  -  TARGET : COUNT( DISTINCT PART.P_NAME ), SUM( PART.P_SIZE )
     2  -  AGGREGATION : SUM( PART.P_SIZE )
           DISTINCT AGGREGATION : COUNT( DISTINCT PART.P_NAME )
```

```
     3  -  SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."P_NAME", "_A1"."P_SIZE" FROM
"PUBLIC"."PART"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 2 rows, G3(G3N1,G3N2) 2 rows
     4  -  HASH SHARD ( # 3 )
           READ COLUMN : PART.P_NAME, PART.P_SIZE
<<<  end print plan
```

When all aggregations do not have distinct

- The plan to process a single row is not configured.
- The generated query includes an aggregation function.
- It configures the result by performing an aggregation after collecting the data.

The following is an example of processing a single row for a sharded table which does not have an aggre gation including distinct.

```
gSQL> \EXPLAIN PLAN
      SELECT COUNT( p_name ), SUM( p_size )
        FROM part;
COUNT( P_NAME ) SUM( P_SIZE )
--------------- -------------
              5            58
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                          |               ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                          |                  1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |                  1 |
|    2  |      SINGLE CLUSTER                        | LOCAL/REMOTE     1 |

```

```
    5  -  HASH SHARD ( # 3 )
          READ COLUMN : _A1.P_NAME, _A1.P_SIZE
          AGGREGATION : COUNT( _A1.P_NAME ), SUM( _A1.P_SIZE )
<<<  end print plan
```

Processing DML in Cluster

In GOLDILOCKS, a user can perform DML for all cluster members configuring a cluster system.

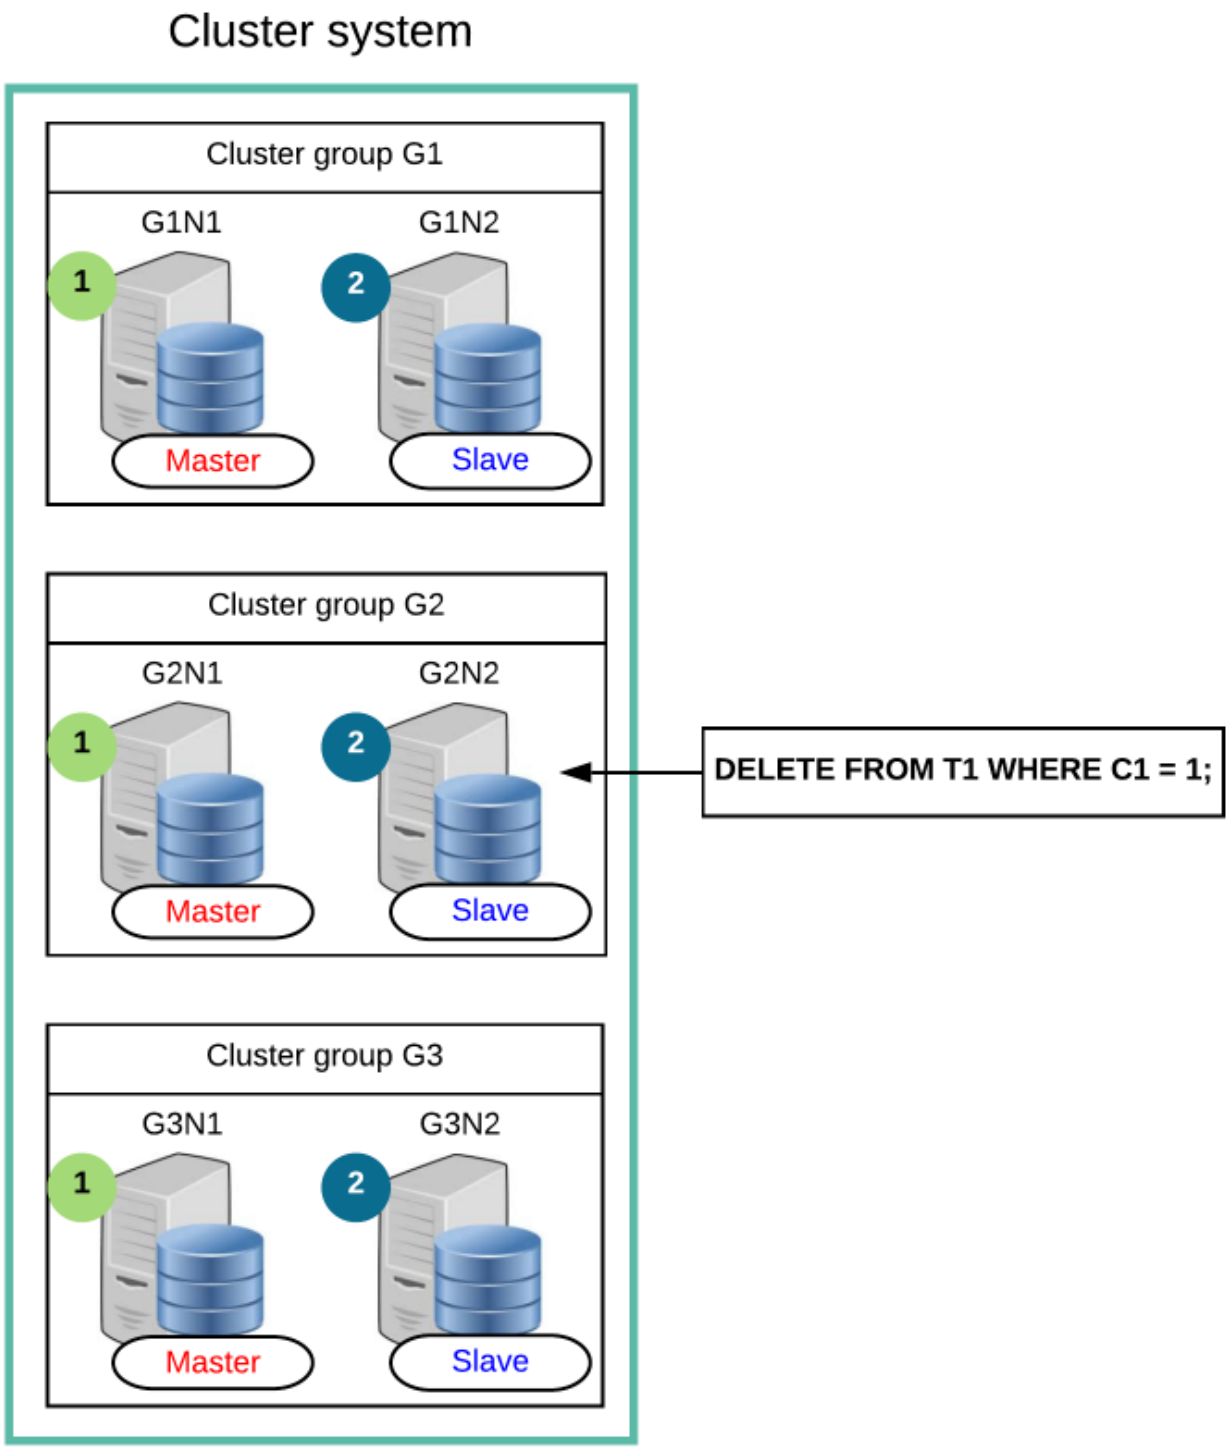
Data manipulation in cluster environment manipulates the data of the cluster member containing the sa me data replication same as well.

The following constructed table is used to describe the data manipulation.

```
CREATE TABLE t1( shard_key INTEGER, c1 INTEGER )
    SHARDING BY RANGE( shard_key )
        SHARD s1 VALUES LESS THAN ( 200 )       AT CLUSTER GROUP G1,
        SHARD s2 VALUES LESS THAN ( 400 )       AT CLUSTER GROUP G2,
        SHARD s3 VALUES LESS THAN ( MAXVALUE )  AT CLUSTER GROUP G3;
```

DML is performed as the figure below in cluster environment.

Figure 9 Processing DML in cluster



A master server and a slave server per each group are defined for the DML processing in cluster.

Selecting Master Server in Each Cluster Group

It selects a cluster member which was included first among cluster members accessible from each cluster group when manipulating data in cluster environment.

Selecting Slave Server in Each Cluster Group

It selects cluster members remained after excluding master servers from accessible cluster members per e ach cluster group when manipulating data in cluster environment.

For more information about cluster group and cluster member configuration, refer to **DBA_CLUSTER**.

```
gSQL> SELECT * FROM DBA_CLUSTER;
GROUP_ID GROUP_NAME MEMBER_ID MEMBER_NAME MEMBER_HOST MEMBER_PORT MEMBER_POSITION
-------- ---------- --------- ----------- ----------- ----------- ---------------
       1 G1                 1 G1N1        127.0.0.1         11150               0
       1 G1                 2 G1N2        127.0.0.1         11250               1
       2 G2                 3 G2N1        127.0.0.1         12150               2
       2 G2                 4 G2N2        127.0.0.1         12250               3
       3 G3                 5 G3N1        127.0.0.1         13150               4
       3 G3                 6 G3N2        127.0.0.1         13250               5
6 rows selected.
```

Performing DML

DML is sequentially performed by applying to a master server phase then applying to a slave server phase.

- Applying to a master server
  - It manipulates the data in the master server in each cluster group.
- Applying to a slave server
  - It manipulates the data in the slave server in the same way as they were applied in the master ser ver in each cluster group.

In GOLDILOCKS, the following two methods are used to manipulate data while synchronizing the master server and the slave server per each cluster group.

- **Query Based DML**
- **Global Rowid Based DML**

Query Based DML

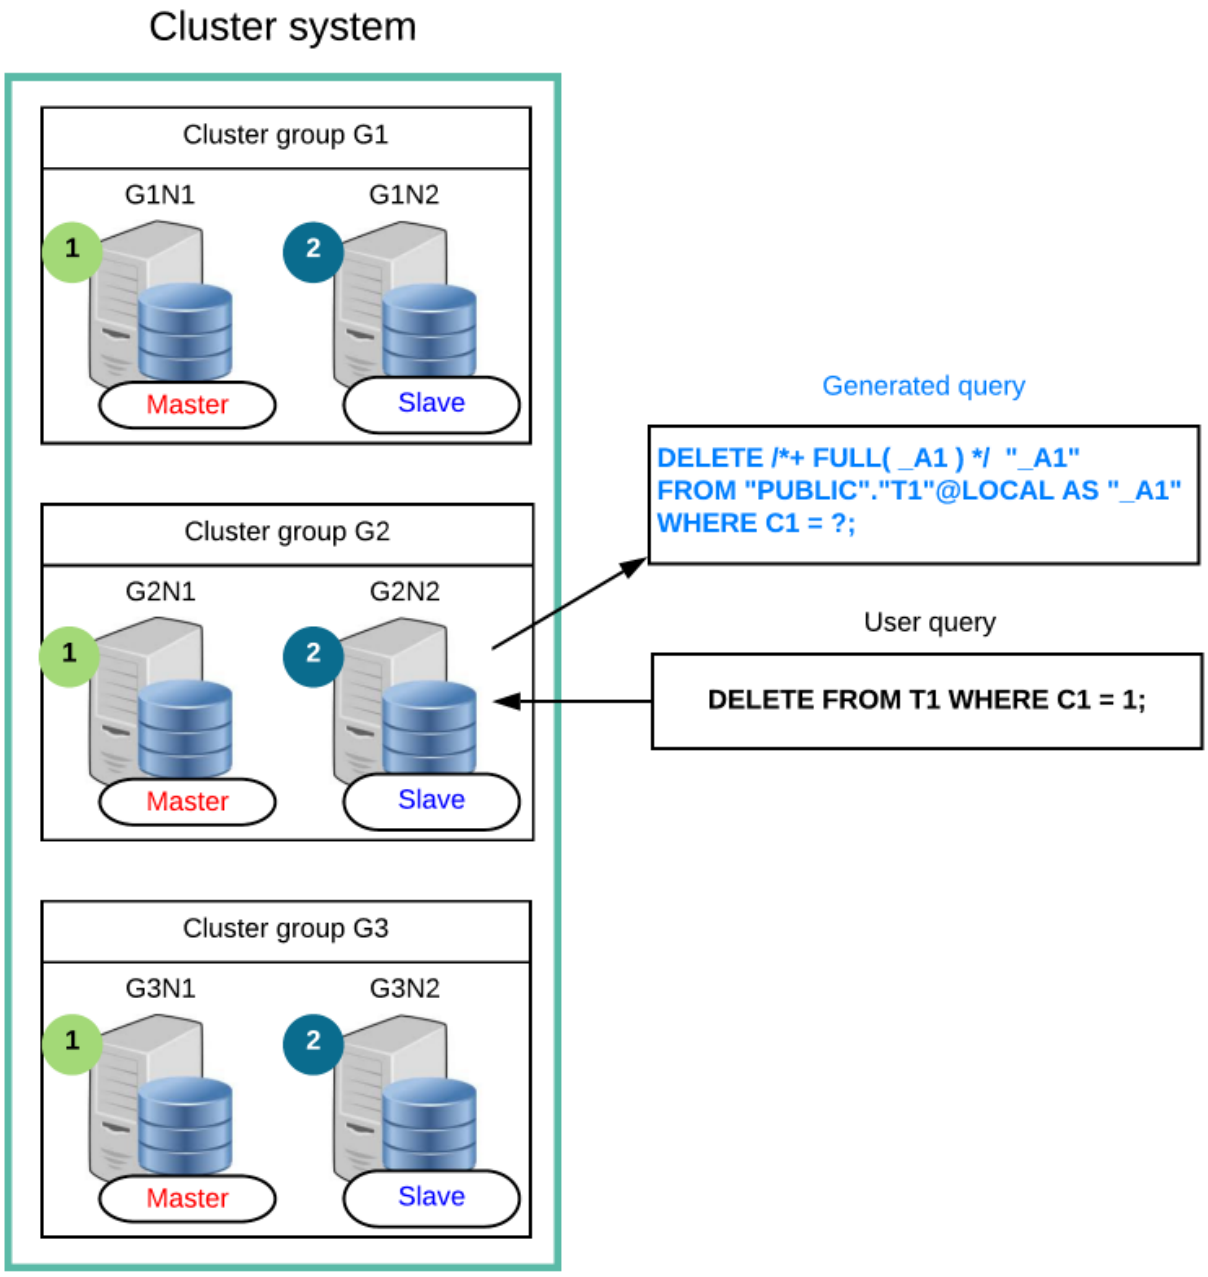
Query based DML is a method to manipulate records of each server by using the generated query. The generated query is internally generated by a server which was given a query from a user. It is supported only if the same result is guaranteed when performing DML with a generated query from each server.

For more information, refer to **Generated Query**.

The generated query for a master server and the generated query for a slave server may be different each other depending on whether the manipulated record returns the result.

The data manipulation using the generated query is performed as the figure below.

Figure 10 Updating data using generated query (Altering the entire cluster group target)



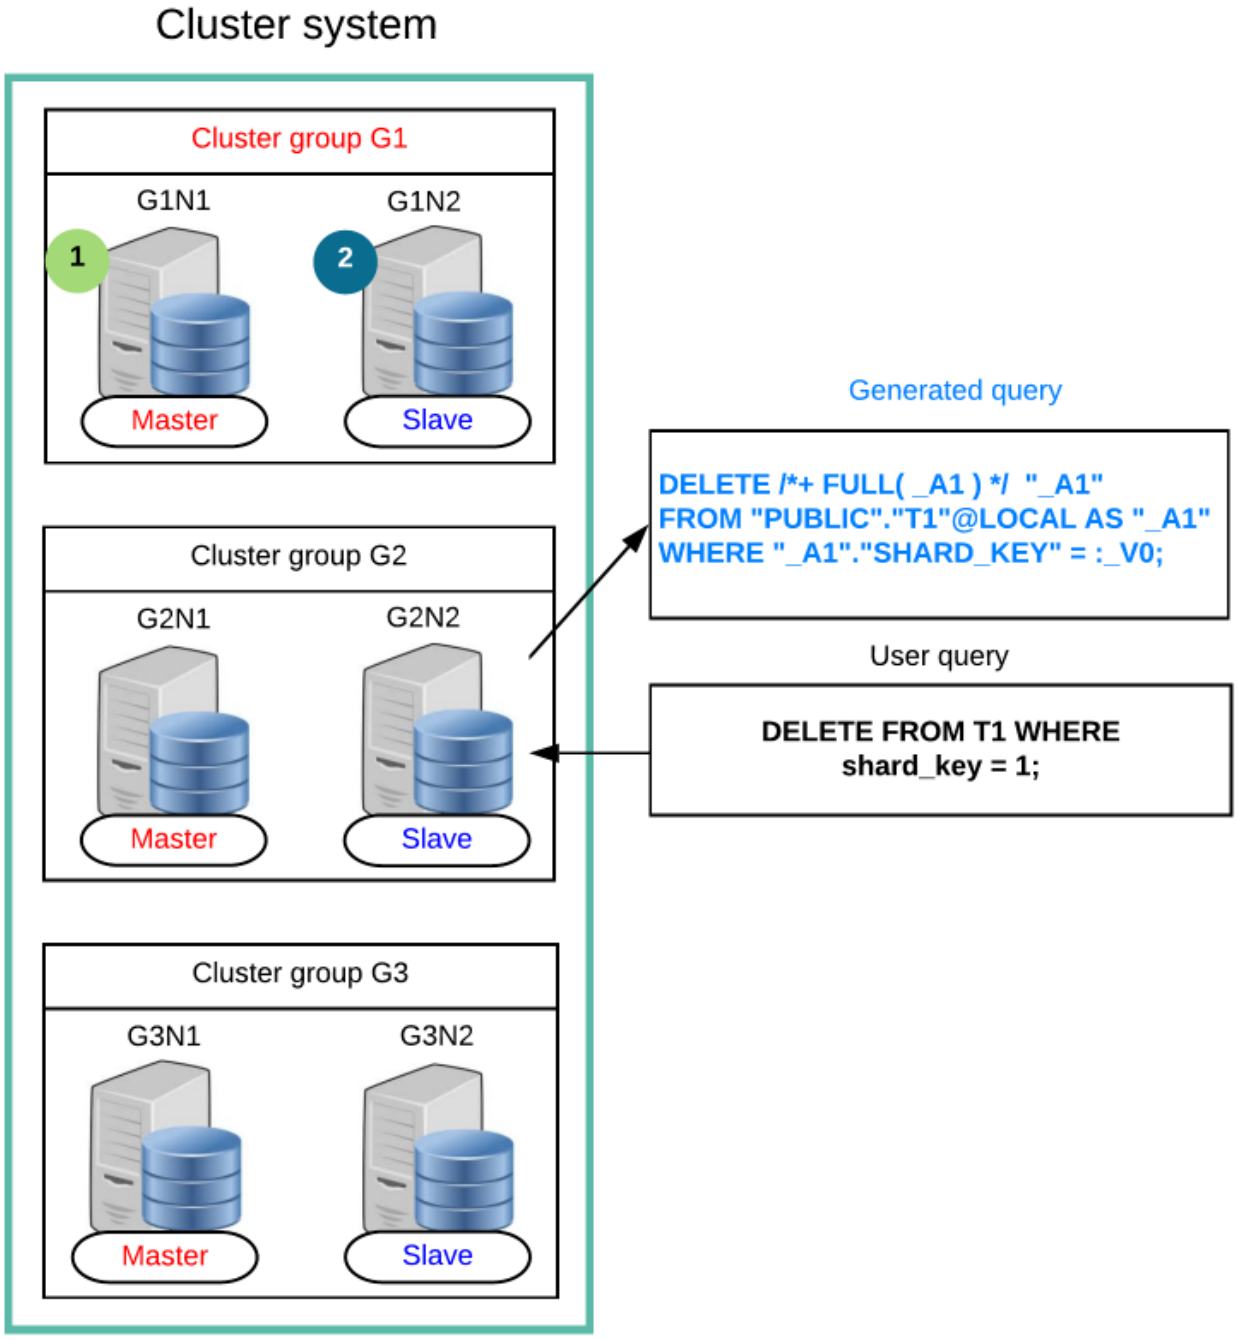
If there is not a condition to select an manipulation target cluster group in a conditional clause as given a bove, then all cluster groups become the data manipulation target of using the generated query.

The data manipulation using the generated query is performed as follows.

1. The generated query is performed on each master server
2. The generated query is performed on each slave server

If only a specific cluster group is selected as a data manipulation target by a conditional clause, then it is p erformed as follows.

Figure 11 Updating data using generated query (Altering a specific cluster group)



If the manipulation target is determined by using the search condition (shard_key = 1) as given above, it i s found that the record whose shard_key is 1 is in G1 cluster group by the sharding strategy. Therefore, o nly the record in G1 cluster group is deleted.

Manipulating the data in a specific cluster group is applied to a slave after it is applied to a master as like manipulating the data in the entire cluster group.

The plan node called as DML cluster performs the query based DML. For more information, refer to **DML Cluster**.

Data manipulation using the generated query is supported only in the following cases.

- If the generated query which guarantees the same result when performing the generated query on e ach cluster member of a cluster group can be generated
  - Refer to **Constraints of Generated Query Configuration**.
- If the data reference target server and the data manipulation target server can be restricted to a same server when configuring the generated query
  - This means that the server performing the generated query does not need to access another serv er while processing the query.

The following user queries support the data manipulation using the generated query.

- **SELECT .. FOR UPDATE**
- **SELECT .. INTO .. FOR UPDATE**
- **DELETE FROM**
- **DELETE FROM name RETURNING**
- **DELETE FROM name RETURNING .. INTO**
- **UPDATE**
- **UPDATE name RETURNING**
- **UPDATE name RETURNING .. INTO**

The data manipulation using the generated query is available even when the **Global Secondary Index** is n ot configured.

DML Cluster

DML cluster manipulates data from each server by using the generated query, and collects data when it is needed.

The following is an example of processing DELETE RETURN statement for a sharded table with the query based DML.

```
gSQL> \EXPLAIN PLAN DELETE FROM part WHERE p_partkey = 5 RETURN p_name;
P_NAME
------
```

```
Part#3
1 row deleted.
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                              |           ROWS |
----------------------------------------------------------------------------
|    0  |  DELETE STATEMENT ("PART")                     |              1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |              0 |
|    2  |      DML CLUSTER                               | REMOTE ONLY  1 |
|    3  |        INDEX ACCESS ("PART", "PART_PK_INDEX") | (    0)      0 |
============================================================================
     1  -  TARGET : PART.P_NAME
     2  -  FETCH
           Fetch SQL : DELETE /*+ INDEX( _A1, "PUBLIC"."PART_PK_INDEX" ) */  "_A1" FROM
"PUBLIC"."PART"@LOCAL AS "_A1" WHERE "_A1"."P_PARTKEY" = :_V0 RETURN "_A1"."$PHYSICAL_ROWID",
"_A1"."P_PARTKEY", "_A1"."P_NAME", "_A1"."P_BRAND"
           Non-Fetch SQL : DELETE /*+ INDEX( _A1, "PUBLIC"."PART_PK_INDEX" ) */  "_A1" FROM
"PUBLIC"."PART"@LOCAL AS "_A1" WHERE "_A1"."P_PARTKEY" = :_V0
           TARGET DOMAIN : G2(G2N1,G2N2) 1 rows
     3  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : PART.P_PARTKEY
           READ TABLE COLUMN : PART.P_NAME, PART.P_BRAND
             MIN RANGE : PART.P_PARTKEY = 5
             MAX RANGE : PART.P_PARTKEY = 5
           FETCH ONE ROW
<<<  end print plan
```

DML cluster is used to perform DELETE statement in the query execution result. DML cluster is a plan wh ose idx of <Execution Plan> is 2 in the execution plan output above.

The detailed information about DML cluster is as follows.

- DML cluster usage type: FETCH, WITHOUT FETCH, SHARD KEY UPDATE
- Fetch SQL: The generated query for performing DML and collecting the data
- Non-fetch SQL: The generated query only for performing DML
- TARGET DOMAIN: The group and member to transfer the generated query and the number of data r eceived from the group
- Shard key update information: The generated query which divided a singe UPDATE statement into U PDATE, SELECT, and DELETE

DML cluster usage type is classified according to the user query.

- WITHOUT FETCH: DML which does not acquire the execution result data (DELETE, UPDATE)
- FETCH: DML to acquire the execution result data (SELECT FOR UPDATE, DELETE RETURN, UPDATE RETURN)
- SHARD KEY UPDATE: UPDATE which updates the sharding key (UPDATE, UPDATE RETURN)

DML Cluster (WITHOUT FETCH)

If DML cluster usage type is WITHOUT FETCH, then the detailed information about DML cluster is configured with non-fetch SQL and TARGET DOMAIN as follows.

```
gSQL> \EXPLAIN PLAN DELETE FROM supplier;
5 rows deleted.
>>>  start print plan
< Execution Plan >
=========================================================================
|  IDX  |  NODE DESCRIPTION                          |           ROWS |
-------------------------------------------------------------------------
|    0  |  DELETE STATEMENT ("SUPPLIER")             |              5 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")               |              0 |
|    2  |      DML CLUSTER                           |              5 |
|    3  |        INDEX ACCESS ("SUPPLIER", ...)      | (     5)     5 |
=========================================================================
     1  -  TARGET : NOTHING
     2  -  WITHOUT FETCH
           Non-Fetch SQL : DELETE /*+ INDEX( _A1, "PUBLIC"."SUPPLIER_PK_INDEX" ) */  "_A1"
FROM "PUBLIC"."SUPPLIER"@LOCAL AS "_A1"
           TARGET DOMAIN : G1(G1N1,G1N2) 5 rows, G2(G2N1,G2N2) 5 rows, G3(G3N1,G3N2) 5 rows
     3  -  CLONED
           READ INDEX COLUMN : SUPPLIER.S_SUPPKEY
<<<  end print plan
```

If sharded table data manipulation affects only a specific group as follows, then the group in which a non-fetch SQL is performed is restricted.

```
gSQL> \EXPLAIN PLAN DELETE FROM part WHERE p_partkey = 5;
1 row deleted.
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                              |         ROWS |
-----------------------------------------------------------------------------
|    0  |  DELETE STATEMENT ("PART")                     |            1 |
```

```
┆    1  ┆    QUERY BLOCK ("$QB_IDX_2")                  ┆           0 ┆
┆    2  ┆      DML CLUSTER                              ┆           1 ┆
┆    3  ┆        INDEX ACCESS ("PART", "PART_PK_INDEX") ┆ (    0)   0 ┆
=========================================================================
     1  -  TARGET : NOTHING
     2  -  WITHOUT FETCH
           Non-Fetch SQL : DELETE /*+ INDEX( _A1, "PUBLIC"."PART_PK_INDEX" ) */  "_A1" FROM
"PUBLIC"."PART"@LOCAL AS "_A1" WHERE "_A1"."P_PARTKEY" = :_V0
           TARGET DOMAIN : G2(G2N1,G2N2) 1 rows
     3  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : PART.P_PARTKEY
           READ TABLE COLUMN : PART.P_BRAND
             MIN RANGE : PART.P_PARTKEY = 5
             MAX RANGE : PART.P_PARTKEY = 5
           FETCH ONE ROW
<<<  end print plan
```

A non-fetch SQL of DML cluster which consists of WITHOUT FETCH is performed equally in all master servers and slave servers without distinguishing a cloned table and a sharded table.

DML Cluster (FETCH)

If DML cluster usage type is FETCH, then the detailed information about DML cluster is configured with fetch SQL, non-fetch SQL and TARGET DOMAIN as follows.

```
gSQL> \EXPLAIN PLAN SELECT p_name FROM part FOR UPDATE;
P_NAME
------
Part#1
Part#4
Part#3
Part#2
Part#5
5 rows selected.
>>>  start print plan
< Execution Plan >
=================================================================
┆  IDX  ┆  NODE DESCRIPTION               ┆              ROWS ┆
-----------------------------------------------------------------
┆    0  ┆  SELECT FOR UPDATE STATEMENT    ┆                 5 ┆
┆    1  ┆    QUERY BLOCK ("$QB_IDX_2")    ┆                 0 ┆
┆    2  ┆      DML CLUSTER                ┆ REMOTE ONLY     5 ┆
```

```
¦    3  ¦        TABLE ACCESS ("PART")     ¦                 2 ¦
=============================================================
     1  -  TARGET : PART.P_NAME
     2  -  FETCH
           Fetch SQL : SELECT /*+ FULL( _A1 ) */ "_A1"."$PHYSICAL_ROWID", "_A1"."P_NAME" FROM
"PUBLIC"."PART"@LOCAL AS "_A1" FOR UPDATE OF "_A1"."P_PARTKEY"
           Non-Fetch SQL : SELECT /*+ FULL( _A1 ) */  NULL FROM "PUBLIC"."PART"@LOCAL AS "_A1"
FOR UPDATE OF "_A1"."P_PARTKEY" WITHOUT FETCH
           TARGET DOMAIN : G1(G1N1,G1N2) 2 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 2 rows
     3  -  HASH SHARD ( # 3 )
           READ COLUMN : PART.P_NAME
<<<  end print plan
```

A non-fetch SQL consists of SELECT FOR UPDATE statement in the result above. The non-fetch SQL confi gured like this is performed in a local server and a remote server, but it does not collect the data through SELECT FOR UPDATE statement.

The fetch SQL of query based DML for a cloned table is performed on a member among the entire group. If a local server has a replication of a cloned table, then the fetch SQL is performed in a local server. If a lo cal server does not have a replication of a cloned table, then the fetch SQL is performed in an arbitrary ser ver. All servers having a replication of a cloned table except for the server performing fetch SQL performs non-fetch SQLs.

The fetch SQL of query based DML for a sharded table is performed on master servers of each group. All of slave servers perform non-fetch SQL.

If sharded table data manipulation affects only a specific group as follows, then the group in which a fetc h SQL and a non-fetch SQL is performed is restricted.

```
gSQL> \EXPLAIN PLAN SELECT p_name FROM part WHERE p_partkey = 5 FOR UPDATE;
P_NAME
------
Part#3
1 row selected.
>>>  start print plan
< Execution Plan >
=============================================================================

<<<  end print plan
```

DML Cluster (SHARD KEY UPDATE)

UPDATE for the sharding key column is classified to the following two types according to whether the sh ard to which the record belongs is altered before and after the data manipulation.

- In-place update: The shard to which the record belongs is same before and after the data manipulati on.
- Out-place update: The shard to which the record belongs is different before and after the data manip ulation.

In-place update alters the value without moving the record. The rowid information of the record which w ere updated through in-place update is not updated.

Out-place update inserts a new record after delete the existing record. New rowid is set in the record whi ch were updated through out-place update.

SHARD KEY UPDATE configures the generated query distinguishing an in-place update and an out-place update.

The generated query for an in-place update consists of UPDATE statement. The generated query has a filt er which guarantees that the shards to which the value belongs before and after update are same.

The generated query for an out-place update separately consists of SELECT statement and DELETE statem ent. Each generated query has a filter which guarantees that the shards to which the value belongs befor e and after update are different. It configures a new record by collecting data before the update through the generated query consisting of SELECT statement. It inserts new records by using <global rowid based DML>. It deletes all previous records through DELETE statement.

If DML cluster usage type is SHARD KEY UPDATE, then the detailed information about DML cluster is con figured with UPDATE SQL for in-place update and SELECT SQL & DELETE SQL for out-place update as foll ows.

```
gSQL> \EXPLAIN PLAN UPDATE part SET p_partkey = p_partkey + 10;
5 rows updated.
>>>  start print plan
< Execution Plan >

Join Operation in DML Cluster

The statement including a subquery can be converted into a join operation by the query processor like as **Join including subquery**. The subquery for DML statement can also be converted to a join operation. DML cluster plan node supports the generated query including a join.

The following is an example of performing DELETE including a subquery.

```
gSQL> \EXPLAIN PLAN
      DELETE FROM part WHERE p_partkey IN ( SELECT ps_partkey FROM partsupp );
3 rows deleted.
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                          ¦            ROWS ¦
-----------------------------------------------------------------------------
¦    0  ¦  DELETE STATEMENT ("PART")                 ¦               3 ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")              ¦               0 ¦
¦    2  ¦      DML CLUSTER                          ¦               3 ¦
¦    3  ¦        HASH JOIN (SEMI)                   ¦               1 ¦
¦    4  ¦          TABLE ACCESS ("PART")            ¦               2 ¦
¦    5  ¦          HASH JOIN INSTANT (UNIQUE)       ¦               1 ¦
¦    6  ¦            INDEX ACCESS ("PARTSUPP", ...) ¦ (     2)      2 ¦
=============================================================================
     1  -  TARGET : NOTHING
     2  -  WITHOUT FETCH
           Non-Fetch SQL : DELETE /*+ KEEP_JOINED_TABLE USE_HASH_IN( _A2, 10 ) FULL( _A1 )
INDEX( _A2, "PUBLIC"."PARTSUPP_PK_INDEX" ) */  "_A1" FROM (
"PUBLIC"."PART"@"G1N1"¦"G1N2"¦"G2N1"¦"G2N2"¦"G3N1"¦"G3N2" AS "_A1" SEMI JOIN
"PUBLIC"."PARTSUPP"@"G1N1"¦"G1N2"¦"G2N1"¦"G2N2"¦"G3N1"¦"G3N2" AS "_A2" ON "_A2"."PS_PARTKEY" =
"_A1"."P_PARTKEY") ALIAS "_A3"
           TARGET DOMAIN : G1(G1N1,G1N2) 1 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 1 rows
     3  -  JOINED COLUMN : PART.$PHYSICAL_ROWID, PART.P_PARTKEY, PART.P_BRAND
     4  -  HASH SHARD ( # 3 )
```

```
           READ COLUMN : PART.P_PARTKEY, PART.P_BRAND
     5  -  HASH KEY : PARTSUPP.PS_PARTKEY
           READ KEY COLUMN : PARTSUPP.PS_PARTKEY
             HASH FILTER : PARTSUPP.PS_PARTKEY = PART.P_PARTKEY
           FETCH ONE ROW
     6  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : PARTSUPP.PS_PARTKEY
<<<  end print plan
```

However, DML cluster plan node does not support the manipulating the collected data. The join operatio n which required the data manipulation after collecting the data through the generated query can not co nfigure DML cluster.

The following is an example of when it converts DML including a subquery to a join operation, but can n ot configure DML cluster.

```
gSQL> \EXPLAIN PLAN
      DELETE FROM supplier WHERE s_suppkey IN ( SELECT ps_partkey FROM partsupp );
5 rows deleted.
>>>  start print plan
< Execution Plan >
================================================================================

```

Global Rowid Based DML

Global rowid based DML is a method to manipulates the same records stored in different cluster member s by using the rowid. This method is used when adding a new record or when **Query Based DML** is not av ailable.

The rowid provided in cluster environment is a logical identification information given to the record and it is a standard to determine whether the records are same. If a single record is stored in different cluster m embers, then all of them have same rowid. Rowid information is given when creating a record, or a new r owid information is given when modifying the value of the sharding key column.

For more information about the rowid, refer to **ROWID Pseudo Column** .

Data manipulation using the rowid information is divided into a rowid information collection phase and a data manipulation phase. When manipulating two or more records, a rowid information collection phase and a data manipulation phase are repeated per record.

- The rowid information collection phase
  - It collects the rowid information of records to be added or to be manipulated.
- The data manipulation phase
  - It manipulates records of a cluster group corresponding to the collected rowid.
  - It sequentially manipulates records in a slave server after manipulating records in a master server.

Data manipulation using the rowid information supports the following two methods depending on whet her to use the **Global Secondary Index**.

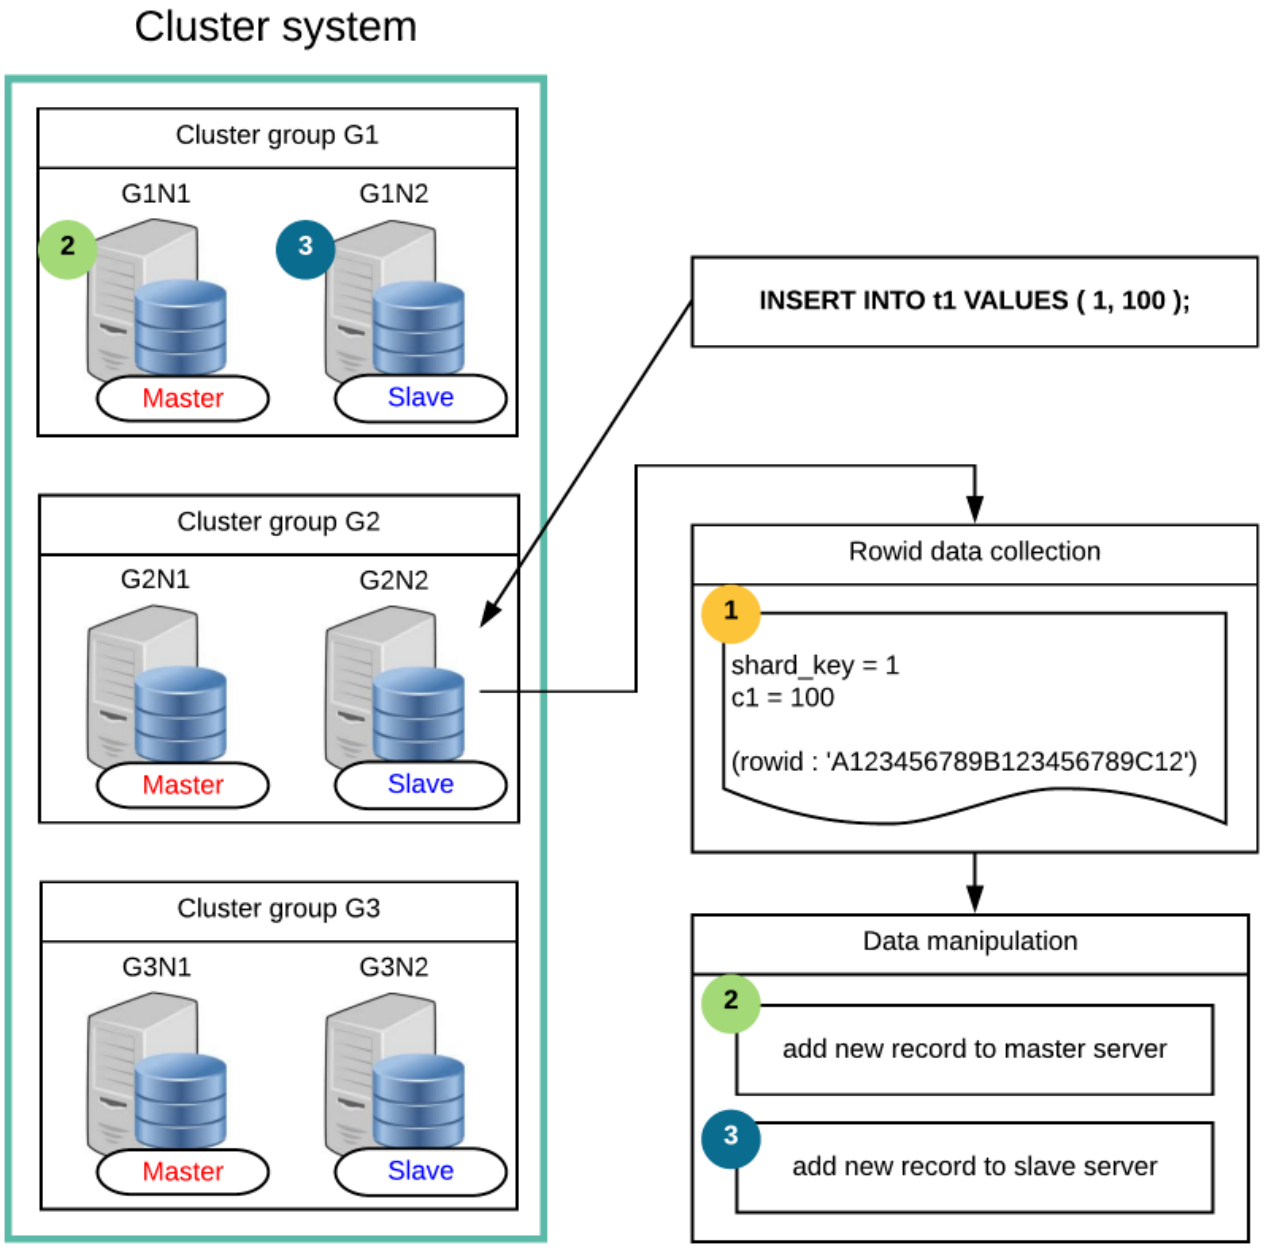
- **Global rowid Based DML without Using Global Secondary Index**
- **Global rowid Based DML Using Global Secondary Index**

Global rowid Based DML without Using Global Secondary Index

Global rowid based DML without using global secondary index is used when it is not required to determi ne whether the update target record in a master server and that in a slave server are same. It is when it c onfigures a new record without referring to the existing record like as INSERT.

Data manipulation using the rowid information without using the global secondary index is performed as follows.

Figure 12 Global rowid based DML without using global secondary index



When adding a record, a rowid is given to a new record and each record is stored at an appropriate positi on in a master server. All records are applied to a slave server after applying to a master server.

If the sharding key column is configured by using the value (shard_key = 1) as given above, it is found tha t the record whose shard_key is 1 is in G1 cluster group by the sharding strategy. Therefore, the record is added only to the G1 cluster group.

The following is a result of performing user query of **Global rowid based DML without using global secon dary index**. As a result, there is not any result output for global rowid based DML.

```
gSQL> \EXPLAIN PLAN INSERT INTO t1 VALUES ( 1, 100 );
1 row created.
>>>  start print plan
< Execution Plan >
=====================================================================
|  IDX  |  NODE DESCRIPTION                      |             ROWS |
---------------------------------------------------------------------
|    0  |  INSERT VALUES STATEMENT ("T1")        |                1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")           |                0 |
|    2  |      TABLE ACCESS ("T1")               |                0 |
=====================================================================
     1  -  TARGET : NOTHING
     2  -  RANGE SHARD ( # 3 )
           READ COLUMN : T1.SHARD_KEY, T1.C1
<<<  end print plan
```

Global rowid based DML without using global secondary index supports the following query types.

- **INSERT INTO**
- **INSERT INTO name RETURNING**
- **INSERT INTO name RETURNING .. INTO**

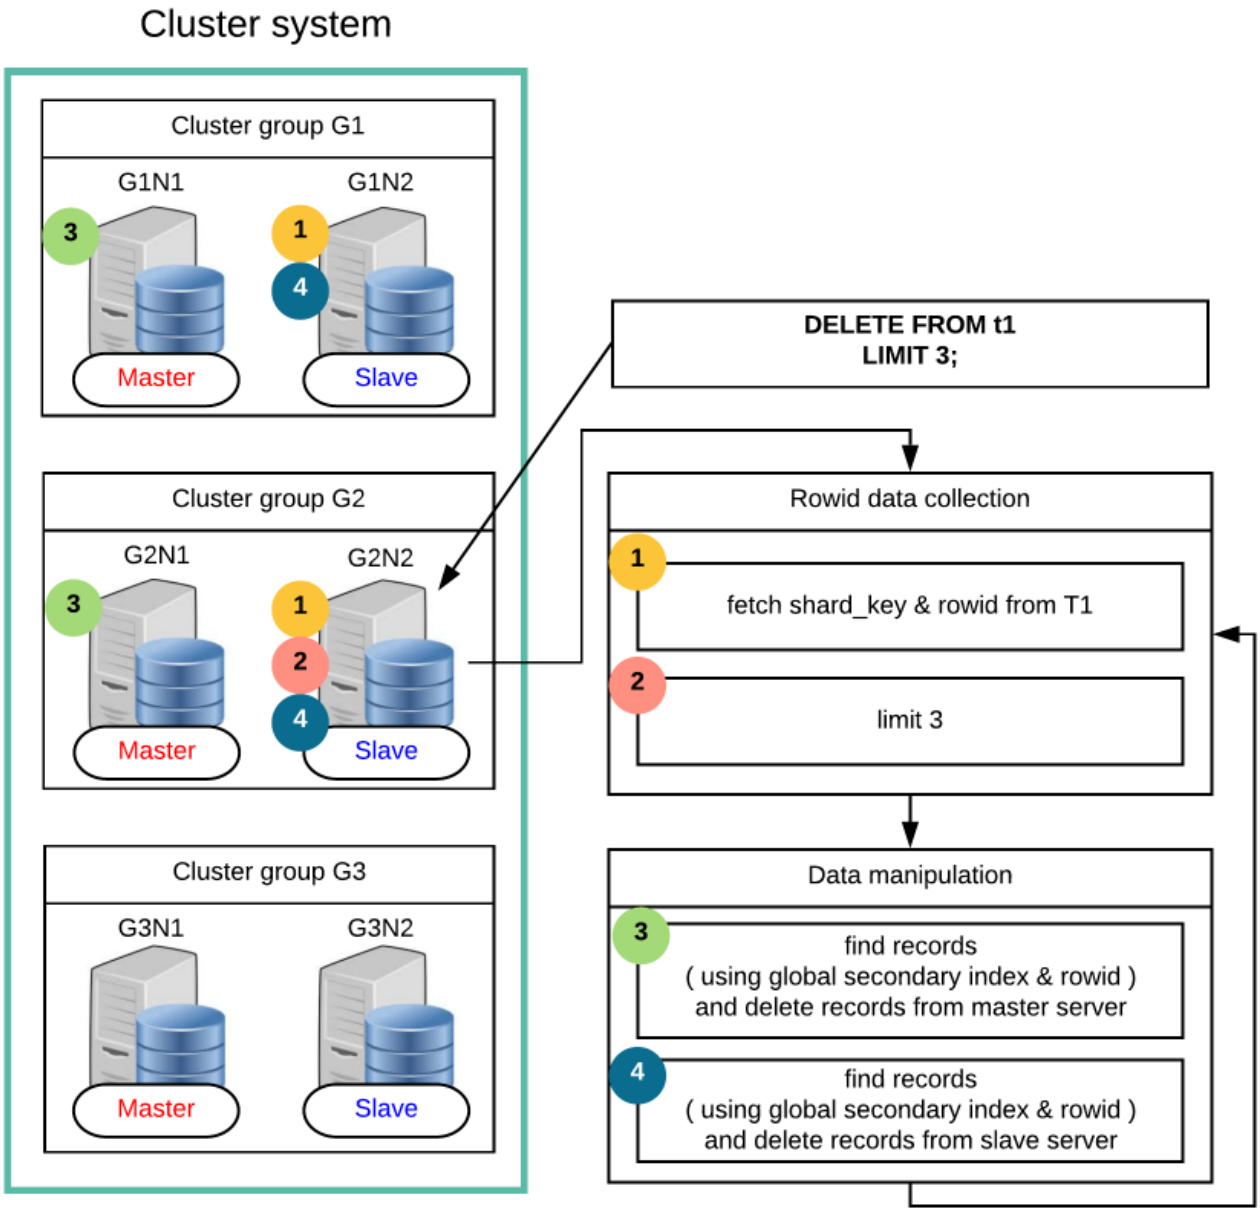
Global rowid Based DML Using Global Secondary Index

The replicated record included in a master server and a slave server have the same global rowid value.

It should be guaranteed that the same data in a master server and a slaver server are manipulated same b y using the global rowid information to manipulate the existing record. The global secondary index is use d to acquire the information about the record replicated through the global rowid.

Data manipulation using the rowid using the global secondary index is performed as follows.

Figure 13 Data manipulation using the rowid using the global secondary index



On the rowid information collection phase, the server received the user query collects row id and column value of the target record to be manipulated.

On the data manipulation phase, data in a master server and a slave server for a cluster group to which th e records selected on the rowid information collection phase belong is sequentially manipulated.

On the data manipulation phase, the server which collected the rowid information, transfers it to a maste r server and a slave server, and requests the data manipulation. The servers received the request retrieve t he target record stored in each server and manipulate it by using the received rowid information and the existing global secondary index.

The rowid information collection phase and the data manipulation phase are repeated until there is not a ny record to be manipulated.

The following is a result of performing user query of **Data manipulation using the rowid using the global secondary index**. As a result, there is not any result output for global rowid based DML.

```
gSQL> \EXPLAIN PLAN DELETE FROM t1 LIMIT 3;
3 rows deleted.
>>>  start print plan
< Execution Plan >
============================================================
|  IDX  |  NODE DESCRIPTION                |             ROWS |
------------------------------------------------------------
|    0  |  DELETE STATEMENT ("T1")         |                3 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")     |                3 |

           TARGET DOMAIN : G1(G1N1,G1N2) 2 rows, G2(G2N1,G2N2) 1 rows, G3(G3N1,G3N2) 0 rows
     3  -  RANGE SHARD ( # 3 )
           READ COLUMN : NOTHING
<<<  end print plan
```

Global rowid based DML using global secondary index supports the following query types.

- SELECT .. FOR UPDATE
- SELECT .. INTO .. FOR UPDATE
- DELETE FROM
- DELETE FROM name RETURNING
- DELETE FROM name RETURNING .. INTO
- DELETE FROM name WHERE CURRENT OF cursor_name
- UPDATE
- UPDATE name RETURNING
- UPDATE name RETURNING .. INTO
- UPDATE name WHERE CURRENT OF cursor_name

13.

SQL Objects

This chapter describes the concepts and features of the following objects which configure the database.

- Authorization: User and privilege
- Schema
- Tablespace
- Table
- Index
- Sequence
- View
- Synonym
- Stored procedure
- Stored function

13.1 Database

Database-related Statements

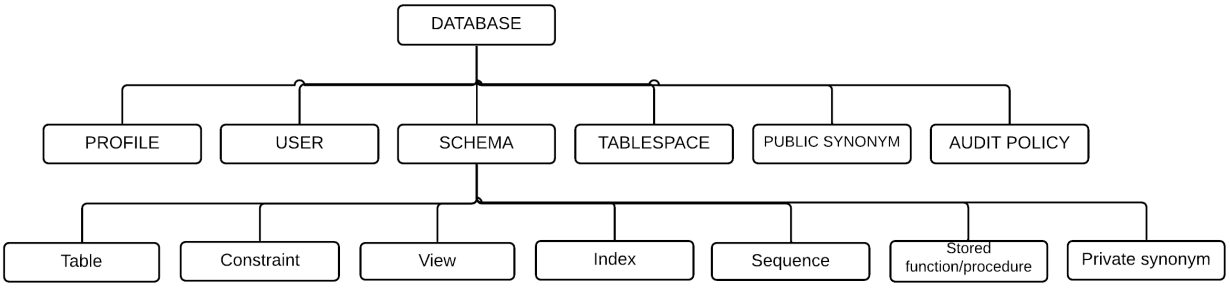
Database Configuration Objects

SQL Objects Which Configures Database

A database consists of multiple SQL objects.

SQL objects in database are classified as SQL schema objects and non-schema objects, depending on whe ther they are included in the SCHEMA.

Figure 1 SQL objects



SQL schema objects are included in the SCHEMA, and they are as follows.

- TABLE: It is an object which stores the physical data, and it consists of columns and rows.
- VIEW: It is a logical object which provides a relation name for the query, and it is similar to a table.
- INDEX: It is an object to improve the query performance.
- SEQUENCE: It is an object to generate numbers.
- CONSTRAINT: It is an object to retain the integrity of tables.
- SYNONYM: It is an alias of TABLE, VIEW, SEQUENCE, and other synonym.
- STORED PROCEDURE: It is a persistent stored module in a procedure form.
- STORED FUNCTION: It is a persistent stored module in a function form.

SQL schema object can be used together with a schema name, or it can be used omitting a schema name. If schema name is omitted, the name is interpreted by the user's schema path.

The following is as example of when objects are created by specifying the schema name.

```
gSQL> CREATE TABLE my_schema.lineitem ( id INTEGER );
gSQL> CREATE INDEX my_schema.my_index ON my_schema.lineitem ( id );
```

Non-schema object is not included in the schema, and they are as follows.

- PROFILE: It is a password management policy.
- AUDIT POLICY: It is an audit policy.
- USER: It is a user.
- SCHEMA: It is the logical locations of the SQL schema objects.
- TABLESPACE: It is the physical spaces of the SQL schema objects.
- PUBLIC SYNONYM: It is an alias of TABLE, VIEW, SEQUENCE, and other synonym which does not hav e schema name

The SQL standard explicitly defines concepts and syntax for the SCHEMA objects. However, the concepts of USER and DATABASE are described only, and their syntaxes are not defined in SQL. The SQL standard does not deal with the TABLESPACE object. Namely, the SQL standard does not explicitly define the non-schema objects.

GOLDILOCKS defines USER, SCHEMA, TABLESPACE as separate descendant of a database. However, oth er DBMS vendors define the concepts of non-schema objects as follows.

- GOLDILOCKS
  - User and schema are separate objects.
  - User either does not have a schema, or has multiple schemas.
  - The relationship between user and schema is User : Schema = 1 : N.
- Oracle
  - User and schema is defined as similar concepts.
  - The relationship between user and schema is User : Schema = 1 : 1.
- DB2
  - User is not a descendant of DATABASE.
  - The relationship between user and schema is User : Schema = 1 : N.
- Postgres
  - User is not a descendant of DATABASE.
  - The relationship between user and schema is User : Schema = 1 : N.
- MySQL
  - User and schema is defined as similar concepts.
  - User is a descendant of DATABASE(SCHEMA).

Name Space of Objects

An object in the database has an identifiable name.
An SQL schema object has a unique name within a schema.
For example, the same lineitem table objects can be created in different schemas as follows.

```
gSQL> CREATE TABLE my_schema.lineitem ( id INTEGER );
gSQL> CREATE TABLE your_schema.lineitem ( name VARCHAR(128) );
```

SQL schema objects have the following name spaces in a single schema as follows.

- TABLE, VIEW, SEQUENCE, PRIVATE SYNONYM, STORED PROCEDURE, STORED FUNCTION
- INDEX
- CONSTRAINT

Table and view can not be created under the same name, but table and index can be created under the s ame name, as follows.

- Table and view can not be created under the same name.

```
gSQL> CREATE TABLE my_relation ( id INTEGER );
gSQL> CREATE VIEW my_relation ( name ) AS SELECT name FROM tmp_relation;
```

- Table and index can be created under the same name.

```
gSQL> CREATE TABLE my_object ( id INTEGER );
gSQL> CREATE INDEX my_object ON my_table ( name );
```

A non-schema object has an identifiable name within a database. Non-schema objects have the name sp aces as follows.

- PROFILE
- AUDIT POLICY
- USER
- SCHEMA
- TABLESPACE

Namely, USERs can not be created under the same name, but USER and SCHEMA can be created under t he same name.

- my_name USER object and my_name SCHEMA object are created.

```
gSQL> CREATE USER my_name IDENTIFIED BY my_name WITH SCHEMA my_name;
```

Built-in Objects

When creating database, GOLDILOCKS automatically creates objects such as user, schema, tablespace which are necessary for system operation.

Built-in User

When creating database, the following accounts are automatically created. The built-in accounts can not be removed except TEST user.

- _SYSTEM account
  - It is an account used by the internal system. When creating database, it is the owner of the built-in objects. When user creates an object, it becomes the grantor who grants the privilege to the object owner.
- SYS account
  - It is a user to manage the database.
- TEST account
  - It is a user for testing, and this object can be removed.
- ADMIN account
  - It is a role to manage the database.
- SYSDBA account
  - It is a role to start up/shut down the database.
- PUBLIC account
  - It is an account for all users. It is used to control the privileges for all users.

Built-in Schema

When creating database, the following schemas are automatically created. All built-in schemas can not be removed.

- DEFINITION_SCHEMA
  - It consists of the physical tables which store all objects information of the database.
- FIXED_TABLE_SCHEMA
  - It consists of the fixed tables which display the data structure information of system in a table form.
- DICTIONARY_SCHEMA
  - It consists of the user perspective views for querying object information of the database.

- INFORMATION_SCHEMA
  - It consists of the views defined in the SQL standard for querying the object information of the dat abase.
- PERFORMANCE_VIEW_SCHEMA
  - It consists of the user perspective views for querying the state of the system.
- SESSION_SCHEMA
  - It is the schema to manage objects in session unit, and the user can not use it.
- PUBLIC
  - It is the schema in which all users can create objects, and it differs from the PUBLIC account, whi ch means all users.

Built-in Tablespace

When creating database, the following tablespaces are created automatically. All the built-in tablespaces can not be removed.

- DICTIONARY_TBS
  - It stores the dictionary tables to manage the SQL objects information.
- MEM_UNDO_TBS
  - It stores undo segments and transactions information.
- MEM_DATA_TBS
  - It is the first created data tablespace.
  - The user created tables are stored in data tablespace.
- MEM_TEMP_TBS
  - It is the first created temporary tablespace.
  - The temporary objects such as sort and hash which are created during query processing are store d in the temporary tablespace.
- DISK_DATA_TBS
  - It is the first created disk data tablespace.
  - The data tablespace stores objects such as a user-created table.
- MEM_AUX_TBS
  - It is a system auxiliary tablespace and it stores records which is automatically created such as an a udit record.
- MEM_TRANS_TBS
  - It is valid in the cluster system, and manages the global transaction information.
  - It is not created in the standalone system.

Built-in Profile

When creating database, the "DEFAULT" profile is automatically created. Password parameter informatio n of the "DEFAULT" profile is as follows.

Table 13-2 Configuration of DEFAULT profile

Parameter	Value
FAILED_LOGIN_ATTEMPTS	10
PASSWORD_LOCK_TIME	1
PASSWORD_LIFE_TIME	180
PASSWORD_GRACE_TIME	7
PASSWORD_REUSE_MAX	UNLIMITED
PASSWORD_REUSE_TIME	UNLIMITED
PASSWORD_VERIFY_FUNCTION	NULL

The followings are characteristics of the default values of "DEFAULT" profile.

- Account lockout
  - An account is locked for one day (PASSWORD_LOCK_TIME) after consecutive 10 (FAILED_LOGIN_ATTEMPTS) times of failed login attempts.
- Password expiration
  - After 180 days (PASSWORD_LIFE_TIME) has elapsed, the password expires after seven days of grace period (PASSWORD_GRACE_TIME).
- Password reusable
  - The old password can be reused.
- Password complexity verification
  - The password complexity is not verified.

13.2 Profile

Profile-related Statements

For more information, refer to the followings.

- Creating a profile: **CREATE PROFILE**.
- Dropping a profile: **DROP PROFILE**.
- Altering a profile: **ALTER PROFILE**.
- Assigning a profile to the user: **CREATE USER**, **ALTER USER**
- Clearing a password history: **ALTER DATABASE CLEAR PASSWORD HISTORY**.

Table 13-3 Profile object related information

Schema	View	Description
DICTIONARY_SCHEMA	**DBA_PROFILES**	All profile information
	DBA_USERS	User profile information

Concepts of Profile

GOLDILOCKS performs user authentication for database security. The password management policy is required because the user authentication password is vulnerable to theft, forgery and misuse.

Profile includes information such as this password management policy. DBA or security managers assign the profile to a user, and apply the password management policy which is appropriate to the corresponding user.

Creating, Altering, Allocating Profile

A profile is created by using CREATE PROFILE statement.

```
CREATE PROFILE profile1 LIMIT
       FAILED_LOGIN_ATTEMPTS     10
       PASSWORD_LOCK_TIME        1
       PASSWORD_LIFE_TIME        180
       PASSWORD_GRACE_TIME       7
       PASSWORD_REUSE_MAX        UNLIMITED
       PASSWORD_REUSE_TIME       UNLIMITED
```

```
        PASSWORD_VERIFY_FUNCTION  NULL;
```

A profile is allocated by using CREATE USER, ALTER USER statements.

```
CREATE USER u1 IDENTIFIED BY u1 PROFILE profile1;
ALTER USER u2 PROFILE profile1;
```

The profile parameters are updated by using ALTER PROFILE statement.

```
ALTER PROFILE profile1 LIMIT
      PASSWORD_REUSE_MAX        3
      PASSWORD_REUSE_TIME       30;
```

If a profile is not allocated to a user, the user is not restricted on creating and using the password.
If the created profile or a DEFAULT profile is allocated to a user, the user complies with the profile's pass word policies when creating and using the password.

Setting Password of DEFAULT Profile

When the default profile is assigned to a user, the password is managed as follows.

Table 13-4 DEFAULT profile of password

Parameter	Default setting	Description
FAILED_LOGIN_ATTEMPS	10	The allowed number of consecutive login failure The account is locked after consecutive 10 times login attempt failures.
PASSWORD_LOCK_TIME	1	The account lockout duration If the consecutive login failures exceed the allowable value, the account is locked for one day.
PASSWORD_LIFE_TIME	180	The password life time The password is expired after 180 days.
PASSWORD_GRACE_TIME	7	The duration to change the password when the the password is expired. The password should be changed within seven days after first login sinc e the password is expired. If a user does not change the password withi n the period, the user can not log in using the password.
PASSWORD_REUSE_MAX	UNLIMITED	The number of times of which passwords are not reusable. PASSWORD_REUSE_MAX should be set together with PASSWORD_RE USE_TIME. If both of the two values are UNLIMITED, the password can always be reused.
PASSWORD_REUSE_TIME	UNLIMITED	The duration which the password can not be reused.

Account Lockout

If the number of consecutive login atempt failures exceed the number of times specified in FAILED_LOGIN_ATTEMPTS, the account is locked during the period specified in PASSWORD_LOCK_TIME.

```
CREATE PROFILE profile1 LIMIT
       FAILED_LOGIN_ATTEMPTS     10
       PASSWORD_LOCK_TIME        1;
ALTER USER u1 PROFILE profile1;
```

When a user u1's login attempts consecutively fails more than 10 times, the account is locked for one days. And after one day the account is automatically unlocked.

If the PASSWORD_LOCK_TIME value is not specified, it is regarded as the value which is specified in PASSWORD_LIFE_TIME of DEFAULT profile.

If the PASSWORD_LOCK_TIME value is UNLIMITED the locked accounts is not automatically released. Therefore, the following statement should be executed to unlock the account.

```
ALTER USER u1 ACCOUNT UNLOCK;
```

If login is successful, the number of failed login attempt is initialized to zero.

A security manager can explicitly lock the user accounts. In this case, the user accounts can not be automatically released so the security manager should unlock the user accounts.

```
ALTER USER u1 ACCOUNT LOCK;
ALTER USER u1 ACCOUNT UNLOCK;
```

Password Lifetime

PASSWORD_LIFE_TIME specifies the life time the password. After the life time, the password is expired. A user, DBA or security manager should change the password after a password is expired.

```
CREATE PROFILE profile1 LIMIT
       PASSWORD_LIFE_TIME        180
       PASSWORD_GRACE_TIME       7;
ALTER USER u1 PROFILE profile1;
```

The grace period starts since when the user u1 has tried to log in for the first time after 180 days.

During seven days of the grace period, the user is reminded to enter a new password whenever accessing the account, until he changes the password.

If seven days of the grace period passed and the password is not changed, the user can not login until en tering a new password.

A password can be expired by using CREATE USER or ALTER USER statements.

```
ALTER USER u1 PASSWORD EXPIRE;
```

When the password is expired, the error (ERR-28000(16312) the password has expired) occurs whenever logging in as follows, then a new password should be entered.

```
% gsql u1 u1
ERR-28000(16312): the password has expired
Changing password for u1
New password:
Retype new password:
Connected to GOLDILOCKS Database.
gSQL>
```

Reusing Password

The password can be reused after it is changed as many times as the specified value in PASSWORD_REUS E_MAX. Also, it should be after the specified time in PASSWORD_REUSE_TIME.

```
CREATE PROFILE profile1 LIMIT
       PASSWORD_REUSE_MAX        2
       PASSWORD_REUSE_TIME       1;
ALTER USER u1 PROFILE profile1;
```

The user u1 can reuse the current password after the password has been changed for two times, and 10 days elapsed.

```
ALTER USER u1 IDENTIFIED BY u1 REPLACE u1;
ALTER USER u1 IDENTIFIED BY u1 REPLACE u1
*
ERROR at line 1:
ORA-28007: the password cannot be reused
ALTER USER u1 IDENTIFIED BY u2 REPLACE u1;
User altered.
ALTER USER u1 IDENTIFIED BY u3 REPLACE u2;
User altered.
```

- 10 days elapsed.

```
ALTER USER u1 IDENTIFIED BY u1 REPLACE u3;
User altered.
```

The both conditions should be satisfied to reuse the old password. If only one of the value in PASSWORD_REUSE_MAX and PASSWORD_REUSE_TIME is UNLIMITED, the password can not be reused.
If both of values are UNLIMITED, the password can always be reused.

Table 13-5 Password reuse

PASSWORD_REUSE_MAX	PASSWORD_REUSE_TIME	Password reusability
Integer value	Integer value	If both of the conditions are satisfied, it can be reused.
Integer value	UNLIMITED	It can not be reused.
UNLIMITED	Integer value	It can not be reused.
UNLIMITED	UNLIMITED	It can always be reused.

Password Complexity Verification

Password complexity verification checks if the password is complex enough to protect against breaking in to the system.
GOLDILOCKS supports the method of password complexity verification as follows.

Table 13-6 Password complexity verification

Method	Description
KISA_VERIFY_FUNCTION	• 8 or more characters • 1 or more letters • 1 or more numbers • 1 or more special characters
ORA12C_VERIFY_FUNCTION	• 8 or more characters • 1 or more letters • 1 or more numbers • Database name should not be included. • Username or the reversed username should not be included. • *goldilocks* should not be included. • *oracle* should not be included. • The following simple password can not be used. ◦ welcome1, database1, account1, user1234, password1, oracle123, computer1, abcdefg1, change_on_intall • The new password should be different at least 3 characters from the old password.
	• 9 or more characters • 2 or more uppercases

Method	Description
ORA12C_STRONG_VERIFY_FUNCTION	• 2 or more lowercases • 2 or more numbers • 2 or more special characters • The new password should be different at least 4 characters from the old password.
VERIFY_FUNCTION_11G	• 8 or more characters • 1 or more letters • 1 or more numbers • Username should not be included. • The new password should be different at least 3 characters from the old password.
VERIFY_FUNCTION	• It should not be same as the username. • 4 or more characters • 1 or more letters • 1 or more numbers • 1 or more special characters • The following simple password can not be used. ◦ welcome, database, account, user, password, oracle, computer, abcd • The new password should be different at least 3 characters from the old password.

For more information about profile and user setting, refer to **CREATE PROFILE**, **CREATE USER**.

13.3 Audit Policy

Audit Policy-related Statement

For more information, refer to the followings.

- Creating audit policy: **CREATE AUDIT POLICY**
- Dropping audit policy: **DROP AUDIT POLICY**
- Altering audit policy: **ALTER AUDIT POLICY**
- Activating audit policy: **AUDIT POLICY**
- Deactivating audit policy: **NOAUDIT POLICY**
- Dropping audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

Table 13-7 Audit policy object information

Schema	View	Description
DICTIONARY_SCHEMA	**AUDIT_POLICIES**	Information about all audit policies
	AUDIT_POLICY_OPTIONS	Information about audit policy option
	AUDIT_POLICY_ENABLED	Information about activating audit policy

Examples

AUDIT SYSTEM ON DATABASE privilege is required to perform the followings.

Creating Audit Policy

Perform **CREATE AUDIT POLICY** statement to create an audit policy object.

The following is an example of creating an audit_t1_dml object to audit the DML for a u1.t1 table.

```
CREATE AUDIT POLICY audit_t1_dml
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
;
Audit policy created.
```

Enquire the information about audit policy options by using **AUDIT_POLICY_OPTIONS** view.

```
SELECT policy_name
     , audit_option
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'AUDIT_T1_DML'
 ORDER BY audit_option
;
POLICY_NAME  AUDIT_OPTION OBJECT_SCHEMA OBJECT_NAME
------------ ------------ ------------- -----------
AUDIT_T1_DML DELETE       U1            T1
AUDIT_T1_DML INSERT       U1            T1
AUDIT_T1_DML UPDATE       U1            T1
3 rows selected.
```

Activating Audit Policy

Use **AUDIT POLICY** statement to activate the audit policy.

The following is an example of activating an audit policy to leave an audit record when a user except for u1, sys succeeded to perform DML for u1.t1 table.

```
AUDIT POLICY audit_t1_dml
      EXCEPT u1, sys
      WHENEVER SUCCESSFUL
;
```

The activated audit policy is applied to the newly created session, but it does not affect the existing sessio ns.

View the information about activated audit policy by using **AUDIT_POLICY_ENABLED**.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
 ORDER BY user_name
;
POLICY_NAME             ENABLED_OPT           USER_NAME  WHEN_SUCCESS WHEN_FAILURE
```

```
-------------------- ---------------------- ---------- ------------ ---------
AUDIT_T1_DML         EXCEPT                 SYS        YES          NO
AUDIT_T1_DML         EXCEPT                 U1         YES          NO
2 rows selected.
```

After the audit policy is activated, the corresponding actions create audit records.

The following is an example of when u2 user successfully performs SQL statements.

```
SELECT COUNT(*) FROM u1.t1;
INSERT INTO u1.t1 VALUES ( 1 );
UPDATE u1.t1 SET id = id + 1 WHERE id = 1;
DELETE u1.t1 WHERE id = 2;
COMMIT;
```

In the example above, INSERT, UPDATE, DELETE are target actions of an audit, so it creates audit records, but SELECT and COMMIT are not a target action of an audit, so it does not create audit records.

Viewing Audit Trail

SELECT ON DICTIONARY_SCHEMA.AUDIT_TRAIL privilege for AUDIT_TRAIL view is required to view audit records.

The following is an example of viewing an audit trail created by an audit_t1_dml audit policy.

```
SELECT policy_name
     , logon_username
     , action_name
     , object_schema
     , object_name
     , sql_text
  FROM audit_trail
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  LOGON_USERNAME ACTION_NAME OBJECT_SCHEMA OBJECT_NAME SQL_TEXT
------------ -------------- ----------- ------------- -----------
----------------------------------------
AUDIT_T1_DML U2             INSERT      U1            T1          INSERT INTO u1.t1 VALUES ( 1
)
AUDIT_T1_DML U2             UPDATE      U1            T1          UPDATE u1.t1 SET c1 = c1 + 1
WHERE c1 = 1
AUDIT_T1_DML U2             DELETE      U1            T1          DELETE u1.t1 WHERE c1 = 2
3 rows selected.
```

Dropping Audit Trail

When an audit policy is activated, the size of an audit trail keeps increasing.
Execute the following statement to drop the audit trail.

```
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Store it in the user table and drop it as follows to store the audit trail.

- Creating a user table

```
CREATE TABLE my_audit_trail
AS SELECT *
     FROM audit_trail
     WITH NO DATA;
```

- Storing it in a user table, then dropping it.

```
INSERT INTO my_audit_trail SELECT * FROM audit_trail;
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Create and manage the view as follows to view both the stored audit trail and the current audit_trail.

```
CREATE VIEW unified_audit_trail
AS
SELECT * FROM my_audit_trail
 UNION ALL
SELECT * FROM dictionary_schema.audit_trail
;
```

Deactivating Audit Policy

Deactivate the audit policy by using the following statement.

```
NOAUDIT POLICY audit_t1_dml;
```

Deactivating audit policy affects the newly created session, but it does not affect the activated informatio n about existing sessions.

Dropping Audit Policy

Execute the following statement to drop the audit policy object.

```
DROP AUDIT POLICY audit_t1_dml;
```

The audit policy object should be deactivated to be dropped, and dropping the object does not affect the existing sessions.

Concepts of Audit Policy

Audit Trail

Viewing Audit Trail

Audit record can be viewed by using DICTIONARY_SCHEMA.AUDIT_TRAIL view.

SELECT privilege is required to view AUDIT_TRAIL view.

```
GRANT SELECT ON DICTIONARY_SCHEMA.AUDIT_TRAIL TO user_name;
```

AUDIT_TRAIL view has the following information.

Table 13-8 Column information

Information	Column name	Description
Session information	MEMBER_NAME	Cluster member name
	SESSION_ID	Session identifier
	SESSION_SERIAL	Session serial number
	LOGON_USERNAME	Logon user name of the user whose actions were audited
	CURRENT_USERNAME	Effective user for the statement execution
	SERVER_PROCESS	Server process identifer for the session
Peer client information	CLIENT_PROGRAM_NAME	Client program used for session
	CLIENT_USERNAME	Client operating system user name for the session
	CLIENT_PROCESS	Client process identifer for the session
	CLIENT_HOST	Client host ip address for the session
	CLIENT_PORT	Client port number for the session
	CLIENT_TERMINAL	Client terminal name for the session
	TRANSACTION_ID	Transaction identifier
	SCN	System change number (SCN) string of the query at the time of the event

Information	Column name	Description
SQL information	GCN	Global change number (GCN) of the query at the time of the event
	DCN	Domain change number (DCN) of the query at the time of the event
	LCN	Local change number (LCN) of the query at the time of the event
	STMT_NO	Numeric number for each statement run in a session
	SQL_TEXT	SQL associated with the event
	SQL_BINDS	List of bind variables, if any, associated with SQL_TEXT
	RETURN_CODE	Error code generated by the action, zero if the action succeeded
	ERROR_MESSAGE	Error message generated by the action, null if the action succeeded
Event information	ENTRY_ID	Audit trail entry identifier in the session
	EVENT_TIMESTAMP	Timestamp of the creation of the audit trail entry in local time zone
	POLICY_NAME	Audit policy name that caused the current audit record
	PRIVILEGE_USED	Database privilege used to execute the action
	ACTION_NAME	Action name executed by the user
	OBJECT_TYPE	Object type of object affected by the action
	OBJECT_SCHEMA	Schema name of object affected by the action
	OBJECT_NAME	Object name of object affected by the action

Storing Audit Trail

AUDIT_TRAIL view consists of the following tables.

- AUDIT_TRAIL_SESSION
  - It records a record per a session.
  - Session information
  - Peer client information
- AUDIT_TRAIL_SQL
  - It records a record per SQL.
  - SQL information
- AUDIT_TRAIL_EVENT
  - It records a record per an audit option.
  - Audit event information

Audit records configuring an audit trail is devided into multiple tables then stored.
The schema of the tables is DEFINITION_SCHEMA, and it is stored in MEM_AUX_TBS tablespace.

- DEFINITION_SCHEMA
  - It is a schema storing dictionary tables.
- MEM_AUX_TBS
  - System auxiliary tablespace
  - It is a tablespace to store a record which automatically created by the database.
  - It is managed by a separate tablespace not to affect the service management by an automatically

created record.

Creating Audit Record

If an audit policy is activated, it creates an audit record when the corresponding action occurs.
It creates one or more audit records when multiple corresponding actions occur.

- If similar audit options are listed as follows, it creates a single audit record.
  - Defining an audit policy

```
CREATE AUDIT POLICY p1
       PRIVILEGES INSERT ANY TABLE
       ACTIONS INSERT;
AUDIT POLICY p1;
```

  - Performing an audit action

```
INSERT INTO other_user.t1 VALUES ( 1 );
```

- If different audit options are listed as follows, it creates two audit records.
  - Defining an audit policy

```
CREATE AUDIT POLICY p1
       ACTIONS SELECT ON u1.t1
             , SELECT ON u1.t2;
AUDIT POLICY p1;
```

  - Performing an audit action

```
SELECT COUNT(*) FROM u1.t1 A, u1.t2 B WHERE A.id = B.id;
```

- If multiple audit policies are activated in the identical action as follows, it creates two audit records.
  - Defining an audit policy

```
CREATE AUDIT POLICY p1
       PRIVILEGES INSERT ANY TABLE;
AUDIT POLICY p1;
CREATE AUDIT POLICY p2
       ACTIONS INSERT;
AUDIT POLICY p2;
```

    - Performing an audit action

```
INSERT INTO other.t1 VALUES (1);
```

Dropping Audit Trail (purge)

Execute the following statement to drop the audit trail.

```
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Create a user table and store old audit record in it as follows.

```
CREATE TABLE my_audit_trail AS SELECT * FROM audit_trail WITH NO DATA;
```

Then, regularly store it by using INSERT .. SELECT statement before dropping the audit trail.

```
INSERT INTO my_audit_trail SELECT * FROM audit_trail;
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Execute DELETE statement by using EVENT_TIMESTAMP column to store the audit record of the specified period.

```
INSERT INTO my_audit_trail SELECT * FROM audit_trail;
DELETE FROM my_audit_trail WHERE event_timestamp < ADD_MONTHS( sysdate, -3 );
ALTER DATABASE CLEAR AUDIT TRAIL;
```

View the old audit record and the current audit record together by creating a view as follows.

```
CREATE VIEW audit_trail_view
AS SELECT * FROM dictionary_schema.audit_trail
   UNION ALL
   SELECT * FROM my_audit_trail;
SELECT * FROM audit_trail_view;
```

Configuring Audit Policy

Audit policy may include the following options.

- Privilege auditing
    - It audits SQL performance by using the database privilege.
- Object action auditing
    - It audits SQL performance for the specific object.
- System action auditing

- It audits SQL performance for all objects.

Multiple audit options can be managed by creating multiple audit policies, but it is recommended to man age multiple audit options by creating a small number of audit policies.

The activated audit policy information is constructed as a session information at logon time, so the less th e number of audit policies, the less the load becomes.
Moreover, if multiple audit policies are activated, then it determines whether to create an audit record for an SQL statement, so a load creating multiple audit records may occur.

Audit policy information constructed in a session at logon time is not affected by dropping, altering, acti vating or deactivating an audit policy.
Altering an audit policy is applied only to a newly logon session.

Privilege Auditing

Privilege auditing is set to audit when SQL statement is successfully performed by using the database privi lege.
It does not create an audit record which is based on the privilege auditing about sys user (the database o wner).

The database privilege which can be listed for the privilege auditing can be viewed through **V$AUDITABL E_DB_PRIVILEGES** view.

```
SELECT privilege_name FROM v$auditable_db_privileges;
PRIVILEGE_NAME
----------------------
ADMINISTRATION
ALTER DATABASE
ALTER SYSTEM
ACCESS CONTROL
CREATE USER
ALTER USER
DROP USER
CREATE TABLESPACE
ALTER TABLESPACE
DROP TABLESPACE
USAGE TABLESPACE
CREATE SCHEMA
DROP SCHEMA
ANALYZE ANY
CREATE ANY TABLE
```

```
ALTER ANY TABLE
DROP ANY TABLE
SELECT ANY TABLE
INSERT ANY TABLE
DELETE ANY TABLE
UPDATE ANY TABLE
LOCK ANY TABLE
CREATE ANY VIEW
DROP ANY VIEW
CREATE ANY SEQUENCE
ALTER ANY SEQUENCE
DROP ANY SEQUENCE
USAGE ANY SEQUENCE
CREATE ANY INDEX
ALTER ANY INDEX
DROP ANY INDEX
CREATE ANY SYNONYM
DROP ANY SYNONYM
CREATE PUBLIC SYNONYM
DROP PUBLIC SYNONYM
CREATE PROFILE
ALTER PROFILE
DROP PROFILE
CREATE ANY PROCEDURE
ALTER ANY PROCEDURE
DROP ANY PROCEDURE
EXECUTE ANY PROCEDURE
AUDIT SYSTEM
PURGE DBA_RECYCLEBIN
44 rows selected.
```

The following is an example of when a user u1 who has SELECT ANY TABLE privilege activates an audit p olicy for the privilege auditing.

```
CREATE AUDIT POLICY p1
       PRIVILEGES SELECT ANY TABLE;
AUDIT POLICY p1;
```

Whether the audit record is created when a user u1 performs the following two statements is as follows.

- SELECT * FROM u1.t1
  - It does not use SELECT ANY TABLE privilege because it is an owner of the object.

    - An audit record does not exist.
- SELECT * FROM other.t1
    - It succeeds with SELECT ANY TABLE privilege even though it does not have SELECT ON other.t1 privilege.
    - It creates an audit record.

Use AUDIT_POLICY_OPTIONS view to view the privilege auditing information as follows.

```
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'P1'
;
AUDIT_OPTION         AUDIT_OPTION_TYPE    OBJECT_SCHEMA     OBJECT_NAME
-------------------- -------------------- ----------------- ------------
SELECT ANY TABLE     DATABASE PRIVILEGE   null              null
```

Auditing Object Action

It audits SQL which is performed for a specific object.
Actions to be audited per each object type are as follows.

Table 13-9 Audit action per object type

Object type	Actions
Table	ALTER, COMMENT, DELETE, GRANT, INDEX, INSERT, LOCK, RENAME, SELECT, UPDATE
View	ALTER, COMMENT, GRANT, SELECT
Sequence	ALTER, COMMENT, GRANT, SELECT
Stored function/ procedure	ALTER, COMMENT, EXECUTE, GRANT

Create the audit policy as follows to audit DML for table u1.t1.

```
CREATE AUDIT POLICY audit_t1_dml
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
;
```

Execute AUDIT_POLICY_OPTIONS view as follows to view the information about object action auditing.

```
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'AUDIT_T1_DML'
 ORDER BY audit_option
;
AUDIT_OPTION AUDIT_OPTION_TYPE OBJECT_SCHEMA OBJECT_NAME
------------ ----------------- ------------- -----------
DELETE       OBJECT ACTION     U1            T1
INSERT       OBJECT ACTION     U1            T1
UPDATE       OBJECT ACTION     U1            T1
3 rows selected.
```

ALL option such as ALL ON schema.object means all audit actions which can be defined for the correspon ding object.

The following is an example of using ALL option together with other options.

```
CREATE AUDIT POLICY p1
       ACTIONS ALL ON u1.seq1
             , ALTER ON u1.seq1
;
Audit policy created.
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'P1'
 ORDER BY audit_option
;
AUDIT_OPTION AUDIT_OPTION_TYPE OBJECT_SCHEMA OBJECT_NAME
------------ ----------------- ------------- -----------
ALL          OBJECT ACTION     U1            SEQ1
ALTER        OBJECT ACTION     U1            SEQ1
2 rows selected.
```

When dropping ALL option as follows, not every audit options are dropped, but only ALL option is dropp ed.

```
ALTER AUDIT POLICY p1
      DROP ACTIONS ALL ON u1.seq1;
Audit Policy altered.
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'P1'
 ORDER BY audit_option;
AUDIT_OPTION AUDIT_OPTION_TYPE OBJECT_SCHEMA OBJECT_NAME
------------ ----------------- ------------- -----------
ALTER        OBJECT ACTION     U1            SEQ1
1 row selected.
```

Auditing success or failure of EXECUTE a stored function or a stored procedure is determined based only on whether it is executable at the time of the execution.

- WHENEVER NOT SUCCESSFUL creates an audit record when it can not performs a stored function/ procedure.
- WHENEVER SUCCESSFUL creates an audit record even when an error occurs while performing an SQL statement in a stored function/ procedure.
- If an auditing the failure of an SQL statement in a stored function/ procedure, then that SQL statement should be included in an auditing target.

The following is an example of executing SELECT statement including a stored function.

```
SELECT others.func1( t1.c1 )
  FROM t1;
```

It corresponds to WHENEVER NOT SUCCESSFUL when it fails to call others.func1() due to an error such as a lack of privilege. It corresponds to WHENEVER SUCCESSFUL even though an error occurs while executing an SQL statement in a stored function when it succeeds to call others.func1().

Auditing System Action

It audits an SQL statement regardless of a specific object.
A valid system action enquires V$AUDITABLE_SYSTEM_ACTIONS.

```
SELECT action_name FROM v$auditable_system_actions;
ACTION_NAME
------------------------
ALL
```

```
DDL
SELECT

FLASHBACK TABLE                                            FLASHBACK TABLE
185 rows selected.
```

The following is an example of creating an audit policy including a system action, and enquiring an audit option.

```
CREATE AUDIT POLICY p1
       ACTIONS SELECT
             , DROP TABLE
             , DROP USER
;
Audit Policy created.
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'P1'
 ORDER BY audit_option
;
AUDIT_OPTION AUDIT_OPTION_TYPE OBJECT_SCHEMA OBJECT_NAME
------------ ----------------- ------------- -----------
DROP TABLE   SYSTEM ACTION     null          null
DROP USER    SYSTEM ACTION     null          null
SELECT       SYSTEM ACTION     null          null
3 rows selected.
```

Useful Audit Policy

The following is an example of defining a useful audit policy.

- Auditing a logon failure

```
CREATE AUDIT POLICY AUDIT_LOGON_FAILURES
       ACTIONS LOGON
;
AUDIT POLICY AUDIT_LOGON_FAILURES
      WHENEVER NOT SUCCESSFUL
;
```

- Auditing a Data Definition Language (DDL) performance

```
CREATE AUDIT POLICY AUDIT_DDL
       ACTIONS DDL
;
AUDIT POLICY AUDIT_DDL
      WHENEVER SUCCESSFUL
;
```

- Auditing a parameter alteration

```
CREATE AUDIT POLICY AUDIT_DATABASE_PARAMETER
       ACTIONS ALTER DATABASE
             , ALTER SYSTEM
;
AUDIT POLICY AUDIT_DATABASE_PARAMETER
      WHENEVER SUCCESSFUL
;
```

- Auditing an account alteration

```
CREATE AUDIT POLICY AUDIT_ACCOUNT_MGMT
       ACTIONS CREATE USER
             , DROP USER
             , ALTER USER
             , CHANGE PASSWORD
             , GRANT
             , REVOKE
;
AUDIT POLICY AUDIT_ACCOUNT_MGMT
```

```
;
```

- Auditing the recommendations of Center for Internet Security (CIS)

```
CREATE AUDIT POLICY AUDIT_CIS_RECOMMENDATIONS
       PRIVILEGES ALTER SYSTEM
                , ALTER DATABASE
          ACTIONS CREATE USER
                , DROP USER
                , ALTER USER
                , CHANGE PASSWORD
                , GRANT
                , REVOKE
                , CREATE PROFILE
                , ALTER PROFILE
                , DROP PROFILE
                , CREATE SYNONYM
                , DROP SYNONYM
                , CREATE PROCEDURE
                , DROP PROCEDURE
                , ALTER PROCEDURE
;
AUDIT POLICY AUDIT_CIS_RECOMMENDATIONS
      WHENEVER SUCCESSFUL
;
```

Operationg Audit Policy

Activating Audit Poilcy

An audit policy object does not start auditing until it is activated.

An audit policy object should be activated by using AUDIT POLICY statement as follows to perform auditi ng.

```
CREATE AUDIT POLICY audit_t1_dml
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
;
Audit policy created.
AUDIT POLICY audit_t1_dml;
```

```
Audit succeeded.
```

When activating an audit policy, it audits new sessions only, but it does not affect the existing sessions.

When activating an audit policy by using AUDIT POLICY statement, it can specifies a user which will audit using BY clause or EXCEPT clause, or it may audit success/ failure of an audit action by using WHENEVER clause.

- BY | EXCEPT
  - BY user_list: It specifies a user to audit.
  - EXCEPT user_list: It audits all users except for specified users.
  - When it is omitted, it audits all users.
- WHENEVER
  - WHENEVER SUCCESSFUL: It creates an audit record when an audit action succeeds.
  - WHENEVER NOT SUCCESSFUL: It creates an audit record when an audit action fails.
  - When it is omitted, it creates an audit record regardless of a success/ failure of an audit action.

The information about activated audit policy can be viewed by executing AUDIT_POLICY_ENABLED view.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME  WHEN_SUCCESS WHEN_FAILURE
------------ ----------- ---------- ------------ ------------
AUDIT_T1_DML BY          ALL USERS  YES          YES
```

If the auditing target user is omitted as the example above, it outputs ALL USERS meaning all users.

Note the followings when using BY clause and EXCEPT clause.

- BY clause and EXCEPT clause can not be used together for the same audit policy.

```
AUDIT POLICY audit_t1_dml BY u1;
Audit succeeded.
AUDIT POLICY audit_t1_dml EXCEPT u2;
ERR-42000(16475): audit policy already applied with the BY clause
```

- If multiple AUDIT POLICY BY clauses are used in the same audit policy, it is activated for the user sets.

In other words, the following examples have the same meaning.

◦ Example 1

```
AUDIT POLICY audit_t1_dml BY u1;
Audit succeeded.
AUDIT POLICY audit_t1_dml BY u2;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          YES
AUDIT_T1_DML BY          U2        YES          YES
2 rows selected.
```

◦ Example 2

```
AUDIT POLICY audit_t1_dml BY u1, u2;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          YES
AUDIT_T1_DML BY          U2        YES          YES
2 rows selected.
```

- If multiple AUDIT POLICY EXCEPT clauses are used in the same audit policy, only the last AUDIT POLICY statement is valid. In other words, the following examples have different meanings.

- Example 1

```
AUDIT POLICY audit_t1_dml EXCEPT u1;
Audit succeeded.
AUDIT POLICY audit_t1_dml EXCEPT u2;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML EXCEPT      U2        YES          YES
1 row selected.
```

- Example 2

```
AUDIT POLICY audit_t1_dml EXCEPT u1, u2;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML EXCEPT      U1        YES          YES
AUDIT_T1_DML EXCEPT      U2        YES          YES
2 rows selected.
```

- WHENEVER clause which is used together with BY clause is accumulated. In other words, the followi ng examples have the same meaning.

- Example 1

```
AUDIT POLICY audit_t1_dml BY u1 WHENEVER SUCCESSFUL;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          NO
1 row selected.
AUDIT POLICY audit_t1_dml BY u1 WHENEVER NOT SUCCESSFUL;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          YES
1 row selected.
```

- Example 2

```
AUDIT POLICY audit_t1_dml BY u1;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
```

```
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          YES
1 row selected.
```

- If WHENEVER clause is used together with EXCEPT clause, then only the last part of it is valid. In othe r words, the following examples have different meanings.
    - Example 1

```
AUDIT POLICY audit_t1_dml EXCEPT u1 WHENEVER SUCCESSFUL;
Audit succeeded.
AUDIT POLICY audit_t1_dml EXCEPT u1 WHENEVER NOT SUCCESSFUL;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML EXCEPT      U1        NO           YES
1 row selected.
```

    - Example 2

```
AUDIT POLICY audit_t1_dml EXCEPT u1;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML EXCEPT      U1        YES          YES
```

```
1 row selected.
```

Deactivating Audit Policy

NOAUDIT POLICY statement should be executed to deactivate an audit policy.
NOAUDIT POLICY statement is applied only to a new session, and it does not affect to the existing sessio n.

If all information is set to be deactivated by using the query below, then an audit policy is completely dea ctivated.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
no rows selected.
```

NOAUDIT POLICY statement deletes each activated information which is created according to the specifie d AUDIT POLICY method.

The following is an example of deactivating only the auditing for u1 user of audit_t1_dml.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ----------- --------- ------------ ------------
AUDIT_T1_DML BY          U1        YES          YES
AUDIT_T1_DML BY          SYS       YES          YES
2 rows selected.
NOAUDIT POLICY audit_t1_dml BY u1;
Noaudit succeeded.
SELECT policy_name
```

```
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ---------- --------- ------------ ------------
AUDIT_T1_DML BY         SYS       YES          YES
1 row selected.
```

If AUDIT POLICY name BY clause is used it should be deactivated by using NOAUDIT POLICY name BY statement. If AUDIT POLICY name EXCEPT clause is used it should be deactivated by using NOAUDIT POLICY name statement without BY clause.

NOAUDIT POLICY statement should be used according to the usage as follows to deactivate each option of AUDIT POLICY statement.

Table 13-10 Activating/ deactivating audit policy

Type	AUDIT POLICY statement	NOAUDIT POLICY statement
All users	AUDIT POLICY p1	NOAUDIT POLICY p1
Using BY	AUDIT POLICY p1 BY u1	NOAUDIT POLICY p1 BY u1
Using EXCEPT	AUDIT POLICY p1 EXCEPT u1	NOAUDIT POLICY p1

If all users are activated as follows, NOAUDIT POLICY BY clause does not affect anything.

```
AUDIT POLICY audit_t1_dml;
Audit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ---------- --------- ------------ ------------
AUDIT_T1_DML BY         ALL USERS YES          YES
1 row selected.
NOAUDIT POLICY audit_t1_dml BY u1;
```

```
Noaudit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'AUDIT_T1_DML'
;
POLICY_NAME  ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
------------ ---------- --------- ------------ ------------
AUDIT_T1_DML BY         ALL USERS YES          YES
1 row selected.
```

If one or more users are separately activated, NOAUDIT POLICY statement should be used according to th e AUDIT POLICY configuration.

- When it is activated by using BY clause
    - The following is an example of activating by using BY clause.

```
AUDIT POLICY p1 WHENEVER NOT SUCCESSFUL;
AUDIT POLICY p1 BY u1;
AUDIT POLICY p1 BY u2;
```

    - The information about activating is viewed as follows.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
----------- ---------- --------- ------------ ------------
P1          BY         ALL USERS NO           YES
P1          BY         U1        YES          YES
P1          BY         U2        YES          YES
3 rows selected.
```

    - The following is the information about activating when NOAUDIT statement is performed.

```
NOAUDIT POLICY p1;
Noaudit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
----------- ----------- --------- ------------ ------------
P1          BY          U1        YES          YES
P1          BY          U2        YES          YES
2 rows selected.
```

In the example above, the auditing for ALL USERS is deactivated, but the auditing for user u1 and u2 are still activated.

If NOAUDIT POLICY statement is used again by using BY option as follows, then it completely deactivate t he audit policy p1.

```
NOAUDIT POLICY p1 BY u1, u2;
Noaudit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
no rows selected.
```

- When it is activated by using EXCEPT
    - The following is an example of activating by using the audit policy.

```
AUDIT POLICY p1 EXCEPT u1, sys;
```

    - The information about activating is viewed as follows.

```
SELECT policy_name
     , enabled_opt
```

```
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME ENABLED_OPT USER_NAME WHEN_SUCCESS WHEN_FAILURE
----------- ----------- --------- ------------ ------------
P1          EXCEPT      U1        YES          YES
P1          EXCEPT      SYS       YES          YES
2 rows selected.
```

- Unlike AUDIT POLICY statement, NOAUDIT POLICY statement does not have an EXCEPT option, and it executes the statement without an option as follows.

```
NOAUDIT POLICY p1;
Noaudit succeeded.
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
no rows selected.
```

In other words, if an audit policy is activated by using an EXCEPT option, then a separate user can not be re activated by using NOAUDIT POLICY statement.

13.4 Authorization

Authorization-related Statements

For more information, refer to the followings.

- Creating a user: **CREATE USER**
- Dropping a user: **DROP USER**
- Altering a user: **ALTER USER**

- Granting privileges: **GRANT privileges TO**
- Revoking privileges: **REVOKE privileges FROM**

Information related to a user object and the authorization can be retrieved through the following views.

Table 13-11 Authorization objects related information

Schema	View	Description
	ALL_COL_PRIVS	Privileges for the user-accessible column
	ALL_COL_PRIVS_MADE	Privileges for the column whose user is the grantor
	ALL_COL_PRIVS_RECD	Privileges for the column whose user is the grantee
	ALL_DB_PRIVS	DB privileges which is related to a user
	ALL_DB_PRIVS_MADE	Privileges for the DB whose user is the grantor
	ALL_DB_PRIVS_RECD	Privileges for the DB whose user is the grantee
	ALL_PROC_PRIVS	Stored procedure/function privileges which is related to a user
	ALL_PROC_PRIVS_MADE	Privileges for the stored procedure/function whose user is the grantor
	ALL_PROC_PRIVS_RECD	Privileges for the stored procedure/function whose user is the grantee
	ALL_SCHEMA_PRIVS	Privileges for the user-accessible schema
	ALL_SCHEMA_PRIVS_MADE	Privileges for the schema whose user is the grantor
	ALL_SCHEMA_PRIVS_RECD	Privileges for the schema whose user is the grantee
	ALL_SEQ_PRIVS	Privileges for the user-accessible sequence
	ALL_SEQ_PRIVS_MADE	Privileges for the sequence whose user is the grantor
	ALL_SEQ_PRIVS_RECD	Privileges for the sequence whose user is the grantee
	ALL_TAB_PRIVS	Privileges for the user-accessible table
	ALL_TAB_PRIVS_MADE	Privileges for the table whose user is the grantor
	ALL_TAB_PRIVS_RECD	Privileges for the table whose user is the grantee
	ALL_TBS_PRIVS	Privileges for the user-accessible tablespace

Schema	View	Description
DICTIONARY_SCHEMA	ALL_TBS_PRIVS_MADE	Privileges for the tablespace whose user is the grantor
	ALL_TBS_PRIVS_RECD	Privileges for the tablespace whose user is the grantee
	ALL_USERS	Information about the user-accessible user
	USER_COL_PRIVS	Privilege information about the user owned column
	USER_COL_PRIVS_MADE	Information of granting privileges about the user owned column
	USER_COL_PRIVS_RECD	Information of acquiring privilege about the user owned column
	USER_PROC_PRIVS	Privilege information about the user owned stored procedure/function
	USER_PROC_PRIVS_MADE	Information of granting privileges about the user owned stored procedure/function
	USER_PROC_PRIVS_RECD	Information of acquiring privilege about the user owned stored procedure/function
	USER_SCHEMA_PRIVS	Privilege information about the user owned schema
	USER_SCHEMA_PRIVS_MADE	Information of granting privileges about the user owned schema
	USER_SCHEMA_PRIVS_RECD	Information of acquiring privilege about the user owned schema
	USER_SEQ_PRIVS	Privilege information about the user owned sequence
	USER_SEQ_PRIVS_MADE	Information of granting privileges about the user owned sequence
	USER_SEQ_PRIVS_RECD	Information of acquiring privilege about t the user owned sequence
	USER_TAB_PRIVS	Privileges information about the user owned table
	USER_TAB_PRIVS_MADE	Information of granting privileges about the user owned table
	USER_TAB_PRIVS_RECD	Information of acquiring privilege about the user owned table
	USER_USERS	Information about the current user
INFORMATION_SCHEMA	COLUMN_PRIVILEGES	Privilege information of user-accessible column
	ROUTINE_PRIVILEGES	Privilege information of user-accessible stored procedure/function
	TABLE_PRIVILEGES	Privilege information of user-accessible table
	USAGE_PRIVILEGES	Privilege information of user-accessible sequence

Concepts of User

A user object consists of the user's execution privilege set. The user should have the appropriate privilege to execute the SQL statements for the corresponding object.

For example, the user which is created by using **CREATE USER** statement is an object without any privileges. The user can not access the database nor does it execute any SQL statement. For access, the user should have CREATE SESSION ON DATABASE privilege which allows creating sessions in database object. The appropriate privilege should be granted after executing CREATE USER statement as follows.

```
CREATE USER u1 IDENTIFIED BY u1_password;
GRANT CREATE SESSION ON DATABASE TO u1;
COMMIT;
```

For more information about granting privilege after creating user object, refer to **Examples** in **CREATE USER** and **GRANT privileges TO**.

Creating Objects and Privileges

Creating SQL Schema Object

When creating an SQL schema object such as a table, the user should have the privileges for the superordinate non-schema object to which the table belongs in order to execute CREATE TABLE statements.

The following is an example of CREATE TABLE statements.

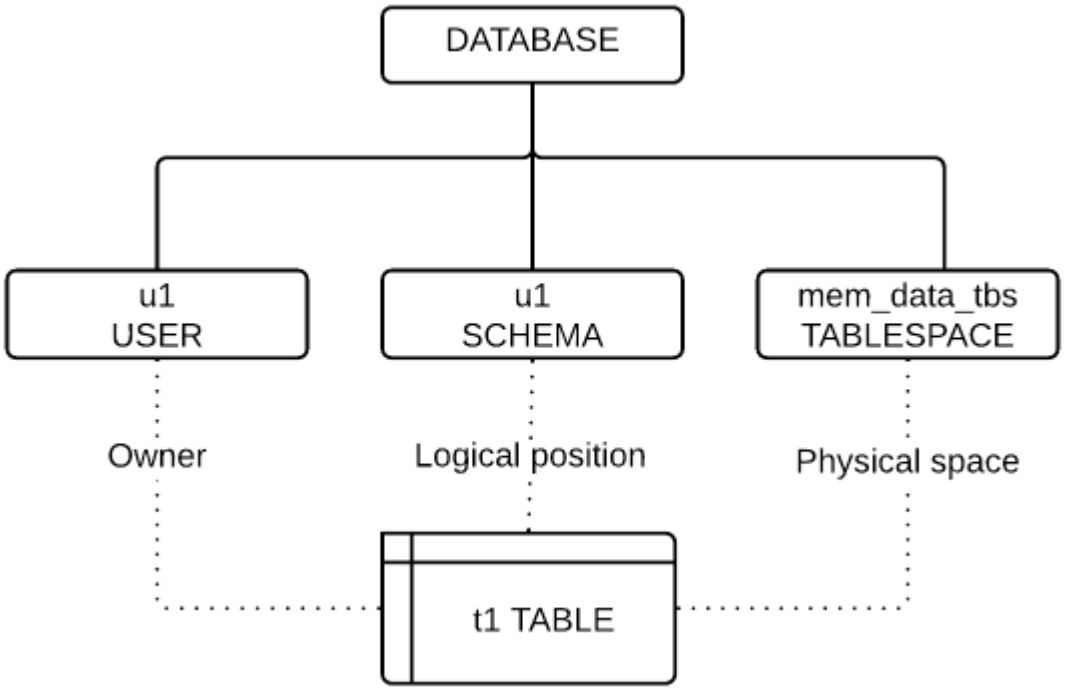
```
CREATE TABLE t1 ( id BIGINT, name VARCHAR(128) );
```

When it is interpreted as follows,

```
CREATE TABLE u1.t1 ( id BIGINT, name VARCHAR(128) ) TABLESPACE mem_data_tbs;
```

In the figure below, the owner of the table t1 is the account u1 who is the owner of the schema u1. The schema u1 is the logical location which includes the table, and the table space mem_data_tbs is the physical storage which stores the table.

Figure 2 CREATE TABLE and non-schema objects



In this case, the user u1 who performed the statement needs the following privileges for the schema and tablespace to which the table t1 will belong.

One of the following privileges is required to create the table which will be stored on its logical location (s chema u1).

- Privilege to create the table on the schema u1
  - CREATE TABLE ON SCHEMA ON u1
- Privilege to create any table on the database
  - CREATE ANY TABLE ON DATABASE
  - A table can be created when having privileges for the database which is superordinate object of t he schama u1 even without the schema privilege.

One of the following privileges is required to create a table in tablespace mem_data_tbs which is the phy sical storage space of tables.

- Privilege to create an object on the tablespace mem_data_tbs
  - CREATE OBJECT ON TABLESPACE mem_data_tbs
- Privilege to use all tablespaces in the database
  - USAGE TABLESPACE ON DATABASE
  - A table can be created when having privileges for the database which is the superordinate object of mem_data_tbs tablespace even without the tablespace privilege.

The owner of the table object is determined as follows.

- The owner of the schema to which the table belongs
- If the owner of the schema to which the table belongs is PUBLIC, then it is the user who executed the statement.

The owner of the table object has the following privileges to change the table structure and manipulate d ata in the table.

- SELECT ON TABLE
  - The privilege to execute SELECT statement on the table
- INSERT ON TABLE
  - The privilege to execute INSERT statement on the table
- UPDATE ON TABLE
  - The privilege to execute UPDATE statement on the table
- DELETE ON TABLE
  - The privilege to execute DELETE statement on the table
- LOCK ON TABLE
  - The privilege to execute LOCK statement on the table
- INDEX ON TABLE
  - The privilege to execute CREATE/DROP/ALTER INDEX statement on the table
- ALTER ON TABLE
  - The privilege to execute ALTER TABLE statement on the table

The grantor of the given privilege is the _SYSTEM account which is internally used, and the grantee is t he table owner. Therefore, any user including SYS account is not allowed to remove or change the owner privilege using **REVOKE privileges FROM**. The table owner's privileges are also removed when the table is removed.

Creating Non-schema Object

As like creating the SQL schema object such as a table, the appropriate privileges for the database (a sup erordinate object) are required to create the non-schema objects such as user, schema, tablespace.

A user who executes the following statements should have the following privileges for the database obje ct (a superordinate object) per each statement.

- CREATE USER statement
  - CREATE USER ON DATABASE
  - The privilege to execute CREATE USER statement on the database
- CREATE TABLESPACE statement
  - CREATE TABLESPACE ON DATABASE
  - The privilege to execute CREATE TABLESPACE statement on the database
- CREATE SCHEMA statement
  - CREATE SCHEMA ON DATABASE

    - The privilege to execute CREATE SCHEMA statement on the database
- CREATE PUBLIC SYNONYM statement
    - The privilege to execute CREATE PUBLIC SYNONYM statement on the database

Unlike creating the SQL schema object, the user who performed CREATE statement is not the owner of n on-schema object. Each object has the following characteristics.

- User object
    - There is not an owner.
    - DROP USER ON DATABASE privilege is required to drop a user object.
- Tablespace object
    - There is not an owner.
    - DROP TABLESPACE ON DATABASE privilege is required to drop a tablespace object.
- Schema object
    - It is an owner which is specified in the CREATE SCHEMA statement.
    - The schema object owner can drop it.
- Public synonym object
    - There is not an owner.
    - DROP PUBLIC SYNONYM ON DATABASE privilege is required to drop a public synonym object.

Privileges

Granting Privileges

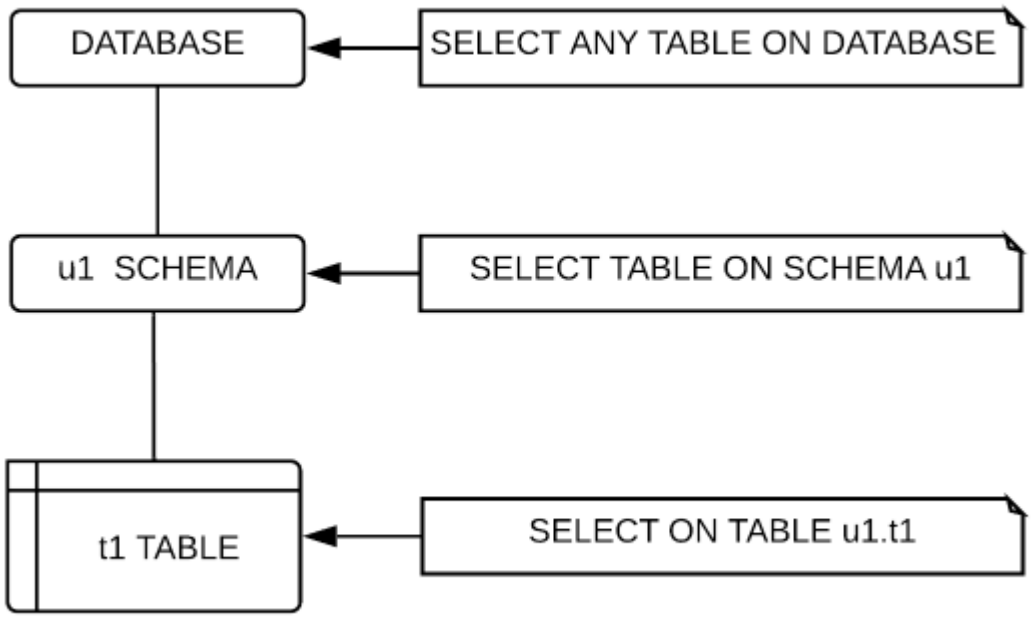
To INSERT, DELETE, UPDATE, or SELECT data when the user is not the owner of SQL schema object such as table, then the user should be granted the appropriate privileges by using **GRANT privileges TO** statem ent.

For example, a user who is not the owner of the table requires one of the following privileges to execute SELECT statement. As the figure below, the user can query the u1.t1 table if the user has SELECT privileg es on the superordinate object u1 schema or the database even when the user does not have SELECT priv ilege on table t1.

- The test user executes the following.

```
SELECT id, name FROM u1.t1 WHERE id < 100;
```

Figure 3 Privilege to execute SELECT statement



- SELECT ON TABLE u1.t1
  - SELECT privilege for the table u1.t1
- SELECT ON SCHEMA u1
  - SELECT privilege for the schema u1 which is the superordinate object
  - SELECT privilege for all tables of the schema u1
- SELECT ANY TABLE ON DATABASE
  - SELECT privilege for the database which is the second superordinate object
  - SELECT privilege for all tables of the database

The user who executed the GRANT statement should be one of the followings to grant the SELECT ON T ABLE u1.t1 privileges to another user.

- Owner of the object u1.t1
  - The object owner has the privilege of SELECT ON TABLE u1.t1 WITH GRANT OPTION granted by the _SYSTEM account.
- User with SELECT ON TABLE u1.t1 WITH GRANT OPTION
  - WITH GRANT OPTION enables the grantee to grant the granted privileges to another user.
- User with the privilege of ACCESS CONTROL ON DATABASE
  - The user can control all privileges on all objects.

The following is an example that the object owner grants privileges to another user.

- The owner of the table u1.t1 executes GRANT statement.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

For more information about the privilege types, refer to **GRANT privileges TO**.
For more information about privileges executing each SQL statements, refer to the Invocation and Access Rule of each statement in **SQL References** part.

Revoking Privileges

The granted privileges are revoked from a user by using **REVOKE privileges FROM**. The privileges of the object's owner can no be revoked until the object is removed.

For example, a user who can execute REVOKE statement to revoke the SELECT privilege from the test user are as follows. The user can not revoke privileges which were not granted by the user even when the user is the owner of the table.

```
REVOKE SELECT ON TABLE u1.t1 FROM test;
```

- User who grants privileges
  - The user grants the privilege of SELECT ON TABLE u1.t1 to the test1 user.
- User who has the privilege of ACCESS CONTROL ON DATABASE
  - The user can control all privileges on all objects.

When the test user is granted the same privileges from multiple users as follows, the test user can execute SELECT statement until all the privileges are revoked.

- The object owner u1 grants the privilege to the test user.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

- The object owner u1 grants the privilege of WITH GRANT OPTION to the user u2.

```
GRANT SELECT ON TABLE u1.t1 TO u2 WITH GRANT OPTION;
```

- The user u2 executes it.
- The u2 user with the privilege of WITH GRANT OPTION grants the privilege to the the test user.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

In the example above, the test user has two SELECT ON TABLE u1.t1 privileges which were granted by user u1 and user u2. The privilege information consists of {grantor, grantee, object privileges}.

PUBLIC Account

PUBLIC account is a special account which means every user.

For example, if the SELECT privilege is granted to PUBLIC account as follows, every user can execute SELECT statements on the table, u1.t1.

```
GRANT SELECT ON TABLE u1.t1 TO PUBLIC;
```

Even a user without SELECT privilege can execute SELECT statements on the table u1.t1 using the SELECT privilege on PUBLIC account.

When a privilege is granted to PUBLIC account, it is granted not to the existing users but to PUBLIC account itself. Even the newly created user can also execute SELECT statements.

Likewise, the user can execute SELECT statements if the user has the SELECT privilege on the table u1.t1 because revoking a privilege from PUBLIC account does not mean revoking the privilege from every user.

- The privilege is granted to the test user.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

- The privilege is granted to PUBLIC account.

```
GRANT SELECT ON TALBE u1.t1 TO PUBLIC;
```

- The privilege is revoked from PUBLIC account, and the test user still has the privilege on SELECT ON TABLE u1.t1.

```
REVOKE SELECT ON TABLE u1.t1 FROM PUBLIC;
```

Column Privilege

By granting privileges only on specific columns of a table, it is possible to control the execution of DML or SELECT statements of other user.

The following is an example table.

```
CREATE TABLE u1.t1
(
   id     BIGINT,
   name   VARCHAR(128),
   addr   VARCHAR(1024),
   salary NUMBER(20,0)
);
```

If SELECT privilege on the table u1.t1 excluding the salary column information is granted to another user, **GRANT privileges TO** statement is executed by listing the columns to be grantees of the privilege as follo ws. The test user who is the grantees of the privilege can not query the salary column.

- The privilege on SELECT columns is granted to the test user.

```
GRANT SELECT( id, name, addr ) ON TABLE u1.t1 TO test;
```

If the privilege on a table is granted as follows, the privilege on every column in the table is automatically granted. If both table privilege and column privilege are granted, the privilege information for a column is duplicated and the information is not dually managed.

- SELECT privilege is granted to the test user.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

- Privileges on every column in the table u1.t1 are automatically granted.

```
GRANT SELECT(id) ON TABLE u1.t1 TO test;
GRANT SELECT(name) ON TABLE u1.t1 TO test;
GRANT SELECT(addr) ON TABLE u1.t1 TO test;
GRANT SELECT(salary) ON TABLE u1.t1 TO test;
```

The privilege on a column is revoked by using **REVOKE privileges FROM** as follows.

- The privilege on SELECT columns is revoked from the test user.

```
REVOKE SELECT( id, name, addr ) ON TABLE u1.t1 FROM test;
```

If the privilege on a table is revoked as follows, the privilege on every column in the table is automatically revoked. Even if the column privileges and table privileges are separately granted, the columns privileges are revoked when the table privileges are revoked.

- SELECT privilege is revoked from the test user.
- Privileges on every column in the table u1.t1 are revoked.

```
REVOKE SELECT ON TABLE u1.t1 FROM test;
```

When revoking only the column privilege and the table privilege still exists as follows, then the following statements can be executed by using the table privilege. Therefore, to grant the privilege only on a specifi c column, the table privilege should be revoked, and then each column privilege should be granted.

- SELECT table privilege is granted to the test user.

```
GRANT SELECT ON TABLE u1.t1 TO test;
```

- The SELECT(salary) column privilege is revoked from the test user.
- The test user can query the salary column in the table u1.t1 because the test user has the SELECT priv ilege on the table.

```
REVOKE SELECT(salary) ON TABLE u1.t1 FROM test;
```

For more information about the privileges on a table and columns, refer to **GRANT privileges TO**.

13.5 Schema

Schema-related Statements

For more information about creating and dropping a schema, refer to the followings.

- Creating a schema: **CREATE SCHEMA**.
- Dropping a schema: **DROP SCHEMA**.

Information which is related to a schema object can be retrieved through the following views.

Table 13-12 Schema object-related information

Schema	View	Description
DICTIONARY_SCHEMA	**ALL_SCHEMAS**	User accessible schema information
	ALL_SCHEMA_PATH	User accessible schema path
	USER_SCHEMAS	User owned schema information
	USER_SCHEMA_PATH	User's schema path information
INFORMATION_SCHEMA	**SCHEMATA**	User accessible schema information

Concepts of Schema

The database consists of one or more schemas. The schema consists of objects such as tables, indexes, vi ews, which processes data. SQL schema object is an object which belongs to the schema.

Schema is similar to the directory in OS. The relationship between schema and tables is similar to the relat ionship between the directories and files in OS.
Schema is the logical position of the SQL schema object and it is criteria of distinguishing the name. Every SQL schema object should have a unique name and the naming space in the schema is as follows.

- Table, view, sequence, private synonym, stored procedure, stored function
- Index
- Constraint

The same name tables can be defined in the different schema. The different tables with same name are a ccessible and executed by specifying together with the schema name.

```
gSQL> SELECT u1.t1.id, u1.t1.name, u2.t1.addr
        FROM u1.t1, u2.t1
       WHERE u1.t1.id = u2.t1.id;
```

The name of SQL schema object is specified together with the schema name or without it. If the schema name is omitted, it is determined by the user's schema path. For more information about the schema pat h, refer to **Schema Path** clause.

- When the schema name is specified

```
gSQL> SELECT u1.t1.id, u1.t1.name FROM u1.t1;
```

- When the schema name is omitted

```
gSQL> SELECT t1.id, t1.name FROM t1;
```

User and Schema

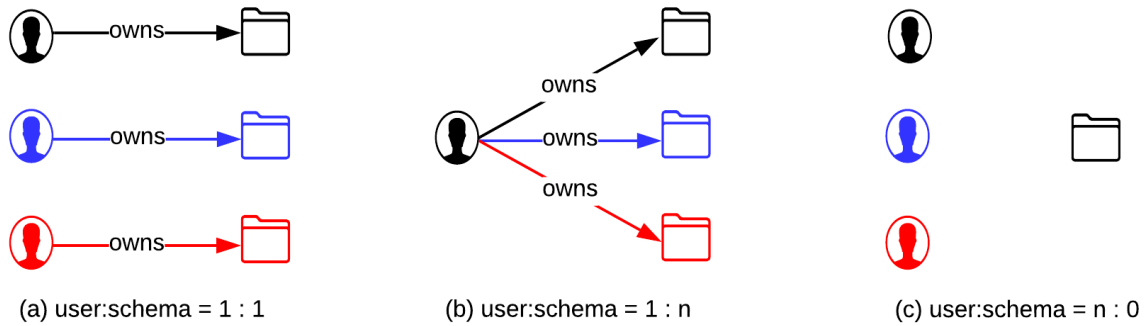
In GOLDILOCKS, relationship between the user and the schema is 1:N. A user does not own a schema, or the user can have multiple schemas.

The SQL standard does not explicitly define the relationship of the non-schema objects such as user, sche ma, database. Each DBMS defines the relationship of the non-schema objects in different ways, and they are as follows.

- Oracle
  - The relationship between the user and the schema is 1:1.
- DB2
  - The relationship between the user and the schema is 1:N.
- Postgres
  - The relationship between the user and the schema is 1:N.
- MySQL
  - The relationship between the database and the schema is 1:1.
  - User is a subordinate object of the schema (database).

When establishing the database, GOLDILOCKS configures various relationships between the users and sc hemas in accordance with the characteristics of the client system as follows.

Figure 4 Relationship between user and schema



To configure the database in which each user has its own schema as shown in the figure (a), create the u sers and schemas as follows.

- Create a user and the schema u1 together so that the user owns the schema.

```
gSQL> CREATE USER u1 IDENTIFIED BY u1_password WITH SCHEMA;
```

- WITH SCHEMA statement is optional and a schema whose name is as same as the user is created.

```
gSQL> CREATE USER u2 IDENTIFIED BY u2_password;
gSQL> CREATE USER u3 IDENTIFIED BY u3_password;
```

To configure the database in which a single user has multiple schemas as shown in the figure (b), create t he users and schemas as follows.

- Create the user u1 only without creating a schema.

```
gSQL> CREATE USER u1 IDENTIFIED BY u1_password WITHOUT SCHEMA;
```

- Create multiple schemas and specify the owner of each schema as a user u1.

```
gSQL> CREATE SCHEMA s1 AUTHORIZATION u1;
gSQL> CREATE SCHEMA s2 AUTHORIZATION u1;
gSQL> CREATE SCHEMA s3 AUTHORIZATION u1;
```

To configure the database in which multiple users share a single schema without creating a schema as sh own in the figure (c), create users as follows.
All users share **PUBLIC Schema** in the following examples.

- Create users only without creating a schema.

```
gSQL> CREATE USER u1 IDENTIFIED BY u1_password WITHOUT SCHEMA;
gSQL> CREATE USER u2 IDENTIFIED BY u2_password WITHOUT SCHEMA;
gSQL> CREATE USER u3 IDENTIFIED BY u3_password WITHOUT SCHEMA;
```

For more information about creating user and schema, refer to **CREATE USER**, **CREATE SCHEMA**.

Schema Path

Schema path is a path to find the schema name when the SQL schema object name such as a table is use d without the schema name. Schema path is similar to the PATH environment variable of Unix system. It i s similar in searching for a command in the PATH in the specified order when executing commands on U nix system.

When a user has multiple schemas, then creates or queries the table without a schema name as follows, t he schema path determines in which schema the table will be created.

- A table t1 is created in the schema s1.

```
gSQL> CREATE TABLE s1.t1 ( id INTEGER );
```

- A table t1 is created in the schema s2.

```
gSQL> CREATE TABLE s2.t1 ( name VARCHAR(128) );
```

- In which schema the table t1 will be created?

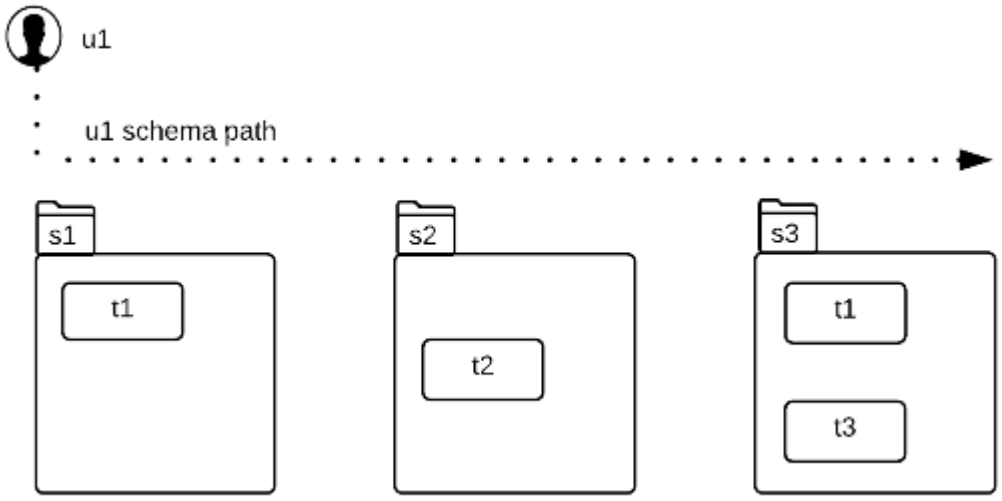
```
gSQL> CREATE TABLE t1 ( address VARCHAR(1024) );
```

- Which schema's table t1 is retrieved?

```
gSQL> SELECT * FROM t1;
```

The figure below illustrates an example of a schema path for user u1. The schema path of user u1 is desi gnated in an order of {s1, s2, s3}. Schema s1 has a table t1, schema s2 has a table t2, and the schema s3 has tables t1 and t3.

Figure 5 Example of schema path



In the SELECT statement without the schema name, the schema name is construed by the schema path a s follows.

- It is construed as table s1.t1 by the schema path.

```
gSQL> SELECT * FROM t1;
gSQL> SELECT * FROM s1.t1;
```

- It is construed as table s2.t2 by the schema path.

```
gSQL> SELECT * FROM t2;
gSQL> SELECT * FROM s2.t2;
```

- It is construed as table s3.t3 by the schema path.

```
gSQL> SELECT * FROM t3;
gSQL> SELECT * FROM s3.t3;
```

When omitting the schema name to retrieve the table s3.t1 as the example above, the table s3.t1 is deter mined by schema path, so the schema name should be specified as follows.

- It retrieves the table s1.t1 by the schema path.

```
gSQL> SELECT * FROM t1;
```

- The schema s3 should be specified to retrieve the table s3.t1.

```
gSQL> SELECT * FROM s3.t1;
```

The following CREATE TABLE statement in which the schema name is omitted creates a table in the first s chema s1 of the schema path.

- An error occurs because the identical table s1.t1 exists.

```
gSQL> CREATE TABLE t1 ( id INTEGER );
gSQL> CREATE TABLE s1.t1 ( id INTEGER );
```

- The table s2.t2 exists, but the table s1.t2 is created in different schemas.

```
gSQL> CREATE TABLE t2 ( name VARCHAR(128) );
gSQL> CREATE TABLE s1.t2 ( name VARCHAR(128) );
```

- The table s3.t3 exists, but the table s1.t3 is created in different schemas.

```
gSQL> CREATE TABLE t3 ( name VARCHAR(128) );
gSQL> CREATE TABLE s1.t3 ( name VARCHAR(128) );
```

If the current user omits the schema name when creating an object, the schema name to be used can be retrieved by using **CURRENT_SCHEMA** which is the SQL standard function.

```
gSQL> SELECT current_schema FROM dual;
CURRENT_SCHEMA
--------------
S1
1 row selected.
```

The schema path information of the current user can be retrieved by using ALL SCHEMA PATH view in DI CTIONARY SCHEMA schema.

```
gSQL> SELECT * FROM all_schema_path;
AUTH_NAME SCHEMA_NAME             SEARCH_ORDER
--------- ----------------------- ------------
U1        S1                                1
U1        S2                                2
U1        S3                                3
U1        PUBLIC                            4
PUBLIC    DICTIONARY_SCHEMA                 5
PUBLIC    INFORMATION_SCHEMA                6
PUBLIC    DEFINITION_SCHEMA                 7
```

```
PUBLIC    PERFORMANCE_VIEW_SCHEMA           8
PUBLIC    FIXED_TABLE_SCHEMA                9
9 rows selected.
```

In the example above, the schema path of the user u1 is in an order of {s1, s2, s3, public}, and the schem a path of PUBLIC account is in an order of {DICTIONARY_SCHEMA, INFORMATION_SCHEMA, DEFINITION _SCHEMA, PERFORMANCE_VIEW_SCHEMA, FIXED_TABLE_SCHEMA}.
If omitting the schema name and retrieving a table t1, then it searches for the schema path for the curren t user u1. If the schema path does not exist in it, then it searches for the schema path of PUBLIC account.

Schema path of a specific user can be altered by using **ALTER USER** statement as follows. The schema pat h of PUBLIC account can be altered by using ALTER USER PUBLIC SCHEMA PATH statement.
CURRENT PATH clause is used to additionally alter other schemas together with the user's current schem a.

- The schema path of user u1 is altered.

```
gSQL> ALTER USER u1 SCHEMA PATH ( s3, s2, s1 );
User altered.
```

- The schema path of PUBLIC account is altered.

```
gSQL> ALTER USER PUBLIC SCHEMA PATH ( s1, s2, s3 );
User altered.
```

- The schema path which includes the current schema path is altered by using CURRENT PATH.

```
gSQL> ALTER USER u1 SCHEMA PATH ( s4, CURRENT PATH );
User altered.
```

The schema path is automatically determined when a user is created by using **CREATE USER** statement. A nd if the user schema is created by using **CREATE SCHEMA** statement later, then it is not automatically in cluded in the user's schema path, so, if necessary, it should be included in the schema path by using **ALTE R USER**. For more information, refer to each statement.

PUBLIC Schema

PUBLIC schema is a shared schema in which any user can create objects. As shown in the example below, if the user who does not have the schema creates the table whose schema name is not specified, then th e table's schema is PUBLIC.

- A user u1 who does not have the schema is created.

```
gSQL> CREATE USER u1 IDENTIFIED BY u1_password WITHOUT SCHEMA;
gSQL> GRANT CREATE SESSION TO u1;
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_data_tbs TO u1;
```

- The user u1 creates a table.

```
% gsql u1 u1_password
gSQL> CREATE TABLE t1 ( id INTEGER );
```

- The statements above have the same meaning as the following.

```
gSQL> CREATE TABLE public.t1 ( id INTEGER );
```

In the example above, the table t1's schema which is created by user u1, is PUBLIC. PUBLIC schema is a built-in schema which is automatically created when creating the database.
It is granted the privilege of the same meaning as the following statement so that any user can create an object in the schema.

```
gSQL> GRANT CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, ADD CONSTRAINT
         ON SCHEMA PUBLIC
         TO PUBLIC;
```

PUBLIC schema, shared schema, is different from PUBLIC account which means all users. In the statement above, the privilege of creating objects in the PUBLIC schema (ON SCHEMA PUBLIC) is granted to PUBLIC account (TO PUBLIC) which means all users.
Any user can create or manage tables, but an appropriate privilege is required for retrieving the table created in PUBLIC schema by another user.

The followings are examples of GRANT statements using PUBLIC account and PUBLIC schema.

- SELECT privilege on table u1.t1 is granted to PUBLIC account.
- Any user can retrieve the table u1.t1.

```
gSQL> GRANT SELECT ON TABLE u1.t1 TO PUBLIC;
```

- SELECT privilege on all tables in PUBLIC schema is granted to user u1.
- The user u1 can retrieve all tables in PUBLIC schema.

```
gSQL> GRANT SELECT TABLE ON SCHEMA PUBLIC TO u1;
```

User and Examples of Using Schema

For example, if a single administrator and multiple developers use a single schema, the schema can be co ntrolled by using the following SQL statement.

The following examples describe how to create a mgr_usr user who manages our_schema schema, and a number of users such as app_user1, app_user2, app_user3 who develops applications using our_schema.

A mgr_user user and a our_schema schema are created as follows.

- mgr_user and our_schema are created.
- mgr_user owns our_schema.

```
gSQL> CREATE USER mgr_user IDENTIFIED BY mgr_user WITH SCHEMA our_schema;
User created.
```

- An appropriate privilege is granted to mgr_user.

```
gSQL> GRANT ALL PRIVILEGES ON DATABASE TO mgr_user;
Grant succeeded.
gSQL> COMMIT;
Commit complete.
```

Multiple app_user users are created as follows.
The app_user users are allowed to execute only SELECT and DML statements on our_schema.

- Multiple app_user users who do not own the schema are created as follows.

```
gSQL> CREATE USER app_user1 IDENTIFIED BY app_user1 WITHOUT SCHEMA;
User created.
gSQL> CREATE USER app_user2 IDENTIFIED BY app_user2 WITHOUT SCHEMA;
User created.
gSQL> CREATE USER app_user3 IDENTIFIED BY app_user3 WITHOUT SCHEMA;
User created.
gSQL> COMMIT;
Commit complete.
```

- The access privileges are granted to multiple app_user users.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO app_user1, app_user2, app_user3;
Grant succeeded.
gSQL> COMMIT;
```

```
Commit complete.
```

- Only read/write privileges on our_schema are granted to multiple app_user users.

```
gSQL> GRANT SELECT TABLE, INSERT TABLE, UPDATE TABLE, DELETE TABLE ON SCHEMA our_schema TO
app_user1, app_user2, app_user3;
Grant succeeded.
gSQL> COMMIT;
Commit complete.
```

- SCHEMA_PATH of multiple app_user users are specified as our_schema.

```
gSQL> ALTER USER app_user1 SCHEMA PATH ( our_schema );
User altered.
gSQL>  ALTER USER app_user2 SCHEMA PATH ( our_schema );
User altered.
gSQL> ALTER USER app_user3 SCHEMA PATH ( our_schema );
User altered.
gSQL> COMMIT;
Commit complete.
```

Through the operations above, mgr_user has DDL privileges of creating/ dropping/ altering an object in o ur_schema, but multiple app_user can only read/write operations on the tables in our_schema.

mgr_user can perform management tasks such as creating a table as follows.

```
gSQL> \connect mgr_user mgr_user
gSQL> CREATE TABLE t1 ( c1 INTEGER );
Table created.
gSQL> INSERT INTO t1 VALUES ( 1 );
1 row created.
gSQL> INSERT INTO t1 VALUES (2), (3);
2 rows created.
gSQL> COMMIT;
Commit complete.
```

Multiple app_user can read/write operation for the table in our_schema without specifying the schema n ame, but they are not allowed to create or drop an object as follows.

```
gSQL> \connect app_user1 app_user1
gSQL> SELECT * FROM t1;
C1
--
```

```
 1
 2
 3
3 rows selected.
gSQL> INSERT INTO t1 VALUES (4);
1 row created.
gSQL> COMMIT;
Commit complete.
gSQL> DROP TABLE t1;
ERR-42000(16208): insufficient privileges
```

13.6 Tablespace

Tablespace-related Statements

For more information, refer to the followings.

- Creating tablespace
  - **CREATE TABLESPACE**
  - **CREATE MEMORY DATA TABLESPACE**
  - **CREATE MEMORY TEMPORARY TABLESPACE**
  - **CREATE DISK DATA TABLESPACE**

- Dropping tablespace: **DROP TABLESPACE**

- Altering tablespace
  - **ALTER TABLESPACE**
  - **ALTER TABLESPACE name RENAME TO**
  - **ALTER TABLESPACE name BACKUP**
  - **ALTER TABLESPACE name [ONLINE|OFFLINE]**

- Adding, dropping, altering the datafile which configures the tablespace
  - **ALTER TABLESPACE name ADD [DATAFILE|MEMORY]**
  - **ALTER TABLESPACE name DROP [DATAFILE|MEMORY]**
  - **ALTER TABLESPACE name RENAME DATAFILE**
  - **ALTER DATABASE DATAFILE AUTOEXTEND**

Information which is related to a tablespace object can be retrieved through the following views.

Table 13-13 Tablespace object related information

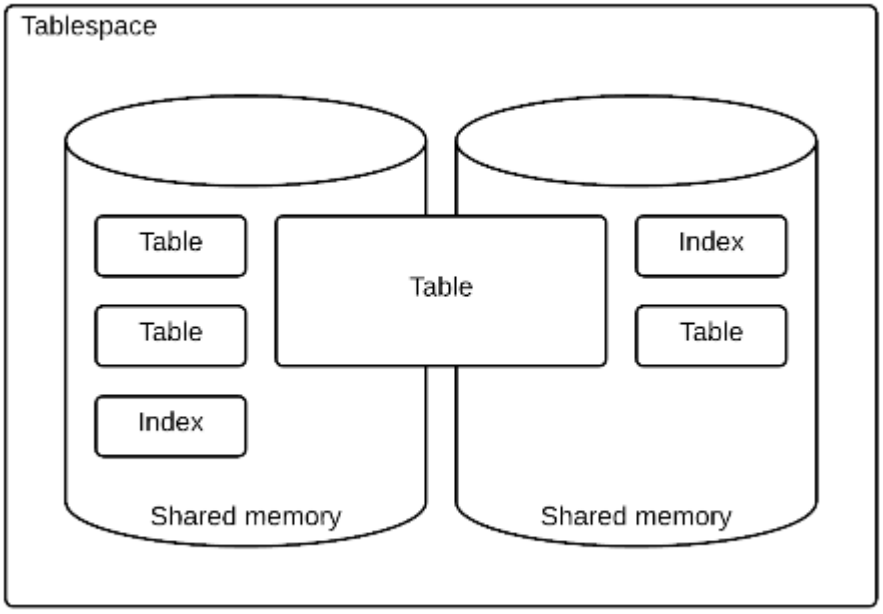
Schema	View	Description
DICTIONARY_SCHEMA	**USER_TABLESPACES**	Information of user accessible tablespaces

Concepts of Tablespace

A tablespace is a logical concept and it consists of one or more physical shared memory. It is a space to st ore data, such as tables, indexes.
Physical objects such as tables, indexes which are stored in a tablespace can be spanned multiple shared memories as shown below.

A tablespace can be extended by adding the shared memory.

Figure 6 Concept of tablespace



Tablespaces are classified into three types depending on the stored data type as follows.

- DATA TABLESPACE
  - It is tablespace to store and manage permanent data such as tables, logging indexes.
- TEMPORARY TABLESPACE
  - It is tablespace to store and manage volatile data such as the indexes without logging, the hash which is generated during query execution and the sort.
- UNDO TABLESPACE
  - It is tablespace to store and manage the data change information for rollback the transaction.

Tables, indexes (LOGGING) stored in DATA tablespace create redo logs to permanently manage data. Ho wever, indexes without logging stored in TEMPORARY tablespace does not create redo logs. The index w ithout logging does not log the changes. When restarting the system, it is rebuilt based on the table data, and the index facility is retained.

A tablespace is a physical storage in which SQL schema objects are stored. A particular tablespace can be specified when creating a table and index. A table, the index which is related to the table, and the indexe s which is created for the constraint condition of the table can be stored in different tablespaces.
For more information about specifying the tablespace when creating an object, refer to the followings.

- **CREATE TABLE**
- **CREATE INDEX**

- ALTER TABLE name ADD CONSTRAINT

If a tablespace is not specified when creating an object such as a table or index, the default tablespace is used.
For more information about the user's default tablespace, refer to the followings.

- CREATE USER
- ALTER USER

For more information about tablespace, refer to **Managing Tablespace**.

13.7 Table

Table-related Statements

Statements for creating, dropping, altering a table are as follows.

- Creating table
  - CREATE TABLE
  - CREATE TABLE AS SELECT
  - CREATE GLOBAL TEMPORARY TABLE
  - CREATE IMMUTABLE TABLE

- Dropping table
  - DROP TABLE
  - TRUNCATE TABLE

- Altering table
  - ALTER TABLE
  - ALTER TABLE name RENAME TO
  - ALTER TABLE name STORAGE

- Adding, dropping, altering a column of the table
  - ALTER TABLE name ADD COLUMN
  - ALTER TABLE name SET UNUSED COLUMN
  - ALTER TABLE name ALTER COLUMN
  - ALTER TABLE name RENAME COLUMN

- Adding, dropping, altering a constraint of the table
  - ALTER TABLE name ADD CONSTRAINT
  - ALTER TABLE name DROP CONSTRAINT
  - ALTER TABLE name ALTER CONSTRAINT

- Adding, dropping additional log of the table
  - ALTER TABLE name ADD SUPPLEMENTAL LOG
  - ALTER TABLE name DROP SUPPLEMENTAL LOG

- Table statistics information: ANALYZE TABLE.

- Managing recycle bin of the table
  - FLASHBACK TABLE

- PURGE

Information which is related to a table object can be retrieved through the following views.

Table 13-14 Table object related information

Schema	View	Description
DICTIONARY_SCHEMA	ALL_ALL_TABLES	Information about user accessible tables
	ALL_COL_COMMENTS	Information about comments of user accessible column
	ALL_CONSTRAINTS	Information about user accessible constraints
	ALL_CONS_COLUMNS	Column information about user accessible constraints
	ALL_TABLES	Information about user accessible tables
	ALL_TAB_COLS	Information about user accessible columns
	ALL_TAB_COLUMNS	Information about user accessible columns
	ALL_TAB_COMMENTS	Information about comments of user accessible tables

	CONSTRAINT_TABLE_USAGE	Table information about user accessible constraints
	KEY_COLUMN_USAGE	Column information about user accessible key constraints
	TABLES	Information about user accessible tables
	TABLE_CONSTRAINTS	Information about user accessible constraints

Concepts of Table

Table is an underlying object which configures the database. In the SQL standard, the table is called as a base table, and the view is called as a viewed table.

The table consists of columns and rows. The table consists of multiple rows, the number and order of columns in each row is same.
The table consists of one or more columns, and each column has a name but a row does not have a name. The order of the row is not always as same as the order in which data is added.
The value is the data in intersection of a column and a row. Column is the set of value which have the same data type.

Each column of a table has a unique name to be distinguished from other columns in the table. It has a data type which corresponds to the characteristics of the value. For more information about data type, refer to **Data Type** section.
The constraints can be added to the table for data integrity. For more information about constraint, refer to **CREATE TABLE**, **ALTER TABLE name ADD CONSTRAINT**.
The table index can be created to improve performance of queries. For more information about index, refer to **Index** section.

The following is an example of creating a lineitem table using **CREATE TABLE** statement.

```
CREATE TABLE lineitem
(
    l_orderkey      INTEGER    NOT NULL
  , l_partkey       INTEGER    NOT NULL
  , l_suppkey       INTEGER    NOT NULL
  , l_linenumber    INTEGER    NOT NULL
  , l_quantity      NUMERIC(12,2)
  , l_extendedprice NUMERIC(12,2)
  , l_discount      NUMERIC(12,2)
  , l_tax           NUMERIC(12,2)
  , l_returnflag    CHAR(1)    NOT NULL  DEFAULT 'F'
  , l_linestatus    CHAR(1)
  , l_shipdate      DATE
  , l_commitdate    DATE
  , l_receiptdate   DATE
  , PRIMARY KEY (l_orderkey, l_linenumber) INDEX lineitem_pk_idx TABLESPACE mem_temp_tbs
) TABLESPACE mem_data_tbs;
```

In the example above, multiple columns and constraints are defined in the lineitem table. When using constraints to define columns, NOT NULL constaints are defined for the columns l_orderkey, l_partkey, l_suppkey, l_linenumber.
PPRIMARY KEY constraint is defined by combining columns of l_orderkey, l_linenumber.
In-line constraint is described together with the column definitions. Out-line constraint is described separately from the column definitions.

Using DEFAULT clause in the column l_returnflag, the value 'F' is declared as a default value for the column. The index which is created when creating PRIMARY KEY constraints is named separately as lineitem_pk_idx. The tablespace in which the index will be stored is named as mem_temp_tbs. The table is physically stored in the tablespace mem_data_tbs.

The following is an example of adding a constraint to a table using **ALTER TABLE name ADD CONSTRAINT** statement.

```
ALTER TABLE lineitem
      ADD CONSTRAINT lineitem_unique_all_key
      UNIQUE( l_orderkey ASC, l_partkey DESC, l_suppkey DESC, l_linenumber ASC);
```

In the example above, UNIQUE constraint is added to the lineitem table, and the column sort order ASC/DESC is specified for the automatically created index of constraints.

The following is an example of adding columns to the table using **ALTER TABLE name ADD COLUMN** statement.

```
ALTER TABLE lineitem ADD COLUMN
(
    l_shipinstruct  CHAR(25)
  , l_shipmode      CHAR(10)
  , l_comment       VARCHAR(44)
);
```

In the example above, multiple columns are added to a table. The in-line constraints or default values can be specified when adding columns.

The following is an example of creating an index in the table using **CREATE INDEX** statement.

```
CREATE INDEX lineitem_idx_shipdate ON lineitem( l_shipdate ASC NULLS LAST );
```

The example above describes the index which is created for the column l_shipdate which is often used as the query conditions. The column sort order is ascending (ASC), and if NULL value exists, it is specified to be located at the end.

For more information about DML statements of inserting/deleting/updating data to a table, refer to **Data Manipulation Language** clause.
For more information about SELECT statements of querying data in a table, refer to **Data Query Language** clause, **SELECT** statement.

Global Temporary Table

Global temporary table is a kind of temporary table and the table definition is shared by all users, but the data is separated per section.

The table definition is created when executing CREATE GLOBAL TEMPORARY TABLE, but the physical se gment is created in a state which is dependent on a session when executing INSERT to that table for the f irst time. The segments which are allocated to all global temporary tables created in the session are releas ed when the session is terminated. An option defined at the time of creating a global temporary table det ermines whether to truncate the data left after committing or rolling back.

It supports all DDL and DML provided by a table except for cluster-related statements. A DDL statement r eturns an error to the global temporary table which is used by the current session. However, TRUNCATE T ABLE statement for a global temporary table is applied only to the current session, so it does not return a n error even when it is used by another session.

A global temporary table can be defined only in a temporary tablespace, so it does not record a redo log f or restart recovery. However, it records the undo log for MVCC and rollback, and the space on which the undo log is recorded can be selected to system undo tablespace or system temp tablespace by using **TEM P_UNDO_ENABLED**.

If TEMP_UNDO_ENABLED is 1, it records undo logs in a temp undo relation of the session separately fro m the undo relation of the transaction. If the transaction performs only DML for a global temporary table, then it does not record the transaction record nor the commit log, so it improves the DML performance.

When releasing the segment used in the session, it is returned to the corresponding tablespace, and it is allocated again from the tablespace when allocating again. The process allocating and returning segment s in a tablespace costs a lot to keep concurrency with other sessions and to allocate and release segments. Therefore, the segment which was released after used in a session can be reused without returning it by using **TEMP_SEGMENT_CACHE_SIZE**.

In other words, if TEMP_SEGMENT_CACHE_SIZE is set to 0 (default value), then it immediately returns th e segement which is released after used to the tablespace. If TEMP_SEGMENT_CACHE_SIZE is set to the value bigger than 1 (maximum 4294967295), then it reuses as many segments as set in a session when r eturning the segment.

When a global temporary table is not used in a session any more, then cleanup segments in a segment ca che at once by using **ALTER SESSION CLEANUP GLOBAL TEMPORARY SEGMENT POOL;**.

The following is an example of creating a global temporary table by using **CREATE GLOBAL TEMPORARY TABLE**.

```
CREATE  GLOBAL TEMPORARY TABLE SESSION_TABLE1(
        COL1    CHAR(10)
       ,COL2    VARCHAR2(20)
       ,COL3    NUMBER(10)
)   ON  COMMIT  DELETE ROWS;
```

The information about the created global temporary table can be viewed in DICTIONARY tables or views i n the same way as viewing the information of an ordinary table.

Table Function Derived Table

The table function derived table is a logical table which consists of the result sets returned by performing the table function. The table function is a function which is defined as the return table type. The definitio n of the table function derived table follows the table column list definition defined in the table function 's return statement. Unlike other general tables, the table function derived table can not have an index n or a constraint. The row of the table function derived table is the result set to which the table function is r eturned. The table function derived table is useful when retrieving the desired data from the desired table by configuring the sub sets of a specific table.
For more information about the table function, refer to **Stored Function**.

Figure 7 Definition of table function derived table

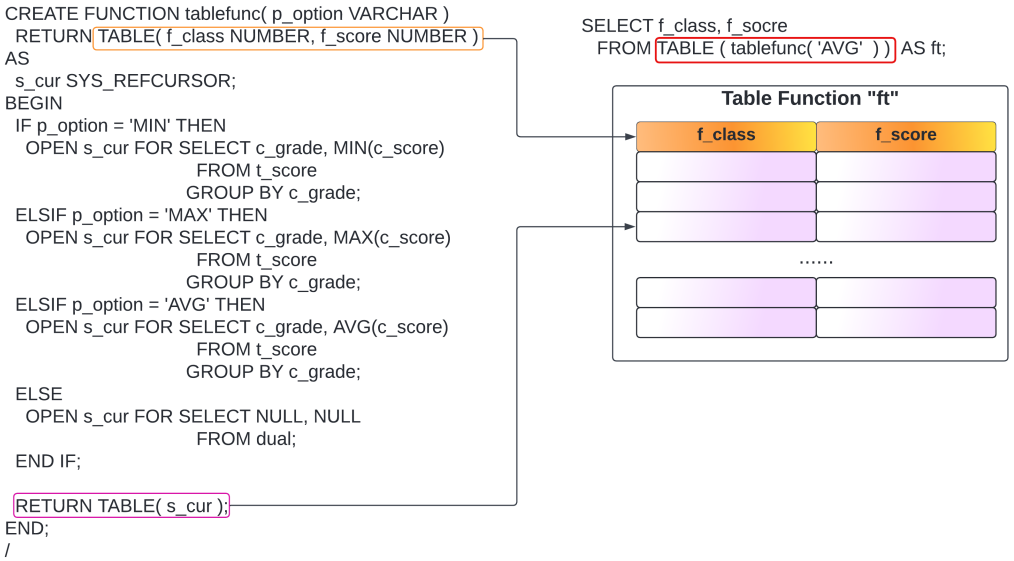

Table in Cluster

For more information about a table in the cluster environment, refer to **Cluster Table and Shard**.

Managing Recycle Bin of Table

Syntax

- Restoring an object stored in the recyclebin.
  - **FLASHBACK TABLE**
- Dropping an object stored in the recyclebin.
  - **PURGE**

The information about the recycle bin can be retrieved through the following views.

Table 13-15 Information about the recyclebin

Schema	View	Description
DICTIONARY_SCHEMA	**DBA_RECYCLEBIN**	Information about all recyclebins in the database
	USER_RECYCLEBIN	Information about the recycle bin which is owned by itself
	RECYCLEBIN	Alias of USER_RECYCLEBIN

Description

It stores the dropped object in the recycle bin instead of completely dropping it. Constraints and indexes r elated to the table are also stored in the recyclebin.

The concept of the recycle bin is also called as *flashback drop* feature, and objects stored in the recycle bi n can be dropped or be restored by using PURGE or FLASHBACK TABLE statement.

If a table is dropped and stored in the recyclebin, then all names of objects related to the table are altered and stored. The altered name is in a form of BIN$unique_name, and the database creates and gives the u nique values. unique_name is created in a value of 32 characters.

When restoring tables stored in the recycle bin, constraints and indexes related to the table are restored i n its original of when before they were dropped. However, if a name of when before the object was drop ped already exists, then the object is restored in the name of when it is stored in the recycle bin.

RECYCLEBIN property should be activated to use the recycle bin feature. The property can be altered with ALTER SESSION and ALTER SYSTEM, and ALTER SYSTEM has DEFERRED property. The default value is FA LSE.

```
gSQL> ALTER SESSION SET RECYCLEBIN = ON;
Session altered.
gSQL> ALTER SYSTEM SET RECYCLEBIN = ON DEFERRED;
System altered.
```

Feature

- The object stored in the recycle bin is not physically dropped. Therefore the tablespace used by the co rresponding object is not released.
- Each user has its own recycle bin and a user can view its own recycle bin.
- If there are multiple tables with the same name, then the oldest object is dropped when dropping an object stored in the recycle bin.
- If there are multiple tables with the same name, then the newest object is restored when restoring an object stored in the recycle bin.
- DICTIONARY VIEW can retrieve objects stored in the recycle bin, but INFORMATION VIEW can not ret rieve objects stored in the recycle bin.
- PURGE DBA_RECYCLEBIN ON DATABASE privilege is required to drop all recycle bins in the database.
- PURGE and FLASHBACK TABLE statements can be audited with AUDIT SYSTEM ACTION.
- If a tablespace is dropped, then the recycle bins included in the tablespace are also dropped.
- If a schema is dropped, then the recycle bins included in the schema are also dropped.
- If a user is dropped, then the user's recycle bin is also dropped.

Only some DML and DDL are allowed for the object stored in the recycle bin, and statements ex cept for the statements below cause an error.

- SELECT
- SELECT .. FOR UPDATE
- LOCK TABLE
- COMMENT ON TABLE name IS
- COMMENT ON COLUMN name IS
- COMMENT ON INDEX name IS
- COMMENT ON CONSTRAINT name IS
- GRANT privileges TO
- REVOKE privileges FROM
- CREATE TABLE AS SELECT
- CREATE GLOBAL TEMPORARY TABLE AS SELECT
- CREATE AUDIT POLICY
- ALTER AUDIT POLICY
- CREATE VIEW
- CREATE SYNONYM
- CREATE FUNCTION

- CREATE PROCEDURE
- ALTER FUNCTION
- ALTER PROCEDURE
- ALTER DATABASE MOVE SHARD
- ALTER DATABASE REBALANCE
- ALTER DATABASE REBALANCE EXCLUDE CLUSTER GROUP
- ALTER TABLE name REBALANCE
- ALTER TABLE name REBALANCE EXCLUDE CLUSTER GROUP
- ALTER TABLE name MOVE SHARD
- ALTER TABLE name SPLIT SHARD
- ALTER TABLE name MERGE SHARD
- ALTER TABLE name SYNCHRONIZE IDENTITY COLUMN

Example

RECYCLEBIN property should be activated to use the recycle bin feature.

```
gSQL> ALTER SESSION SET RECYCLEBIN = ON;
Session altered.
gSQL> CREATE TABLE t1 ( id INTEGER PRIMARY KEY, name VARCHAR(32) );
Table created.
gSQL> DROP TABLE t1;
Table dropped.
gSQL> CREATE TABLE t1 ( id INTEGER PRIMARY KEY, name VARCHAR(32) );
Table created.
gSQL> DROP TABLE t1;
Table dropped.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT OBJECT_NAME, ORIGINAL_NAME, OBJECT_TYPE, DROPPED_TIME FROM USER_RECYCLEBIN;

13.8 Index

Index-related Statements

Statements for creating, dropping, altering an index are as follows.

- Creating an index: Refer to **CREATE INDEX**.
- Dropping an index: Refer to **DROP INDEX**.
- Updating an index: Refer to **ALTER INDEX**.

Information which is related to an index object can be retrieved through the following views.

Table 13-16 Index object related information

Schema	View	Description
DICTIONARY_SCHEMA	**ALL_INDEXES**	Information about user accessible indexes
	ALL_IND_COLUMNS	Column information about user accessible index
	USER_INDEXES	Information about user owned indexes
	USER_IND_COLUMNS	Column information about user owned index

Concepts of Index

Index is a table related object, and it is used to improve data access performance when retrieving the tabl e. Each index consists of key values using the data in one or more columns of the table. It is an object whi ch is separate from a table.
Database automatically builds the key data of the index when creating the index, and the index key data i s automatically managed when adding/deleting/ updating the table data.

The following is an example of a query.

```
SELECT data FROM t1 WHERE id = 12345;
```

If an index does not exist, the results which satisfy the condition are found by checking all rows in the tab le. If the table consists of multiple rows while the number of results to satisfy the condition is relatively sm all, the query above has a very inefficient response time.
When creating an index in id column by using the **CREATE INDEX** statement as follows, the optimizer eva luates the costs between the full scan and index scan of a table, and selects the index scan to improve qu ery performance.

```
CREATE INDEX t1_idx_id ON t1(id);
```

When creating an index, two or more columns can be used as an index key, and the index which consists of two or more keys is called as a composite index. The composite Index is sorted by the first key, or sorte d by the second key if the first key value is same. It is sorted as many as the number of the keys in this wa y.

When creating indexes, the column sort order can be specified in ascending (ASC) or descending(DESC). The sort order of NULL value can be specified as NULLS FIRST or NULLS LAST. Refer to the following exam ple.

```
gSQL> CREATE TABLE t1 ( value INTEGER );
Table created.
gSQL> INSERT INTO t1 VALUES (1), (NULL), (3), (2), (NULL);
5 rows created.
gSQL> CREATE INDEX idx1 ON t1 ( value ASC NULLS LAST );
Index created.
gSQL> CREATE INDEX idx2 ON t1 ( value DESC NULLS FIRST );
Index created.
gSQL> SELECT /*+ INDEX(t1, idx1) */ * FROM t1;
VALUE
-----
    1
    2
    3
 null
 null
5 rows selected.
gSQL> SELECT /*+ INDEX(t1, idx2) */ * FROM t1;
VALUE
-----
 null
 null
    3
    2
    1
5 rows selected.
```

In the example above, the index idx1 is specified in the ascending order (ASC), which is NULLS LAST, and the index idx2 is specified in the descending order (DESC), which is NULLS FIRST.
It uses the different index hints when retrieving the table with the same query, so all rows are retrieved by using each index. Results using the index idx1 is sorted in ascending order, and NULL value is located at t

he end. However, the results using the index idx2 is sorted in descending order and NULL value is located in the first.

Concepts of UNIQUE

Index can be created as UNIQUE index or non-unique index. If the key values is not UNIQUE when creatin g UNIQUE index, then an error occurs.
NULL value is allowed as a key value in UNIQUE index and UNIQUE constraint.
If NULL value is included, the truth table for UNIQUE is as follows. In other words, if the key is one, then it can have multiple null value.

Table 13-17 Truth table for UNIQUE in two values

Value1	Value2	UNIQUE
1	1	false
1	2	true
1	null	true
null	null	true

The UNIQUE index or UNIQUE constraint consisting of two or more keys can have null as the whole value or partial value. If NULL is included in the composite key, the truth table for UNIQUE is as follows.

Table 13-18 Truth table for UNIQUE in composite key

Row1	Row2	UNIQUE
(1, 1)	(1, 1)	false
(1, 1)	(1, 2)	true
(1, null)	(1, null)	false
(1, null)	(2, null)	true
(null, null)	(null, null)	true

Note that the definition of the UNIQUE has been changed in the SQL standard as follows.

- UNIQUE definition until SQL1999
  If there are no two rows in T such that the value of each column in one row is non-null and **is equal to** the value of the corresponding column in the other row according to Subclause 8.2, “<comparison predicate>”, then the result of the <unique predicate> is true; otherwise, the result of the <unique predicate> is false.

- UNIQUE definition after SQL2003

> If there are no two rows in T such that the value of each column in one row is non-null and **is not distinct from** the value of the corresponding column in the other row, then the result of the <unique predicate> is True; otherwise, the result of the <unique predicate> is False.

GOLDILOCKS follows the SQL2011 standards which is the standard after SQL2003, and the SQL standard UNIQUE is defined by whether or not UNIQUE of composite key exists as shown in the following table.

Table 13-19 Truth table for UNIQUE of the SQL standard composite key

Row1	Row2	Until SQL1999	After SQL2003
(1, 1)	(1, 1)	false	false
(1, 1)	(1, 2)	true	true
(1, null)	(1, null)	true	false
(1, null)	(2, null)	true	true
(null, null)	(null, null)	true	true

Each DBMS vendor follows the SQL standard for UNIQUE definition as follows.

- DBMS which follows the UNIQUE definition after SQL2003: Oracle, SQL server
- DBMS which follows the UNIQUE definition until SQL1999: Postgres, MySQL

13.9 View

View-related Statements

Statements for creating, dropping, altering a view are as follows.

- Creating a view: Refer to **CREATE VIEW**.
- Dropping a view: Refer to **DROP VIEW**.
- Altering a view: Refer to **ALTER VIEW**.

Information which is related to a view object can be retrieved through the following views.

Table 13-20 View object related information

Schema	View	Description
DICTIONARY_SCHEMA	**ALL_VIEWS**	Information about user accessible views
	ALL_DEPENDENCIES	Information about objects related to user accessible views
	USER_VIEWS	Information about user owned views
	USER_DEPENDENCIES	Information about objects related to user owned views
INFORMATION_SCHEMA	**VIEWS**	Information about user accessible views
	VIEW_TABLE_USAGE	Information about the table used when creating a view
	VIEW_ROUTINE_USAGE	Information about the stored function used when creating a view

Concepts of View

While a table is a physical relation of storing data, a view is a logical relation consisting of queries. In the SQL standard, it is called as the viewed table. Queries about view can be used as same as the table.

A view has the following advantages.

- Data access can be restricted to allow querying only part of the information in the table.
- The complex and frequent queries can be written in a single view to decrease query's complexity.
- Data can be presented in a perspective different from the table perspective by changing the column names or data of the view.
- Creating applications of views is not affected by the changes in table structures.

The view which is created by a **CREATE VIEW** statement is replaced with in-line view when executing queries as follows.

- Creating a view

```
CREATE VIEW v1 ( v_id, v_sum )
AS
SELECT l_partkey, SUM( l_quantity )
  FROM lineitem
 GROUP BY l_partkey;
```

- Querying the view

```
SELECT v_id, v_sum
  FROM v1
 WHERE v_sum > 1000;
```

- Translating the view

```
SELECT v_id, v_sum
  FROM ( SELECT l_partkey, SUM( l_quantity )
           FROM lineitem
          GROUP BY l_partkey
       ) v1 ( v_id, v_sum )
 WHERE v_sum > 1000;
```

In the following example, the asterisk (*) is used in SELECT statement when creating a view v1, and the a sterisk means all columns.
In this case, as follows, all the columns including the added column can be retrieved by executing query o f view v1 even after a new column addr is added to the table t1 of which the view is approaching.

```
gSQL> CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) );
Table created.
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
```

- Creating a view by using an asterisk (*)

```
gSQL> CREATE VIEW v1 AS SELECT * FROM t1;
View created.
```

- Querying the view

```
gSQL> SELECT * FROM v1;
ID NAME
```

```
-- ------
 1 leekmo
1 row selected.
```

- Adding a column to the table which is referenced by the view

```
gSQL> ALTER TABLE t1 ADD COLUMN addr VARCHAR(1024) DEFAULT 'N/A';
Table altered.
```

- Querying the view after adding the column

```
gSQL> SELECT * FROM v1;
ID NAME   ADDR
-- ------ ----
 1 leekmo N/A
1 row selected.
```

However, creating a view using the asterisk (*) is not recommended because it can cause changes in the application when changing the table structure.

13.10 Sequence

Sequence-related Statements

Statements for creating, dropping, altering, using a sequence are as follows.

- Creating a sequence: Refer to **CREATE SEQUENCE**.
- Dropping a sequence: Refer to **DROP SEQUENCE**.
- Altering a sequence: Refer to **ALTER SEQUENCE**.
- Using a sequence: Refer to **NEXTVAL**, **CURRVAL**.

Information which is related to a sequence object can be retrieved through the following views.

Table 13-21 Sequence object related information

Schema	Vew	Description
DICTIONARY_SCHEMA	**ALL_SEQUENCES**	Information about user accessible sequences
	USER_SEQUENCES	Information about user owned sequences
INFORMATION_SCHEMA	**SEQUENCES**	Information about user accessible sequences

Concepts of Sequence

Sequence is an object which automatically creates a sequential number, and it is called as sequence gene rator in the SQL standard. Sequence is a useful object to automatically manage the unique key or primary key. A sequence can be spanned multiple tables.

The following is an example of using a single sequence object to automatically generate the id column va lue, and using it across multiple tables.

```
gSQL> CREATE SEQUENCE seq;
Sequence created.
gSQL> INSERT INTO t1 (id, name) VALUES ( seq.NEXTVAL, 'leekmo' );
1 row created.
gSQL> INSERT INTO t2 (id, addr) VALUES ( seq.CURRVAL, 'Seoul, Korea' );
1 row created.
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
1 row selected.
```

```
gSQL> SELECT * FROM t2;
ID ADDR
-- ------------
 1 Seoul, Korea
1 row selected.
```

In the example above, the next number of the id column in table t1 is automatically created by using the seq.NEXTVAL function. The same value is used for id column in table t2 by using the seq.CURRVAL functi on.
When creating the sequence, the starting value, incremental value, minimum value, maximum value, cycl e or no cycle and cached value of the automatically generated number can be specified.
For more information, refer to **CREATE SEQUENCE** statement.

An identity column is similar to a sequence, and it automatically generates numbers in a table. It can be u sed as follows.

```
gSQL> CREATE TABLE t1 ( id INTEGER GENERATED ALWAYS AS IDENTITY, name VARCHAR(128) );
Table created.
gSQL> INSERT INTO t1 (name) VALUES ( 'leekmo' );
1 row created.
gSQL> INSERT INTO t1 (name) VALUES ( 'mkkim' );
1 row created.
gSQL> INSERT INTO t1 (name) VALUES ( 'xcom73' );
1 row created.
gSQL> SELECT * FROM t1;
ID NAME
-- ------
 1 leekmo
 2 mkkim
 3 xcom73
3 rows selected.
```

In the example above, the id column is created as an identity column when creating table t1. The identity column automatically generated id column values, and the values are inserted when executing INSERT sta tement.
For more information, refer to **<identity column specification>** clause of **CREATE TABLE** statement.

The sequence and the identity column are functionally similar because they create the sequential number s. However, they are different in the following aspects.

- Sequence is an SQL schema object but identity column is a column of the table.
- Sequence can be spanned multiple tables but identity column can be used only in one table.

After creating a sequence, the sequence values can be used by using **NEXTVAL** or **CURRVAL** function. Th e sequence value is created independently from the transaction, and it is not affected by COMMIT or ROL LBACK of the transaction.

```
gSQL> INSERT INTO t1(id) VALUES( seq.NEXTVAL );
1 row created.
gSQL> SELECT id FROM t1;
ID
--
 1
1 row selected.
gSQL> ROLLBACK;
Rollback complete.
gSQL> INSERT INTO t1(id) VALUES( seq.NEXTVAL );
1 row created.
gSQL> SELECT id FROM t1;
ID
--
 2
1 row selected.
```

In the example above, seq.NEXTVAL function generates a value of 1 in the first INSERT statement.
Then, the seq.NEXTVAL value 2 is generated after the transaction ROLLBACK by increasing the value sinc e the next value, independently from the transaction.

The sequence value can be used only in the following statements.

- The select list value of the top-level SELECT statement
  - SELECT seq.NEXTVAL FROM dual;
- The select list value of INSERT .. SELECT statement
  - INSERT INTO t1(id) SELECT seq.NEXTVAL FROM daul;
- Input value of INSERT .. VALUES statement
  - INSERT INTO t1(id) VALUES (seq.NEXTVAL);
- SET value of UPDATE statement
  - UPDATE t1 SET id = seq.NEXTVAL;

The sequence value can be used only in the location as specified above. It can not be used in subquery, a ggregation function argument, or clauses such as WHERE, DISTINCT, GROUP BY, HAVING, ORDER BY.

Cluster Sequence

When using GOLDILOCKS by configuring the cluster system, the global sequence object is internally used. The global sequence object sets the pool of sequence values to be commonly used over all cluster system, and allocates it as much as the cache size when each member node calls NEXTVAL. In other words, if valu es of 20 sequences are alloceted to a specific node, then the value allocated to other nodes starts from th e next value. A member node loads sequence values allocated by the global sequence object in its local c ache, then returns them as a result of NEXTVAL call until all of them are run out.

The global sequence object has the following features and constraints comparing to the sequence for the standalone database.

- The sign can not be modified by using the INCREMENT BY option in the ALTER SEQUENCE statement. (The size can be modified.)
- When using the CYCLE option, a duplicated value can be returned to member nodes due to the size of the entire sequence pool. Therefore, if the CYCLE option is required, then the sequence pool shoul d be set big enough considering INCREMENT BY, CACHE SIZE, and the numner of cluster member no des.
- Even when there is not an error, the sequence values returned by a specific member node may not be sequential. However, a sequential sequence value is obtained when only a single member node calls NEXTVAL.
- If it is NOCACHE, then the CACHE SIZE is 1, so the additional sequence values are not loaded on a loc al cache. In this case, the global sequence object allocates a single sequence whenever calling NEXTV AL, then it increases the networking cost and may cause the poor performance.
- It is generally operated as AUTO COMMIT when creating, altering and deleting the sequence.
- When modifying the size of CACHE and INCREMENT by using the ALTER statement, then all sequenc e values loaded on local caches of all nodes are reset. In other words, the new sequence set should b e allocated again by the global sequence object when calling NEXTVAL later.

13.11 Synonym

Synonym-related Statements

Statements for creating and dropping a synonym are as follows.

- Creating a synonym: Refer to **CREATE SYNONYM**.
- Dropping a synonym: Refer to **DROP SYNONYM**.

Information which is related to a synonym object can be retrieved through the following views.

Table 13-22 Synonym object related information

Schema	View	Description
DICTIONARY_SCHEMA	**ALL_SYNONYMS**	All synonym information
	USER_SYNONYMS	Information about user owned synonym

Concepts of Synonym

Synonym is an alias for the following objects.

- Table
- View
- Sequence
- Stored procedure
- Stored function
- Other synonyms

Synonyms can be used as an alias in SELECT, INSERT, UPDATE, DELETE, LOCK TABLE, GRANT, REVOKE, C OMMENT statements.

Using synonym is very convenient. It is because only the synonym should be redefined without modifying the application even when the schema of underlying objects is changed.
The database security can be improved by hiding the object's real name and its owner. Moreover, the dat abase usability is enhanced by changing the long object name to a short name.

Synonyms are classified as private synonym and public synonym. Private synonym is a schema object and public synonym is a non-schema object.

The following examples of creating and using the private synonym and the public synonym indicated by t

he table below describe the concepts of them.

```
gSQL> \CONNECT u1 u1
gSQL> CREATE TABLE u1.t1 (col1 INTEGER );
gSQL> INSERT INTO u1.t1 VALUES(1);
gSQL> COMMIT;
```

Private Synonym

Private synonym is a schema object. If a synonym is created without the schema name, the default schem a name of the user performing the statement is used.

```
gSQL> \CONNECT u2 u2
gSQL> CREATE SYNONYM u2.syn1 FOR u1.t1;
Synonym created.
gSQL> SELECT * FROM u2.syn1;
ERR-42000(16254): lacks privilege (SELECT ON TABLE "U1"."T1")
```

Synonym is only an alias. Therefore, if a user does not have the appropriate privileges on the underlying o bject u1.t1, then the user can not use it even when the user created the synonym.

```
gSQL> \CONNECT u1 u1
gSQL> GRANT SELECT ON TABLE u2.syn1 TO u2;
gSQL> \CONNECT u2 u2
gSQL> SELECT * FROM u2.syn1;
COL1
----
   1
1 row selected.
gSQL> SELECT * FROM u1.t1;
COL1
----
   1
1 row selected.
gSQL> DROP SYNONYM u2.syn1;
Synonym dropped.
```

In the example above, the SELECT privilege of u2.syn1 is granted to u2. This is as same as the SELECT priv ilege of u1.t1 is granted to u2. Therefore, be cautious when granting privileges to synonyms.

Public Synonym

Public Synonym is a non schema object. It is not allowed to specify the schema name when it is created o r droppped.

```
gSQL> \CONNECT u2 u2
gSQL> CREATE PUBLIC SYNONYM pubSyn1 FOR u1.t1;
Synonym created.
gSQL> SELECT * FROM pubSyn1;
ERR-42000(16254): lacks privilege (SELECT ON TABLE "U1"."T1")
```

Public synonym dose not have an owner, and it is accessible for all users. However, a user without an app ropriate privilege on the underlying objects can not access the underlying objects.

```
gSQL> \CONNECT u1 u1
gSQL> GRANT SELECT ON TABLE pubSyn1 TO u2;
gSQL> \CONNECT u2 u2
gSQL> SELECT * FROM pubSyn1;
COL1
----
   1
1 row selected.
gSQL> SELECT * FROM u1.t1;
COL1
----
   1
1 row selected.
gSQL> DROP SYNONYM pubSyn1;
Synonym dropped.
```

13.12 Stored Procedure

Stored Procedure-related Statements

Statements for creating, dropping and altering a stored procedure are as follows.

- Creating a stored procedure: Refer to **CREATE PROCEDURE**.
- Dropping a stored procedure: Refer to **DROP PROCEDURE**.
- Altering a stored procedure: Refer to **ALTER PROCEDURE**.

Information which is related to a stored procedure can be retrieved through the following views.

Table 13-23 Stored procedure object related information

Schema	View	Description
DICTIONARY_SCHEMA	ALL_ARGUMENTS	Argument information of user accessible procedure and function
	ALL_DEPENDENCIES	Information of an object related to user accessible procedure and function
	ALL_PROCEDURES	Object information of user accessible procedure and function
	ALL_SOURCE	Source text information of user accessible procedure and function
	USER_ARGUMENTS	Argument information of user owned procedure and function
	USER_DEPENDENCIES	Information of an object related to user owned procedure and function
	USER_PROCEDURES	Object information of user owned procedure and function
	USER_SOURCE	Source text information of user accessible procedure and function
INFORMATION_SCHEMA	PARAMETERS	Argument information of user accessible procedure and function
	ROUTINES	Object information of user accessible procedure and function
	ROUTINE_ROUTINE_USAGE	Information of procedure and function which is referenced by user accessible procedure and function
	ROUTINE_SEQUENCE_USAGE	Information of sequence which is referenced by user accessible procedure and function
	ROUTINE_TABLE_USAGE	Information of table and view which is referenced by user accessible procedure and function

Concepts of Stored Procedure

A stored procedure is a kind of a persistent stored module in procedure form and it is defined and managed in schema unit as like other schema-level database objects. The return value is not defined because it is in procedure form. It is used by directly calling it in CALL statement, another stored procedure, or stored

function.

For more information about a stored procedure, refer to **Schema-level Procedure**.

A store procedure is used as follows.

```
CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 INTEGER )
IS
  V1 INTEGER;
BEGIN
  SELECT COUNT(*)
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A2;
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
BEGIN
  PROC1( 2, 4 ); -- call schema-level procedure
END;
/
V1 = 3
Anonymous PL block executed.
```

13.13 Stored Function

Stored Function-related Statements

Statements for creating, dropping and altering a stored function are as follows.

- Creating a stored function: Refer to **CREATE FUNCTION**.
- Dropping a stored function: Refer to **DROP FUNCTION** .
- Altering a stored function: Refer to **ALTER FUNCTION**.

Information which is related to a stored function can be retrieved through the following views.

Table 13-24 Stored function object related information

Schema	View	Description
DICTIONARY_SCHEMA	ALL_ARGUMENTS	Argument information of user accessible procedure and function
	ALL_DEPENDENCIES	Information of an object related to user accessible procedure and function
	ALL_PROCEDURES	Object information of user accessible procedure and function
	ALL_SOURCE	Source text information of user accessible procedure and function
	USER_ARGUMENTS	Argument information of user owned procedure and function
	USER_DEPENDENCIES	Information of an object related to user owned procedure and function
	USER_PROCEDURES	Object information of user owned procedure and function
	USER_SOURCE	Source text information of user accessible procedure and function
INFORMATION_SCHEMA	PARAMETERS	Argument information of user accessible procedure and function
	ROUTINES	Object information of user accessible procedure and function
	ROUTINE_ROUTINE_USAGE	Information of procedure and function which is referenced by user accessible procedure and function
	ROUTINE_SEQUENCE_USAGE	Information of sequence which is referenced by user accessible procedure and function
	ROUTINE_TABLE_USAGE	Information of table and view which is referenced by user accessible procedure and function

Concepts of Stored Function

A stored function is a kind of a persistent stored module in function form and it is defined and managed in schema unit as like other schema-level database objects. The stored function is classified as follows according to the definition of RETURN clause.

- The function which defined the datatype of the return value returned from the function like as RETU RN <datatype>
- The function which defined the table type of the returning result set like as RETURN TABLE (<column _list>)
  - This is a table function.

For more information about a stored function, refer to **schema-level function**.

RETURN <datatype> Function

It defines the datatype of an expression returned by performing the function in RETURN clause. The funct ion should define the result value to return. Such functions can be directly executed through CALL statem ent. Or, it is used as an expression within the stored procedure or the stored function, or used as an expr ession in SQL statement.

```
gSQL> CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
RETURN INTEGER
IS
  V1 INTEGER;
BEGIN
  SELECT COUNT(*)
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A2;
  RETURN V1;
END;
/
Function created.
gSQL> SELECT FUNC1( 2, 4 ) FROM DUAL;
FUNC1( 2, 4 )
-------------
            3
1 row selected.
```

Table Function

RETURN clause defines the table column list of the result set returned by executing the function, and it is called as a table function. The table function defines the result set to return by using the select statement or the cursor variable. The table function can be used as a table function derived table in FROM clause of SELECT statement.

The table function returns the defined select statement or the result set of performing the cursor variable

's cursor query to the superordinate SELECT statement. The returned result set configures the table functi on derived table in SELECT statement. Also, it can refer to columns of the table listed before the table fun ction derived table in FROM clause as a table function's argument.

```
gSQL> CREATE TABLE t_score( c_grade INTEGER, c_score INTEGER );
Table created.
gSQL> INSERT INTO t_score VALUES ( 1 , 98 ) , ( 1 , 97 ) , ( 1 , 99 ),
                                 ( 2 , 95 ) , ( 2 , 98 ) , ( 2 , 92 ),
                                 ( 3 , 98 ) , ( 3 , 96 ) , ( 3 , 94 );
9 rows created.
gSQL> COMMIT;
Commit complete.
```

- Returning the execution result of the cursor variable

```
gSQL>
CREATE OR REPLACE FUNCTION tf_cv( p_grade INTEGER )
  RETURN TABLE( rf_grade INTEGER, rf_score INTEGER ) AS
  cv SYS_REFCURSOR;
BEGIN
  OPEN cv FOR SELECT * FROM t_score WHERE c_grade = p_grade;

  RETURN TABLE( cv );
END;
/
Function created.
gSQL> SELECT rf_grade, rf_score FROM TABLE( tf_cv( 2 ) );
RF_GRADE RF_SCORE
-------- --------
       2       95
       2       98
       2       92
3 rows selected.
```

- Returning the execution result of the SELECT statement

```
gSQL>
CREATE OR REPLACE FUNCTION tf_select( p_grade INTEGER )
  RETURN TABLE( rf_grade INTEGER, rf_score INTEGER ) AS
BEGIN
  RETURN TABLE ( SELECT * FROM t_score WHERE c_grade = p_grade );
END;
```

```
/
Function created.
gSQL> SELECT rf_grade, rf_score FROM TABLE( tf_select( 2 ) );
RF_GRADE RF_SCORE
-------- --------
       2       95
       2       98
       2       92
3 rows selected.
```

13.14 Package

Package-related Statement

Statements for creating, dropping and altering a package are as follows.

- Creating package: Refer to **CREATE PACKAGE**
- Creating package body: Refer to **CREATE PACKAGE BODY**
- Altering package: Refer to **ALTER PACKAGE**
- Dropping package: Refer to **DROP PACKAGE**

The information related to the package object can be retrieved through the following views.

Table 13-25 Stored function object-related information.

Schema	View	Description
DICTIONARY_SCHEMA	ALL_OBJECTS	It is the information about the object which is accessible by a user.
	ALL_PACKAGE_PRIVS	It is the information about the privilege related to the user package.
	ALL_PACKAGE_PRIVS_MADE	It is the information about the privilege which a user granted to allow access to the package.
	ALL_PACKAGE_PRIVS_RECD	It is the information about the privilege which was granted to a user allow access to the package.
	ALL_SOURCE	It is the information about the source text of procedure, function, package which are accessible by a user.
	USER_OBJECTS	It is the information about the user-owned object.
	USER_PACKAGE_PRIVS	It is the information about the privilege related to the user-owned package.
	USER_PACKAGE_PRIVS_MADE	It is the information about the privilege which granted to allow access to user-owned package.
	USER_PACKAGE_PRIVS_RECD	It is the information about the privilege which was granted to allow access to user-owned package.
	USER_SOURCE	It is the information about the source text of procedure, function, package which are owned by a user.
	MODULES	It is the information about SQL-server module (package) accessible by a user.
	MODULE_BODY	It is the information about package body accessible by a user.
	MODULE_BODY_MODULE_USAGE	It is the information about another package which is being used by the package body accessible by a user.
	MODULE_BODY_ROUTINE_USAGE	It is the information about the procedure or the function which is being used by the package body accessible by a user.

Schema	View	Description
INFORMATION_SCHEMA	MODULE_BODY_SEQUENCE_USAGE	It is the information about the sequence which is being used by the package body accessible by a user.
	MODULE_BODY_TABLE_USAGE	It is the information about the table which is being used by the package body accessible by a user.
	MODULE_MODULE_USAGE	It is the information about another package which is being used by the package accessible by a user.
	MODULE_PRIVILEGES	It is the information about privilege related the package accessible by a user.
	MODULE_ROUTINE_USAGE	It is the information about the procedure or the function which is being used by the package accessible by a user.
	MODULE_SEQUENCE_USAGE	It is the information about the sequence which is being used by the package accessible by a user.
	MODULE_TABLE_USAGE	It is the information about the table which is being used by the package accessible by a user.
	ROUTINE_MODULE_USAGE	It is the information about the package being used by the procedure or by the function, which is accessible by a user.
	VIEW_MODULE_USAGE	It is the information about the package which is being used by the view accessible by a user.

Concepts of Package

A package is a schema object which binds PSM type, a variable, a subprogram, a cursor, and an exception which are logically related. The package is stored in the database through compiling so that another program (another package, a procedure, an external program) to refer, share and execute the package items.

For more information about the package, refer to **PSM Packages**.

The following is an example of creating the package.

```
CREATE TABLE emp( empno NUMBER, sal NUMBER, comm NUMBER );
Table created.
INSERT INTO emp VALUES( 3548, 6000, 1000 );
1 row created.
INSERT INTO emp VALUES( 9369, 5000, NULL );
1 row created.
INSERT INTO emp VALUES( 7294, 4000, 500 );
1 row created.
COMMIT;
Commit complete.
```

```
CREATE OR REPLACE PACKAGE emp_mgmt
IS
  PROCEDURE adjust_sal(v_flag VARCHAR, v_empno NUMBER, v_pct NUMBER);
  FUNCTION get_annual_sal(v_empno NUMBER) RETURN NUMBER;
END;
/
Package created.
CREATE OR REPLACE PACKAGE BODY emp_mgmt
IS
  PROCEDURE adjust_sal(v_flag VARCHAR, v_empno NUMBER, v_pct NUMBER) IS
  BEGIN
    IF v_flag = 'INCREASE' THEN
      UPDATE emp SET sal = sal + (sal * (v_pct / 100)) WHERE empno = v_empno;
    ELSE
      UPDATE emp SET sal = sal - (sal * (v_pct / 100)) WHERE empno = v_empno;
    END IF;
  END;
  FUNCTION get_annual_sal (v_empno NUMBER) RETURN NUMBER
  IS
    v_sal NUMBER;
  BEGIN
    SELECT (sal + NVL(comm,0)) * 12 INTO v_sal FROM emp WHERE empno = v_empno;
    RETURN v_sal;
  END;
END;
/
Package created.
```

The following is an example of using the package.

```
call emp_mgmt.adjust_sal('INCREASE',7369, 10);
Procedure Call complete.
SELECT emp_mgmt.get_annual_sal(7294) FROM DUAL;
EMP_MGMT.GET_ANNUAL_SAL(7294)
-----------------------------
                        54000
1 row selected.
```

14.

Cluster Objects

14.1 Cluster System

Cluster System Related Statements

For more information, refer to the followings.

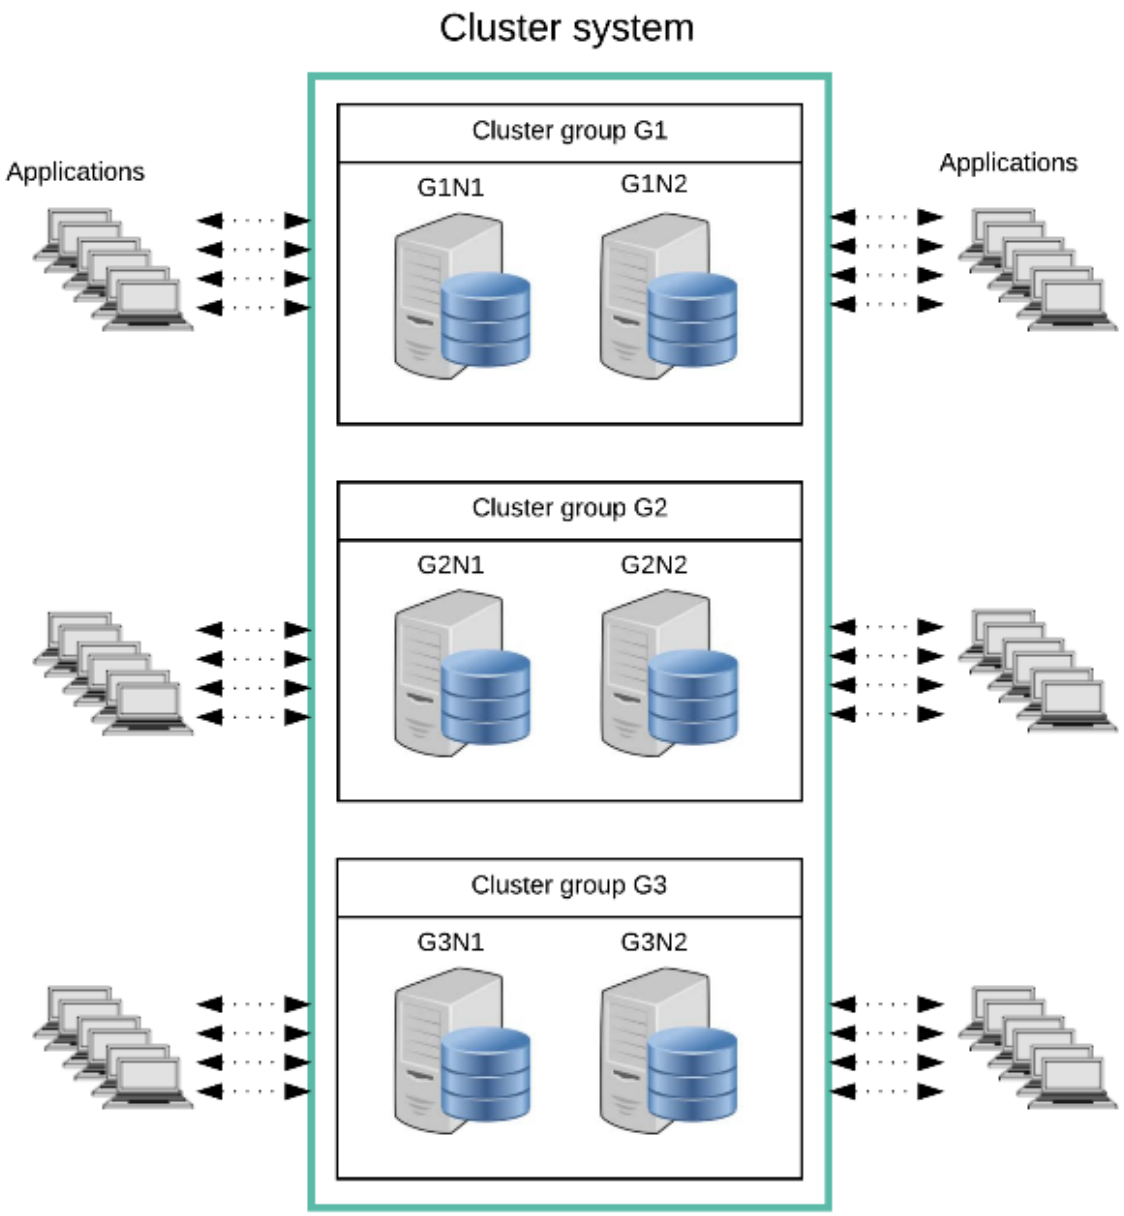
PERFORMANCE_VIEW_SCHEMA	**V$CLUSTER_MEMBER**	Status information of a cluster member

Concepts of Cluster System

GOLDILOCKS cluster system manages data of a single database by sharding or duplicating the data into several servers. Applications can be run on every server configuring a cluster system, and run in the same way as using a single database system regardless of a system configuration or a connected server.

GOLDILOCKS cluster system consists of one or more cluster groups, and a cluster group consists of one or more cluster members. It does not require a separate application server or a meta server, but applications are connected to a cluster member corresponding to a data server, and run.

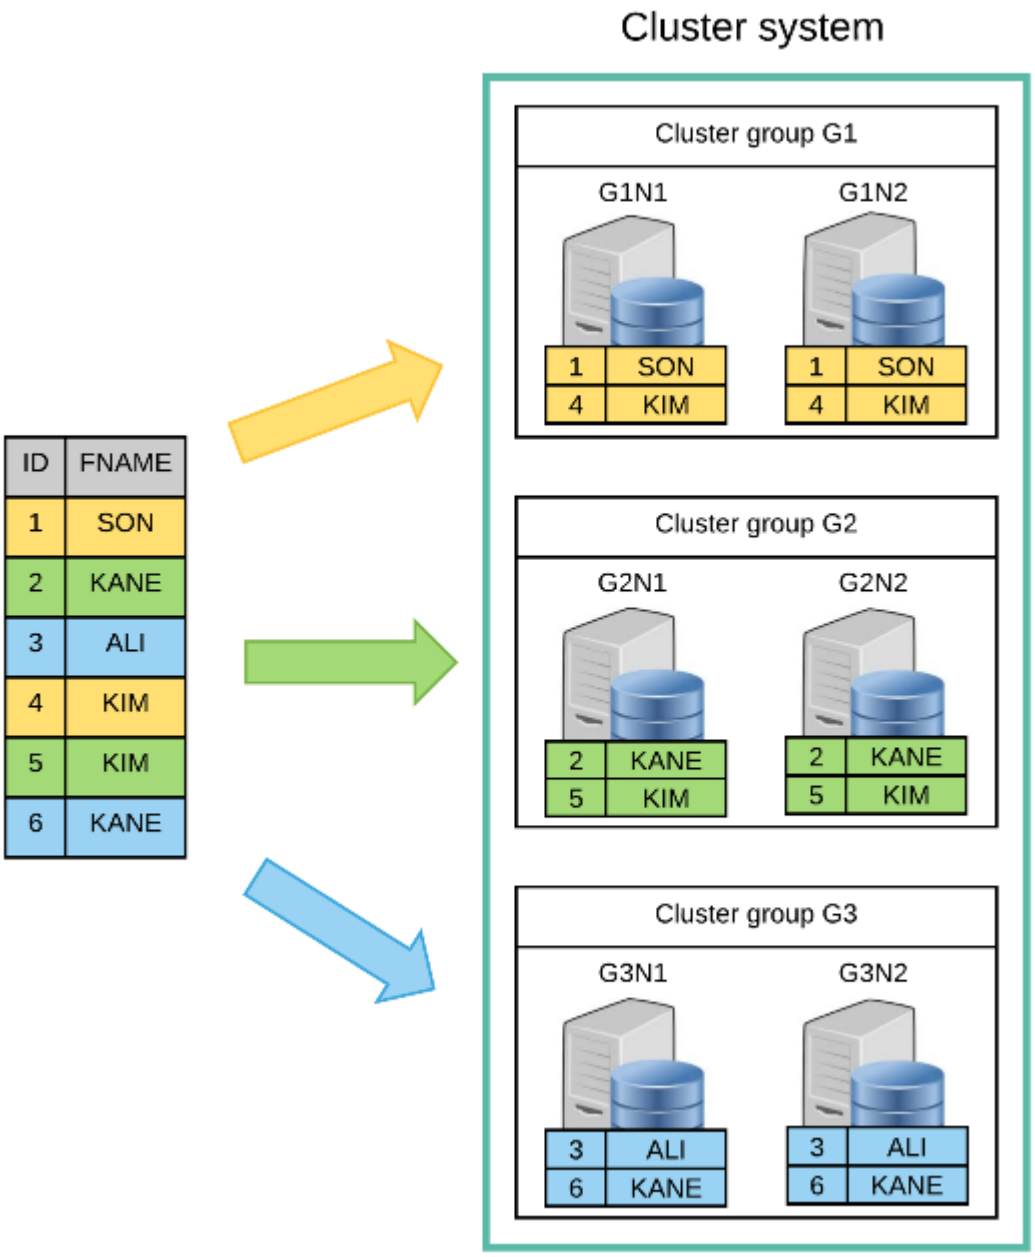
Figure 1 3 x 2 cluster system



The figure above is a 3x2 cluster system which consists of two cluster members consisting of three cluster groups and a single cluster group. In the figure above, the cluster system consists of cluster groups (G1, G2, G3), and the cluster group G1 consists of cluster members (G1N1, G1N2), the cluster group G2 cons ists of cluster members (G2N1 and G2N2), and the cluster group G3 consists of cluster members (G3N1, G3N2). Applications can access any of those six cluster members and it is run as same as using a single da tabase.

The table data is sharded and placed in each cluster group, and cluster members in a cluster group maint ain the replications same. The figure below describes the concepts of the table data placement in a 3x2 cl uster.

Figure 2 Concepts of sharding and duplicating by the cluster



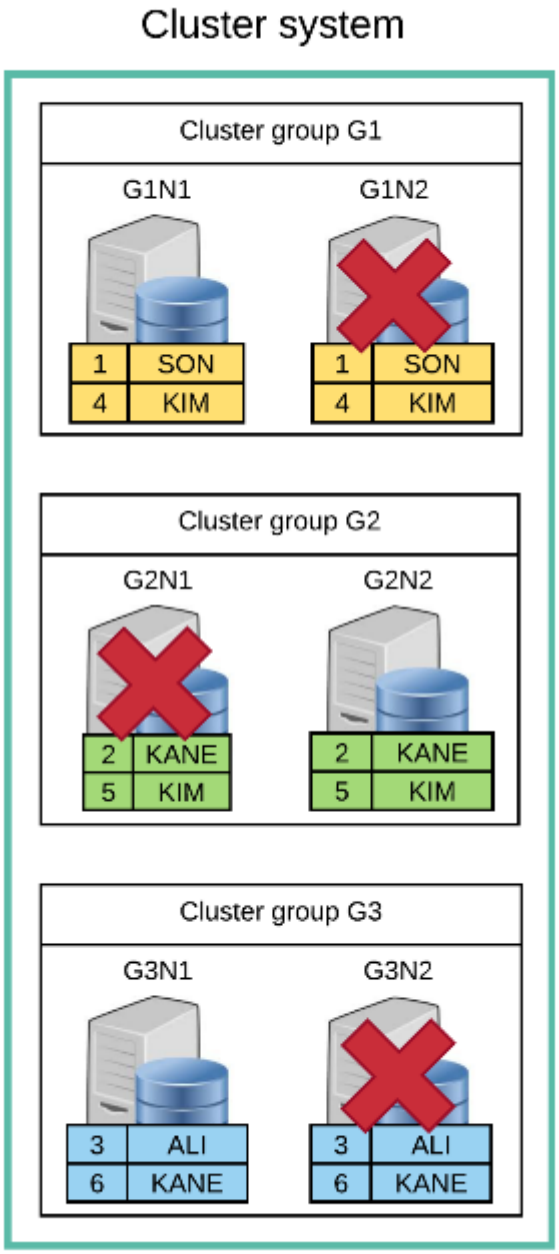
The table data is sharded and placed in each cluster group according to the sharding strategy defined by a user. (According to the ID column in the figure above) The placed data in a cluster group maintains the replication of a cluster member in a cluster group.

Availability of Cluster System

Cluster continues to provide service even when a specific server is broken or the network is cut. Cluster m embers configuring each cluster group maintain the same data replications, so the service does not stop even when a single cluster member is broken. In other words, unless the data is lost due to the malfuncti on of all cluster members in a cluster group, the service continues to be provided.

The cluster continues to provide service even when three devices are broken in the 3x2 cluster as follows.

Figure 3 Cluster availability



If an additional errors occur in G1N1, G2N2, G3N1 in the situation above, then the data loss occurs and t he service can not be provided any more. Therefore, a user should make the broken device to participate i n a cluster system, or add a new cluster member before an additional error occurs.

- **ALTER SYSTEM JOIN DATABASE** statement is used to make the broken cluster member to participate in a cluster system again.
- **ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS** statement is used to drop the broken cluster member from the cluster system.
- **ALTER CLUSTER GROUP name ADD MEMBER** statement is used to add a cluster member to a cluster group for the high availability.
- **ALTER DATABASE REBALANCE** statement and **ALTER TABLE name REBALANCE** statement are used t o rebalance data to a newly added cluster member.

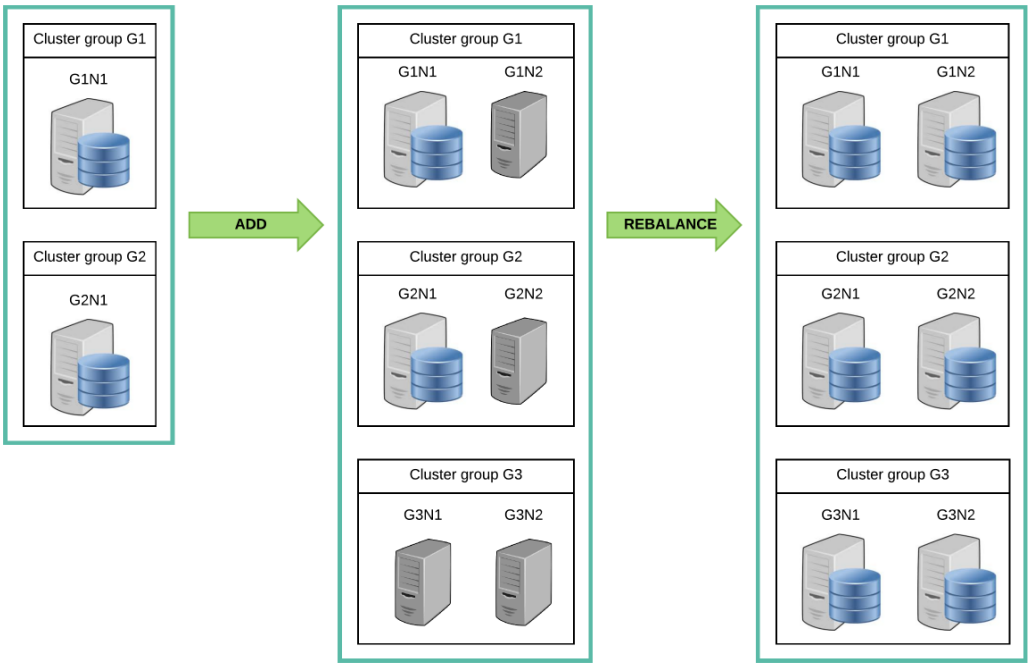
Expanding Cluster System

The cluster can be expanded by adding a new server without stopping the service.

Cluster is expanded by adding a cluster member or a cluster group and by rebalancing the data to an crea ted server.

The following is an example of expanding a 2x1 cluster to a 3x2 cluster.

Figure 4 Expanding cluster system



Add a cluster group and a cluster member by using the following statements to expand a cluster.

- ALTER CLUSTER GROUP name ADD MEMBER
- CREATE CLUSTER GROUP

To add a new cluster member to the cluster system, tablespaces in the cluster member and those in the cluster system should be same. In other words, tablespaces as same as all tablespaces in the cluster system should be created in the cluster member.

The following is an example of adding a cluster group and a cluster member of the 3x2 cluster to the 2x1 cluster. Add the member G1N2 to the group G1, and add the member G2N2 to the group G2. Then, create the group G3 including the members (G3N1, G3N2).

- Add the member G1N2 to the group G1.

```
gSQL>
ALTER CLUSTER GROUP G1
      ADD CLUSTER MEMBER G1N2 HOST '192.168.0.12' PORT 10120;
Cluster Group altered.
```

- Add the member G2N2 to the group G2.

```
gSQL>
ALTER CLUSTER GROUP G2
      ADD CLUSTER MEMBER G2N2 HOST '192.168.0.22' PORT 10220;
Cluster Group altered.
```

- Create the group G3.

```
gSQL>
CREATE CLUSTER GROUP G3
       CLUSTER MEMBER G3N1 HOST '192.168.0.31' PORT 10310,
       CLUSTER MEMBER G3N2 HOST '192.168.0.32' PORT 10320;
Cluster Group created.
```

The cluster group and the cluster member which are newly added to the cluster system can provide the service by synchronizing the dictionary information of the SQL object. However, the data is not yet placed in the added cluster member, so the availability can not be increased nor can the load balancing be expected. Therefore, the data should be rebalanced to the created cluster member for the high availability and the load balancing.

Use the following statements sequentially to rebalance the data.

- ALTER DATABASE REBALANCE

- **ALTER TABLE name REBALANCE**

The following is an example of rebalancing data to all tables in the database.

```
gSQL> ALTER DATABASE REBALANCE;
Database altered.
```

14.2 Cluster Group

Cluster Group Related Statements

For more information about creating, dropping, and altering a cluster group, refer to the followings.

- Creating a cluster group: **CREATE CLUSTER GROUP**
- Dropping a cluster group: **DROP CLUSTER GROUP**
- Altering a cluster group: **ALTER CLUSTER GROUP name ADD MEMBER**

Information which is related to a cluster group can be retrieved through the following views.

Table 14-2 Cluster group related information

Schema	View	Description
DICTIONARY_SCHEMA	DBA_CLUSTER	Object information of a cluster group and a cluster member which configure the cluster
	DBA_CLUSTER_COMMENTS	Comment information of a cluster group and a cluster member

Concepts of Cluster Group

At least one cluster group should be created to run the cluster system.

Creating Cluster Group

The first created cluster group should include itself as a cluster member. For more information about creating a cluster group, refer to **CREATE CLUSTER GROUP**.

A cluster member is a physical concept meaning the data server, but a cluster group is a logical concept consisting of one or more cluster members.

The availability and load balancing of the cluser system depends on the configration of the cluster group. The more cluster member the cluster group includes the higher the availability. The more the number of the cluster groups the bigger the throughput of the cluster system because the data is distributed.

All cluster members in a cluster group maintain the same data replications, so it can continuously provides the service unless an error occurs in all cluster members configuring a cluster group. It is recommended to configure the cluster group with two or more cluster members to maintain the availability of the cluste

r system.

The table data is sharded according to the sharding strategy, and it is stored and managed in each differe nt cluster group according to the shard placement strategy. An appropriate table sharding strategy and t he placement strategy according to the service feature determines the entire system performance. Each tr ansaction and query is processed focusing on a cluster group in which the data is stored, so the performa nce is improved if the referenced data exist in the same cluster group.

Dropping Cluster Group

The cluster group participating in a cluster system and providing a service can be dropped for various reas ons. For more information about dropping the cluster group, refer to **DROP CLUSTER GROUP**.

To drop the cluster group, all shards in a sharded table which is created in that cluster group should be tr ansferred to another cluster group. It should be transferred separately according to cluster-wide, group-s pecific table.

14.3 Cluster Member

Cluster Member Related Statements

For more information, refer to the followings.

- Adding a cluster member: **ALTER CLUSTER GROUP name ADD MEMBER**
- Dropping a cluster member: **ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS**
- Controlling a cluster member
  - **ALTER SYSTEM JOIN DATABASE**
  - **ALTER CLUSTER GROUP name OFFLINE MEMBER**
  - **ALTER DATABASE RESET LOCAL CLUSTER MEMBER**

Information which is related to a cluster member can be retrieved through the following views.

Table 14-3 Cluster member related information

Schema	View	Description
DICTIONARY_SCHEMA	**DBA_CLUSTER**	Object information of a cluster group and a cluster member which configure a cluster
	DBA_CLUSTER_COMMENTS	Comment information of a cluster group and a cluster member
PERFORMANCE_VIEW_SCHEMA	**V$CLUSTER_MEMBER**	Status information of a cluster member

Concepts of Cluster Member

The cluster member is a server configuring a cluster system, and it maintains the replications as same as those of cluster member in a cluster group.

The cluster member is a data server storing a part of the cluster database data, and it is also an application server processing the connection and request of an application. Moreover, it is a meta server duplicating and managing the meta information. In other words, GOLDILOCKS cluster does not require any data server, application server, or meta server.

Cluster members which belong to the same cluster group have the same data replications. Therefore, an error in a specific cluster member does not cause an error in the entire system. It is recommended to include two or more cluster members in each cluster group for the high availability of the system. A single cluster group can be configured with maximum 32 cluster members.

Perform **ALTER CLUSTER GROUP name ADD MEMBER** statement to add a new cluster member to a clust er group.

The added cluster member maintains the meta information of the SQL object as same as that in the clust er system, so it can process the connection and request of the application. However, the data is not place d, so adding a cluster member does not guarantee the high availability of the cluster group.

Perform the following statements to place the data after adding a cluster member.

- The placement of the entire data: Refer to **ALTER DATABASE REBALANCE**.
- The placement of only a part of the table: **ALTER TABLE name REBALANCE**.

When an error occurs on a cluster member, service is continously provided but DDL can not be performed. For a nomal service operation, an appropriate action should be taken for the cluster member with an erro r.

To make the cluster member with an error to participate in the cluster system again, then perform **ALTER SYSTEM JOIN DATABASE** statement after connecting to the cluster member and driving up to the LOCAL OPEN phase.

Even when a part of cluster members are not driven or the cluster system is driven while the network is di sconnected, perform **ALTER SYSTEM JOIN DATABASE** statement after driving up the cluster member to t he LOCAL OPEN phase.

If the cluster member device with an error can not be restored, then drop that cluster member by perfor ming **ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS** statement in the cluster system.

The cluster member dropped from the cluster system still includes the previous information, and it can no t participate in the cluster system again. Perform **ALTER DATABASE RESET LOCAL CLUSTER MEMBER** stat ement to reset the cluster member to when it is before participating in the cluster system.

The statement above is different from newly creating the database of the cluster member because it main tains the tablespace information. Therefore, it can shorten the time to create the tablespace when adding a new cluster member to the cluster system.

14.4 Cluster Location

Cluster Location Related Statements

For more information about creating, dropping, and altering a cluster location, refer to the followings.

- Creating a cluster location: **CREATE CLUSTER LOCATION**
- Dropping a cluster location: **DROP CLUSTER LOCATION**
- Altering a cluster location: **ALTER CLUSTER LOCATION**

Information which is related to a cluster location can be retrieved through the following views.

Table 14-4 Cluster location related information

Schema	View	Description
PERFORMANCE_VIEW_SCHEMA	**V$CLUSTER_LOCATION**	Information of cluster location

Concepts of Cluster Location

Cluster location is a connection information to connect the internal cluster networks of each cluster mem ber registered on the cluster system. Each cluster members use the cluster-exclusive tcp network to transf er and receive various protocols such as the transaction processing and the exchanging the management information. In this case, the member name, host ip address, and port are used for the connection and th ey are called as a cluster location by the lump.

A unique cluster location information should be specified for each member, and if the information is dupl icate, then the cluster network connection fails and the cluster system does not operate normally.

Cluster location information is automatically added or deleted when adding or dropping a cluster membe r, so a user rarely need to directly and solely add or delete the location information. However, DDL statem ent related to the cluster location can be used in the following case.

- When the cluster location information is lost due to the deleted location control file: **CREATE CLUSTE R LOCATION**
- When the previously registered connection information of the cluster member is altered, which mean s that the hardware or the connected ip and port is altered: **ALTER CLUSTER LOCATION**

14.5 Cluster Table and Shard

Shard Related Statements

For more information about definition and rebalance of the shard, refer to the followings.

- Definition of a shard: <table sharding strategy> clause of **CREATE TABLE**.
- Rebalancing a shard: **ALTER TABLE name REBALANCE**

Information which is related to a shard in a cluster table can be retrieved through the following views.

Table 14-5 Shard in a cluster table related information

Schema	View	Description
DICTIONARY_SCHEMA	ALL_CLUSTER_TABLES	Information of user accessible cluster table
	ALL_SHARD_KEY_COLUMNS	Shard key column information of user accessible cluster table
	ALL_TAB_PLACE	Placement information of user accessible cluster table
	ALL_TAB_SHARDS	Shard information of user accessible cluster table
	USER_CLUSTER_TABLES	Information of user owned cluster table
	USER_SHARD_KEY_COLUMNS	Shard key column information of user owned cluster table
	USER_TAB_PLACE	Placement information of user owned cluster table
	USER_TAB_SHARDS	Shard information of user owned cluster table

Cluster Table Type

A table which is created by a user in a cluster environment is one of the followings.

- Cloned table: Equally duplicating the table data and managing it
- Sharded table: Horizontally sharding the table data and managing it

A cloned table is appropriate for a table such as a product list or a provider list whose data is relatively small and is not often altered, because a cloned table duplicates all table data and manages it. When inserting, deleting, updating data to the cloned table, they are applied same to all cluster members to which the cloned table is placed.

A sharded table is appropriate for a table such as a transaction history or a call history whose data is big so required to be sharded. They are classifed according to three sharding strategies as follows.

- Hash sharded table
  - It divides the table data into several shards based on the hash value of a sharding key, then place s them in the cluster system.
- Range sharded table
  - It divides the table data into several shards based on the range value of a sharding key, then plac es them in the cluster system.
- List sharded table
  - It divides the table data into several shards based on the list value of a sharding key, then places t hem in the cluster system.

A sharded table horizontally divides rows and manages them in shard unit, the sharding strategy is define d by using the SHARDING BY clause in **CREATE TABLE** statement. The row set classified by the sharding s trategy is called as shard.

Each shard is placed in a cluster group according to the placement strategy defined by a user. A shard ca n automatically be placed by using AT CLUSTER WIDE of **CREATE TABLE**, or a cluster group to place a sha rd can be specified by using AT CLUSTER GROUP clause. When a shard is automatically placed by using A T CLUSTER WIDE, **ALTER TABLE name REBALANCE** is performed after creating the cluster group by using **CREATE CLUSTER GROUP**. However, when specifying a cluster group to allocate a shard, the shard is not placed in the newly created cluster group.

The following is an example of creating a table according to the cluster table type and placing the data in the 3x2 cluster environment.

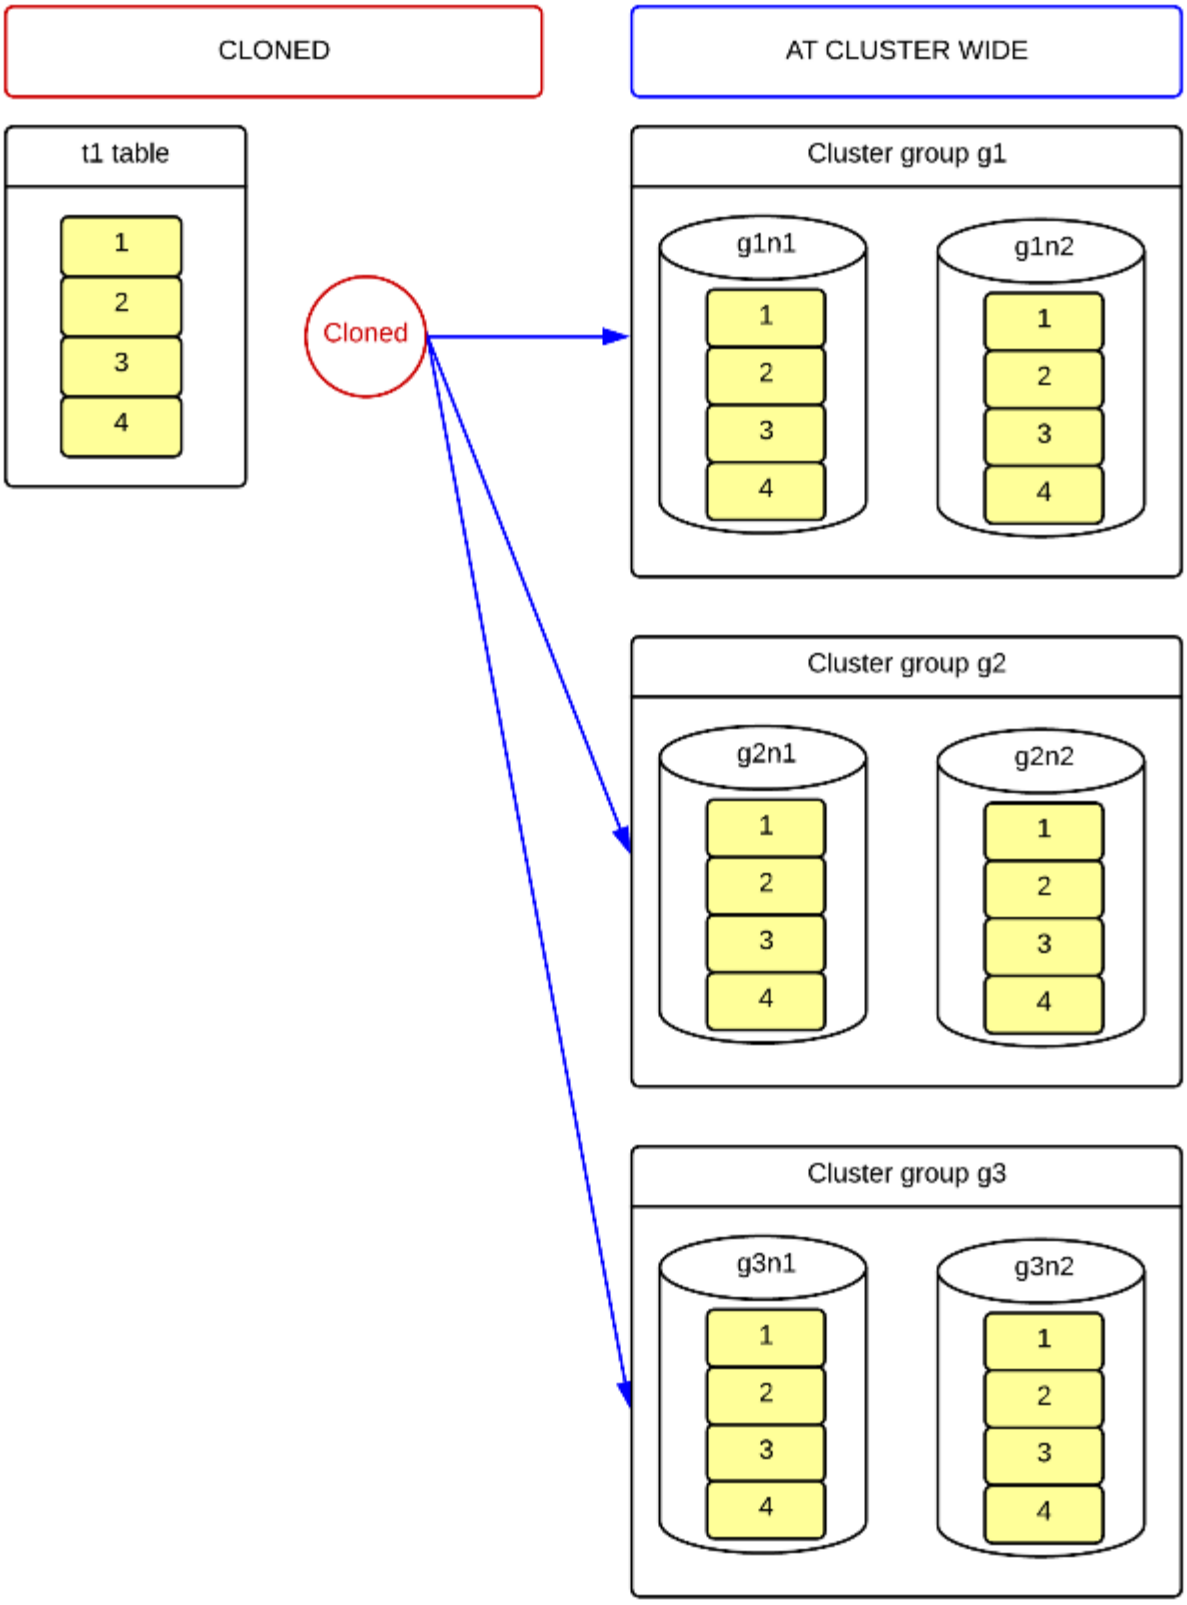
Cloned Table

A cloned table equally duplicates the table data and manages it.

The following is an example of creating a cluster-wide cloned table. All table data is equally duplicated an d placed in 3x2 cluster members.

```
CREATE TABLE t1 ( id INTEGER )
   CLONED
   AT CLUSTER WIDE
;
```

Figure 5 Cluster-wide cloned table

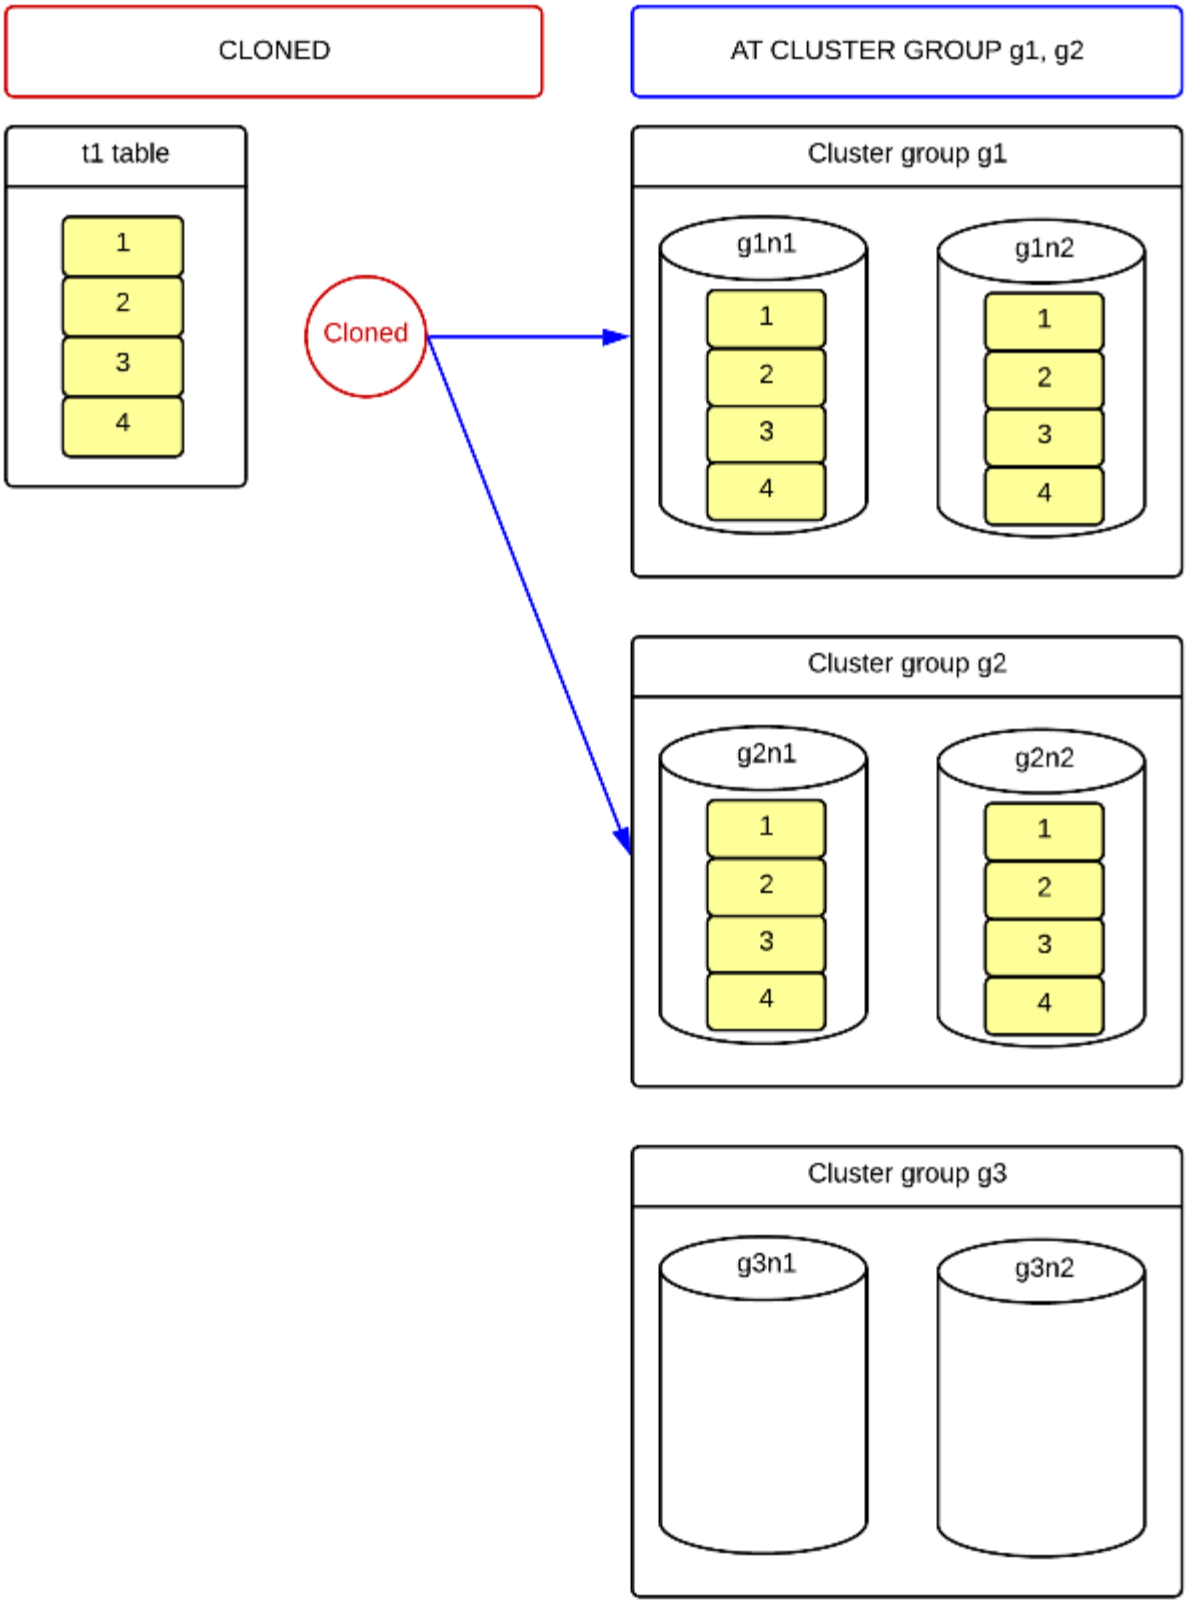


The following is an example of creating a group-specific cloned table. All table data is equally duplicated

and managed, but the duplicated table data exists only in cluster members of group g1 and g2 which are specified by a user, but it does not exist in a group g3.

```
CREATE TABLE t1 ( id INTEGER )
   CLONED
   AT CLUSTER GROUP g1, g2
;
```

Figure 6 Group-specific cloned table



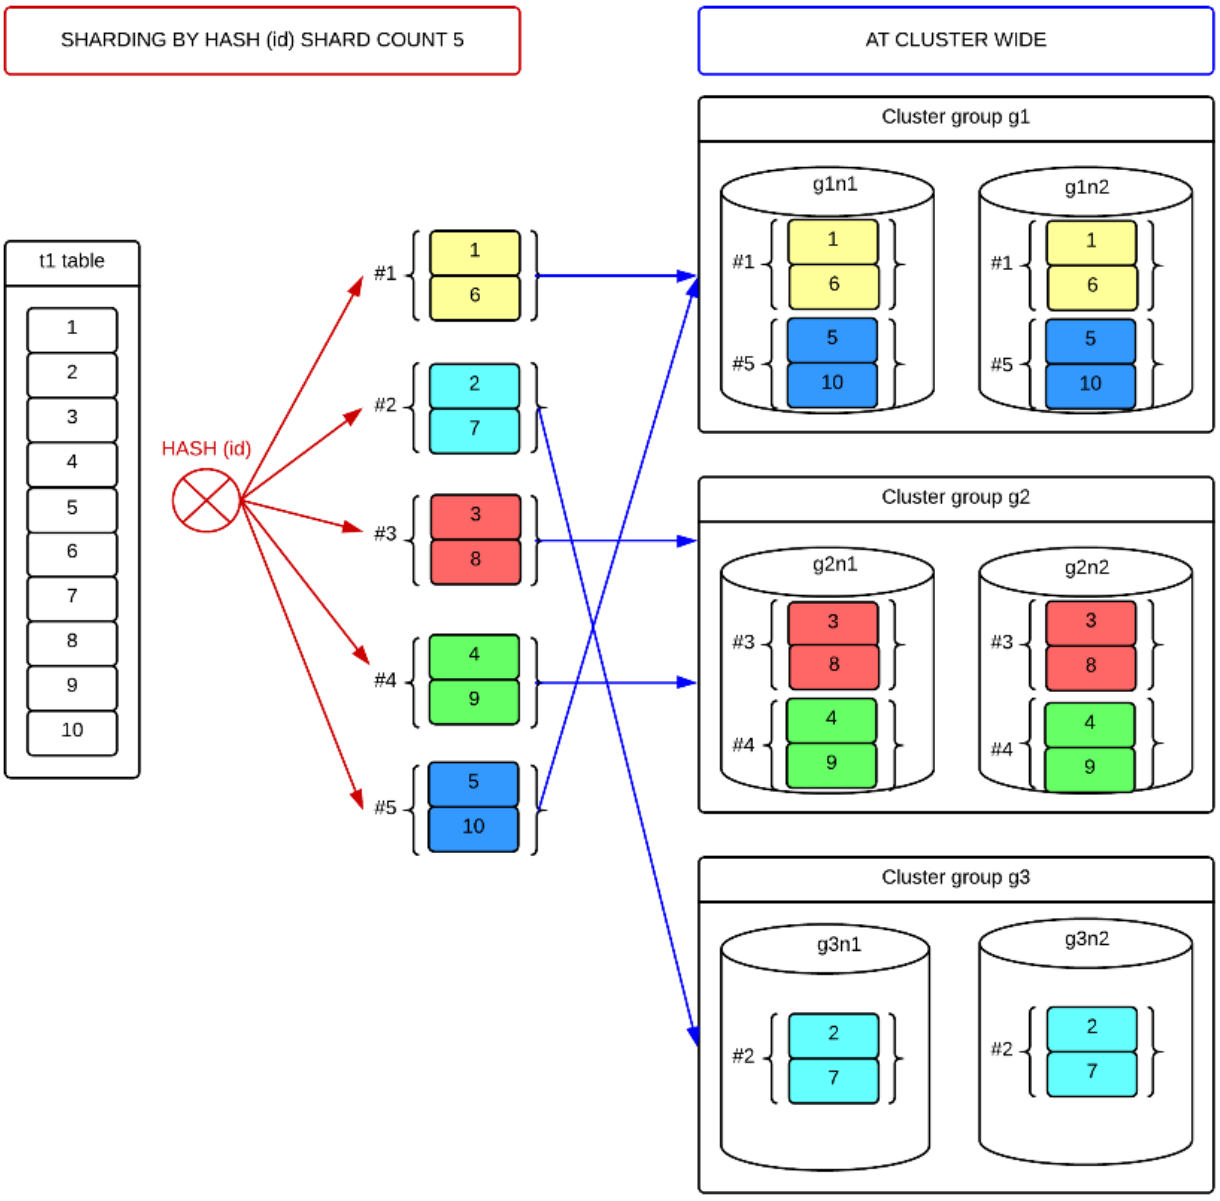
Hash-sharded table

A hash-sharded table divides the table data into several shards based on the hash value of a sharding key, then places them in the cluster system.

The following is an example of creating the cluster-wide hash-sharded table. When adding data to a tabl e, the hash value is created based on the ID column value, and the shard to place row is selected among f ive shards by using the hash value. Each shard is automatically placed. All rows with the same ID column value are included in the same shard, and placed in the same cluster group.

```
CREATE TABLE t1 ( id INTEGER )
   SHARDING BY HASH(id)
   SHARD COUNT 5
   AT CLUSTER WIDE
;
```

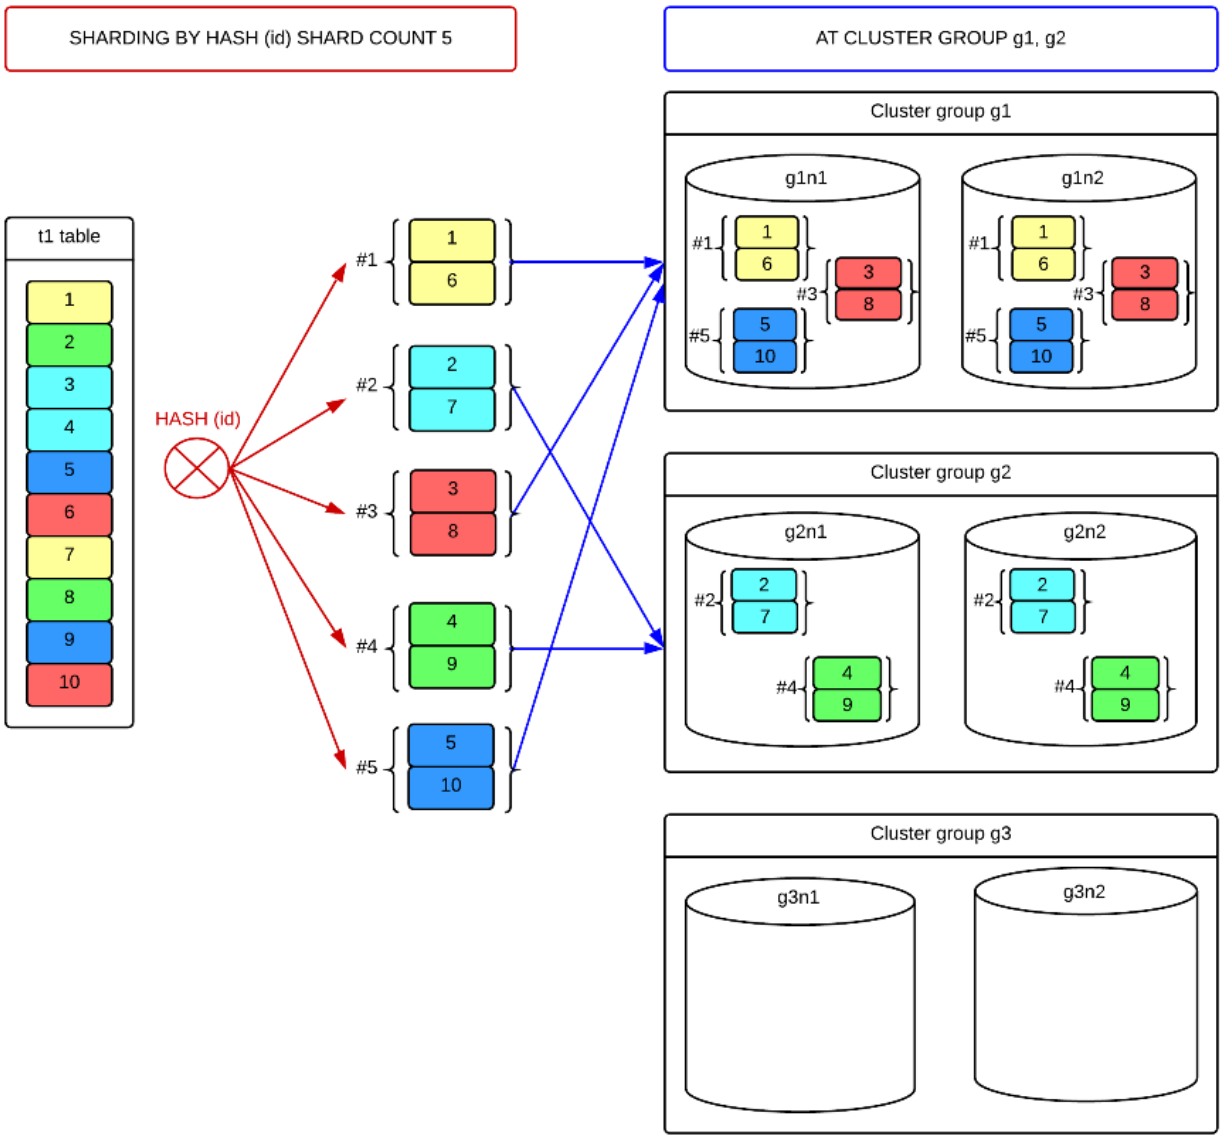
Figure 7 Cluster-wide hash-sharded table



The following is an example of creating the group-specific hash-sharded table. The hash value of an ID co lumn determines the shard, but each shard is placed only in the cluster group g1 and g2 which are specifi ed by a user.

```
CREATE TABLE t1 ( id INTEGER )
   SHARDING BY HASH(id)
   SHARD COUNT 5
   AT CLUSTER GROUP g1, g2
;
```

Figure 8 Group-specific hash-sharded table



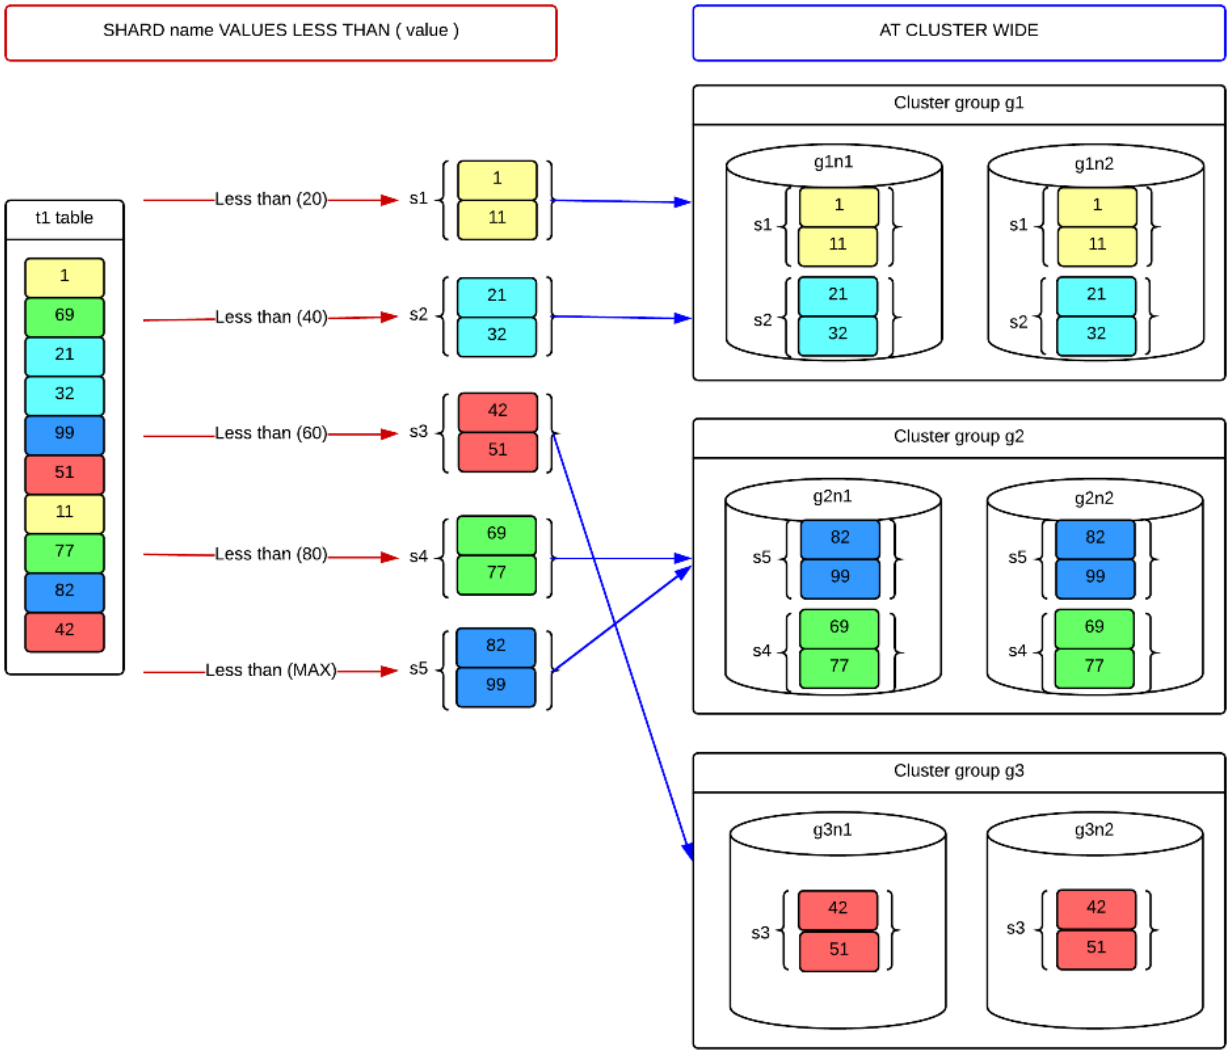
Range-sharded Table

A range-sharded table divides the table data into several shards based on the range value of a sharding key, then places them in the cluster system.

The following is an example of creating the cluster-wide range-sharded table. When adding data to a table, the shard to place row is selected among five shards based on the range value of the ID column. Each shard is automatically placed. All rows of the ID column within the same range are included in the same shard, and placed in the same cluster group.

```
CREATE TABLE t1 ( id INTEGER )
   SHARDING BY RANGE(id)
   AT CLUSTER WIDE
       SHARD s1 VALUES LESS THAN ( 20 ),
       SHARD s2 VALUES LESS THAN ( 40 ),
       SHARD s3 VALUES LESS THAN ( 60 ),
       SHARD s4 VALUES LESS THAN ( 80 ),
       SHARD s5 VALUES LESS THAN ( MAXVALUE )
;
```

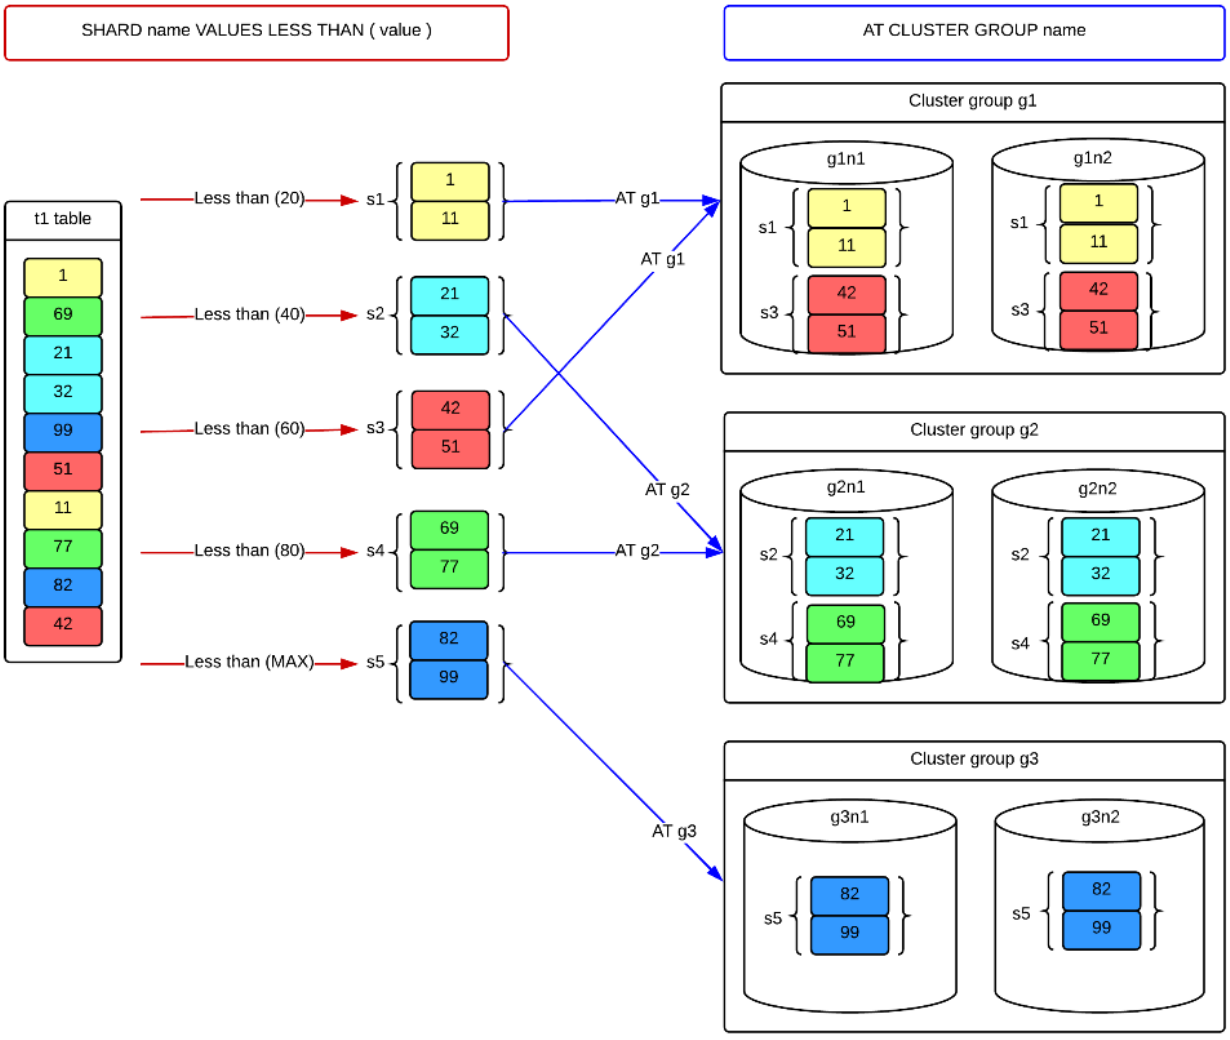
Figure 9 Cluster-wide range-sharded table



The following is an example of creating the group-specific range-sharded table. The range value of the ID column defines the shard, but each shard is placed in a cluster group specified by a user.

```
CREATE TABLE t1 ( id INTEGER )
   SHARDING BY RANGE(id)
       SHARD s1 VALUES LESS THAN ( 20 )       AT CLUSTER GROUP g1,
       SHARD s2 VALUES LESS THAN ( 40 )       AT CLUSTER GROUP g2,
       SHARD s3 VALUES LESS THAN ( 60 )       AT CLUSTER GROUP g1,
       SHARD s4 VALUES LESS THAN ( 80 )       AT CLUSTER GROUP g2,
       SHARD s5 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP g3
;
```

Figure 10 Group-specific range-sharded table



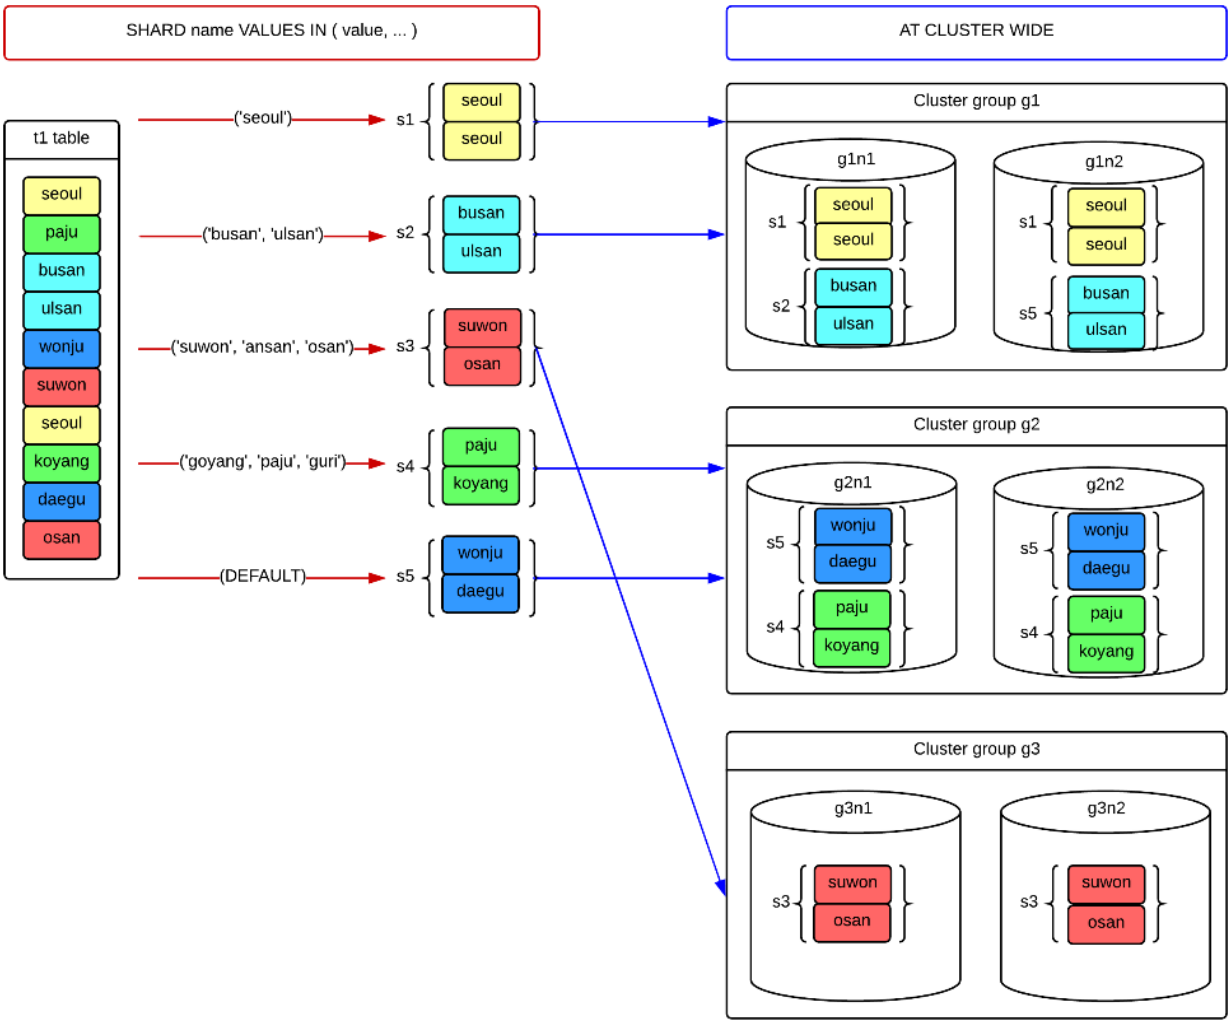
List-sharded Table

A list-sharded table divides the table data into several shards based on the list value of a sharding key, the n places them in the cluster system.

The following is an example of creating the cluster-wide list-sharded table. When adding data to a table, rows are placed in a shard with the list value as same as the CITY column value. Each shard is automatical ly placed.

```
CREATE TABLE t1 ( city VARCHAR(128) )
   SHARDING BY LIST (city)
      AT CLUSTER WIDE
      SHARD s1 VALUES IN ( 'seoul' ),
      SHARD s2 VALUES IN ( 'busan', 'ulsan' ),
      SHARD s3 VALUES IN ( 'suwon', 'ansan', 'osan' ),
      SHARD s4 VALUES IN ( 'goyang', 'paju', 'guri' ),
      SHARD s5 VALUES IN ( DEFAULT )
;
```

Figure 11 Cluster-wide list-sharded table

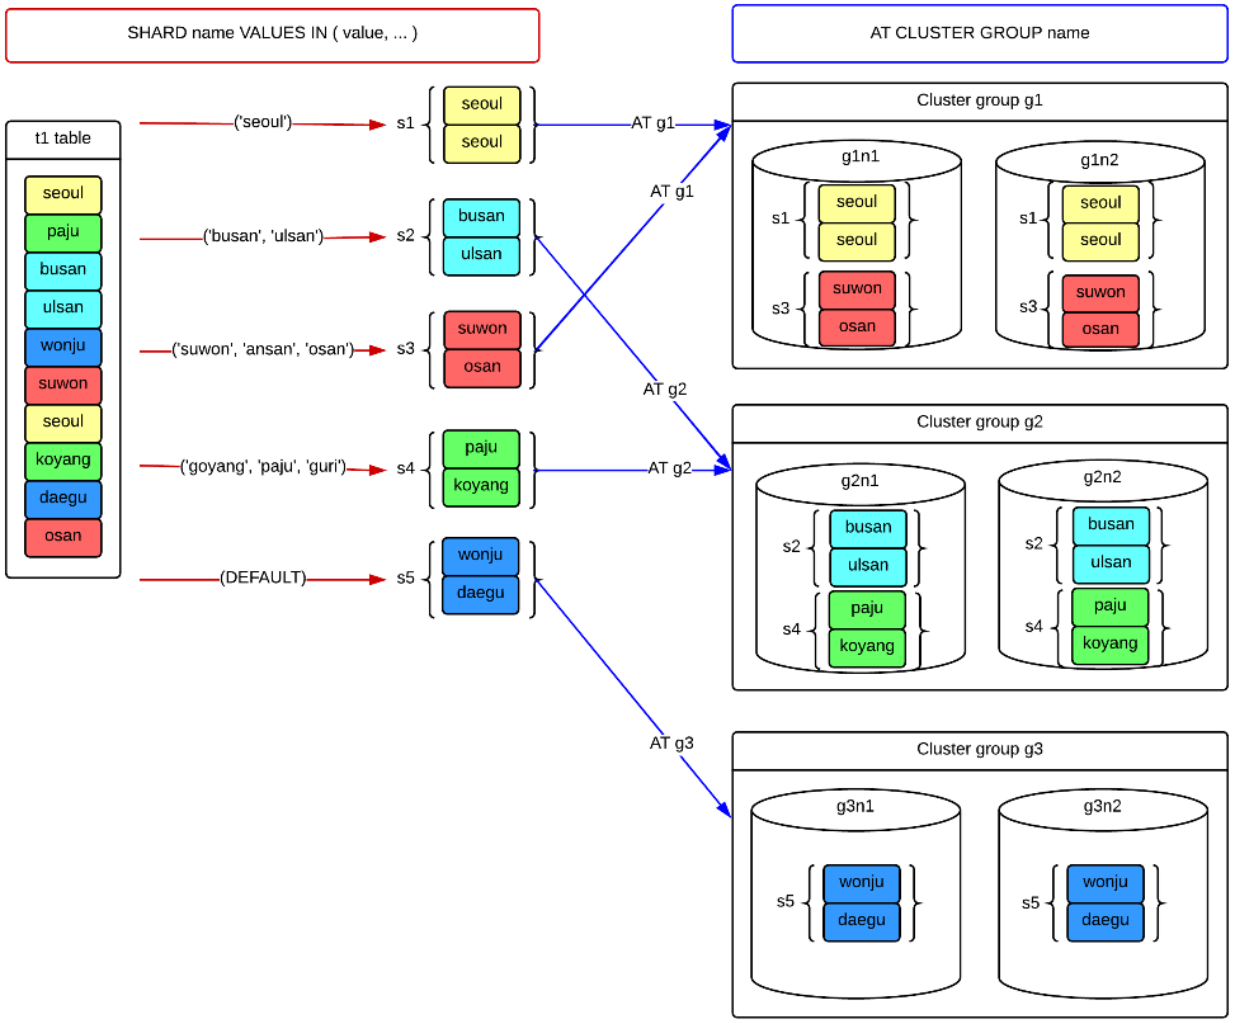


The following is an example of creating the group-specific list-sharded table. The shard is selected by the l

ist value of the CITY column, but each shard is placed in the cluster group specified by a user.

```
CREATE TABLE t1 ( city VARCHAR(128) )
   SHARDING BY LIST (city)
      SHARD s1 VALUES IN ( 'seoul' )                  AT CLUSTER GROUP g1,
      SHARD s2 VALUES IN ( 'busan', 'ulsan' )         AT CLUSTER GROUP g2,
      SHARD s3 VALUES IN ( 'suwon', 'ansan', 'osan' ) AT CLUSTER GROUP g1,
      SHARD s4 VALUES IN ( 'goyang', 'paju', 'guri' ) AT CLUSTER GROUP g2,
      SHARD s5 VALUES IN ( DEFAULT )                  AT CLUSTER GROUP g3
;
```

Figure 12 Group-specific list-sharded table



Rebalancing Cluster Table

Rebalance the data of the cluster table by using **ALTER TABLE name REBALANCE** statement.

Data of the cluster table is rebalanced in the following unit.

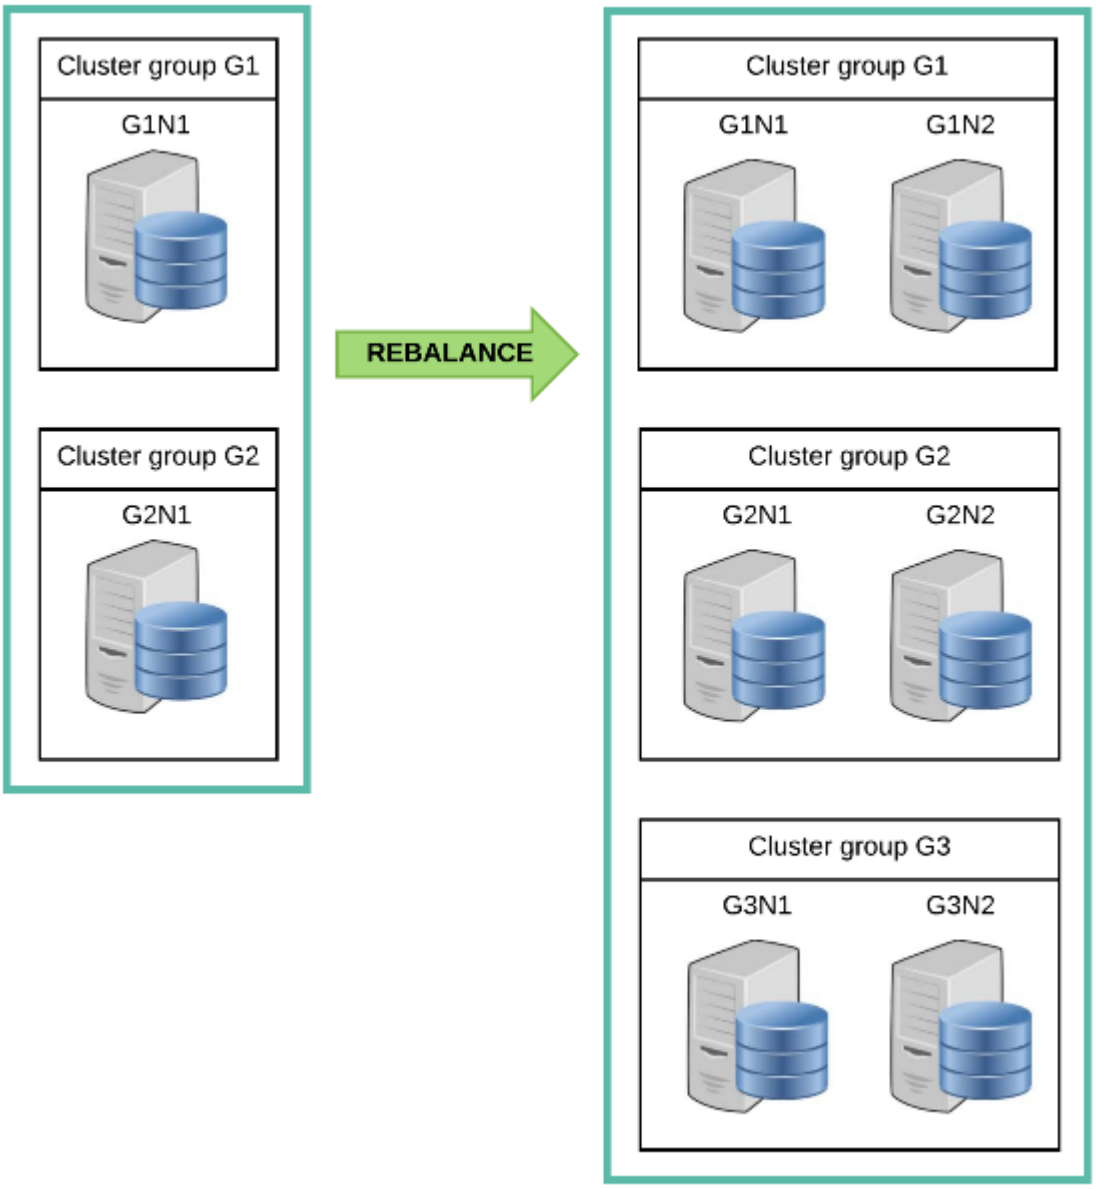
- Cloned table: The entire table
- Sharded table: shard unit

If the table is specified as AT CLUSTER WIDE, the shard is automatically rebalanced to the created cluster group, but if the cluster group to place the shard is specified by AT CLUSTER GROUP, the shard is not reb alanced to the created cluster group.

- When automatically rebalancing by using AT CLUSTER WIDE, then the data can be rebalanced to a n ew cluster group and a new cluster member.

```
CREATE TABLE region
(
    r_regionkey    INTEGER
  , r_name         CHAR(25)
  , r_comment      VARCHAR(152)
)
CLONED
AT CLUSTER WIDE;
```

Figure 13 Rebalancing the region table defined by AT CLUSTER WIDE

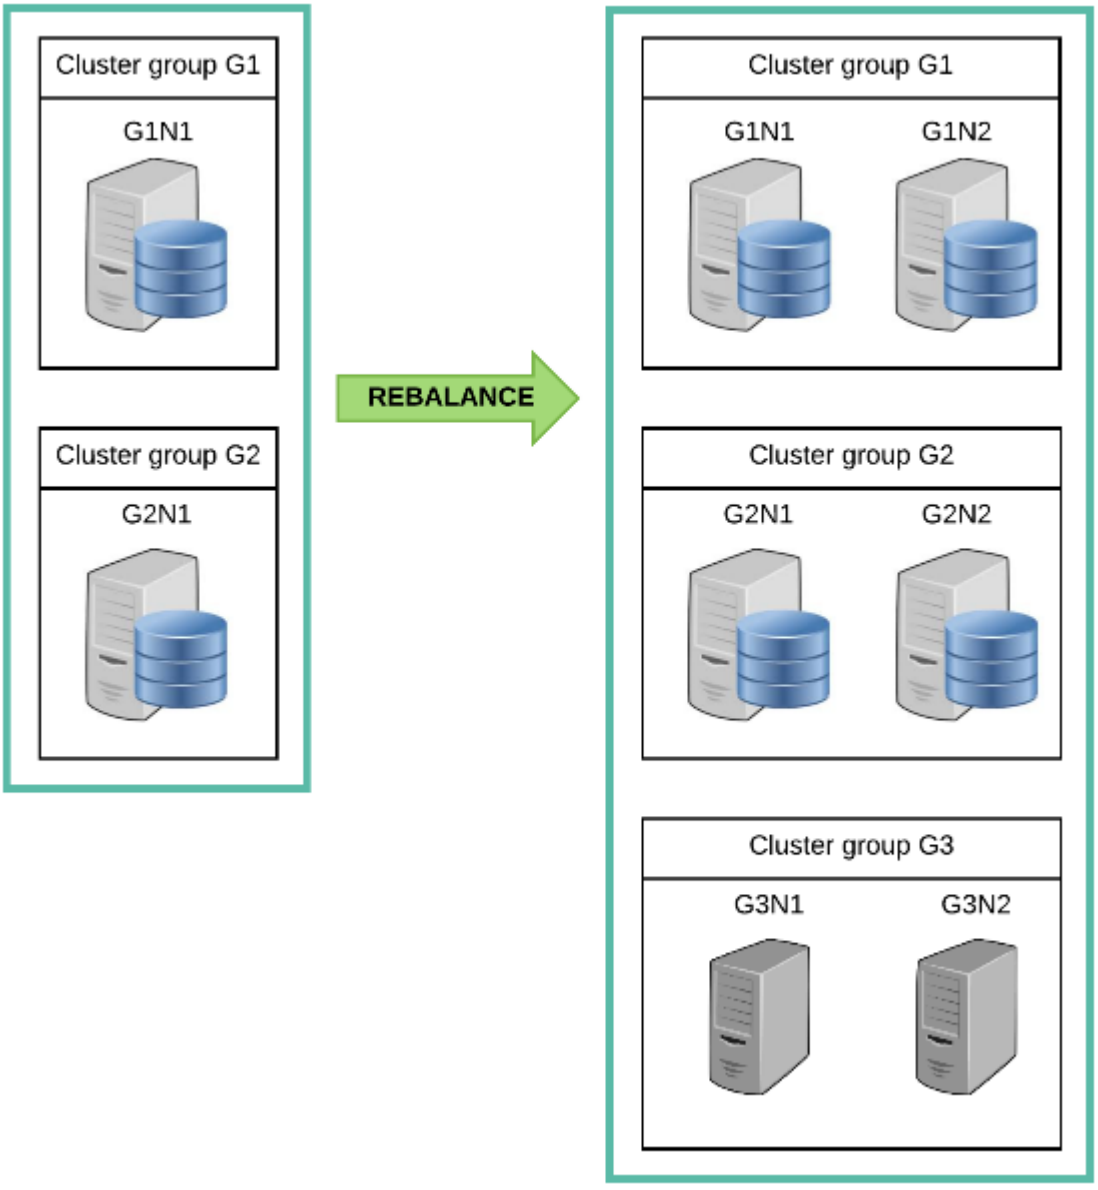


- When specifying the location to place the shard by using AT CLUSTER GROUP
  - The data is not rebalanced on the new cluster group.
  - The data can be rebalanced on the new cluster member which is added to the specified cluster gr oup.

```
CREATE TABLE nation
(
    n_nationkey    INTEGER
  , n_name         CHAR(25)
  , n_regionkey    INTEGER
  , n_comment      VARCHAR(152)
```

```
)
CLONED
AT CLUSTER GROUP g1, g2;
```

Figure 14 Rebalancing the nation table defined by AT CLUSTER GROUP



Information about the table placement can be retrieved through the following views.

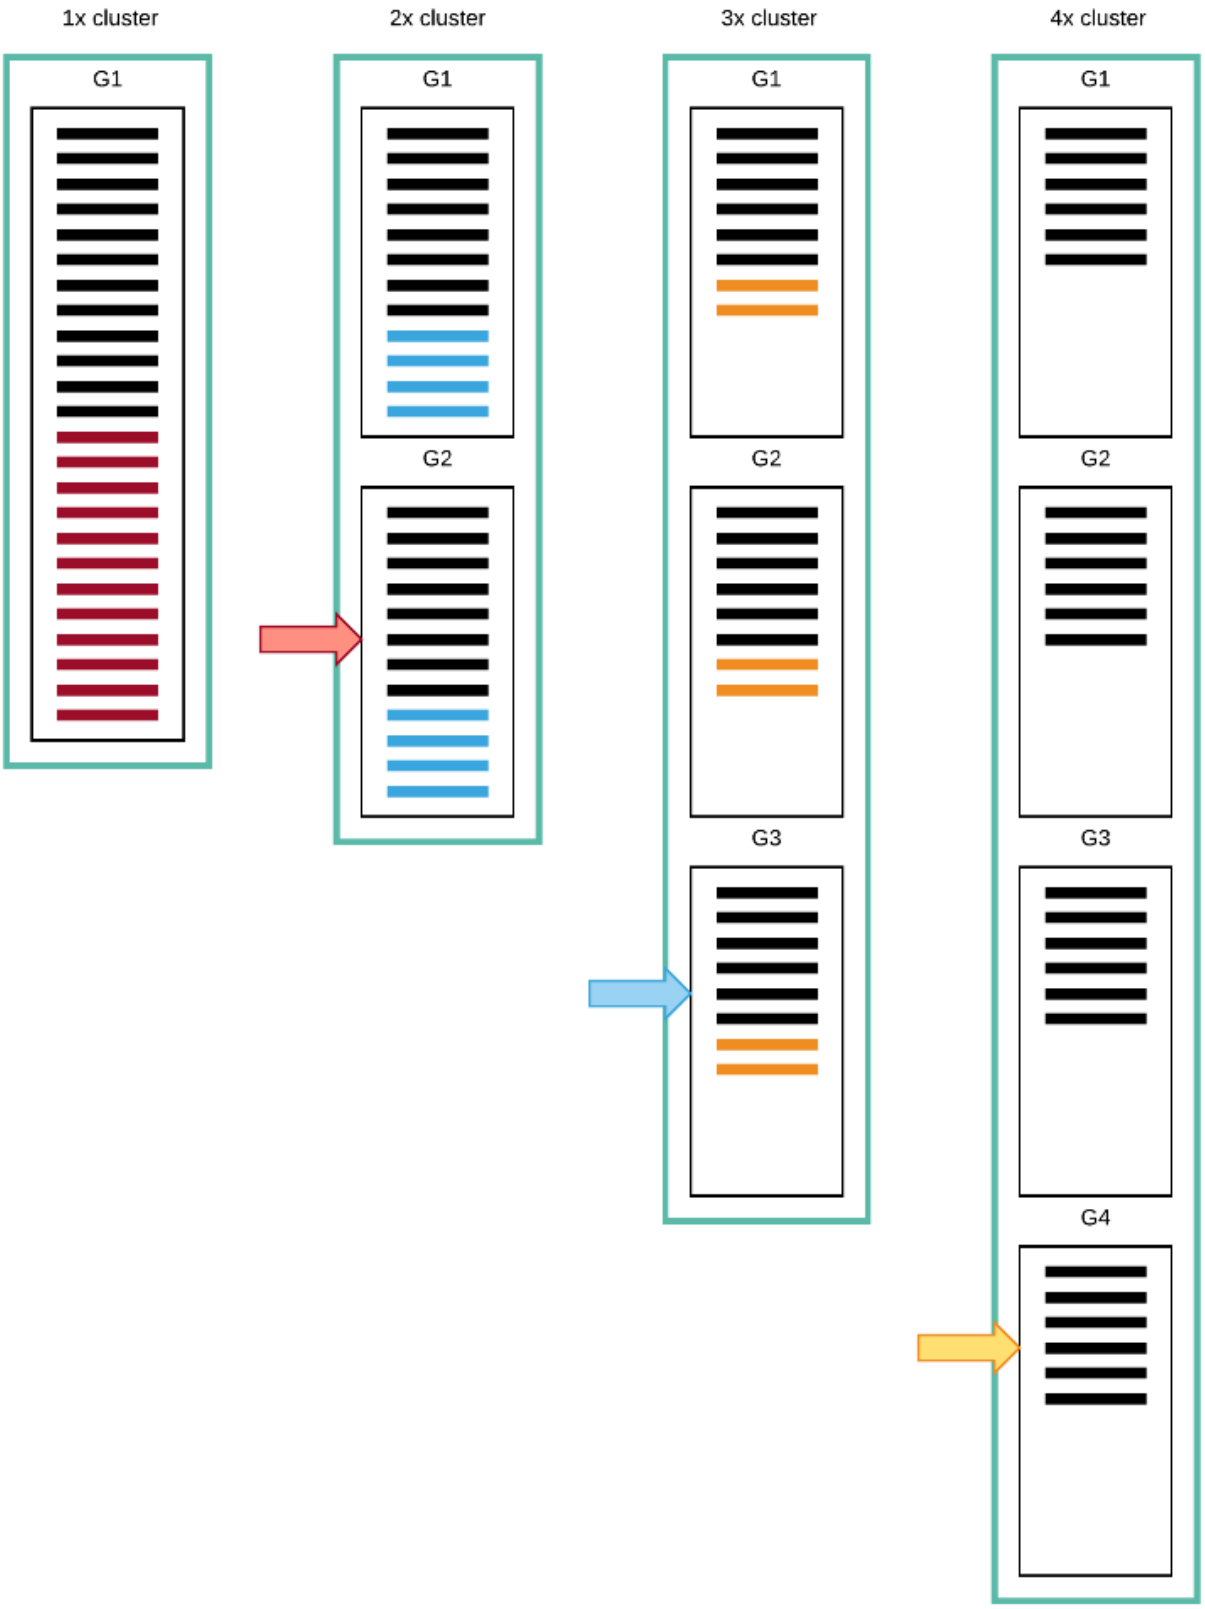
- USER_TAB_PLACE
- ALL_TAB_PLACE

```
gSQL>
SELECT group_name, member_name
  FROM user_tab_place
 WHERE table_name = 'REGION';
GROUP_NAME MEMBER_NAME
---------- -----------
G1         G1N1
G1         G1N2
G2         G2N1
G2         G2N2
G3         G3N1
G3         G3N2
6 rows selected.
```

The sharded table is rebalanced in shard unit, and rebalancing shards due to the increase of groups is as f ollows.

```
CREATE TABLE orders
(
    o_orderkey     INTEGER
  , o_custkey      INTEGER
  , o_orderstatus  CHAR(1)
  , o_totalprice   NUMERIC(12,2)
  , o_orderdate     DATE
  , o_orderpriority CHAR(15)
  , o_clerk        CHAR(15)
  , o_shippriority INTEGER
  , o_comment      VARCHAR(79)
)
SHARDING BY HASH( o_orderkey )
SHARD COUNT 24
AT CLUSTER WIDE
;
```

Figure 15 Rebalancing shards due to the increase of groups



In the example above, the data of orders table is divided into 24 shards and placed. All shards are placed i

n a single group of 1x cluster which has only one group. 12 shards are placed in each group of 2x cluster which has two groups.

When expanding 2x cluster to 3x cluster, shards are transferred from an old group to the new group, but the number of shards in each group is same (8). When expanding 3x cluster to 4x cluster, then each G1, G2, G3 rebalances two shards to the newly created group G4.

In other words, the shard rebalancing minimize the movement when shards are transferred from an old g roup to the new group, then data is equally rebalanced maintaining the same number of shards in each g roup.

Information about the shard placement of the sharded table can be retrieved through the following view s.

- USER_TAB_SHARDS
- ALL_TAB_SHARDS

```
gSQL>
SELECT shard_name, group_name
  FROM user_tab_shards
 WHERE table_name = 'ORDERS';
SHARD_NAME   GROUP_NAME
------------ ----------
SHARD_000000 G1
SHARD_000001 G1
SHARD_000002 G1
SHARD_000003 G1
SHARD_000004 G1
SHARD_000005 G1
SHARD_000006 G1
SHARD_000007 G1
SHARD_000008 G3
SHARD_000009 G3
SHARD_000010 G3
SHARD_000011 G3
SHARD_000012 G2
SHARD_000013 G2
SHARD_000014 G2
SHARD_000015 G2
SHARD_000016 G2
SHARD_000017 G2
SHARD_000018 G2
SHARD_000019 G2
```

```
SHARD_000020 G3
SHARD_000021 G3
SHARD_000022 G3
SHARD_000023 G3
24 rows selected.
```

When tables which have the same <sharding strategy> are completely rebalanced as follows, then the sha rd placement result is same. Rows with the same shard key is guaranteed to be placed in the same shard and the same group even when the tables are different.

- Table t1
  - It is created in the 2x cluster.
  - CREATE TABLE t1 (c1 INTEGER) SHARDING BY (c1);
  - It is rebalanced in the 4x cluster.
  - ALTER TABLE t1 REBALANCE:
- Table t2
  - It is created in the 3x cluster.
  - CREATE TABLE t2 (a1 INTEGER) SHARDING BY (a1);
  - It is rebalanced in the 4x cluster.
  - ALTER TABLE t2 REBALANCE:
- Table t3
  - It is created in the 4x cluster.
  - CREATE TABLE t3 (i1 INTEGER) SHARDING BY (i1);

In other words, the following query can access only to a single cluster member and process it.

```
SELECT COUNT(*)
  FROM t1, t2, t3
 WHERE t1.c1 = t2.a1
   AND t2.a1 = t3.i1
   AND t1.c1 = 1;
```

14.6 Global Secondary Index

Global Secondary Index Related Statements

For more information about creating, dropping, and altering a global secondary index, refer to the follow ings.

- Creating a global secondary index: **ALTER TABLE name ADD GLOBAL SECONDARY INDEX**
- Dropping a global secondary index: **ALTER TABLE name DROP GLOBAL SECONDARY INDEX**
- Altering a global secondary index: **ALTER TABLE name ALTER GLOBAL SECONDARY INDEX**

Information related to a global secondary index can be retrieved through the following views.

Table 14-6 Global secondary index related information

Schema	View	Description
DICTIONARY_SCHEMA	ALL_CLUSTER_TABLES	Existence of a global secondary index in user accessible table
	ALL_GLOBAL_SECONDARY_INDEXES	Object information of user accessible global secondary index
	ALL_GSI_PLACE	Placement information of user accessible global secondary index
	USER_CLUSTER_TABLES	Existence of a global secondary index in user owned table
	USER_GLOBAL_SECONDARY_INDEXES	Object information of user owned global secondary index
	USER_GSI_PLACE	Placement information of user owned global secondary index

Concepts of Global Secondary Index

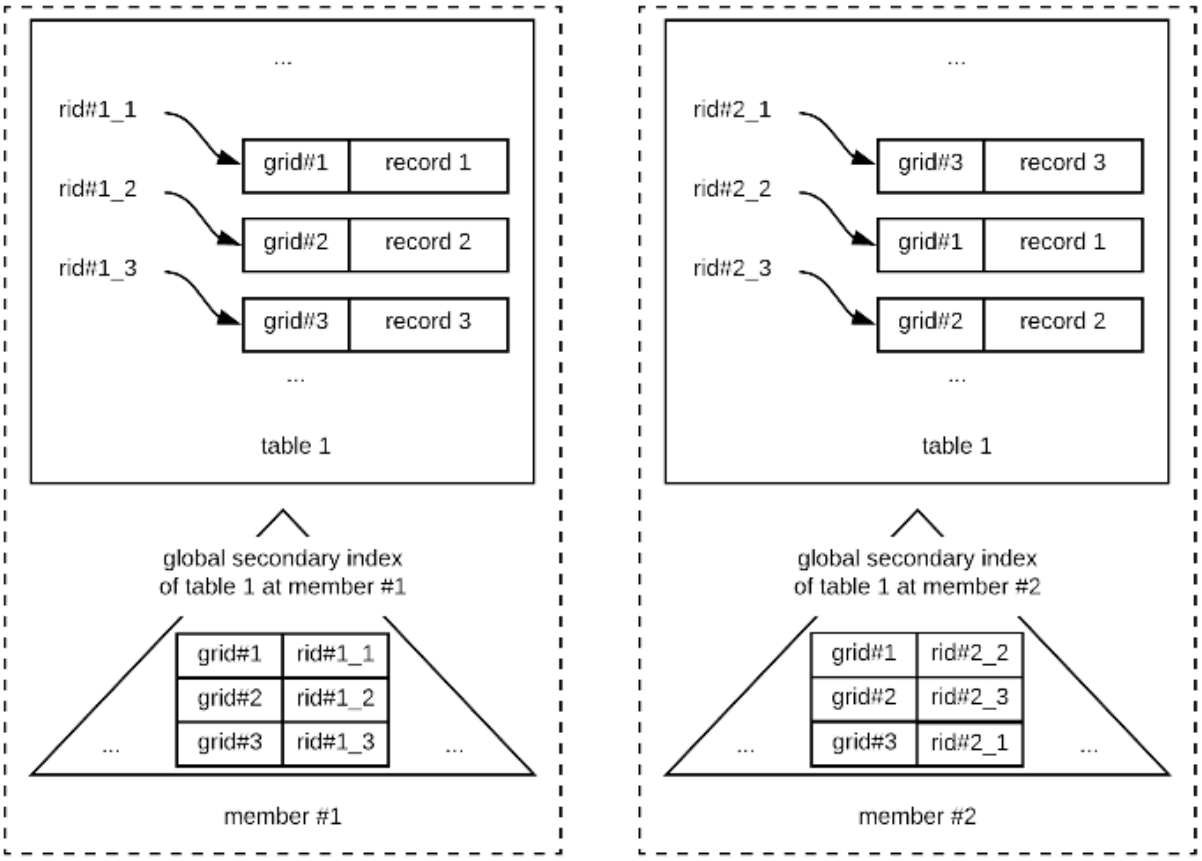
A global secondary index is a B-Tree index which configures the GRID (global row identifier) value as a key in each cluster member of the cluster environment.

Tables in the cluster environment is duplicated to all members in a group and the same records are applied and retrieved when performing DML or select. GRID is a unique value identifying the same records in cluster members, and it is allocated when the record is inserted for the first time, and it is spreaded over all members in a group, then stored together with the record.

When creating a table in a cluster environment, a global secondary index may or may not be created, and

it can be separately created or deleted after the table is created. A table may not have a global secondary index, or it may have maximum one global secondary index.

Figure 16 Structure of a global secondary index



A global secondary index is required to perform a non-deterministic query for a table. If the table dose no t have a global secondary index, then the non-deterministic query fails as follows.

```
gSQL> DELETE FROM T1 LIMIT 1;
ERR-42000(16423): does not support non-deterministic DML in the cluster system : global
secondary index expected
```

Refer to the dictionary such as ALL_GSI_PLACE, DBA_GSI_PLACE, and USER_GSI_PLACE to check if a tabl e has a global secondary index.

15.

SQL Tuning

15.1 SQL Tuning

Overview

SQL tuning is a process of analyzing and modifying a query statement to improve the performance.

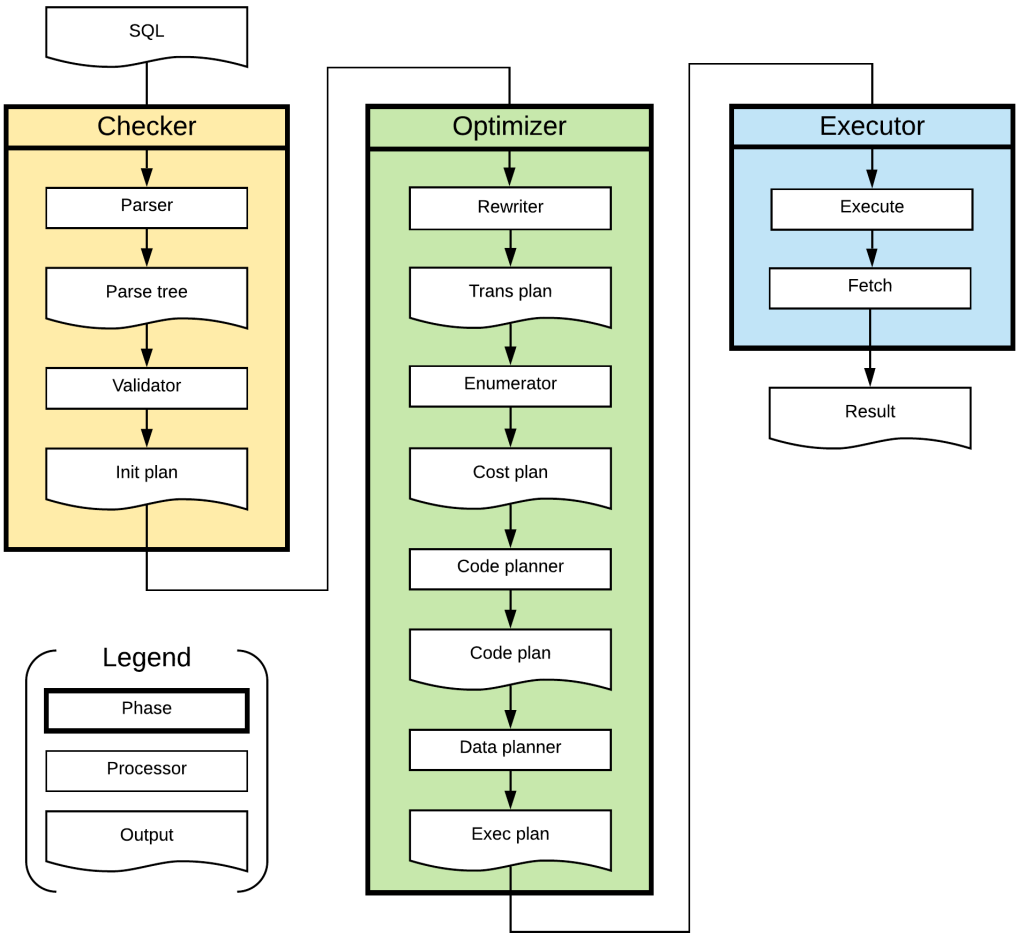
This process helps a query statement reach to the desired performance level by decreasing the response ti me of a query statement or by increasing the throughput.

The knowledge about SQL processing and an optimizer is required to perform SQL tuning, so this chapter describes them.

SQL Processing

The following figure describes the SQL processing.

Figure 1 SQL processing



The user query returns the result through a parser, a validator, a rewriter, an enumerator, a code planner, a data planner, an executor phases. The following paragraphs describes each phase.

Parser

A parser checks a grammatical error of SQL statement input by a user.

```
gSQL> SELECT * FORM customer;
ERR-42000(40000): syntax error
SELECT * FORM customer
.........^  ^
Error at line 1
```

If the SQL statement does not have a grammatical error, then it creates a parse tree. Then it becomes an i nput argument of a validator in the next phase.

Validator

A validator checks semantic error of a parse tree which was input.

For example, it checks whether an object such as a table or a column specified in a query exists, and if a u ser has s privilege to refer to those objects.

```
gSQL> SELECT * FROM customer;
ERR-42000(16040): table or view does not exist :
SELECT * FROM customer
              *
ERROR at line 1:
```

If a parse tree does not have a semantic error, then an init plan is created based on it.

Rewriter

A rewriter converts a SQL statement into a high performance SQL with the same meaning.

It analyzes an init plan, creates a trans plan, converts it to a trans plan in a form whose high performance is expected. The converted trans plan becomes an input argument of enumerator phase.

For more information about converting SQL statement, refer to **Rewriter**.

Enumerator

An enumerator calculates the cost of multiple plans based on the statistics information, and creates the b est cost plan.

For more information about various optimization methods such as an access path to a table a join orderin g and a join method determination, refer to **Enumerator**.

Code Planner

A code planner creates a code plan.

A code plan creates the plan finally selected by an enumerator into a execution plan form. An execution plan consists of tree structure nodes, and it includes the following information.

- How to access each table
- The sequence to refer to tables
- How perform the operation joining tables
- The information about the data filter
- The information about grouping and aggregating the data
- The information about sorting the data

Plan Cache

Code plans created by a code planner are registered in a plan cache. The registered plans are classified ac cording to whether plan cache parameters values match.

Table 15-1 Plan cache parameters

Parameter	Description
Query text	Case-sensitive query text
User information	User ID
Cursor property	Cursor property of a query requiring fetch
Bind parameter	The number of bind parameters and IN/ OUT property of each bind parameter
Enable atomic	Whether to use an atomic insertion
Enable hint error	Whether a validation error occurs in a hint

When a user query is input, then it checks whether the plan with the same plan cache parameters values exist in a plan cache. If exists, it omits parser-validator-rewriter-enumerator-code planner process, and us ed the plan registered in the plan cache.
When using the plan registered in the plan cache in this way, then the cost for parser-validator-rewriter-e numerator-code planner process decreases, so it improves the performance.

The following is an example of queries whose query texts values are different. Though they are same que

ries, but their capitalization is different, so the queries below are not recognized as a same plan.

```
"SELECT * FROM customer"
"select * from customer"
"Select * From customer"
"SELECT * FROM  customer"
```

If a schema object (table, index, view, sequence) referenced by a plan is not committed, then th e plan is not registered.

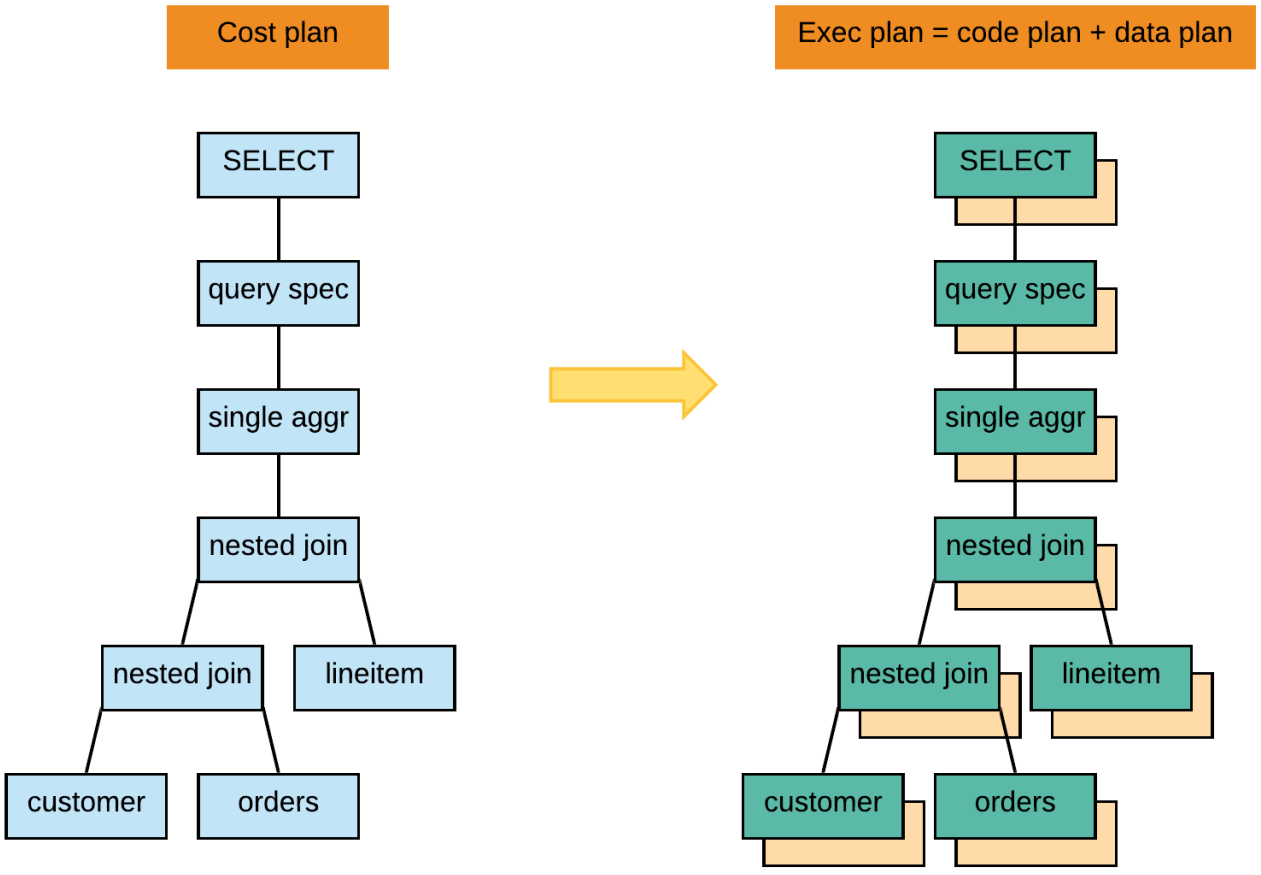
Data Planner

A data planner creates a data plan. A data plan has a space to store the intermediate result and a tempor ary space to store the expression result while performing code plans.

Executor

An executor returns the actual executed result of performing a code plan and a data plan.

Figure 2 Executor



Execution Plan

The execution plan consists of a code plan and a data plan. It is a tree form whose top node is INSERT, DELETE, UPDATE, SELECT statement.

The execution is a basic analysis tool of SQL tuning. The execution plan describes how the query is converted by a rewriter and which access path, join order, join method is selected by an enumerator.

The followings are a syntax and an example to output the execution plan.

Syntax

The following is a syntax to output the execution plan.

```
<explain plan> ::=
      \explain plan [ on ¦ only ] <sql statement>
<sql statement> ::=
        <query expression>
      ¦ <select for update statement>
      ¦ <select statement: single row>
      ¦ <insert statement>
      ¦ <update statement: searched>
      ¦ <delete statement: searched>
```

Invocation and Access Rules

The privilege to access <sql statement> statement is required to perform <explain plan> statement.

Syntax Rules and Parameters

```
\EXPLAIN PLAN ON
\EXPLAIN PLAN
```

When specifying as above, it performs the query then outputs the execution plan.

```
\EXPLAIN PLAN ONLY
```

When specifying as above, it does not perform the query but only outputs the execution plan.

Example

When executing as follows, it performs SQL statement, and outputs the query result and the execution plan together.

The following example is executed in a cluster system which consists of G1(G1N1, G1N2), G2(G2N1, G2

N2) and G3(G3N1, G3N2). The customer is a cloned table and orders is a sharded table whose data is div ided by do_orderkey.

Figure 3 Read plan

```
\EXPLAIN PLAN
  SELECT  c_name,
          o_orderdate,
          o_orderstatus
    FROM  customer,
          orders
   WHERE  c_custkey = o_custkey
     AND  o_orderdate >= date '1995-03-15'
     AND  o_orderdate < date '1995-03-15' + interval '1' month;
...

19343 rows selected.

>>>  start print plan

< Execution Plan >

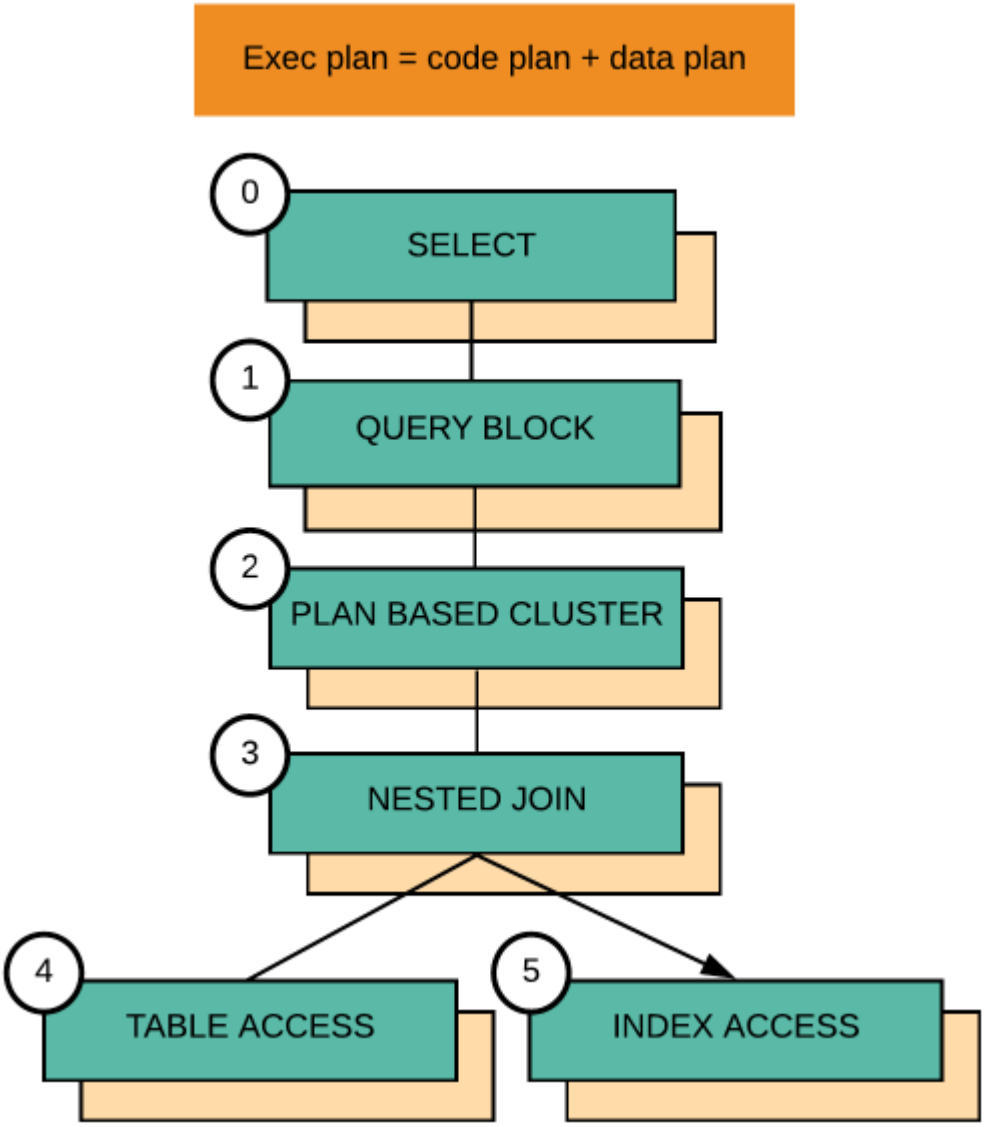
IDX	NODE DESCRIPTION		ROWS
0	SELECT STATEMENT		19343
1	QUERY BLOCK ("$QB_IDX_2")		19343
2	PLAN BASED CLUSTER	LOCAL/REMOTE	19343
3	NESTED JOIN (INNER JOIN)		6389
4	TABLE ACCESS ("ORDERS")		6389
5	INDEX ACCESS ("CUSTOMER", "CUSTOMER_PK_INDEX")	(6389)	6389

```
     1  -  TARGET : CUSTOMER.C_NAME, ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
     2  -  SQL : SELECT /*+ KEEP_JOINED_TABLE
                            USE_NL_IN( _A1 )
                            FULL( _A2 )
                            INDEX( _A1, "PUBLIC"."CUSTOMER_PK_INDEX" )
                       */
                        "_A1"."C_NAME", "_A2"."O_ORDERDATE", "_A2"."O_ORDERSTATUS"
                  FROM ( "PUBLIC"."ORDERS"@LOCAL AS "_A2"
                         INNER JOIN
                         "PUBLIC"."CUSTOMER"@LOCAL AS "_A1" ON true
                        ) ALIAS "_A3"
                 WHERE "_A2"."O_ORDERDATE" < :_VO
                   AND "_A2"."O_ORDERDATE" >= :_V1
                   AND "_A1"."C_CUSTKEY" = "_A2"."O_CUSTKEY"
           TARGET DOMAIN : G1(G1N1,G1N2) 6389 rows, G2(G2N1,G2N2) 6462 rows, G3(G3N1,G3N2) 6492 rows
     3  -  JOINED COLUMN : CUSTOMER.C_NAME, ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
     4  -  HASH SHARD ( # 3 )
           READ COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_ORDERSTATUS, ORDERS.O_ORDERDATE
             PHYSICAL FILTER : ORDERS.O_ORDERDATE < DATE'1995-03-15' + CAST( '1' AS INTERVAL(MONTH) )
                               AND ORDERS.O_ORDERDATE >= DATE'1995-03-15'
     5  -  CLONED
           READ INDEX COLUMN : CUSTOMER.C_CUSTKEY
           READ TABLE COLUMN : CUSTOMER.C_NAME
             MIN RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
             MAX RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
           FETCH ONE ROW

<<<  end print plan
```

The execution plan above is represented as the following tree. The execution starts from the bottom nod e.

Figure 4 Read plan tree



The execution tree above is performed as follows.

First, PLAN BASED CLUSTER(IDX 2) transfers the following SQL to G1, G2 and G3.

```
SELECT /*+ KEEP_JOINED_TABLE
           USE_NL_IN( _A1 )
           FULL( _A2 )
           INDEX( _A1, "PUBLIC"."CUSTOMER_PK_INDEX" )
       */
       "_A1"."C_NAME", "_A2"."O_ORDERDATE", "_A2"."O_ORDERSTATUS"
  FROM ( "PUBLIC"."ORDERS"@LOCAL AS "_A2"
         INNER JOIN
         "PUBLIC"."CUSTOMER"@LOCAL AS "_A1" ON true
       ) ALIAS "_A3"
```

```
WHERE "_A2"."O_ORDERDATE" < :_V0
  AND "_A2"."O_ORDERDATE" >= :_V1
  AND "_A1"."C_CUSTKEY" = "_A2"."O_CUSTKEY"
```

TABLE ACCESS(IDX:4) and INDEX ACCESS(IDX:5) read data from customer table and orders table and perform NESTED JOIN(IDX 3) in G1, G2, G3.

PLAN BASED CLUSTER brings all NESTED JOIN(IDX 3) results of G1, G2, G3 to local.

Then, it returns the result.

Execution Plan Information

The information about each column in the execution plan table is as follows.

- IDX
  - It is an identifier given to each plan node.
- NODE DESCRIPTION
  - It is the name of a plan node.
  - The contents in brackets are additional information which distinguishes plan nodes.
  - The indented plan node means the subordinate plan node.
    - The execution starts from the bottom plan node, and the result is transferred to the superordinate node.
- ROWS
  - It is the number of result records according to the plan node execution.

Each plan node contains the following optimization information.

- **Access Paths** to each table
- The sequence to process **Join** and join method
- The information about **Group By** processing
- The information about **Distinct** processing
- The information about **Single Row Aggregation** processing
- The information about **Order By** processing
- The information about **Cluster Puller** processing
- The information about **Cluster Pusher** processing

15.2 Rewriter

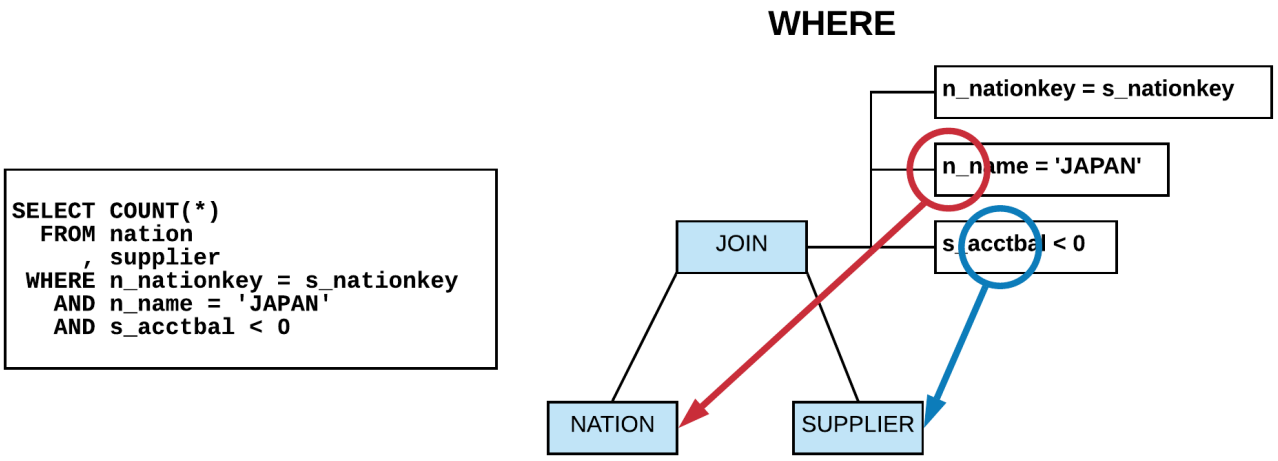
This chapter describes various query transformation methods processed by a rewriter.

Filter Push Down

It pushes down the filter as down as possible so that it reduces the intermediate result to be processed.

The following is an example of filter push down.

Figure 5 Filter push down



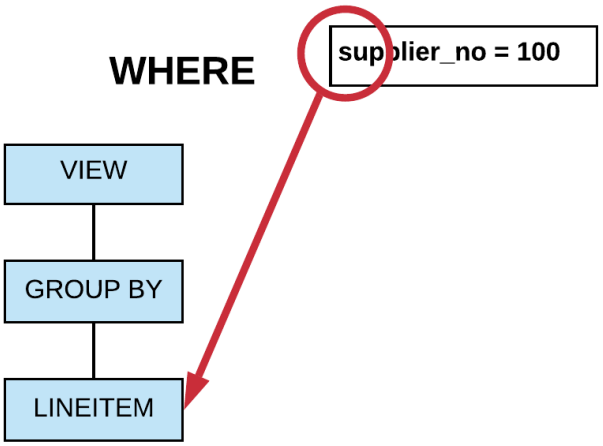
It filters rows satisfying n_name = JAPAN condition in NATION, and filters rows satisfying s_acctbal < 0 co ndition in SUPPLIER before performing join. In this case the number of join target rows decreases so it im proves the performance.

The following is an example of performing filter push down into the view.

Figure 6 Filter push down into view

```
CREATE VIEW revenue (supplier_no, total_revenue) AS
  SELECT l_suppkey,
         ROUND( sum(l_extendedprice * (1 - l_discount)), 2)
    FROM lineitem
   WHERE l_shipdate >= date '1996-01-01'
     AND l_shipdate < date '1996-01-01' + interval '3' month
GROUP BY l_suppkey;
```

```
SELECT total_revenue
  FROM revenue
     , supplier
 WHERE supplier_no = 100
```



When pushing it down to lineitem TABLE ACCESS node after converting supplier_no = 100 to l_suppkey = 100, then target rows of GROUP BY decreases so it improves the performance.

DISTINCT Elimination

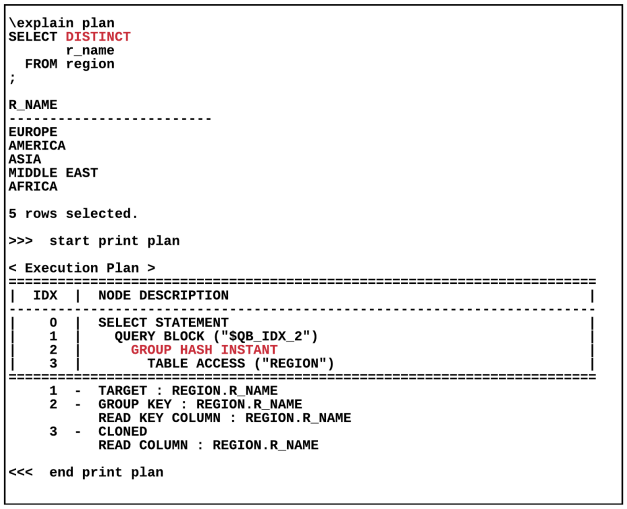
It eliminates the unnecessary DISTINCT.

DISTINCT is eliminated in the following cases.

- The query result of a single-row aggregation is one, so a duplicate results does not occur even withou t DISTINCT.
- If *group by* exists and all key columns of *group by* exist in a select list, then the result is unique so a d uplicate results does not occur even without DISTINCT.
- If all key columns in a primary key exist in a select list, then the result is unique so a duplicate results d oes not occur even without DISTINCT.

The following is an example of eliminating DISTINCT.

Figure 7 DISTINCT elimination



```
\explain plan
SELECT DISTINCT
       r_name
  FROM region
;

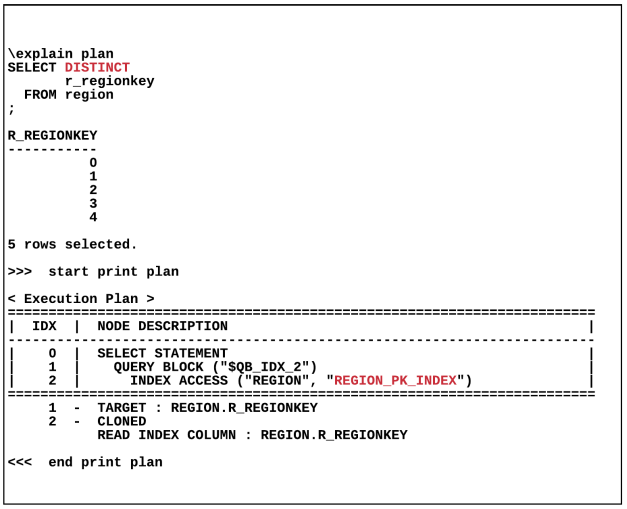
R_NAME
-------------------------
EUROPE
AMERICA
ASIA
MIDDLE EAST
AFRICA

5 rows selected.

>>>  start print plan

< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("SQB_IDX_2")                                      |
|    2  |      GROUP HASH INSTANT                                           |
|    3  |        TABLE ACCESS ("REGION")                                    |
=============================================================================
     1  -  TARGET : REGION.R_NAME
     2  -  GROUP KEY : REGION.R_NAME
           READ KEY COLUMN : REGION.R_NAME
     3  -  CLONED
           READ COLUMN : REGION.R_NAME

<<<  end print plan
```



```
\explain plan
SELECT DISTINCT
       r_regionkey
  FROM region
;

R_REGIONKEY
-----------
          0
          1
          2
          3
          4

5 rows selected.

>>>  start print plan

< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("SQB_IDX_2")                                      |
|    2  |      INDEX ACCESS ("REGION", "REGION_PK_INDEX")                   |
=============================================================================
     1  -  TARGET : REGION.R_REGIONKEY
     2  -  CLONED
           READ INDEX COLUMN : REGION.R_REGIONKEY

<<<  end print plan
```

The left execution plan has GROUP HASH INSTANT node to process DISTINCT, but the right execution pla n does not have GROUP HASH INSTANT node to process DISTINCT.

r_regionkey is a primary key, so it is guaranteed that the result is distinct even when DISTINCT is eliminate d. Therefore, the unnecessary DISTINCT is eliminated.

ORDER BY Elimination

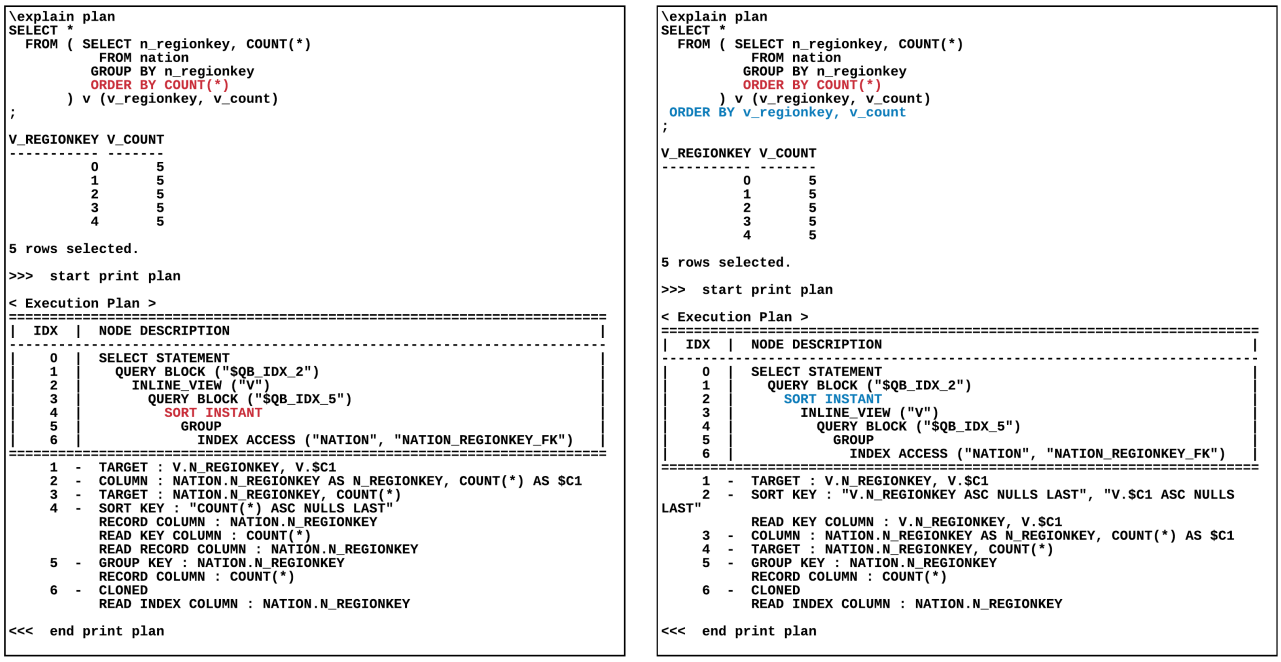
It eliminates unnecessary ORDER BY.

ORDER BY is not required in the following cases.

- When only a view exists in *from* clause, and *group by* clause, *distinct* clause or *order by* clause exists, then *order by* exists in a query block within a view is not necessary. It is because the sequence ordere d by *group by*, *distinct*, *order by* disappears even though it was ordered.
- *order by* exists in a a query block within a subquery is not necessary. It is because the subquery result i s used only when determining whether to return the row of an outer query.

The following is an example of eliminating ORDER BY.

Figure 8 ORDERBY elimination



```
\explain plan
SELECT *
  FROM ( SELECT n_regionkey, COUNT(*)
           FROM nation
         GROUP BY n_regionkey
         ORDER BY COUNT(*)
       ) v (v_regionkey, v_count)
;

     5  -  GROUP KEY : NATION.N_REGIONKEY
           RECORD COLUMN : COUNT(*)
     6  -  CLONED
           READ INDEX COLUMN : NATION.N_REGIONKEY

<<<  end print plan
```

The left and right views are same in the figure above, but the right SQL has *order by* in a superordinate q uery of the view, so the *order by* within the view is eliminated.

Simple View Merging

It merges a simple view which does not include *group by*, *distinct*, *aggregation* into a superordinate quer y block.

Applying a simple view merging enables an optimizer to select various access path, join ordering, join me thod, so it can acquire the better execution plan.

A simple view merging can not be applied to the following cases.

- When a query block within the view includes the followings
  - Set operator
  - LIMIT, OFFSET
  - DISTINCT
  - GROUP BY
  - Single row aggregation
  - Full outer join
  - Natural join
  - ROWNUM
  - When a subquery expression exists in SELECT list
- When a view participates in the following query.

- A view participate in a full outer join.
- A view participate in a left outer join, and two or more tables exist within a view.

The following is an example of merging a simple view.

```
CREATE VIEW v_nation
(
    v_nationkey,
    v_nation_name,
    v_region_name
)
AS
SELECT n_nationkey,
       n_name,
       r_name
  FROM nation, region
 WHERE n_regionkey = r_regionkey;
```

```
\EXPLAIN PLAN
SELECT v_nation_name, COUNT(*)
  FROM customer, v_nation
 WHERE c_nationkey = v_nationkey
   AND v_region_name = 'ASIA'
GROUP BY v_nation_name;
V_NATION_NAME             COUNT(*)
------------------------- --------

```

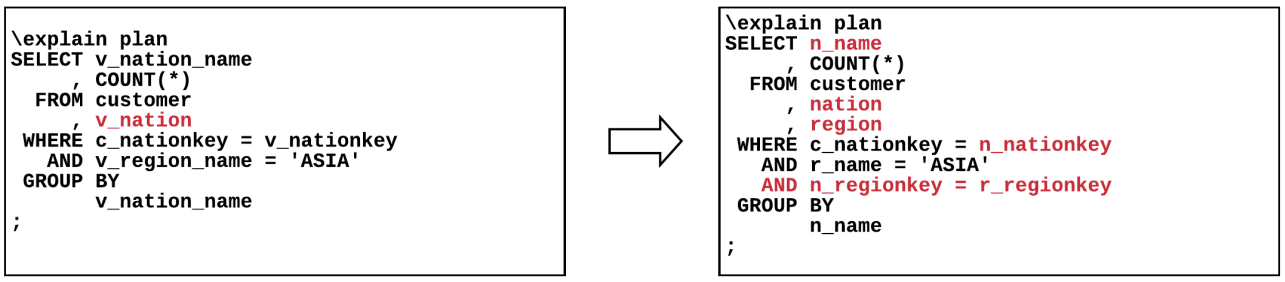
A view does not exist in the execution plan above. The view is merged to an outer query, then it is perfor med as a converted query form form as follows.

Figure 9 Simple view merging



Outer Join Table Elimination

It eliminates an unnecessary outer join table.

Neither an outer join nor access to the right table is required in the following cases.

- It is a left outer join, and
- a predicate in a form of *left_table.col = right_table.col* exists in ON clause.
- a unique index for right_table.col of ON clause exists.
- a column in a right table is not used in any other clauses except for ON clause condition.

The following is an example of eliminating an outer join table.

The access to nation table exists only in ON clause, and n_nationkey is a primary key column in the followi ng example, so it is unique and even null data does not exist. Therefore, eliminating nation table does no t affect the result.

```
\EXPLAIN PLAN
SELECT COUNT(*)
  FROM supplier
       LEFT OUTER JOIN
       nation
       ON s_nationkey = n_nationkey
 WHERE s_acctbal < 0
;
COUNT(*)
--------
     886

>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                              | ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                              |    1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                   |    1 |
|    2  |      TABLE ACCESS ("SUPPLIER")                                 |    1 |
================================================================================
     1  -  TARGET : COUNT(*)
     2  -  CLONED
           READ COLUMN : SUPPLIER.S_ACCTBAL
           AGGREGATION : COUNT(*)
```

```
            PHYSICAL FILTER : SUPPLIER.S_ACCTBAL < 0
<<<  end print plan
```

All accesses to OUTER JOIN and right table are eliminated in the execution plan above.

Outer Join Operation Elimination

It eliminates an unnecessary outer join operation.

- For a left outer join,
  - If a conditional clause corresponding to the right table exists in where clause, and the conditional clause is not IS NULL,
    - It can be changed to an inner join
- For a full outer join,
  - If a conditional clause corresponding to the right table exists in where clause, and the conditional clause is not IS NULL,
    - It can be changed to a right outer join
  - If a conditional clause corresponding to the left table exists in where clause, and the conditional c lause is not IS NULL,
    - It can be changed to a left outer join.
  - If a conditional clause corresponding to both left and right tables exists in where clause, and the conditional clause is not IS NULL,
    - It can be changed to an inner join

The following is an example of eliminating an outer join operation.

```
\EXPLAIN PLAN
  SELECT MAX(COUNT(*))
    FROM customer
         LEFT OUTER JOIN
         orders
         ON  c_custkey = o_custkey
         AND o_comment LIKE '%special%requests%'
   WHERE o_orderpriority = '1-URGENT'
GROUP BY c_custkey;
MAX(COUNT(*))
-------------
            3
1 row selected.
>>>  start print plan
< Execution Plan >
```

```
================================================================================
|  IDX  |  NODE DESCRIPTION                                                    |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                    |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                         |
|    2  |      AGGREGATION BY HASH                                             |
|    3  |        GROUP                                                         |
|    4  |          HASH JOIN (INNER JOIN)                                      |
|    5  |            INDEX ACCESS ("CUSTOMER", "CUSTOMER_PK_INDEX")           |
|    6  |            HASH JOIN INSTANT                                         |
|    7  |              TABLE ACCESS ("ORDERS")                                 |
================================================================================
     1  -  TARGET : MAX( COUNT(*) )
     2  -  AGGREGATION : MAX( COUNT(*) )
     3  -  GROUP KEY : CUSTOMER.C_CUSTKEY
           RECORD COLUMN : COUNT(*)
     4  -  JOINED COLUMN : CUSTOMER.C_CUSTKEY
     5  -  READ INDEX COLUMN : CUSTOMER.C_CUSTKEY
     6  -  HASH KEY : ORDERS.O_CUSTKEY
           READ KEY COLUMN : ORDERS.O_CUSTKEY
             HASH FILTER : ORDERS.O_CUSTKEY = CUSTOMER.C_CUSTKEY
     7  -  READ COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_ORDERPRIORITY,
                         ORDERS.O_COMMENT
             PHYSICAL FILTER : ORDERS.O_ORDERPRIORITY = '1-URGENT'
             LOGICAL FILTER : ORDERS.O_COMMENT LIKE '%special%requests%'
<<<  end print plan
```

o_orderpriority = '1-URGENT condition exists in WHERE clause in the example above. Therefore, rows all of whose data is NULL can not exist as a result of the right table due to this condition.

Therefore, the results are same even when converting a left outer join to an inner join.

EXISTS/NOT EXIST Operation Target Optimization

It decreases unnecessary expressions from SELECT list of a subquery which exists in EXISTS or NOT EXISTS, so that it improves the query processing performance.

EXISTS or NOT EXISTS operation is a operator which determines whether the result row of a subquery exi sts, so neither the number of expressions in SELECT list of a subquery nor does the processing result affec t the operation result. Therefore, it changes SELECT list of the subquery to TRUE (BOOLEAN constant).

The following is an example of optimizing EXISTS operation target.

```
\EXPLAIN PLAN
SELECT o_orderpriority,
       count(*) as order_count
  FROM orders
 WHERE o_orderdate = date '1993-07-01'
   AND EXISTS (
               SELECT /*+ NO_UNNEST */
                      *
                 FROM lineitem
                WHERE l_orderkey = o_orderkey
                  AND l_commitdate < l_receiptdate
             )
GROUP BY o_orderpriority
ORDER BY o_orderpriority;
O_ORDERPRIORITY ORDER_COUNT
--------------- -----------
1-URGENT                113
2-HIGH                  136
3-MEDIUM                112
4-NOT SPECIFIED         103
5-LOW                    97
5 rows selected.
>>>  start print plan

     1  -  TARGET : ORDERS.O_ORDERPRIORITY, COUNT(*) AS ORDER_COUNT
     2  -  SORT KEY : "ORDERS.O_ORDERPRIORITY ASC NULLS LAST"
```

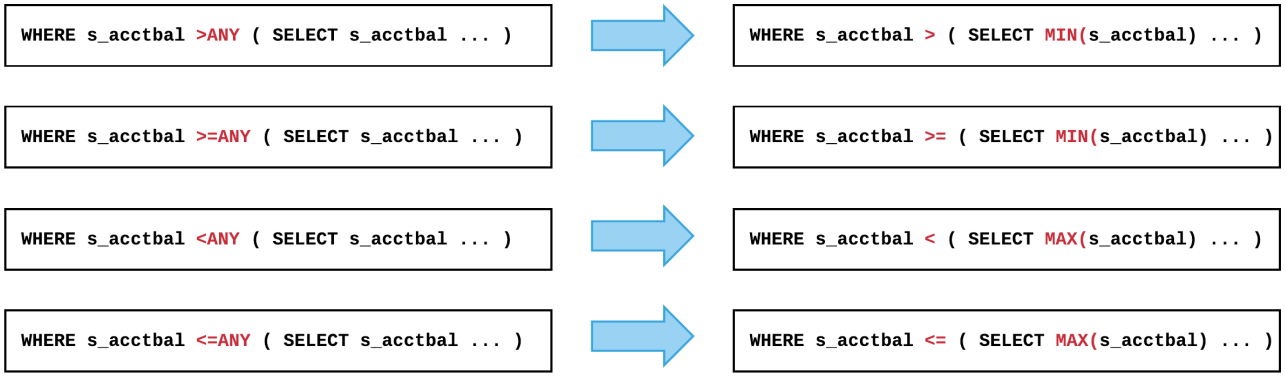
```
            RECORD COLUMN : COUNT(*)
            READ KEY COLUMN : ORDERS.O_ORDERPRIORITY
            READ RECORD COLUMN : COUNT(*)
      3   -  GROUP KEY : ORDERS.O_ORDERPRIORITY
            RECORD COLUMN : COUNT(*)
            READ KEY COLUMN : ORDERS.O_ORDERPRIORITY
            READ RECORD COLUMN : COUNT(*)
      4   -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_ORDERDATE,
                           ORDERS.O_ORDERPRIORITY
              PHYSICAL FILTER : ORDERS.O_ORDERDATE = DATE'1993-07-01'
              POST FILTER : EXISTS( ( $V6.DUMMY_COL ) )
      6   -  COLUMN : $V6.DUMMY_COL AS DUMMY_COL
      7   -  TARGET : NOTHING
      8   -  READ INDEX COLUMN : LINEITEM.L_ORDERKEY
            READ TABLE COLUMN : LINEITEM.L_COMMITDATE, LINEITEM.L_RECEIPTDATE
              MIN RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
              MAX RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
              PHYSICAL TABLE FILTER : LINEITEM.L_RECEIPTDATE > LINEITEM.L_COMMITDATE
<<<  end print plan
```

lineitem is a table with 16 columns in the example above. It is specified to read all columns in lineitem by using * in SELECT list within EXISTS subquery of a user query. However, it fetches only the information ab out whether the row satisfying the condition exists, but target column value does not fetch anything at t he time of execution.

Quantifier Elimination

It alters SQL as follows to eliminate ANY quantifier.

Figure 10 Quantifier elimination



The following is an example of eliminating a quantifier.

```
\EXPLAIN PLAN
SELECT COUNT(*)
  FROM supplier
 WHERE s_acctbal >ANY ( SELECT s_acctbal
                          FROM supplier, nation
                         WHERE s_nationkey = n_nationkey
                           AND n_name = 'CHINA' )
;
COUNT(*)
--------
    9950
1 row selected.
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                                |

              MAX RANGE : SUPPLIER.S_NATIONKEY = {NATION.N_NATIONKEY}
<<<  end print plan
```

Transitive Closure

It creates a constant condition in another table by using a join condition. In this way, the throughput of jo in is decreased and the performance is improved.

The following is an example of a transitive closure.

Figure 11 Transitive closure

```
\explain plan
SELECT COUNT(*)
  FROM customer, supplier
 WHERE c_nationkey = s_nationkey
   AND c_nationkey < 5
;

COUNT(*)

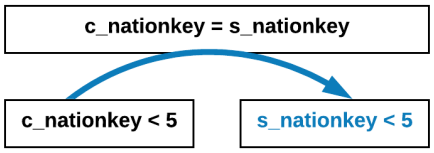
<<<  end print plan
```



Join Transitive Closure

It creates a join condition in another table by using a join condition. Various join orderings and join meth ods are available, so a better execution plan can be made.

It is performed in a way of adding a join condition (A=C) to the other join condition (A = B AND B = C).

The following is an example of a join transitive closure.

Figure 12 Join transitive closure

```
\explain plan

Subquery Unnesting

A subquery unnesting converts a subquery in a conditional clause into a join statement guaranteeing the same result. It enables to select various access path, join method, join order, so a better execution plan ca n be made.

Subqueries are classified into the following two types.

- Nested subquery (Regular non-scalar subquery)
  - EXISTS/NOT EXIST subquery
  - Comparison operator (=, >,>=, <, <=, <>) ANY subquery
  - Comparison operator (=, >,>=, <, <=, <>) ALL subquery
  - IN/NOT IN subquery
- Scalar subquery: It is used in WHERE clause or a SELECT list, and returns only a single result.

Not all subqueries are unnested. The subquery can be unnested only when it satisfies the following constr aints.

- It should not include set operator.
- A scalar subquery is available only when it is specified on WHERE clause.
- It should include a correlated predicate.

A correlated predicate is a predicate including a column of an undefined outer query block in a subquery. In the example below, *c.cust_id* is a correlated column and *s.cust_id = c.cust_id* is a correlated predicate.

```
SELECT C.cust_last_name, C.country_id
FROM   customers C
WHERE  EXISTS (SELECT 1
                 FROM sales S
                WHERE S.quantity_sold > 1000
                  AND S.cust_id = C.cust_id);
```

Nested Subquery Unnesting

It converts a subquery into a semi join, an anti-join, or an inner join.

Figure 13 Nested subquery unnesting

```
SELECT COUNT(*)
  FROM customer
 WHERE c_custkey IN ( SELECT o_custkey
                        FROM orders
                       WHERE o_orderdate = DATE'1997-02-01'
                    )
```

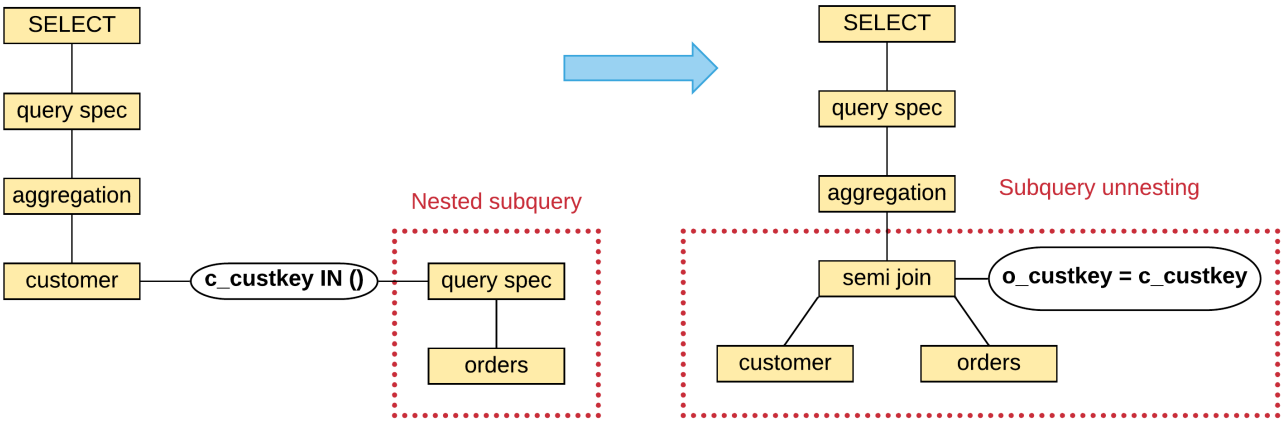

Figure 14 Nested subquery unnesting plan

```
>>>  start print plan

            FETCH ONE ROW
<<<  end print plan
```

Scalar Subquery Unnesting

It can unnest only a scalar subquery in WHERE clause, and the following conditions should be satisfied.

- It should be a single row aggregation

- It should include a correlated predicate.

The following is an example of unnesting a scalar subquery.

Figure 15 Scalar subquery unnesting

```
\explain plan
SELECT ps_suppkey
  FROM partsupp,
       part
 WHERE ps_partkey = p_partkey
   AND p_name like 'forest%'

Complex View Merging

It merges a view including *group by* with a superordinate query block.
A complex view merging is useful when *group by* can not decrease the intermediate results a lot and the join filtering with a superordinate query block is effective. In other words, if a complex view merging is us ed when *group by* can decrease the intermediate results a lot, then it may degrade the performance.

A complex view merging can not be applied in the following cases.

- When a query block within a view includes the following item
  - SET operator
  - ROWNUM
  - LIMIT/OFFSET
  - Single row aggregation

  - ORDER BY
  - SELECT list including a subquery
  - FULL OUTER JOIN
  - NATURAL JOIN
- When a view participates in the following query
  - Join other than an inner join
  - An equi Join predicate does not exist

The following is an example of merging a complex view.

Figure 17 Complex view merging

```
\explain plan
SELECT ps_suppkey
  FROM partsupp,
       part,
       ( SELECT l_partkey,
                l_suppkey,
                0.5 * sum(l_quantity) qty
           FROM lineitem
          WHERE l_shipdate >= date'1994-01-01'
            AND l_shipdate < date'1994-01-01' + interval '1' year
          GROUP BY l_partkey, l_suppkey
       ) v1

15.3 Enumerator

An enumerator calculates the cost based on statistics information to find the most efficient plan.

It receives a trans plan and creates various cost plans about it, then calculates the cost per each cost plan based on statistics information to select the plan of the lowest cost.

Access Paths

An access path is a method to access a single table, and there are following four types.

- Table access
- Index access
- Rowid access
- Index concat

It calculates the cost according to the methods above, and select an access of the lowest cost as an execu tion plan.

Table Access

A table access reads all rows stored in a table in a way as they were stored.

A table access is selected in the following cases.

- When an index does not exist
- When a predicate for using an index does not exist even though an index exists (e.g. WHERE col1 + 1 = 10)
- When the table accessing cost is big because a condition for the first key column of an index does no t exist
  (e.g. WHERE col2 > 3 when only a condition for the second column of composite index (col1, col2) e xists)
- When a table access cost is smaller than an index access cost because the table data is small
- When a user gives a table access hint (e.g. FULL(t1))
- When an index selectivity is poor or the data is extremely disproportionately distributed

The following is an example of using an table access.

```
\EXPLAIN PLAN
SELECT r_regionkey, r_name
```

```
  FROM region;
R_REGIONKEY R_NAME
----------- -------------------------
          0 AFRICA
          1 AMERICA
          2 ASIA
          3 EUROPE
          4 MIDDLE EAST
5 rows selected.

¦    2  ¦      TABLE ACCESS ("REGION")                                        ¦
================================================================================
     1  -  TARGET : REGION.R_REGIONKEY, REGION.R_NAME
     2  -  READ COLUMN : REGION.R_REGIONKEY, REGION.R_NAME
<<<  end print plan
```

Index Access

An index access uses an index to read a table.

Index access types are an index full scan, an index unique scan, an index range scan and an in key range s can, and the best type is selected by the cost estimation.

Index Full Scan

It fully scans the index.

The following is an example of an index full scan.

```
\EXPLAIN PLAN
SELECT p_partkey
  FROM part;
...
200000 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
```

```
¦  IDX  ¦  NODE DESCRIPTION                                          ¦
-------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                          ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                             ¦
¦    2  ¦      INDEX ACCESS ("PART", "PART_PK_INDEX")              ¦
=========================================================================
     1  -  TARGET : PART.P_PARTKEY
     2  -  READ INDEX COLUMN : PART.P_PARTKEY
<<<  end print plan
```

It retrieves p_partkey which is a key column of PART_PK_INDEX only, so making the result by the index fu ll scan costs less than the table full scan.

Index Unique Scan

It fetches only one row through the index.

The following is an example of an index unique scan.

```
\EXPLAIN PLAN
SELECT *
  FROM part
 WHERE p_partkey = 1;
...
1 row selected.
>>>  start print plan
< Execution Plan >
=========================================================================
¦  IDX  ¦  NODE DESCRIPTION                                          ¦
-------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                          ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                             ¦
¦    2  ¦      INDEX ACCESS ("PART", "PART_PK_INDEX")              ¦
=========================================================================
     1  -  TARGET : PART.P_PARTKEY, PART.P_NAME, PART.P_MFGR, PART.P_BRAND,
                    PART.P_TYPE, PART.P_SIZE, PART.P_CONTAINER,
                    PART.P_RETAILPRICE, PART.P_COMMENT
     2  -  READ INDEX COLUMN : PART.P_PARTKEY
           READ TABLE COLUMN : PART.P_NAME, PART.P_MFGR, PART.P_BRAND,
                               PART.P_TYPE, PART.P_SIZE, PART.P_CONTAINER,
                               PART.P_RETAILPRICE, PART.P_COMMENT
             MIN RANGE : PART.P_PARTKEY = 1
```

```
            MAX RANGE : PART.P_PARTKEY = 1
          FETCH ONE ROW
<<<  end print plan
```

Index Range Scan

It reads rows in the range satisfying a predicate condition through an index. The result rows are sorted fo r an index key column because they are read through the index.

The following is an example of an index range scan.

```
\EXPLAIN PLAN
SELECT p_partkey, p_brand, p_type
  FROM part
 WHERE p_partkey >= 10
   AND p_partkey < 20;
P_PARTKEY P_BRAND    P_TYPE
--------- ---------- -------------------------
       10 Brand#54   LARGE BURNISHED STEEL
       11 Brand#25   STANDARD BURNISHED NICKEL
       12 Brand#33   MEDIUM ANODIZED STEEL
       13 Brand#55   MEDIUM BURNISHED NICKEL
       14 Brand#13   SMALL POLISHED STEEL
       15 Brand#15   LARGE ANODIZED BRASS
       16 Brand#32   PROMO PLATED TIN
       17 Brand#43   ECONOMY BRUSHED STEEL
       18 Brand#11   SMALL BURNISHED STEEL
       19 Brand#23   SMALL ANODIZED NICKEL
10 rows selected.
>>>  start print plan
< Execution Plan >
------------------------------------------------------------------------
|  IDX  |  NODE DESCRIPTION                                            |
------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                            |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                 |
|    2  |      INDEX ACCESS ("PART", "PART_PK_INDEX")                  |
------------------------------------------------------------------------
     1  -  TARGET : PART.P_PARTKEY, PART.P_BRAND, PART.P_TYPE
     2  -  READ INDEX COLUMN : PART.P_PARTKEY
           READ TABLE COLUMN : PART.P_BRAND, PART.P_TYPE
             MIN RANGE : PART.P_PARTKEY >= 10
```

```
            MAX RANGE : PART.P_PARTKEY IS NOT NULL AND PART.P_PARTKEY < 20
<<<  end print plan
```

In Key Range Scan

An in key range scan is available when the following predicate exists.

```
( col1, col2 ) IN ( (val1, val2), (val3, val4) )
```

- IN or =ANY list function filter exists in WHERE clause.
- col1 and col2 should be base columns. (It should be a column without an operation or a function.)
- (val1, val3) corresponding to col1 should be convertible to a single data type.
- (val2, val4) corresponding to col2 should be convertible to a single data type.

The following is an example of an in key range scan.

```
\EXPLAIN PLAN
  SELECT o_orderstatus
    FROM orders
   WHERE o_custkey IN ( 1, 10, 100, 1000, 10000 );
...
91 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                      ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                     ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                        ¦
¦    2  ¦      INDEX ACCESS ("ORDERS", "ORDERS_CUSTKEY_FK")                   ¦
================================================================================
     1  -  TARGET : ORDERS.O_ORDERSTATUS
     2  -  READ INDEX COLUMN : ORDERS.O_CUSTKEY
           READ TABLE COLUMN : ORDERS.O_ORDERSTATUS
           IN KEY RANGE
             MIN RANGE : ORDERS.O_CUSTKEY = ?
             MAX RANGE : ORDERS.O_CUSTKEY = ?
<<<  end print plan
```

Rowid Access

A rowid access directly accesses to the corresponding page by using a rowid.

A predicate for the rowid should exist when using the rowid access. Generally, a rowid access is faster th an other access paths, so an estimator most likely to select a rowid access as the best access path as long as a predicate for a rowid exists.

```
gSQL> \EXPLAIN PLAN
SELECT p_brand, p_type
  FROM part
 WHERE rowid = 'AAAAAAAAYe8AACAAAEMJAAA';
P_BRAND    P_TYPE
---------- ------------------------
Brand#33   STANDARD POLISHED COPPER
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                     ¦
--------------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                     ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                        ¦
¦    2  ¦      ROWID ACCESS ("PART")                                          ¦
================================================================================
     1  -  TARGET : PART.P_BRAND, PART.P_TYPE
     2  -  READ COLUMN : PART.P_BRAND, PART.P_TYPE
             ROWID FILTER : PART.ROWID = 'AAAAAAAAYe8AACAAAEMJAAA'
<<<  end print plan
```

Index Concat

An index concat intergrates results of index access, and makes it into a single result. Therefore, it can be used only when OR predicate exists and each predicate can use an index access.

If OR predicate exists, an estimator calculates the cost of index concat, and selects the method when the cost is smaller than that of other access path.

The following is an example of using an index concat.

```
gSQL> \EXPLAIN PLAN
SELECT p_brand, p_type
  FROM part
```

```
 WHERE p_partkey = 1 OR p_partkey = 20;
P_BRAND    P_TYPE
---------- ----------------------
Brand#13   PROMO BURNISHED COPPER
Brand#12   LARGE POLISHED NICKEL
2 rows selected.
>>>  start print plan
< Execution Plan >
============================================================================

           FETCH ONE ROW
<<<  end print plan
```

Join

Join combines two or more tables to make them into a single result set.

In this case, a join condition defines the relation between tables. If a join condition does not exist, then m ultiplying rows of every table compose a new result set.

An estimator creates various cost plans considering join order, join method, and access path according to the join type, and calculates a cost, then selects the best cost plan. **Access Paths** are described in a chapte

r above and this chapter describes a join type, a join method and a join order.

Join Type

Cross Join

A join condition does not exist. Therefore, a multiplication set of two tables composes a new result of joi n.

The following is an example of a cross join.

```
gSQL> \EXPLAIN PLAN SELECT r_regionkey, n_nationkey FROM region, nation;
R_REGIONKEY N_NATIONKEY
----------- -----------
          0           0
          0           1
          0           2
          0           3
          0           4
          0           5
          0           6
          0           7
          0           8
          0           9
          0          10
          0          11
          0          12
          0          13
          0          14
          0          15
          0          16
          0          17
          0          18
          0          19
R_REGIONKEY N_NATIONKEY
----------- -----------
          0          20
          0          21
          0          22
          0          23
          0          24
          1           0
```

```
          1           1
         ...         ...
          4          24
125 rows selected.
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      NESTED JOIN (INNER JOIN)                                     |
|    3  |        INDEX ACCESS ("REGION", "REGION_PK_INDEX")                 |
|    4  |        INDEX ACCESS ("NATION", "NATION_PK_INDEX")                 |
=============================================================================
     1  -  TARGET : REGION.R_REGIONKEY, NATION.N_NATIONKEY
     2  -  JOINED COLUMN : REGION.R_REGIONKEY, NATION.N_NATIONKEY

     4  -  READ INDEX COLUMN : NATION.N_NATIONKEY
<<<  end print plan
```

Inner Join

Only the rows satisfying a join condition from a multiplication set of two tables configure a result set.

The following is an example of an inner join.

```
gSQL> \EXPLAIN PLAN
SELECT r_regionkey, n_nationkey
  FROM region, nation
 WHERE r_regionkey = n_nationkey;
R_REGIONKEY N_NATIONKEY
----------- -----------
          0           0
          1           1
          2           2
          3           3
          4           4
5 rows selected.
>>>  start print plan
< Execution Plan >
=============================================================================
```

```
¦  IDX  ¦  NODE DESCRIPTION                                                ¦

           FETCH ONE ROW
<<<  end print plan
```

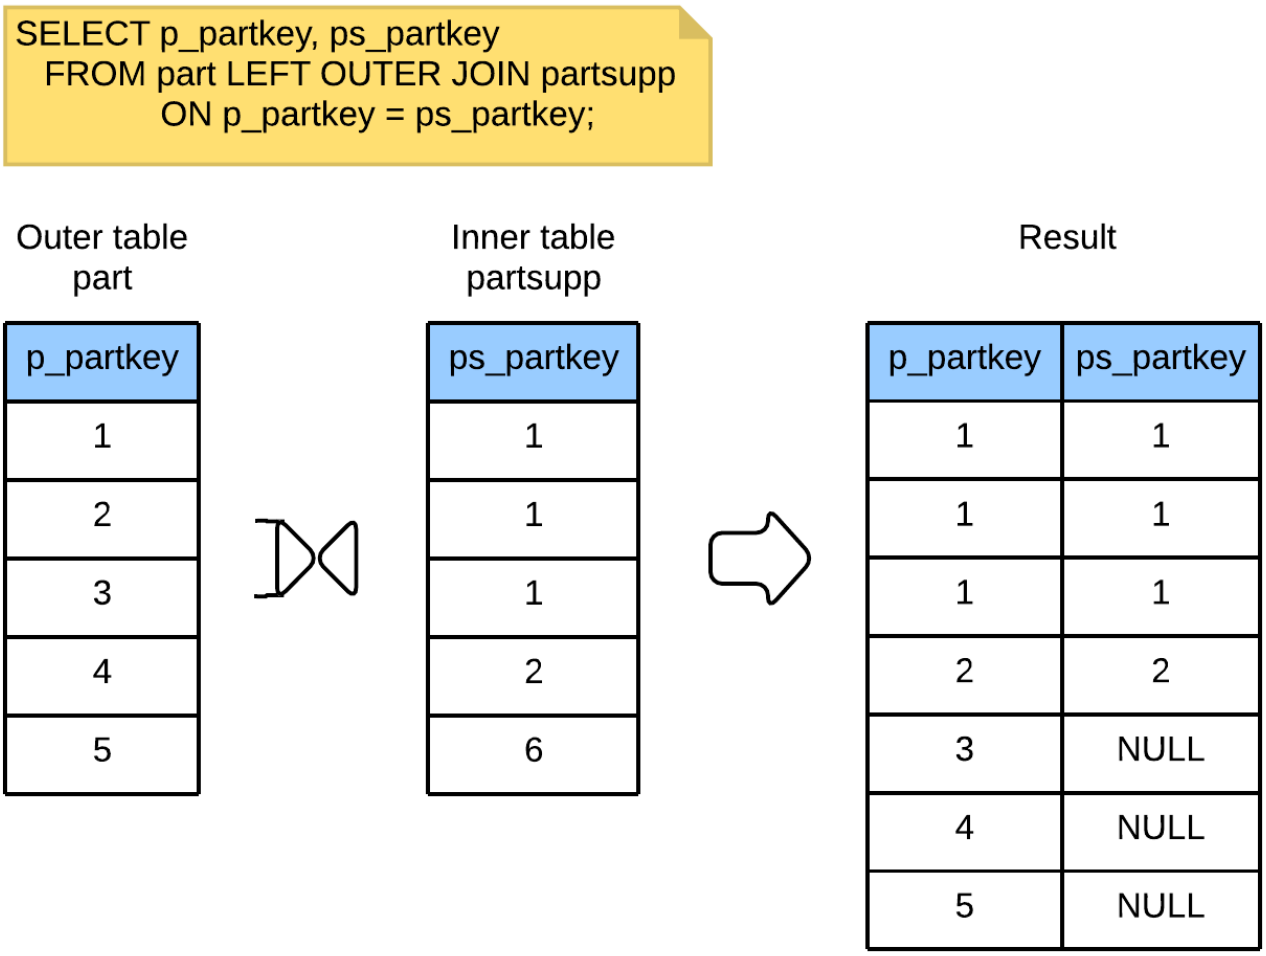
Outer Join

It returns rows satisfying a join condition from a multiplication set of two tables as result, and it also retur ns rows in an outer table as result even though the rows do not satisfy the join condition. In other words, an outer join is used to output even the rows which do not satisfy the join condition as well.

In this case, values corresponding to an inner table are NULL padded.

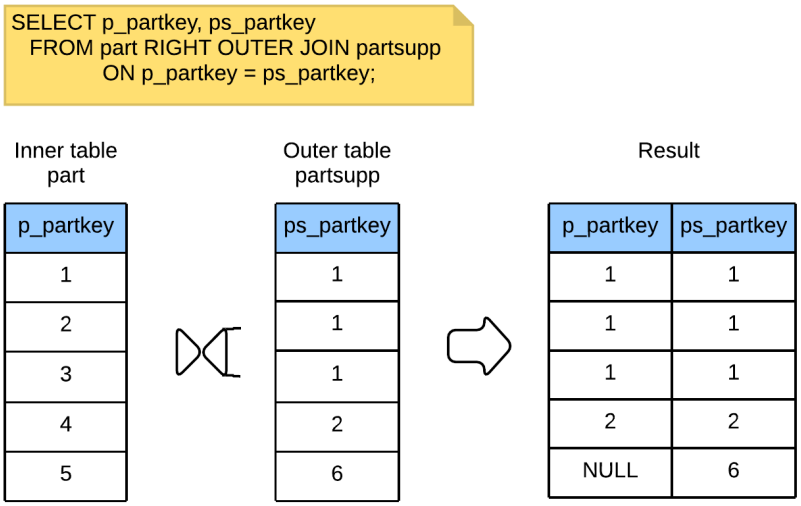
The left table becomes an outer table in a left outer join. Therefore, *part* which is a left table becomes an outer table so it outputs even the rows which do not satisfy the join condition as well in the example belo w. In this case, *partsupp* value which is an inner table is NULL padded.

Figure 19 Left outer join



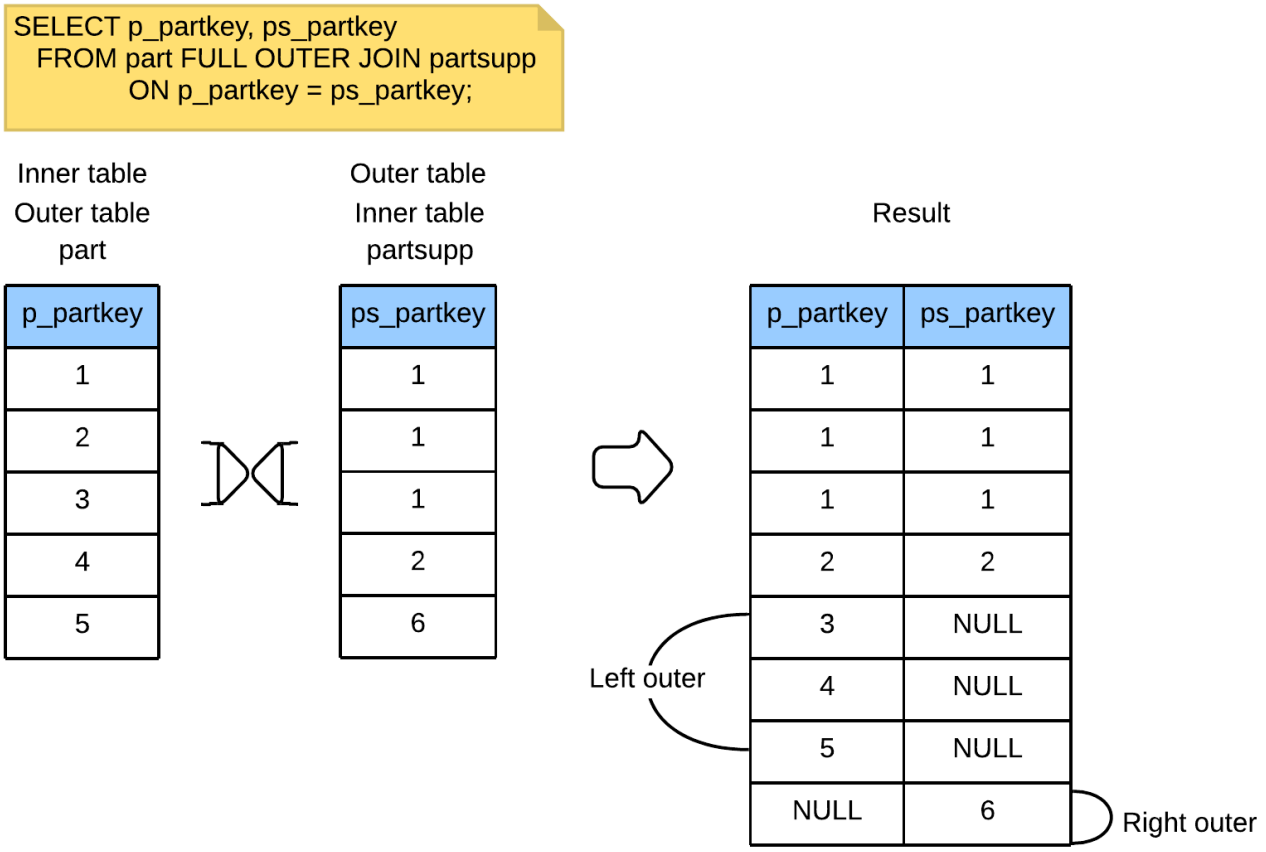
The right table becomes an outer table in a right outer join.
Therefore, *partsupp* which is a right table becomes an outer table so it outputs even the rows which do n ot satisfy the join condition as well in the example below. In this case, *parts* value which is an inner table i s NULL padded.

Figure 20 Right outer join



A full outer join join outputs rows satisfying the join condition, then it performs left outer join and a right outer join so that it outputs all rows.

Figure 21 Full outer join



Left Outer Join

It returns all rows satisfying a join condition as result, and also returns rows in a left table as result even th ough the rows do not satisfy the join condition.

The following is an example of a left outer join.

```
gSQL> \EXPLAIN PLAN
SELECT r_name, n_name
  FROM region
       LEFT OUTER JOIN
       nation
       ON  r_regionkey = n_regionkey
       AND n_nationkey > 20;
R_NAME                    N_NAME

Semi Join

A semi join can not be explicitly specified by using SQL statement. When a user used a subquery together with a quantifier such as IN, EXISTS, =ANY, then a rewriter converts it to a semi join while unnesting the s ubquery.

When a row satisfying the join condition exists, then it returns the row of a main query as result.

The following is an example of a semi join.

```
\EXPLAIN PLAN
SELECT o_orderpriority,
       count(*) as order_count
  FROM orders
 WHERE o_orderdate = date '1993-07-01'
   AND EXISTS (
               SELECT *
                 FROM lineitem
                WHERE l_orderkey = o_orderkey
                  AND l_commitdate < l_receiptdate
             )
GROUP BY o_orderpriority
ORDER BY o_orderpriority;
O_ORDERPRIORITY ORDER_COUNT

                         LINEITEM.L_RECEIPTDATE > LINEITEM.L_COMMITDATE
<<<  end print plan
```

Anti Semi Join

An anti semi join can not be explicitly specified by using SQL statement. When a user used a subquery tog ether with a quantifier such as NOT IN, NOT EXISTS, !=ALL, =ALL, then a rewriter converts it to an anti se mi join while unnesting the subquery.

When a row satisfying the join condition does not exist, then it returns the row of a main query as result.

When a nullable column exists in the join condition, then it is performed as a null-aware anti-semi join. O therwise, it is performed as an anti-semi join.

The following is an example of an anti semi join.
Both p_partkey and ps_partkey are primary key columns. Therefore, all of them are not null columns.

```
\EXPLAIN PLAN
SELECT p_name, p_brand
  FROM part
 WHERE p_partkey NOT IN ( SELECT ps_partkey
                            FROM partsupp
                           WHERE ps_availqty > 5000 );
...
12511 rows selected.
>>>  start print plan

```

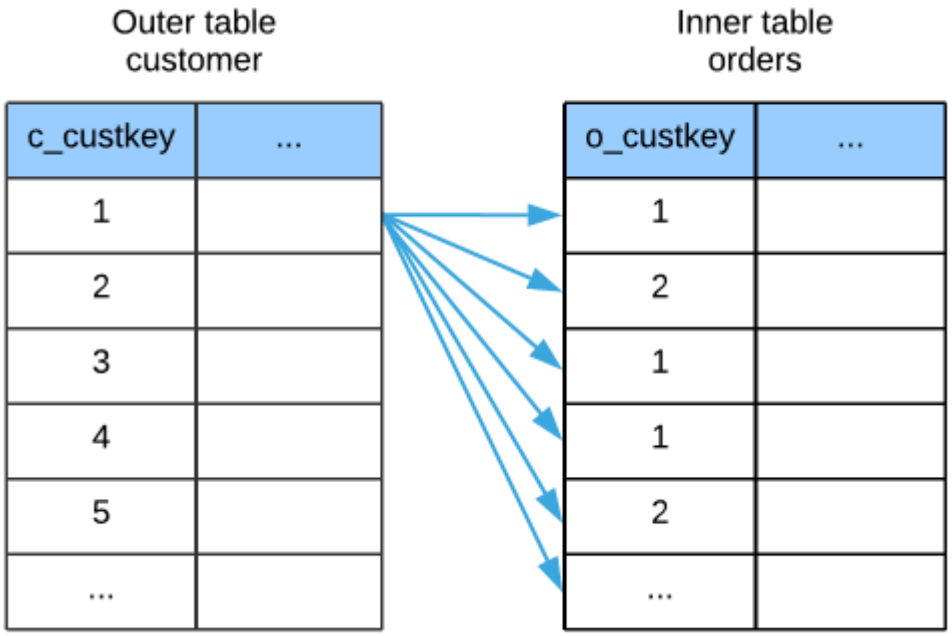
Join Method

Join operation methods between two tables are a nested loops join, a sort merge join and a hash join. An enumerator calculates the cost for those join methods, then select the join operation of the lowest cost.

Nested Loops Join

It scans all rows in an inner table for each row of an outer table, then retrieves results satisfying the join c ondition.

Figure 22 Nested loop join



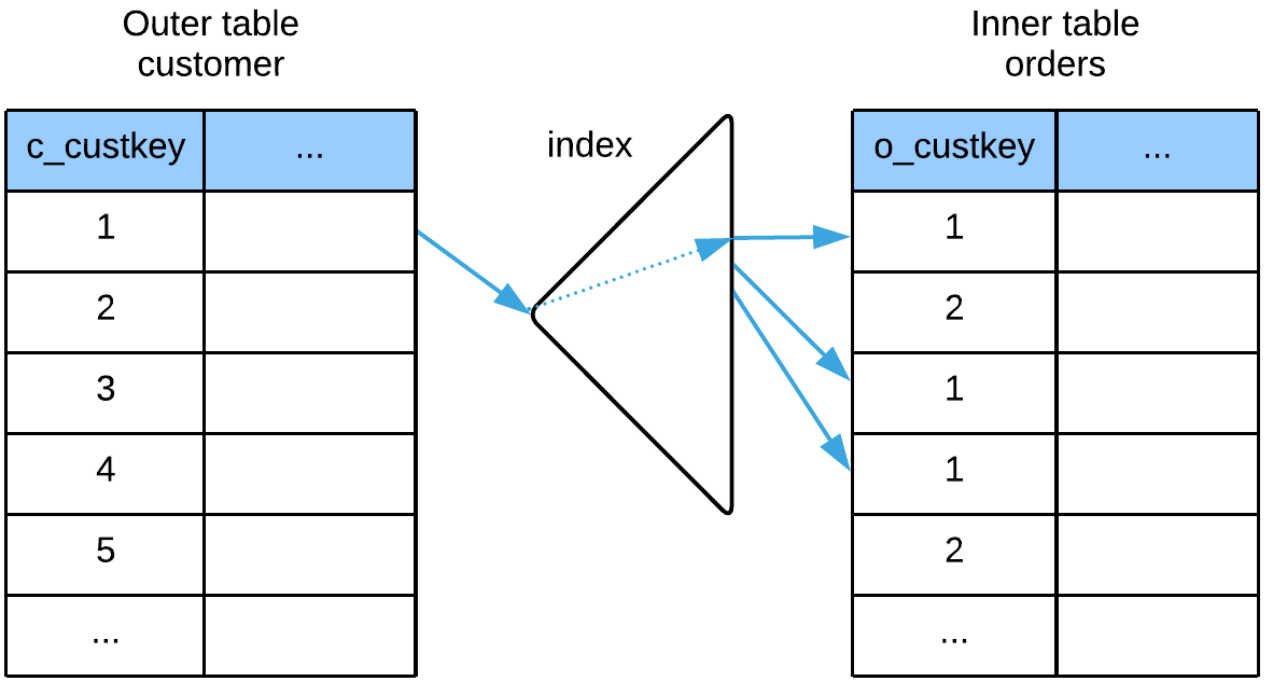
It performs the full scan for the inner table as many as the number of rows in an outer table, so the less r ows in an outer table the better.

Even the join without a join condition can return the execution result to a cartesian product through a ne sted loop join. Therefore, a nested loop join is available even when a hash join and a sort merge join are not available.

Index Nested Loops Join

It performs an index nested loop join when it can retrieve the row satisfying the join condition by using a n index in an Inner table. An index access accesses only to necessary rows, so the performance is improve d.

Figure 23 Index nested loop join



The following is an example of an index nested loop join.

```
\EXPLAIN PLAN
  SELECT c_custkey, count(o_orderkey)
    FROM customer, orders
   WHERE c_custkey = o_custkey
     AND c_comment like '%special%requests%'
GROUP BY c_custkey;
...
2265 rows selected.
>>>  start print plan
< Execution Plan >

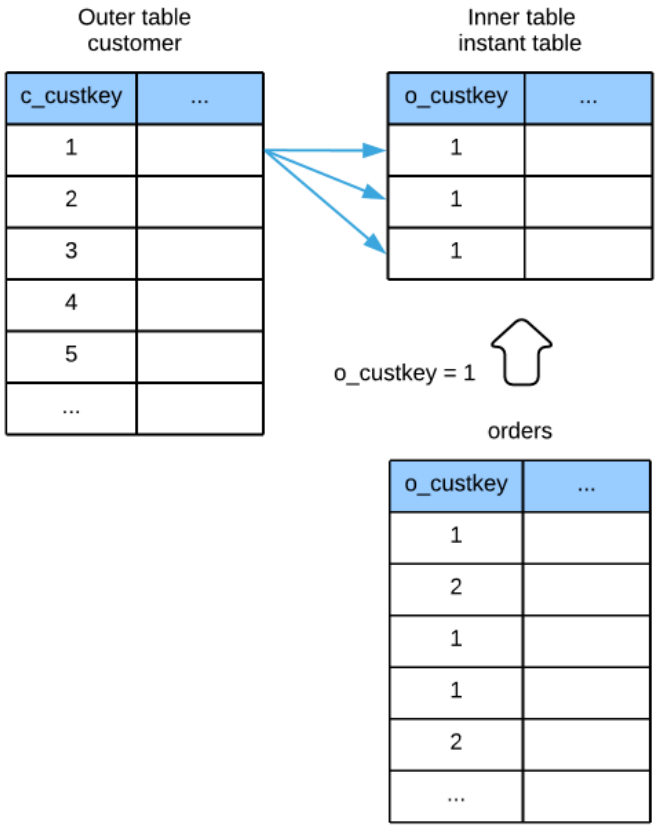
             MAX RANGE : ORDERS.O_CUSTKEY = {CUSTOMER.C_CUSTKEY}
<<<  end print plan
```

Instant Nested Loops Join

It performs a nested loop join after loading the intermediate result of an inner table on an instant table.

Figure 24 Instant nested loop join



When the condition such as o_custkey = 1 exists as the example above, a nested loop join is available by l oading the intermediate result of *orders* on an instant table.

The following is an example of an instant nested loop join.

```
\EXPLAIN PLAN
  SELECT c_custkey, count(o_orderkey)
    FROM customer, orders
   WHERE c_comment like '%special%requests%'
     AND o_orderdate = date '1995-03-15'
GROUP BY c_custkey;
...
3380 rows selected.
>>>  start print plan
< Execution Plan >
=============================================================================

     5  -  RECORD COLUMN : CUSTOMER.C_CUSTKEY
           READ COLUMN : CUSTOMER.C_CUSTKEY
     6  -  READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_COMMENT
             LOGICAL FILTER : CUSTOMER.C_COMMENT LIKE '%special%requests%'
<<<  end print plan
```

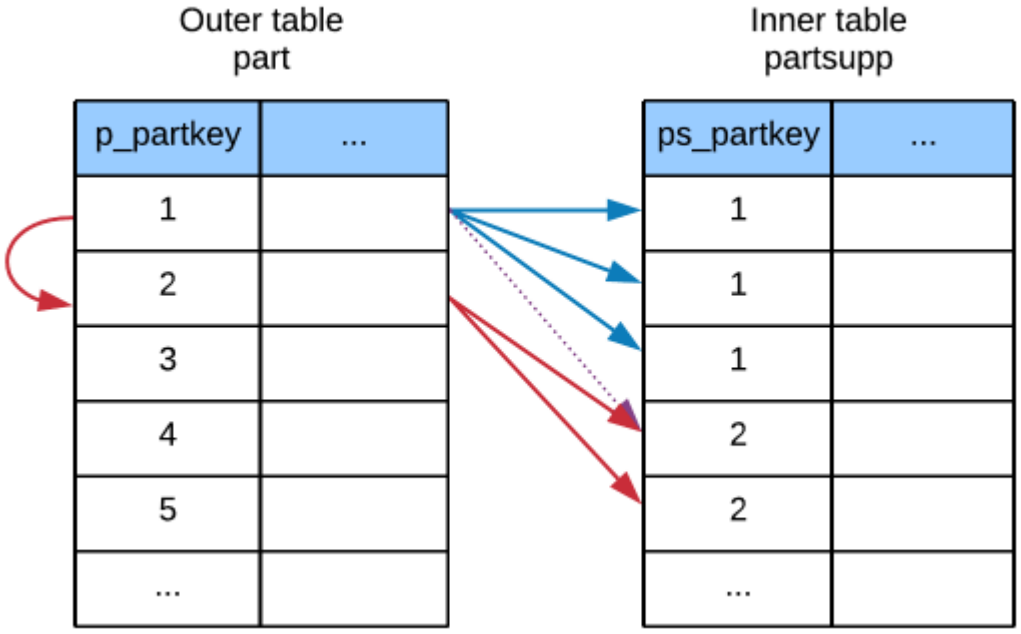
Sort Merge Join

It sorts the intermediate results of an outer table and an inner table, then sequentially compares them, ch ecks whether they satisfy the join condition and returns the join result.

When an index available exists in either an outer table or an inner table, then the table obtains the sorted intermediate results by using an index instead of using a sort instant.

One or more equi join conditions are required to perform a sort merge join.

Figure 25 Sort merge join



The following is an example of a sort merge join.

```
\EXPLAIN PLAN
SELECT p_name, p_brand, p_type
  FROM part, partsupp
 WHERE p_partkey = ps_partkey
   AND p_partkey < 10;
...
36 rows selected.
>>>  start print plan

```

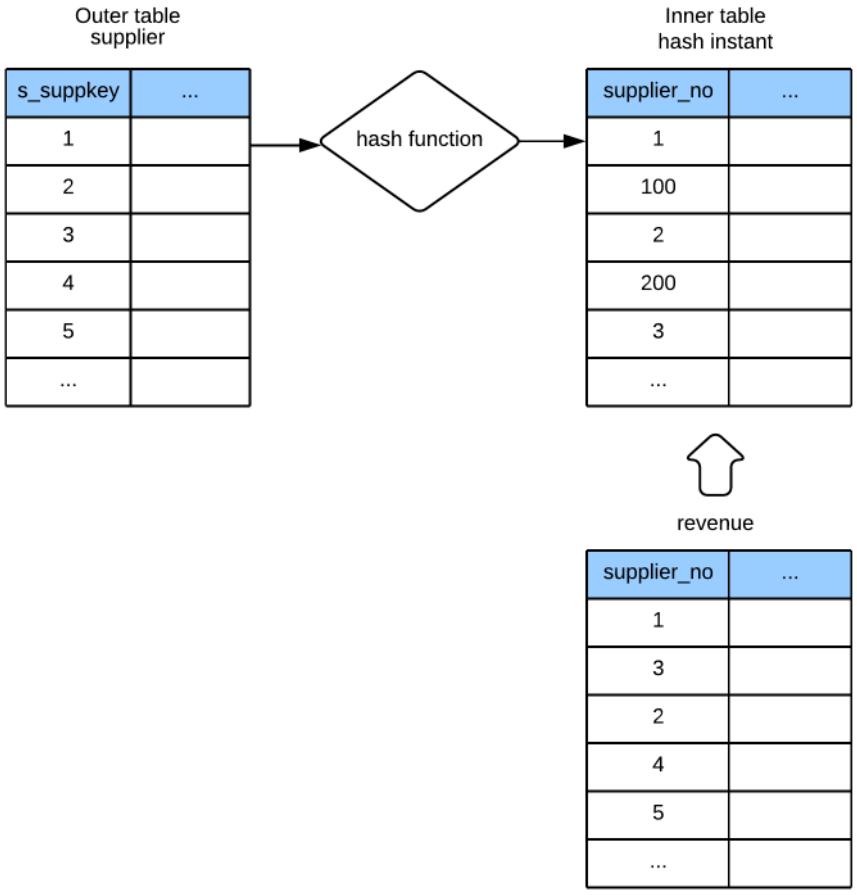
Hash Join

It creates a hash instant in an inner table, then returns the join result satisfying the join condition by using a hash.

One or more equi join conditions are required to perform a hash join.

Figure 26 Hash join



The following is an example of a hash join.

```
\EXPLAIN PLAN
SELECT s_suppkey,
       s_name,
       total_revenue
  FROM supplier,
         (
            SELECT l_suppkey,
                   ROUND( sum(l_extendedprice * (1 - l_discount)), 2)
              FROM lineitem
             WHERE l_shipdate >= date '1996-01-01'
               AND l_shipdate < date '1996-01-01' + interval '3' month
             GROUP BY l_suppkey
       ) revenue(supplier_no, total_revenue)
 WHERE
      s_suppkey = supplier_no;
...
10000 rows selected.

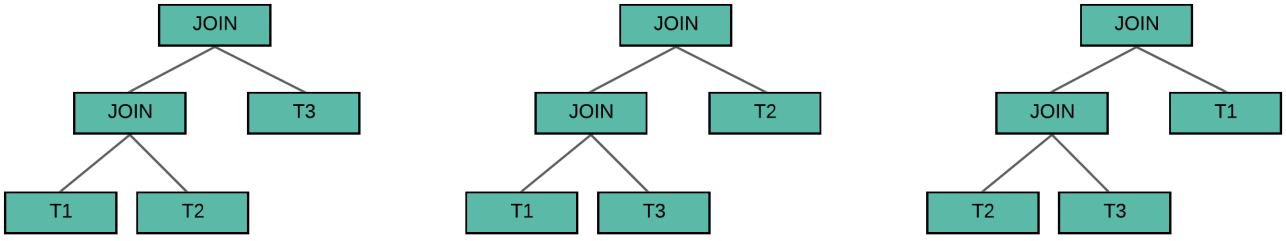
Join Order

When joining three or more tables, the join order should be determined. The join order is determined in t he way of joining two tables, then joining the intermediate result and the next table.

When there are three table, then there are various join orders as follows.

Figure 27 Join order



An enumerator creates sets of various execution plans according to join orders, join methods and access paths available, then it determines the join ordering by selecting the plan whose intermediate results and cost is low.

Group By

It processes *group by*.

Generally, it processes *group by* by creating GROUP HASH INSTANT.

If the intermediate result is sorted for *group by key column* and ascends from the subordinate node, then it can be processed without accumulating separate hash instants.

The following is an example of processing *group by* by creating GROUP HASH INSTANT.

```
\EXPLAIN PLAN
  SELECT c_custkey, count(o_orderkey)
    FROM customer, orders
 WHERE c_custkey = o_custkey
     AND c_comment like '%special%requests%'
     AND o_orderdate = date '1995-03-15'
GROUP BY c_custkey;
...
12 rows selected.
>>>  start print plan

```
           AGGREGATION : MIN( CUSTOMER.C_CUSTKEY ), MAX( CUSTOMER.C_CUSTKEY )
<<<  end print plan
```

Order By

It processes *order by*.

Generally, it processes order by by creating SORT INSTANT.

The following two methods are used to process *order by* of SORT INSTANT node.

- Sorting by using sort instant table
- Sorting by using limit sort (If *order by* is used together with *limit,* limit sort method is applied.)

If the intermediate result is sorted for order by key column and ascends from the subordinate node, then i t can be processed without accumulating separate sort instants.

The following is an example of processing *order by* by creating SORT INSTANT.

```
\EXPLAIN PLAN
  SELECT c_nationkey
    FROM customer
   WHERE c_comment like '%special%requests%'
ORDER BY c_nationkey;
...
>>>  start print plan
< Execution Plan >

```

15.4 Cluster

This chapter describes optimizing the cluster query in the cluster system.
For more information about the cluster system, refer to **GOLDILOCKS Cluster System Architecture**.

Table Sharding Strategy

There are two types of table sharding strategies as follows.

- Cloned table
- Sharded table

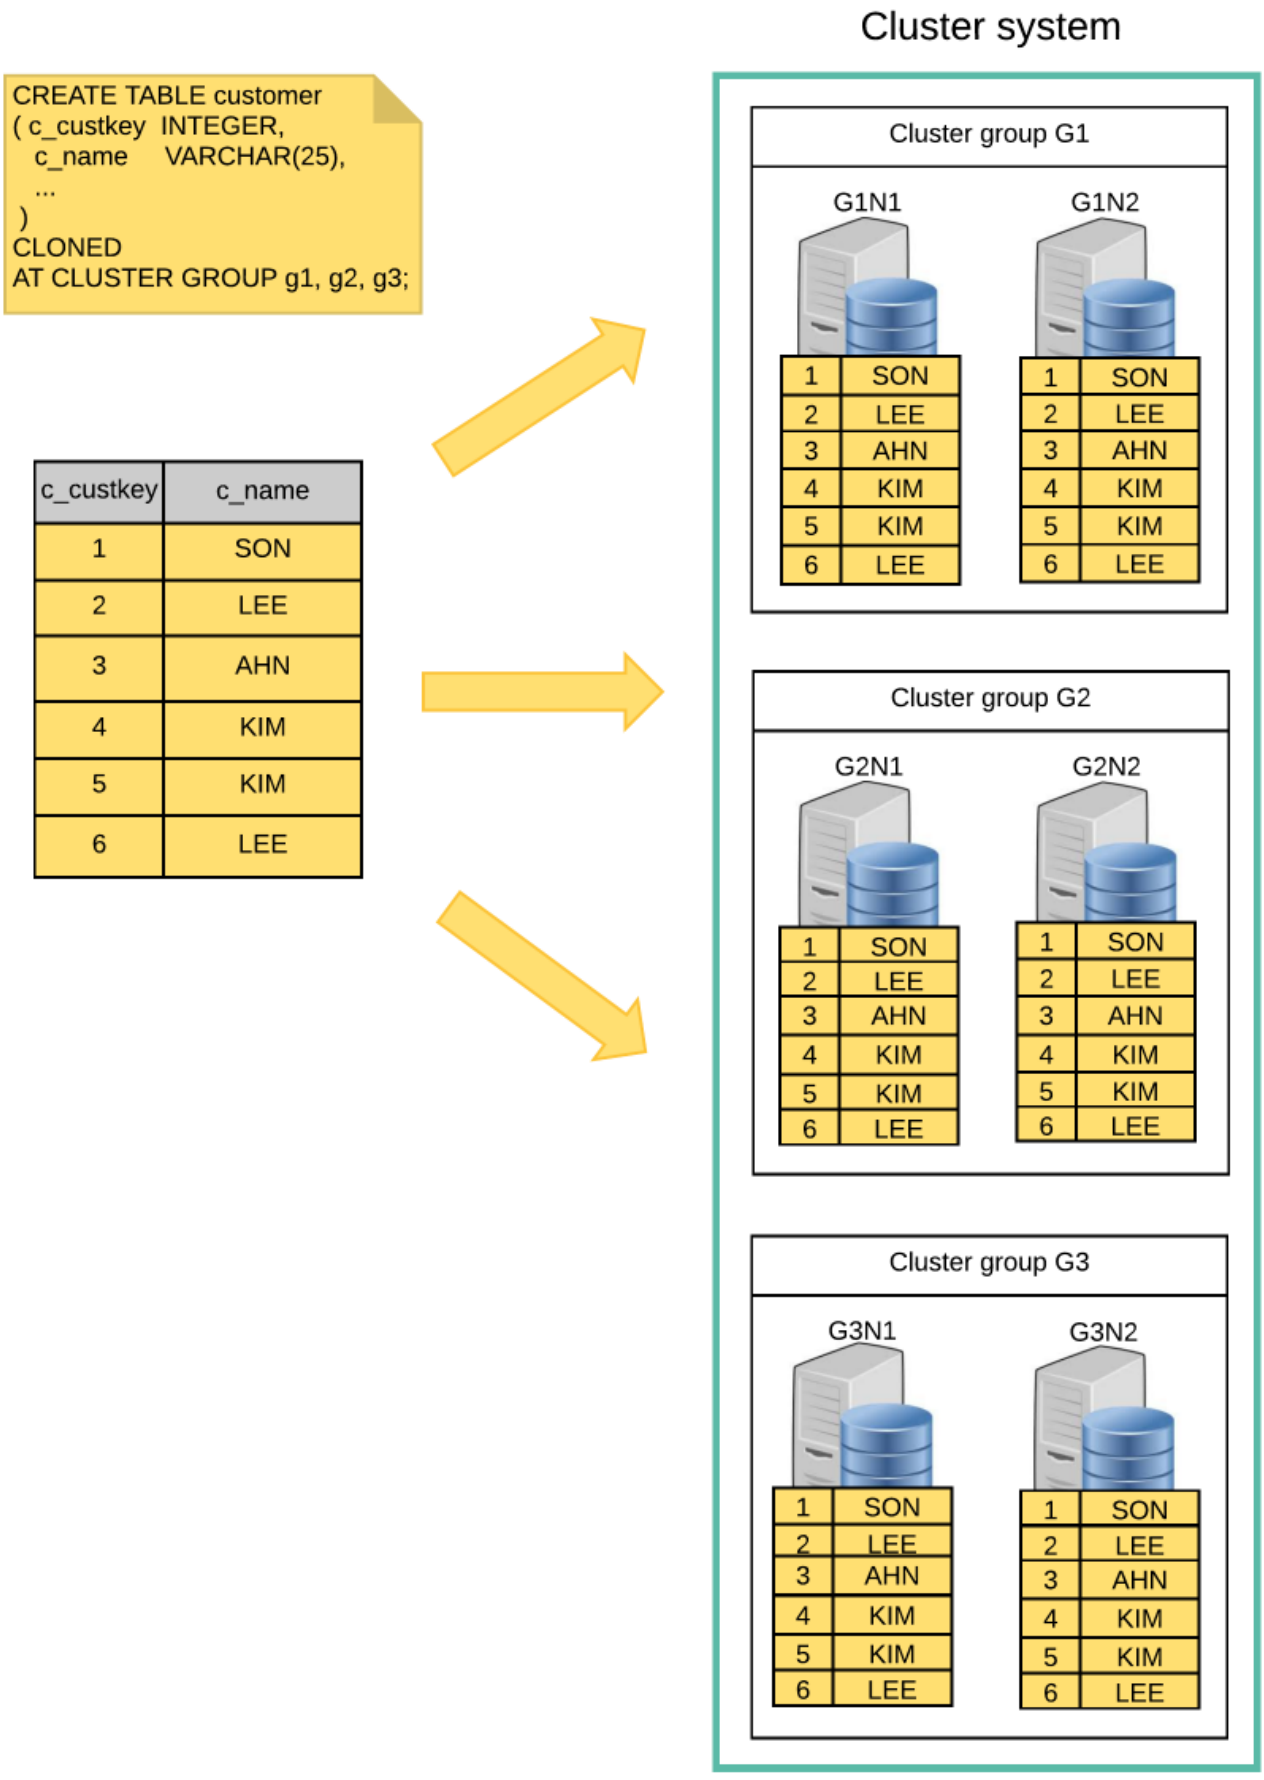
The description and examples of table sharding strategies are as follows.

Cloned Table

All table data of every node in every group are stored same in the cloned table. Therefore it is appropriate for the table which is rarely updated and whose data is little.

The following is an example of creating a customer table with a cloned table.

Figure 28 Cloned table



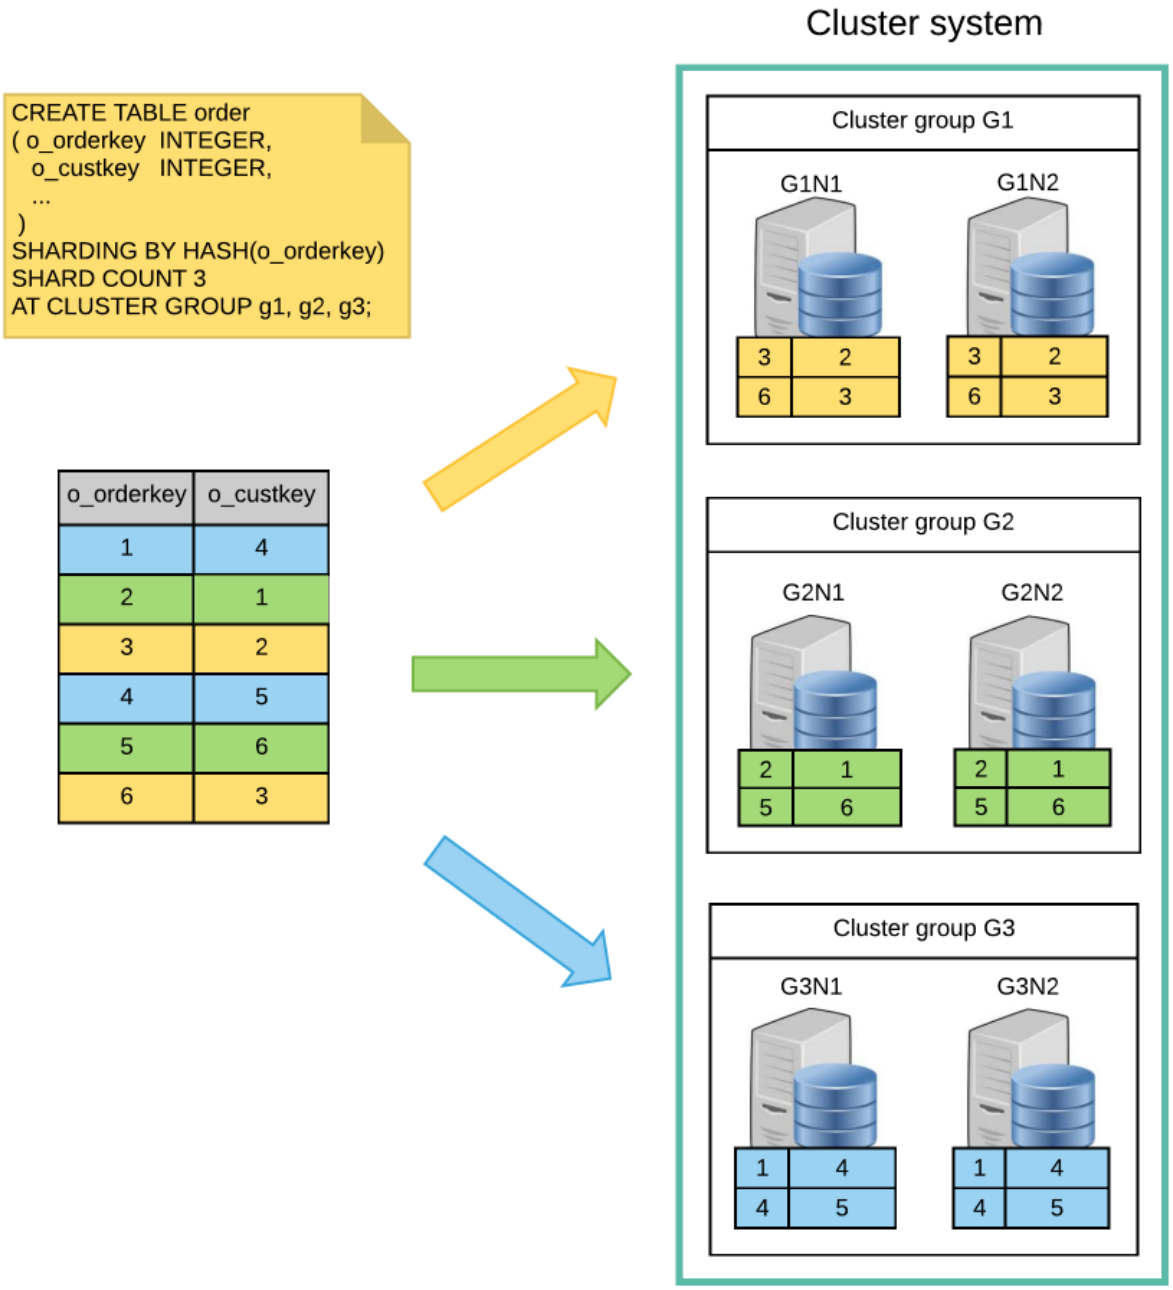
Sharded Table

The data is divided in a group by a shard key, then stored. Nodes in a single group have the same data. T herefore, it is it is appropriate for the table which should be divided due to many data. There are three ty pes of shards according to the sharding strategies as follows.

- Hash shard
- Range shard
- List shard

The following is an example of creating an order table by using hash shards.

Figure 29 Sharded table

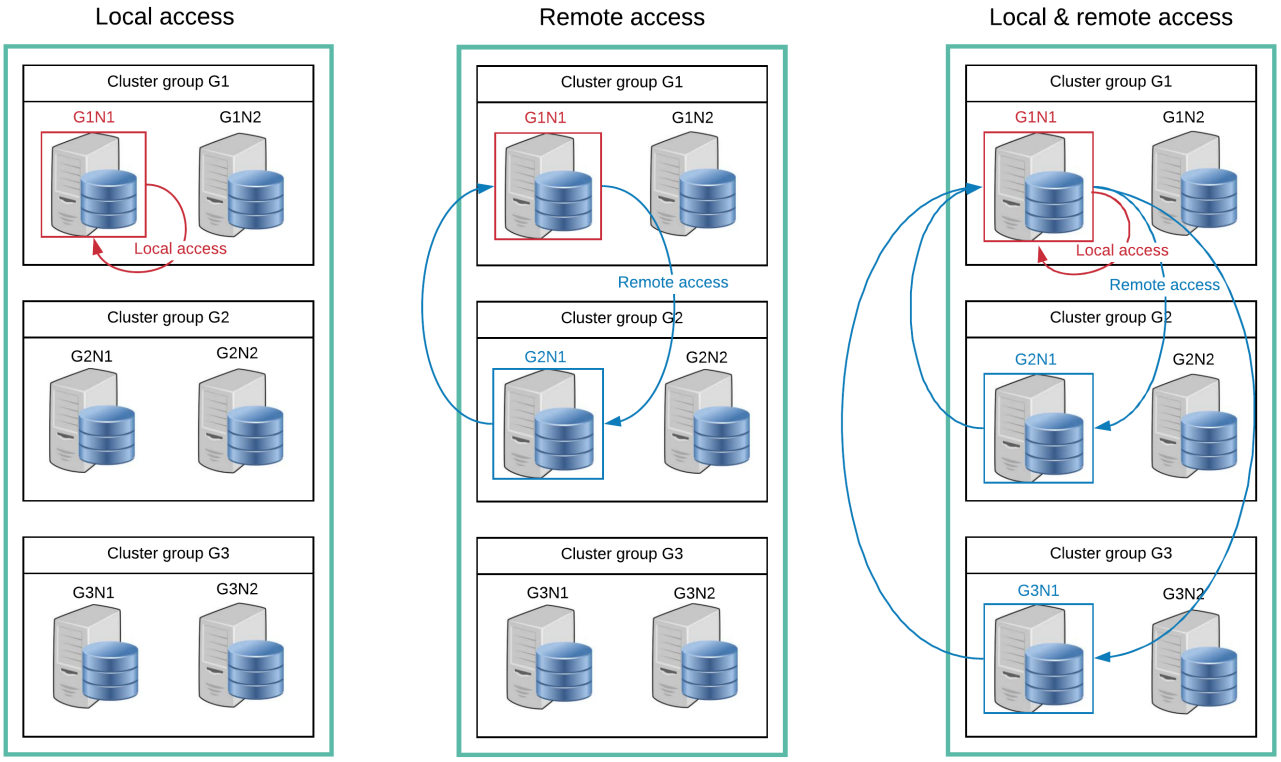


Access

This paragraph describes the case of which a cluster query access to a single table.

The following figure describes a local access and a remote access of when the current server is G1N1.

Figure 30 Cluster access



Local Access

It performs the operation only on the current server in driver aspect.

If enquiring about the cloned table as follows, then it only needs to be performed in the current server be cause data in every node in all group are the same.

Figure 31 Local access (cloned table)

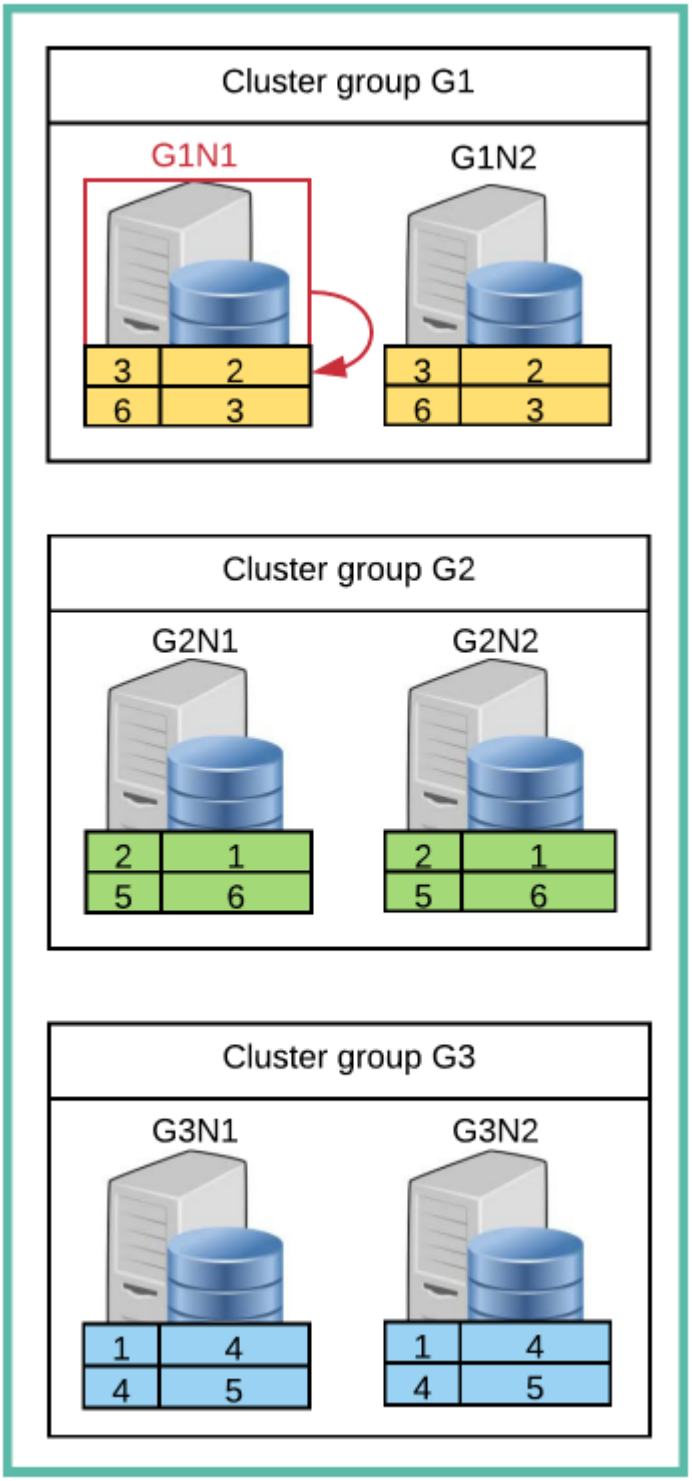
     2  -  CLONED
           READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME
<<<  end print plan
```

The data is divided in a group by a shard key, then stored in the sharded table. Therefore, it performs the local access when a filter for a shard key exists and the value can be performed only in the current server.

Figure 32 Local access (sharded table)



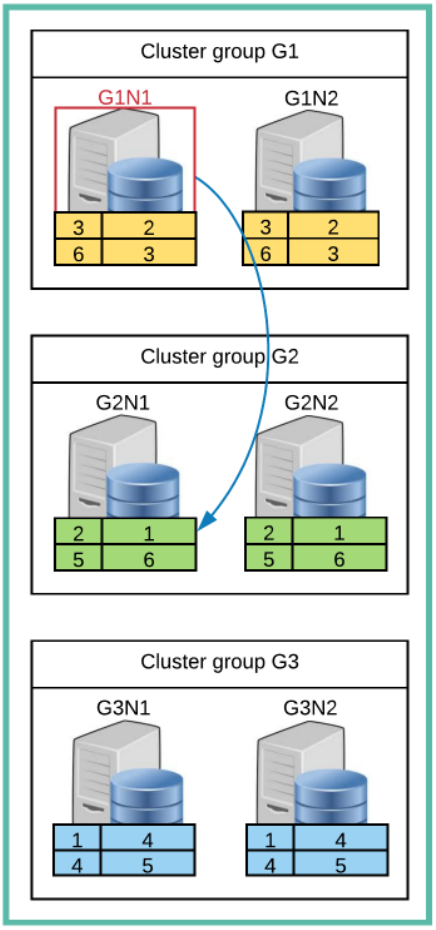
```
\EXPLAIN PLAN SELECT * FROM orders WHERE o_orderkey = 3;
O_ORDERKEY O_CUSTKEY
---------- ---------
         3         2
1 row selected.
>>>  start print plan
```

```
< Execution Plan >
============================================================================
| IDX |  NODE DESCRIPTION                                            | ROWS |
----------------------------------------------------------------------------
|  0  |  SELECT STATEMENT                                            |    1 |
|  1  |    QUERY BLOCK ("$QB_IDX_2")                                 |    1 |
|  2  |      TABLE ACCESS ("ORDERS")                                 |    1 |
============================================================================
     1  -  TARGET : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
     2  -  HASH SHARD ( # 3 )
           READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
             PHYSICAL FILTER : ORDERS.O_ORDERKEY = 3
<<<  end print plan
```

Remote Access

The data is divided in a group by a shard key, then stored in the sharded table. Therefore, it can fetch the result by the remote access only to a specific server when a filter for a shard key exists.

Figure 33 Remote access

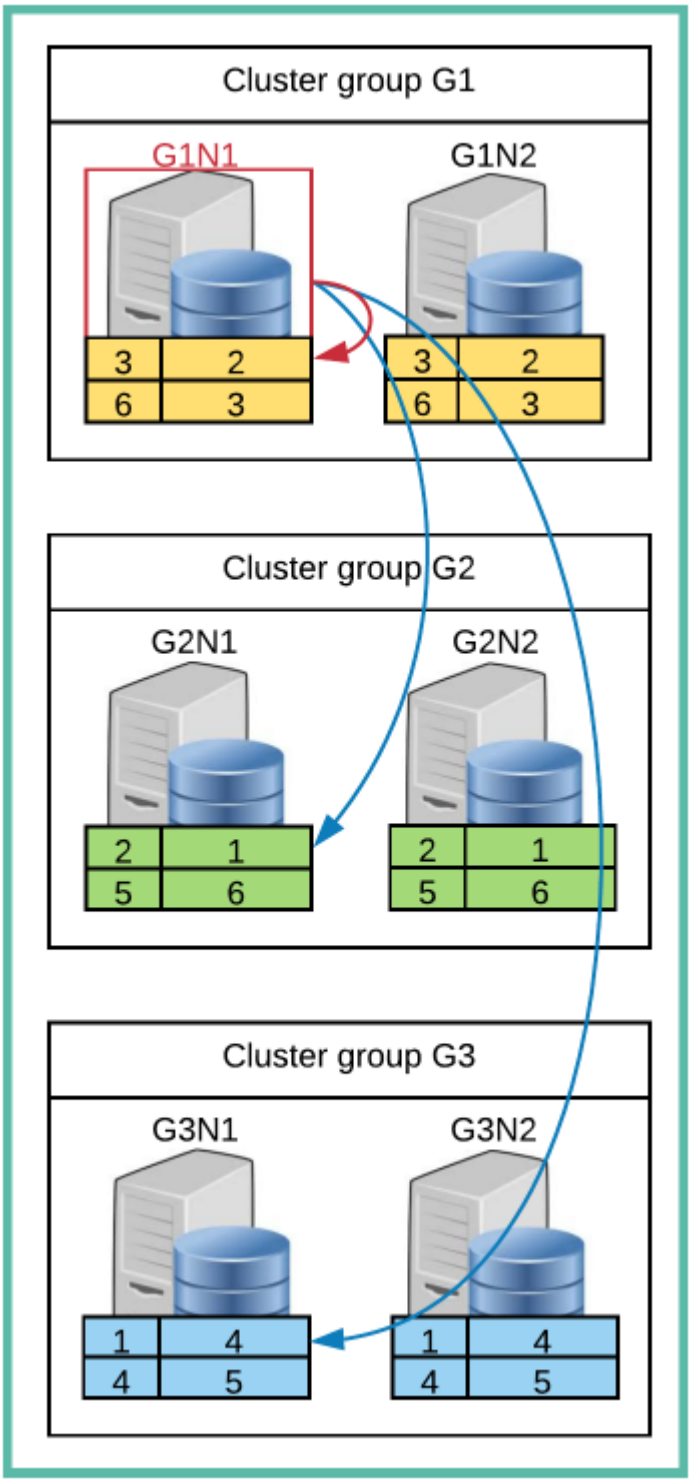


```
\EXPLAIN PLAN SELECT * FROM orders WHERE o_orderkey = 2;
O_ORDERKEY O_CUSTKEY
---------- ---------
         2         1
1 row selected.
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                |          ROWS |
--------------------------------------------------------------------------------
|  0  |  SELECT STATEMENT                                  |             1 |
|  1  |    QUERY BLOCK ("$QB_IDX_2")                       |             1 |
|  2  |      PLAN BASED CLUSTER                            | REMOTE ONLY 1 |
|  3  |        TABLE ACCESS ("ORDERS")                     |             0 |
================================================================================
     1  -  TARGET : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
     2  -  SQL : SELECT /*+ FULL( _A1 ) */
                         "_A1"."O_ORDERKEY", "_A1"."O_CUSTKEY"
                    FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
                   WHERE "_A1"."O_ORDERKEY" = :_V0
           TARGET DOMAIN : G2(G2N1,G2N2) 1 rows
     3  -  HASH SHARD ( # 3 )
           READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
             PHYSICAL FILTER : ORDERS.O_ORDERKEY = 2
<<<  end print plan
```

In the execution plan above, it fetched the result by remotely transferring SQL to G2.

If the sharded table does not have a filter for the shard key, then it should receive the result by transferrin g the query to each server.

Figure 34 Local & remote access



```
\EXPLAIN PLAN SELECT * FROM orders WHERE o_custkey = 1;

|  3    |        TABLE ACCESS ("ORDERS")                   |             0 |
================================================================================
     1  -  TARGET : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
     2  -  SQL : SELECT /*+ FULL( _A1 ) */
                         "_A1"."O_ORDERKEY", "_A1"."O_CUSTKEY"
                    FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
                   WHERE "_A1"."O_CUSTKEY" = :_V0
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows,
                           G2(G2N1,G2N2) 1 rows,
                           G3(G3N1,G3N2) 0 rows
     3  -  HASH SHARD ( # 3 )
           READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_CUSTKEY
             PHYSICAL FILTER : ORDERS.O_CUSTKEY = 1
<<<  end print plan
```

In the execution plan above, it fetched the result by remotely transferring SQL to G1, G2, G3.

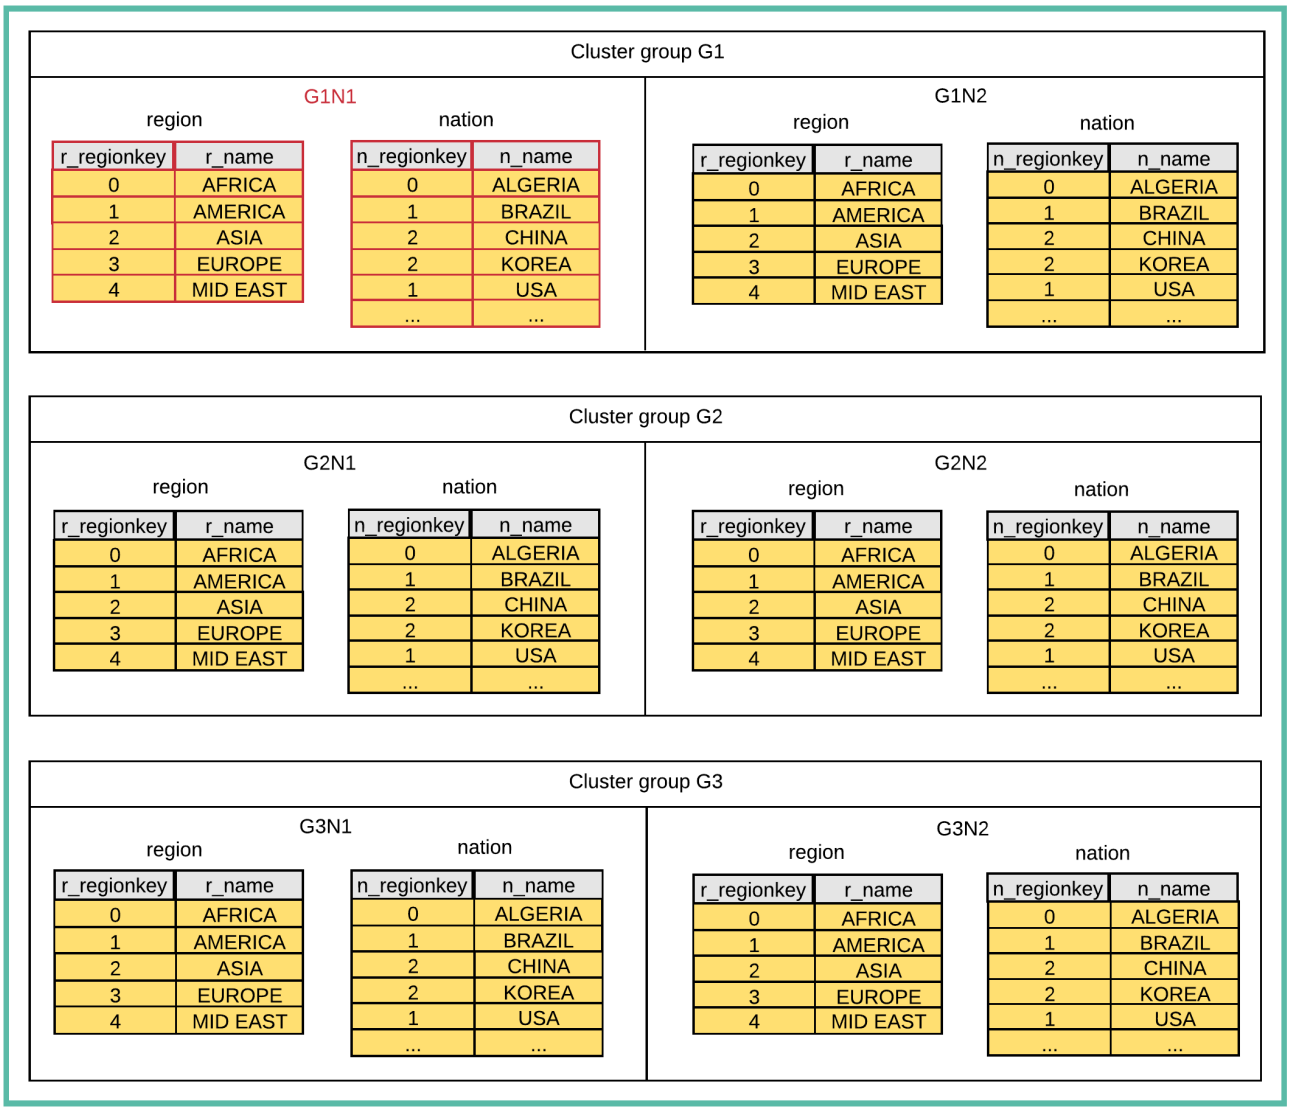
Join

Local Join

It performs join in the current server. Local join types are various as follows.

The following is an example of joining *region* and *nation*. Both tables are cloned tables. All nodes in every group of the cloned tables has the same data. Therefore, it can perform the join only with data in G1N1 i n the following example whose drive is G1N1.

```
\EXPLAIN PLAN
SELECT r_name, n_name
  FROM region, nation
 WHERE r_regionkey = n_regionkey;
```

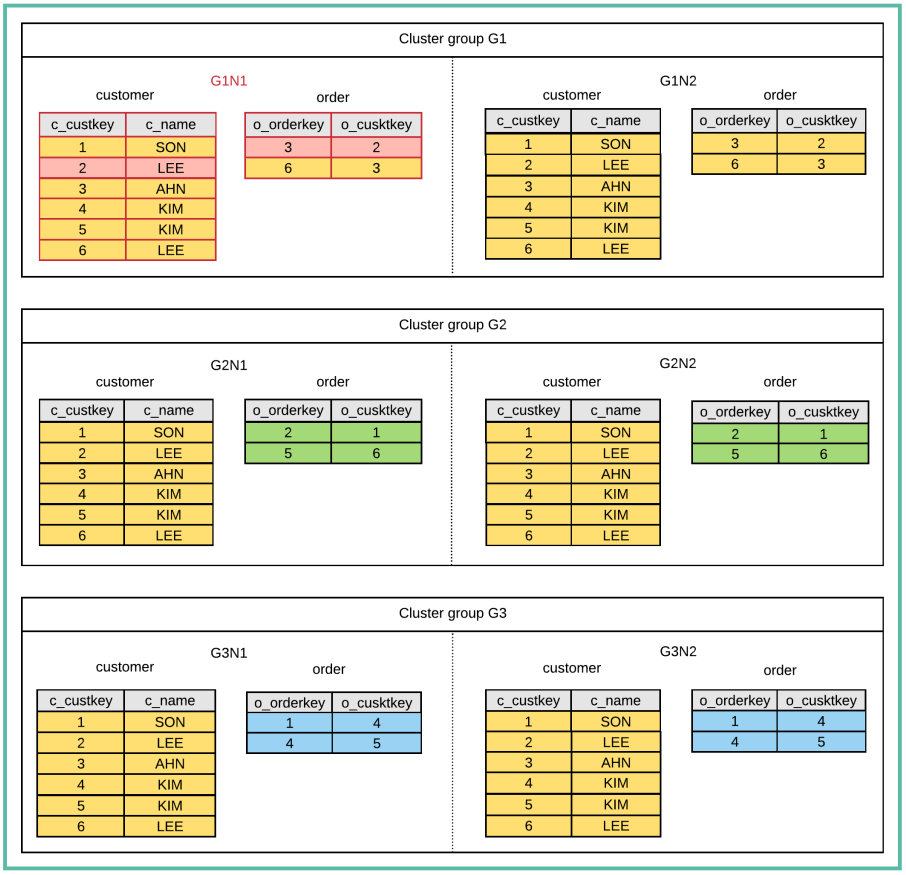


```
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      HASH JOIN (INNER JOIN)                                       |
|    3  |        TABLE ACCESS ("NATION")                                    |
|    4  |        HASH JOIN INSTANT                                          |
|    5  |          TABLE ACCESS ("REGION")                                  |
=============================================================================
     1  -  TARGET : REGION.R_NAME, NATION.N_NAME
     2  -  JOINED COLUMN : REGION.R_NAME, NATION.N_NAME
     3  -  CLONED
```

```
        READ COLUMN : NATION.N_NAME, NATION.N_REGIONKEY
    4  -  HASH KEY : REGION.R_REGIONKEY
        RECORD COLUMN : REGION.R_NAME
        READ KEY COLUMN : REGION.R_REGIONKEY, REGION.R_NAME
          HASH FILTER : REGION.R_REGIONKEY = NATION.N_REGIONKEY
        FETCH ONE ROW
    5  -  CLONED
        READ COLUMN : REGION.R_REGIONKEY, REGION.R_NAME
<<<  end print plan
```

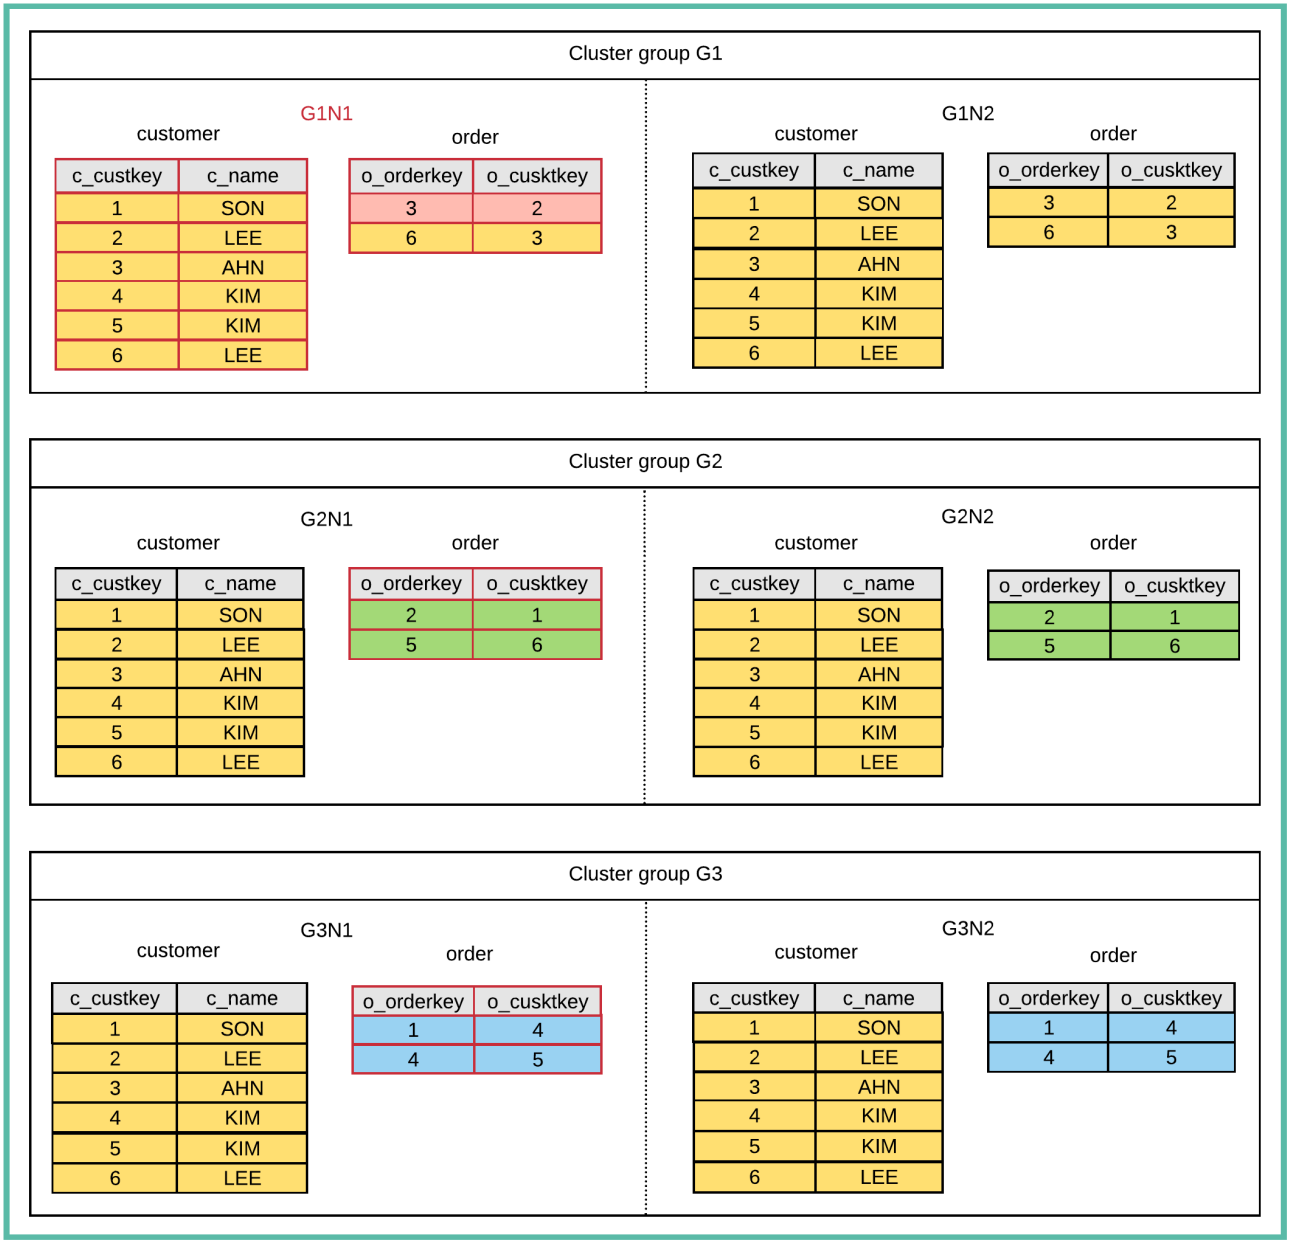
The following is an example of joining customer and orders. Customer is a cloned table and order is a sha rded table. The data in the sharded table divided in a group by a shard key. Therefore, it can perform the local join when a filter for a shard key column exists and the data exists in the current server as the follow ing example.

```
\EXPLAIN PLAN
SELECT c_custkey, COUNT(o_orderkey)
  FROM customer, orders
 WHERE c_custkey = o_custkey
   AND o_orderkey = 3
GROUP BY c_custkey;
```



```
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                                     |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                     |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                          |
|    2  |      GROUP HASH INSTANT                                               |
|    3  |        NESTED JOIN (INNER JOIN)                                       |
|    4  |          INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")                   |
|    5  |          INDEX ACCESS ("CUSTOMER", "CUSTOMER_PK_INDEX")               |
================================================================================
     1  -  TARGET : CUSTOMER.C_CUSTKEY, COUNT( ORDERS.O_ORDERKEY )
     2  -  GROUP KEY : CUSTOMER.C_CUSTKEY
           RECORD COLUMN : COUNT( ORDERS.O_ORDERKEY )
           READ KEY COLUMN : CUSTOMER.C_CUSTKEY
           READ RECORD COLUMN : COUNT( ORDERS.O_ORDERKEY )
     3  -  JOINED COLUMN : CUSTOMER.C_CUSTKEY, ORDERS.O_ORDERKEY
     4  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_CUSTKEY
             MIN RANGE : ORDERS.O_ORDERKEY = 3
             MAX RANGE : ORDERS.O_ORDERKEY = 3
           FETCH ONE ROW
     5  -  CLONED
           READ INDEX COLUMN : CUSTOMER.C_CUSTKEY
             MIN RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
             MAX RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
           FETCH ONE ROW
<<<  end print plan
```

The following is an example of joining customer and orders without a filter for a shard key column. In this case, the local join is available only after fetching all data in the sharded table.



```
\EXPLAIN PLAN
SELECT /*+ LOCAL_JOIN(orders) */
       c_custkey, COUNT(o_orderkey)
  FROM customer, orders
 WHERE c_custkey = o_custkey
GROUP BY c_custkey;
```

```
< Execution Plan >
================================================================================

             HASH FILTER : CUSTOMER.C_CUSTKEY = ORDERS.O_ORDERKEY
           FETCH ONE ROW
     6  -  CLONED
           READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME
<<<  end print plan
```

In the execution plan above, it fetched all data in order table by transferring SQL to G1, G2, G3.

Remote Join

It performs join in each server.

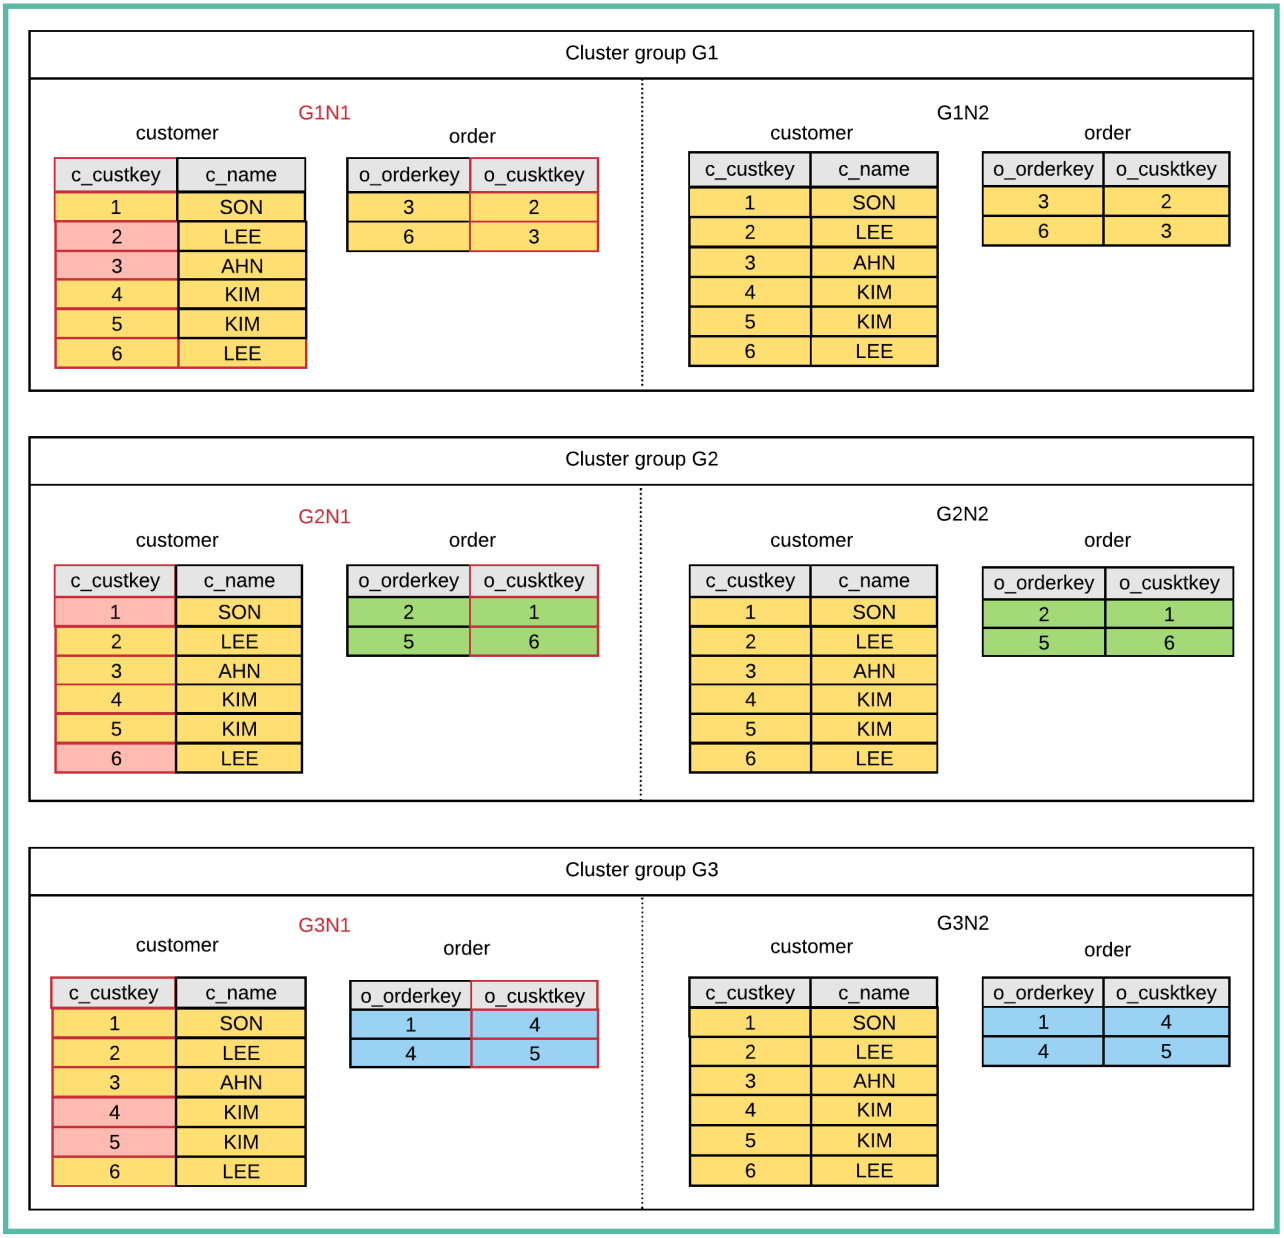
Join processing in each server has a parallel processing effect. Also, when results are decreased a lot by th e join, then bringing the result by performing join in the server reduces the network cost.

This chapter describes various forms of remote.

Joining Cloned Table and Sharded Table

This chapter describes about joining a cloned table and a sharded table.

The following is an example of joining customer and orders. Customer is a cloned table, order is a sharde d table, and the data is distributed as follows.



```
\EXPLAIN PLAN
SELECT /*+ REMOTE_JOIN(orders) */
       c_custkey, COUNT(o_orderkey)
  FROM customer, orders
 WHERE c_custkey = o_custkey
GROUP BY c_custkey;
>>>  start print plan
< Execution Plan >
================================================================================
¦IDX¦  NODE DESCRIPTION                                ¦           ROWS ¦
--------------------------------------------------------------------------------

```

```
| 1 |    QUERY BLOCK ("$QB_IDX_2")                          |              6 |
| 2 |      PLAN BASED CLUSTER                               | LOCAL/REMOTE 6 |
| 3 |        HASH JOIN (INNER JOIN)                         |              6 |
| 4 |          TABLE ACCESS ("ORDERS")                      |              6 |
| 5 |          HASH JOIN INSTANT                            |              6 |
| 6 |            TABLE ACCESS ("CUSTOMER")                  |              6 |
=============================================================================
     1  -  TARGET : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME, ORDERS.O_ORDERKEY
     2  -  SQL : SELECT /*+ KEEP_JOINED_TABLE USE_HASH_IN( _A1, 10 )
                            FULL( _A2 )
                            FULL( _A1 ) */
                       "_A1"."C_CUSTKEY", "_A1"."C_NAME", "_A2"."O_ORDERKEY"
                  FROM ("PUBLIC"."ORDERS"@LOCAL AS "_A2"
                        INNER JOIN
                        "PUBLIC"."CUSTOMER"@LOCAL AS "_A1"
                    ON "_A1"."C_CUSTKEY" = "_A2"."O_ORDERKEY") ALIAS "_A3"
           TARGET DOMAIN : G1(G1N1,G1N2) 2 rows,
                           G2(G2N1,G2N2) 2 rows,
                           G3(G3N1,G3N2) 2 rows
     3  -  JOINED COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME, ORDERS.O_ORDERKEY
     4  -  HASH SHARD ( # 3 )
           READ COLUMN : ORDERS.O_ORDERKEY
     5  -  HASH KEY : CUSTOMER.C_CUSTKEY
           RECORD COLUMN : CUSTOMER.C_NAME
           READ KEY COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME
             HASH FILTER : CUSTOMER.C_CUSTKEY = ORDERS.O_ORDERKEY
     6  -  CLONED
           READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME
<<<  end print plan
```

In the execution plan above, it performed join in each server and fetched the result by transferring SQL to G1, G2, G3.

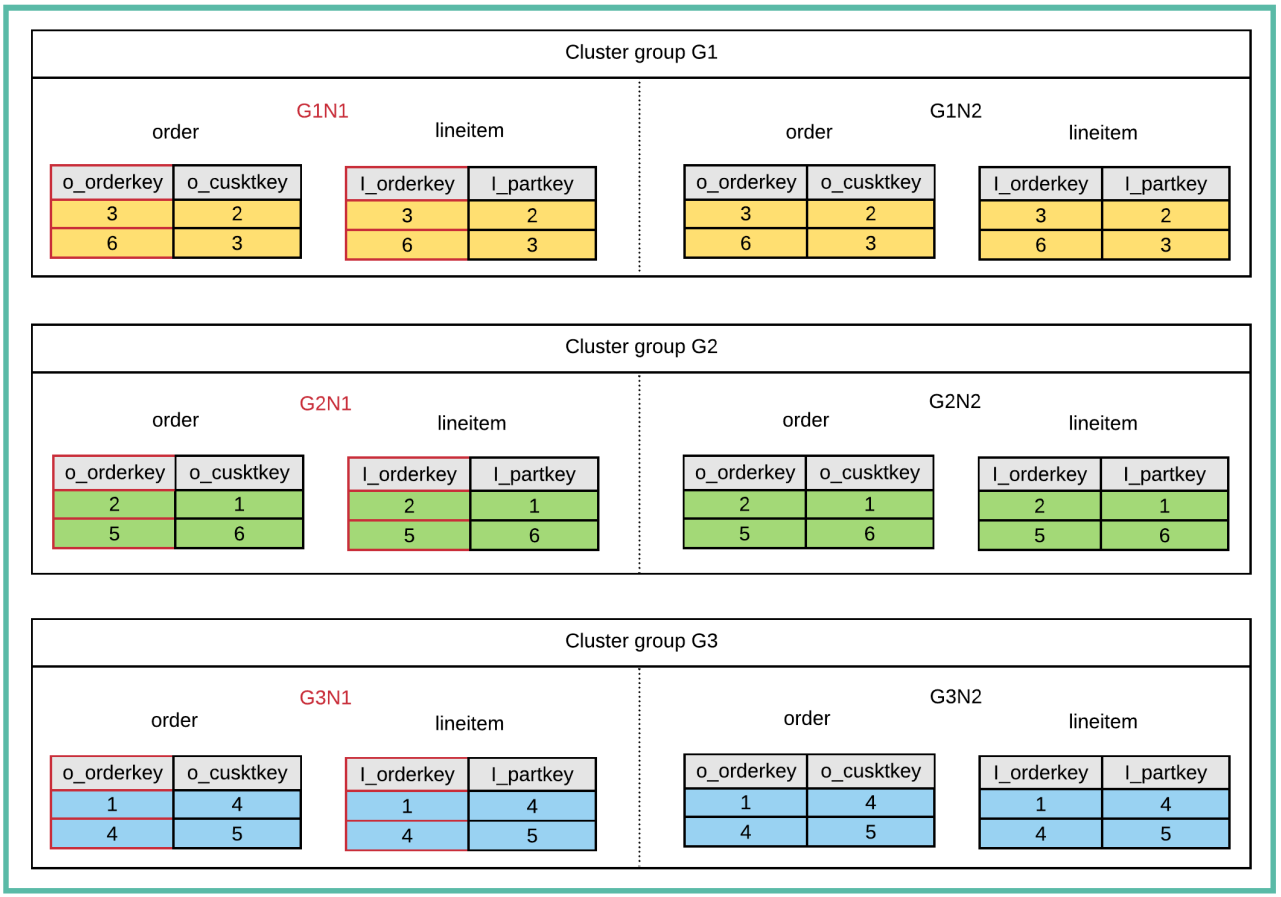
Joining Sharded Table and Sharded Table

The remote join is available when satisfying the following conditions.

- A shard key join condition exsists. (e.g. t1.shardKeyCol = t2.shardKeyCol)
- Shard strategies are same.
  - Joining hash sharded table and hash sharded table
  - Joining range shard and range shard
  - Joining list shard and list shard

- Shard counts are same.
- Shard key column types are same.
- The number of shard key columns are same.

The following is an example of joining orders and lineitem. Both tables are hash sharded tables, and a sh ard key join condition exists. They are sharded for orderkey of the same standard, so the join is performed in each server.



```
\EXPLAIN PLAN
SELECT o_orderkey, l_partkey
  FROM orders, lineitem
 WHERE o_orderkey = l_orderkey;
```

```
>>>  start print plan
< Execution Plan >
================================================================================

                            INDEX( _A2, "PUBLIC"."ORDERS_PK_INDEX" )
                            FULL( _A1 ) */
                       "_A2"."O_ORDERKEY", "_A1"."L_PARTKEY"
                  FROM ( "PUBLIC"."ORDERS"@LOCAL AS "_A2"
                         INNER JOIN
                         "PUBLIC"."LINEITEM"@LOCAL AS "_A1"
                    ON "_A1"."L_ORDERKEY" = "_A2"."O_ORDERKEY") ALIAS "_A3"
           TARGET DOMAIN : G1(G1N1,G1N2) 2 rows,
                           G2(G2N1,G2N2) 2 rows,
                           G3(G3N1,G3N2) 2 rows
     3  -  JOINED COLUMN : ORDERS.O_ORDERKEY, LINEITEM.L_PARTKEY
     4  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : ORDERS.O_ORDERKEY
     5  -  HASH KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : LINEITEM.L_PARTKEY
           READ KEY COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_PARTKEY
             HASH FILTER : LINEITEM.L_ORDERKEY = ORDERS.O_ORDERKEY
     6  -  HASH SHARD ( # 3 )
           READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_PARTKEY
<<<  end print plan
```

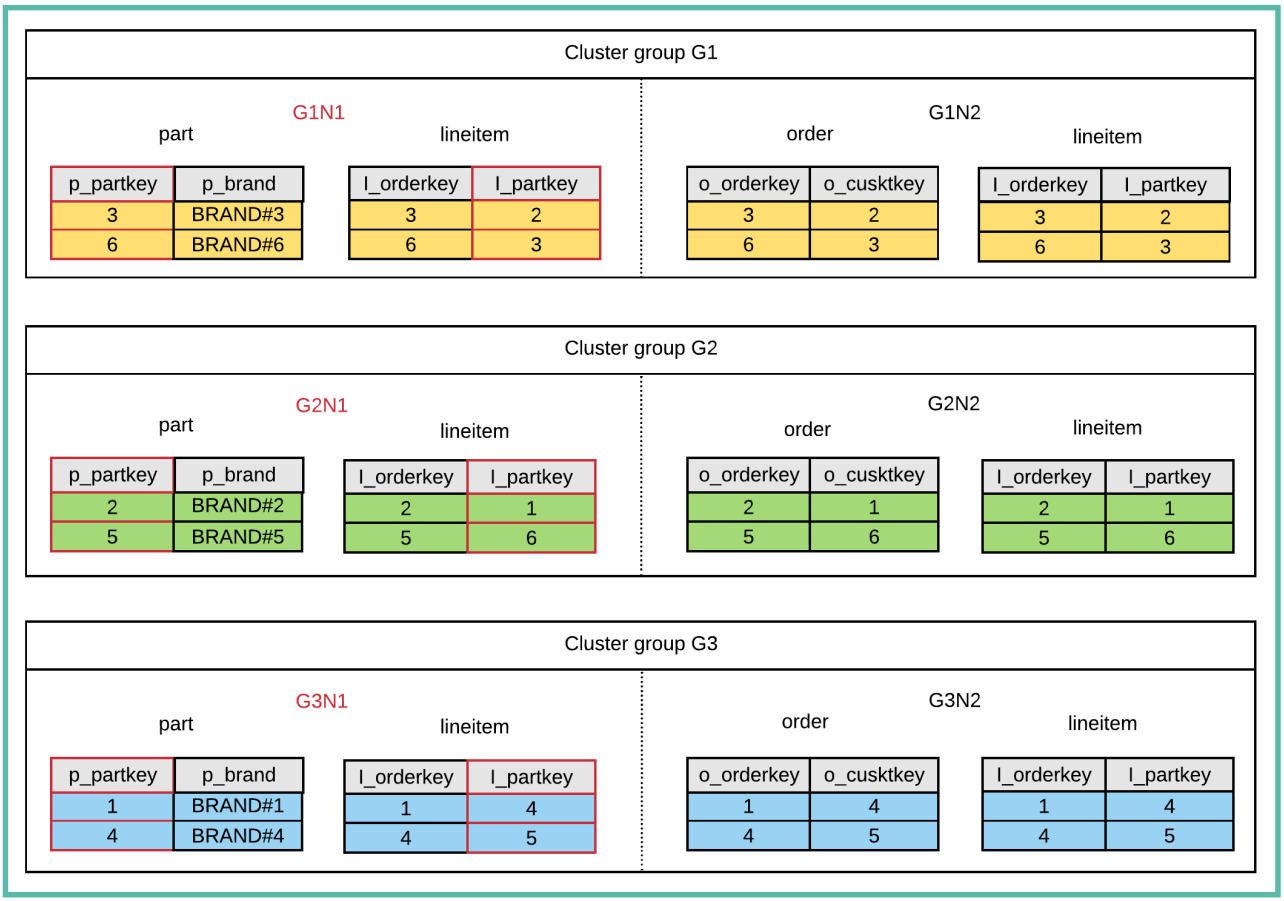
In the execution plan above, it performed join in each server and fetched the result by transferring join SQL to each server.

The following is an example of joining part and lineitem. Both tables are hash sharded tables. However, a shard key join condition does not exist.

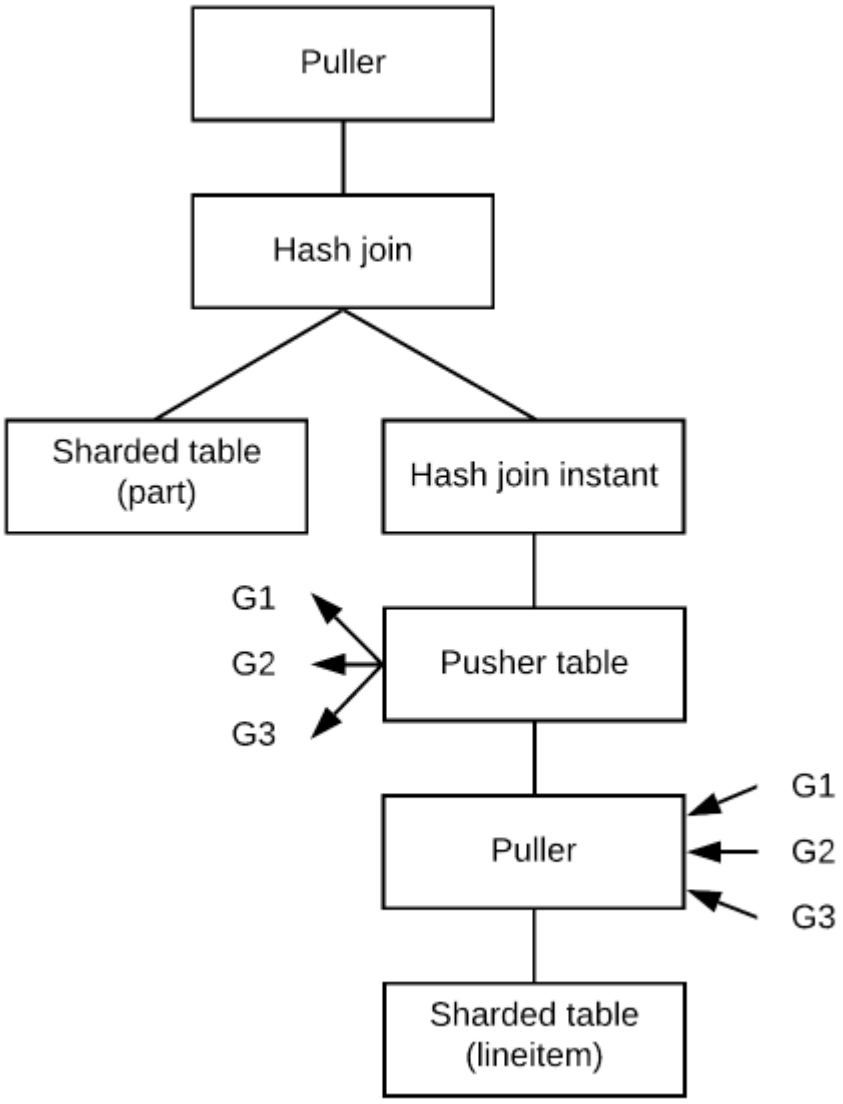
Both part and lineitem are hash sharded tables. However, data in part is sharded based on p_partkey because the shard key of part is p_partkey. On the other hand, data in lineitem is sharded based on l_orderkey because the shard key of lineitem is l_orderkey.

```
\EXPLAIN PLAN
SELECT /*+ REMOTE_JOIN(lineitem) */
       l_orderkey, p_partkey
```

```
 FROM part, lineitem
WHERE p_partkey = l_partkey;
```



For the query above to perform the remote join, it should fetch all data of lineitem, then shard them with l_partkey and transfer to G1, G2, G3 . In this case, a puller and a pusher take this role.



- **Cluster Puller**: It fetches data by transferring SQL each server.
- **Cluster Pusher**: It transfers data to each server.

In the figure above, a puller fetches all data from lineitem. Then, l_partkey makes a pusher table which is a shard key, and transfers data to G1, G2, G3. And it performs a remote join of part table and pusher tab le in G1, G2 and G3.

The execution plan is as follows.

```
>>>  start print plan
< Execution Plan >
================================================================================

     4  -  SQL : SELECT /*+ FULL( _A1 ) */
                        "_A1"."L_ORDERKEY", "_A1"."L_PARTKEY"
                   FROM "PUBLIC"."LINEITEM"@LOCAL AS "_A1"
          TARGET DOMAIN : G1(G1N1,G1N2) 2 rows,
                          G2(G2N1,G2N2) 2 rows,
                          G3(G3N1,G3N2) 2 rows
     5  -  HASH SHARD ( # 3 )
          READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_PARTKEY
     7  -  TARGET : _A1.L_ORDERKEY, _A2.P_PARTKEY
```

```
     8  -  JOINED COLUMN : _A1.L_ORDERKEY, _A2.P_PARTKEY
     9  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : _A2.P_PARTKEY
    10  -  HASH KEY : _A1.L_PARTKEY
           RECORD COLUMN : _A1.L_ORDERKEY
           READ KEY COLUMN : _A1.L_PARTKEY, _A1.L_ORDERKEY
             HASH FILTER : _A1.L_PARTKEY = _A2.P_PARTKEY
    11  -  READ COLUMN : _A1.L_PARTKEY, _A1.L_ORDERKEY
<<<  end print plan
```

In the execution plan above, (l_orderkey, l_partkey) is fetched by transferring SQL to G1, G2, G3 in 4. And (l_partkey, l_orderkey) value fetched from 4 is stored in a pusher table whose shard key is (l_partkey, l_orderkey) in 3. This pusher table is sharded by l_partkey, then transferred and temporarily stored in G1, G2, G3.
A remote join is performed as joining part table and pusher table.

Group By

Local Group By

It performs *group by* in current server.

If it is group by for a cloned table, then every node in all groups have the same data, so just perform *group by* in the current server.

```
\EXPLAIN PLAN
  SELECT c_nationkey, COUNT(c_custkey)
    FROM customer
GROUP BY c_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                  ¦
-----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                  ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                     ¦
¦    2  ¦      GROUP HASH INSTANT                                          ¦

```

Distinct

Local Distinct

It performs distinct in current server.

The following is an example of using distinct in customer which is a cloned table. Every node in all groups in a cloned table has the same data, so just perform distinct in the current server.

```
\EXPLAIN PLAN
SELECT DISTINCT c_nationkey
  FROM customer;
>>>  start print plan
< Execution Plan >
```

```
================================================================================
|  IDX  |  NODE DESCRIPTION                                                    |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                    |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                         |
|    2  |      GROUP                                                           |
|    3  |        INDEX ACCESS ("CUSTOMER", "CUSTOMER_NATIONKEY_FK")            |
================================================================================
     1  -  TARGET : CUSTOMER.C_NATIONKEY
     2  -  GROUP KEY : CUSTOMER.C_NATIONKEY
     3  -  CLONED
           READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
<<<  end print plan
```

The following is an example of using distinct in orders which is a sharded table. The data in a sharded tab le is sharded based in a shard key, so the data from all groups should be fetched when it is needed to loc ally perform distinct.

```
\EXPLAIN PLAN
SELECT /*+ LOCAL_DISTINCT */
       DISTINCT o_orderstatus
  FROM orders
 WHERE o_orderdate = date '1995-03-15';
>>>  start print plan
< Execution Plan >
================================================================================
|IDX|  NODE DESCRIPTION                              |             ROWS |
--------------------------------------------------------------------------------

     2  -  SQL : SELECT /*+ USE_DISTINCT_HASH(3) FULL( _A1 ) */
                        DISTINCT "_A1"."O_ORDERSTATUS"
                   FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
                  WHERE "_A1"."O_ORDERDATE" = :_V0
          TARGET DOMAIN : G1(G1N1,G1N2) 3 rows,
                          G2(G2N1,G2N2) 3 rows,
```

```
                        G3(G3N1,G3N2) 3 rows
          RE-GROUPING
            GROUP KEY : ORDERS.O_ORDERSTATUS
     4  -  TARGET : _A1.O_ORDERSTATUS
     5  -  GROUP KEY : _A1.O_ORDERSTATUS
           READ KEY COLUMN : _A1.O_ORDERSTATUS
     6  -  HASH SHARD ( # 3 )
           READ COLUMN : _A1.O_ORDERSTATUS, _A1.O_ORDERDATE
             PHYSICAL FILTER : _A1.O_ORDERDATE = :_V0
<<<  end print plan
```

In the execution plan above, It fetched results of performing distinct from G1, G2, G3, then performed di stinct again with RE-GROUPING. Though RE-GROUPING is performed, the results are decreased a lot so t he network cost is reduced and it is efficient.

Order By

Local Order By

It performs *order by* in the current server.

The following is an example of using *order by* in customer which is a cloned table. Every node in all group s in a cloned table has the same data, so just perform *order by* in the current server.

```
\EXPLAIN PLAN
  SELECT c_nationkey, COUNT(c_custkey)
    FROM customer
GROUP BY c_nationkey
ORDER BY c_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
¦ IDX ¦  NODE DESCRIPTION                                    ¦   ROWS ¦
-----------------------------------------------------------------------------
¦  0  ¦  SELECT STATEMENT                                    ¦     25 ¦
¦  1  ¦    QUERY BLOCK ("$QB_IDX_2")                        ¦     25 ¦
¦  2  ¦      SORT INSTANT                                   ¦     25 ¦
¦  3  ¦        GROUP HASH INSTANT                           ¦     25 ¦
¦  4  ¦          TABLE ACCESS ("CUSTOMER")                  ¦ 150000 ¦
=============================================================================
     1  -  TARGET : CUSTOMER.C_NATIONKEY, COUNT( CUSTOMER.C_CUSTKEY )
```

```
     2  -  SORT KEY : "CUSTOMER.C_NATIONKEY ASC NULLS LAST"
           RECORD COLUMN : COUNT( CUSTOMER.C_CUSTKEY )
           READ KEY COLUMN : CUSTOMER.C_NATIONKEY
           READ RECORD COLUMN : COUNT( CUSTOMER.C_CUSTKEY )
     3  -  GROUP KEY : CUSTOMER.C_NATIONKEY
           RECORD COLUMN : COUNT( CUSTOMER.C_CUSTKEY )
           READ KEY COLUMN : CUSTOMER.C_NATIONKEY
           READ RECORD COLUMN : COUNT( CUSTOMER.C_CUSTKEY )
     4  -  CLONED
           READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NATIONKEY
<<<  end print plan
```

The following is an example of using *order by* in orders which is a sharded table. The data in a sharded ta ble is sharded based in a shard key, so the data from all groups should be fetched when it is needed to lo cally perform *order by*.

```
\EXPLAIN PLAN
  SELECT /*+ LOCAL_ORDER */ o_orderdate, o_shippriority
    FROM orders
   WHERE o_orderdate >= date '1993-07-01'
     AND o_orderdate < date '1993-07-01' + interval '1' month
ORDER BY o_orderdate;
>>>  start print plan
< Execution Plan >
================================================================================
¦IDX¦  NODE DESCRIPTION                                ¦               ROWS ¦

           READ KEY COLUMN : ORDERS.O_ORDERDATE
           READ RECORD COLUMN : ORDERS.O_SHIPPRIORITY
     3  -  SQL : SELECT /*+ FULL( _A1 ) */
                        "_A1"."O_ORDERDATE", "_A1"."O_SHIPPRIORITY"
                   FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
```

```
                WHERE "_A1"."O_ORDERDATE" < :_V0
                  AND "_A1"."O_ORDERDATE" >= :_V1
          TARGET DOMAIN : G1(G1N1,G1N2) 6453 rows,
                          G2(G2N1,G2N2) 6450 rows,
                          G3(G3N1,G3N2) 6416 rows
     4  -  HASH SHARD ( # 3 )
          READ COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_SHIPPRIORITY
            PHYSICAL FILTER : ORDERS.O_ORDERDATE < DATE'1993-07-01' + CAST( '1' AS
INTERVAL(MONTH) ) AND ORDERS.O_ORDERDATE >= DATE'1993-07-01'
<<<  end print plan
```

In the execution plan above, It fetched data satisfying the condition from G1, G2, G3, then performed S ORT INSTANT.

Remote Order By

It performs *order by* in each server.

Order by processing in each server has a parallel processing effect. Also, if results are sorted on the subor dinate node and ascends to the superordinate node, then each server does not need to separately proces s *order by* and the driver just merges and sorts the result received from each server.

The following is an example of remote order by. orders is a sharded table.

```
\EXPLAIN PLAN
  SELECT o_custkey, o_orderstatus
    FROM orders
   WHERE o_custkey > 0 AND o_custkey < 10
ORDER BY o_custkey;
>>>  start print plan
< Execution Plan >
================================================================================
¦IDX¦ NODE DESCRIPTION                                                  ¦ ROWS ¦

            MAX RANGE : _A1.O_CUSTKEY IS NOT NULL AND _A1.O_CUSTKEY < :_V1
<<<  end print plan
```

In the execution plan above, it fetched ordered data from G1, G2, G3, then merged data, and sorted for order by key col.

Aggregation

Local Aggregation

It performs aggregation in the current server.

The following is an example of a local aggregation. customer is a cloned table.

```
\EXPLAIN PLAN
SELECT COUNT(DISTINCT c_nationkey)
  FROM customer;
>>>  start print plan
< Execution Plan >
================================================================================
¦IDX¦  NODE DESCRIPTION                                          ¦   ROWS ¦
--------------------------------------------------------------------------------
¦ 0 ¦  SELECT STATEMENT                                          ¦      1 ¦
¦ 1 ¦    QUERY BLOCK ("$QB_IDX_2")                               ¦      1 ¦
¦ 2 ¦      AGGREGATION BY HASH                                   ¦      1 ¦
```

```
| 3 |        INDEX ACCESS ("CUSTOMER", "CUSTOMER_NATIONKEY_FK")   | 150000 |
================================================================================
     1  -  TARGET : COUNT( DISTINCT CUSTOMER.C_NATIONKEY )
     2  -  DISTINCT AGGREGATION : COUNT( DISTINCT CUSTOMER.C_NATIONKEY )
     3  -  CLONED
           READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
<<<  end print plan
```

Remote Aggregation

It performs aggregation in each server.

Aggregation processing in each server has a parallel processing effect. Also, generally aggregation reduce s results, so it reduces the network cost to bring the data.

```
\EXPLAIN PLAN
SELECT sum(ps_supplycost * ps_availqty) * 0.0001
  FROM partsupp,
       supplier,
       nation
 WHERE ps_suppkey = s_suppkey
   AND s_nationkey = n_nationkey
   AND n_name = 'GERMANY';
>>>  start print plan
< Execution Plan >
================================================================================

        MAX RANGE : _A1.PS_SUPPKEY = {_A2.S_SUPPKEY}
```

```
<<<  end print plan
```

In the execution plan above, it fetched aggregation results from G1, G2, G3, then performed re-aggregat
ion and returned the result.

15.5 Statistics Information

A query optimizer calculates the cost by using the statistics information. The statistics information used by a query optimizer are table statistics information, column statistics information, index statistics informatio n.

- Table statistics information
  - The number of rows
  - The number of pages
- Column statistics information
  - The number of each different values
  - The number of NULL values
  - The average length of value
  - The minimum value
  - The maximum value
- Index statistics information
  - The number of each different keys
  - The number of pages
  - The number of leaf pages
  - The tree level
  - The clustering factor of the index

Perform **ANALYZE TABLE** statement to build the statistics information. The built statistics information is st ored in the database, and the same statistics information is used until it is rebuilt.

If the statistics information is not built for a table, then build a simple statistics information by using a cat alog information and the page information at the time of query execution and use it.

Adjusting Optimizer

Generally, a query optimizer select the most efficient plan by using the given statistics information. Howe ver, there could be a better plan than the plan selected by a query optimizer, so a user can specify to sele ct the plan when it was not selected by a query optimizer.

Currently, a query optimizer of GOLDILOCKS provides a hint, and the hint specified by a user is preferenti ally applied when it is applicable regardless of the calculated cost. Therefore, if the better plan exists, a us er can forcibly change the plan by using a hint.

For more information about hints, refer to **SQL Hint**.

15.6 SQL Hint

Description

A hint is a comment which is used by a user to directly instruct the GOLDILOCKS optimizer how to perform the SQL statement. The user uses the hint to select the execution plan when GOLDILOCKS optimizer can not select the appropriate execution plan due to an inaccurate statistics information.

GOLDILOCKS optimizer preferentially selects the user defined hints to when selecting the execution plan. However, if the hint specified by the user is not available, then GOLDILOCKS optimizer selects the plan by itself.

If a user specifies a hint, then GOLDILOCKS optimizer is operated as described in the hint as possible. Therefore, it is recommended to use the hint only when GOLDILOCKS optimizer determines that SQL execution plan is wrong.

Especially, if a hint is used when repeatedly using the same SQL statements, then GOLDILOCKS optimizer performs the SQL statement according to the described hint. In this case, the data in other tables or views including that SQL statement is updated, so the performance may be degraded.

The hint in GOLDILOCKS can be used in SELECT, INSERT SELECT, UPDATE, DELETE statements. The hint should be described next to the keyword of each statement between /*+ keyword and */ keywords.

Syntax

The following is a hint syntax.

```
<hint clause> ::=
    /*+ <hint element> [ comment ] [ [ , ] <hint element> [ comment ] ] */
<hint element> ::=
      <statement hints>
    ¦ <query block hints>

Invocation and Access Rules

The user should have the privilege to perform the query to perform <hint clause> statement.

Syntax Rules and Parameters

The followings are syntax rules to use <hint clause>.

- Multiple <hint element> can be described by using white space or comma (,) in <hint clause>.
- If there are two or more <hint element> and they can not be applied simultaneously, then only the pr eviously described <hint element> is applied.
- If a syntactic error occurs in <hint element>, then the <hint element> is ignored, and if hint_error pro perty is turned on, then it is processed as a validation error for <hint clause>.
- table_name and view_name described in <hint clause> should be matched with one of table_name, v iew_name described in <from clause> or aliases indicating them.
- table_name can not be described together with a schema name.
- Even when <hint element> is correctly described, but if it is not applicable, then the <hint element>is i gnored.

Examples

The following is an example of using <hint clause> in SELECT, INSERT SELECT, UPDATE, DELETE statemen t.

- Using <hint clause> in SELECT statement

```
SELECT /*+ INDEX(orders, o_orderdate_idx) */ *
  FROM orders
 WHERE o_orderdate < date '2019-04-12';
```

- Using <hint clause> in INSERT SELECT statement

```
INSERT INTO orders_bk SELECT /*+ INDEX(orders, o_orderdate_idx) */ *
                        FROM orders
                       WHERE o_orderdate < date '2019-04-12';
```

- Using <hint clause> in UPDATE statement

```
UPDATE /*+ INDEX(lineitem, l_shipdate_idx) */ * lineitem
   SET l_receiptdate = CURRENT_DATE
 WHERE l_shipdate = date '2020-04-12';
```

- Using <hint clause> in DELETE statement

```
DELETE /*+ INDEX(lineitem, l_shipdate_idx) */ * lineitem
 WHERE l_receiptdate < date '2020-04-12';
```

The following is an example of incorrectly using a hint after setting HINT_ERROR property to *ON* by using ALTER statement.

```
ALTER SESSION SET HINT_ERROR = ON;
SELECT /*+ INDEX(orders, o_orderdate_idxx) */ *
  FROM orders
 WHERE o_orderdate < date '2019-04-12';
ERR-42000(16058): not applicable hint ( cannot find index ) :
SELECT /*+ INDEX(orders, o_orderdate_idxx) */ *
                          *
ERROR at line 1:
```

For more information about descriptions and examples of all hints, refer to **Query Block Hint** and **Operation Hint**.

Statement Hint

Those hints are applied per each statement.

<dml hints>

DML_GLOBAL_ROWID

When processing DML statement in cluster environment, a node received a user query transfers the updated information of the record to another node, then applies it.

DML statement in cluster environment is processed with the following two methods.

- Query based DML: It creates a new query to transfer the updated statement.
- Global rowid based DML: It uses the record identifier information to transfer the updated information of a specific record.

If DML_GLOBAL_ROWID hint is specified, then the global rowid based DML method is preferentially appli ed.
This hint is applied to SELECT FOR UPDATE, INSERT, UPDATE, DELETE statements.

The following is an example of applying the query based DML.

```
\EXPLAIN PLAN
DELETE FROM orders;
>>>  start print plan
< Execution Plan >
=============================================================================

```

〈fetch fail over hints〉

FETCH_FAIL_OVER

The fetch fail over feature provides an intact fetch result by considering communication error situation w hile performing fetch for SELECT statement in cluster environment.
Using FETCH_FAIL_OVER hint enables the fetch fail over feature.
This hint is applied to SELECT statement.

The following is an example of using FETCH_FAIL_OVER hint.

```
\EXPLAIN PLAN
SELECT /*+ FETCH_FAIL_OVER */ o_orderkey FROM orders;
>>>  start print plan
< Execution Plan >
=========================================================================
¦  IDX  ¦  NODE DESCRIPTION                                              ¦
-------------------------------------------------------------------------

     3  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : ORDERS.O_ORDERKEY
<<<  end print plan
```

Query Block Hint

Those hints are applied per each query block.

〈push subquery hints〉

PUSH_SUBQ

If PUSH_SUBQ hint is specified, then an optimizer pushes the subquery to the lowest node of available ex ecution plan nodes. It is a hint for a subquery which is not unnested, so PUSH_SUBQ hint is ignored when 〈unnest subquery hints〉 is specified beforehand.

If PUSH_SUBQ hint is not specified, then an optimizer calculates a cost, then pushes the subquery to the node whose cost is the best.

If PUSH_SUBQ hint is used, the subquery is applied unnested as soon as possible. Therefore, the performa nce is upgraded, when subquery filtering has a large effect and the intermediate result can be stored by p erforming the subquery only once.
The following is an example of using PUSH_SUBQ hint in this case.

```
\EXPLAIN PLAN
SELECT
       c_name,
       o_totalprice
  FROM
       customer,
       orders,
       lineitem
 WHERE c_custkey = o_custkey
   AND o_orderkey = l_orderkey
   AND o_orderkey IN (
                       SELECT   /*+ PUSH_SUBQ */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     );
>>>  start print plan
< Execution Plan >
=========================================================================

           ON FILTER (Equi) : ORDERS.O_ORDERKEY = LINEITEM.L_ORDERKEY
     4  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_TOTALPRICE
           POST FILTER : ( ORDERS.O_ORDERKEY ) IN ( $V8.L_ORDERKEY )
     5  -  READ INDEX COLUMN : LINEITEM.L_ORDERKEY
           MIN RANGE : LINEITEM.L_ORDERKEY >= {ORDERS.O_ORDERKEY}
           MAX RANGE : LINEITEM.L_ORDERKEY IS NOT NULL
     6  -  READ INDEX COLUMN : CUSTOMER.C_CUSTKEY
           READ TABLE COLUMN : CUSTOMER.C_NAME
           MIN RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
           MAX RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
           FETCH ONE ROW
     8  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     9  -  TARGET : LINEITEM.L_ORDERKEY
    10  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
    11  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The subquery in the example above can be performed either in join or on orders, and it is performed on *INDEX ACCESS ("ORDERS")* which is the lowest node of available execution nodes, and it is not unnested

either.

NO_PUSH_SUBQ

If NO_PUSH_SUBQ hint is specified, then an optimizer does not push the subquery. Therefore, the subquery is performed on the top node of available execution plan nodes. It is a hint for a subquery which is not unnested, so NO_PUSH_SUBQ hint is ignored when <unnest subquery hints> is specified beforehand.

If NO_PUSH_SUBQ hint is not specified, then an optimizer calculates a cost, then pushes the subquery to the node whose cost is the best.

If NO_PUSH_SUBQ hint is specified, the subquery is applied unnested as late as possible. Therefore, if the subquery is applied before the intermediate result is reduced by the join when the subquery filtering has a small effect and the subquery is repeatedly performed, then the performance gets slow because the subquery is repeatedly performed. In this case, it is recommended to delay the time of applying the subquery as long as possible by using NO_PUSH_SUBQ hint.

The following is an example of using NO_PUSH_SUBQ hint in this case.

```
\EXPLAIN PLAN
SELECT
       c_name,
       o_totalprice
  FROM
       customer,
       orders,
       lineitem
 WHERE c_custkey = o_custkey
   AND o_orderkey = l_orderkey
   AND o_orderkey IN (
                       SELECT   /*+ NO_PUSH_SUBQ */
                              l_orderkey
                         FROM  lineitem
                        WHERE  o_orderdate = l_shipdate
                      );
>>>  start print plan
< Execution Plan >
============================================================================

             ON FILTER (Equi) : ORDERS.O_ORDERKEY = LINEITEM.L_ORDERKEY
     4  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     5  -  READ INDEX COLUMN : LINEITEM.L_ORDERKEY
             MIN RANGE : LINEITEM.L_ORDERKEY >= {ORDERS.O_ORDERKEY}
             MAX RANGE : LINEITEM.L_ORDERKEY IS NOT NULL
     6  -  READ INDEX COLUMN : CUSTOMER.C_CUSTKEY
           READ TABLE COLUMN : CUSTOMER.C_NAME
             MIN RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
             MAX RANGE : CUSTOMER.C_CUSTKEY = {ORDERS.O_CUSTKEY}
           FETCH ONE ROW
     8  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     9  -  TARGET : LINEITEM.L_ORDERKEY
    10  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_SHIPDATE
             PHYSICAL FILTER : LINEITEM.L_SHIPDATE = {ORDERS.O_ORDERDATE}
```

The subquery in the example above can be performed either in nested join, merge join or orders index ac cess, and it is performed on NESTED JOIN (INNER JOIN) which is the top node of available execution node s.

〈 cte query hints 〉

This hint is for the query block of the common table expression.

The common table expression is performed either in inline method or in materialize method.

- Inline method: It is performed in the form of inline view.

- Materialize method: It stores the result of the common table expression in an instant, then perform t he query by reading rows from the instant table.

Generally, in case of when using the common table expression only once, then it is performed in inline m ethod. In case of when using the common table expression two or more times, then it is performed in ma terialize method.

INLINE

INLINE hint is valid only in a query block of the common table expression, and if this hint is specified, then the common table expression is performed like as inline view.

The following is an example of using INLINE hint.

```
gSQL> \explain plan
WITH revenue ( supplier_no, total_revenue ) AS
     (
        SELECT /*+ INLINE */
               l_suppkey,
               SUM(l_extendedprice * (1 - l_discount))
          FROM lineitem
         WHERE l_shipdate >= DATE '1996-01-01'
           AND l_shipdate < DATE '1996-01-01' + INTERVAL '3' MONTH
         GROUP BY
               l_suppkey
     )
SELECT
    s_suppkey,
    s_name,
    ROUND( total_revenue, 2 ) as total_revenue
FROM
    supplier,
    revenue
WHERE
      s_suppkey = supplier_no
  AND total_revenue = (
                        select
                            max(total_revenue)
                        from
                            revenue
                      )
ORDER BY
   s_suppkey;
```

<<<  end print plan
```

In the query above, revenue defined in WITH clause is used twice in SELECT query.
In this case, it is recommended to process it in materialize method not to perform revenue multiple times. However, if the cost of materialize is bigger than that of performing it twice, then use INLINE hint to prev ent it performing in materialize method.

MATERIALIZE

MATERIALIZE hint is valid only in a query block of the common table expression, and if this hint is specifie d, then the common table expression is performed once and the result is stored in an instant table.

The following is an example of using MATERIALIZE hint.

```
gSQL> \explain plan
WITH revenue ( supplier_no, total_revenue ) AS
     (
```

```
        SELECT /*+ MATERIALIZE */
               l_suppkey,
               SUM(l_extendedprice * (1 - l_discount))
          FROM lineitem
         WHERE l_shipdate >= DATE '1996-01-01'
           AND l_shipdate < DATE '1996-01-01' + INTERVAL '3' MONTH
         GROUP BY
               l_suppkey
     )
SELECT
    s_suppkey,
    s_name,
    ROUND( total_revenue, 2 ) as total_revenue
FROM
    supplier,
    revenue
WHERE
      s_suppkey = supplier_no
  AND total_revenue = (
                        select
                            max(total_revenue)
                        from
                            revenue
                       )
ORDER BY
   s_suppkey;
S_SUPPKEY S_NAME                    TOTAL_REVENUE

    15  -  READ COLUMN : REVENUE.TOTAL_REVENUE
           AGGREGATION : MAX( REVENUE.TOTAL_REVENUE )
<<<  end print plan
```

In the query above, revenue defined in WITH clause is used twice in SELECT query.
When performing it in materialize method, then it performs the common table expression only once and stores the result in an instant table, then uses it, so the operating time is reduced.

NO_QUERY_TRANSFORMATION

If NO_QUERY_TRANSFORMATION hint is specified, then the query block in which the hint is specified an d all query blocks below it do not perform the query transformation.

The following is an example of using NO_QUERY_TRANSFORMATION hint.

```
\EXPLAIN PLAN
SELECT /*+ NO_QUERY_TRANSFORMATION */
       s_name,
       l_quantity
  FROM supplier,
       (
        SELECT
               l_suppkey,
               l_quantity
          FROM lineitem
         WHERE l_shipdate >= date '1996-01-01'
           AND l_shipdate < date '1996-01-01' + interval '3' month
       ) lineitem_view
 WHERE s_suppkey = l_suppkey
   AND s_nationkey IN (
                        SELECT n_nationkey
                          FROM nation
                         WHERE n_name = 'FRANCE' OR n_name = 'GERMANY'
                       )
;
>>>  start print plan
< Execution Plan >
```

```

```

A simple view merging and a subquery unnesting can be applied in the example above, but neither of th ose query transformation method are applied due to NO_QUERY_TRANSFORMATION hint.

〈unnest subquery hints〉

<unnest subquery hints> are <unnest hints>, <unnest join operation hints>, <unnest join driver hints>, <unnest join pusher hints>, <unnest merge hints>.

Subquery unnesting is a part of the query transformation process. Therefore, if NO_QUERY_TRANSFORMATION hint is specified, then subquery unnesting is not performed.

If NO_QUERY_TRANSFORMATION hint and <unnest subquery hints> are simultaneously specified in the same subquery, then the first specified hint is applied only and other hints are ignored.

If <push subquery hinst> and <unnest subquery hints> are simultaneously specified in the same subquery, then then the first specified hint is applied only and other hints are ignored as well. It is because that it can not be applied together with <unnest subquery hints> because <push subquery hints> is a hint for an unnested subquery.

Descriptions and examples for the hints are as follows.

<unnest hints>

UNNEST

If UNNEST hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result. However, the hint can be applied when it satisfies the subquery unnesting constraints. If the hint is not applicable to the subquery, then the hint is ignored.
For more information about constraints, refer to **SubQuery Unnesting**.

The following is an example of using UNNEST hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan

     6  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     7  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
             MIN RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
             MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
           FETCH ONE ROW
<<<  end print plan
```

NO_UNNEST

If NO_UNNEST hint is specified, an optimizer does not unnest a subquery. In other words, the subquery is filtered as it is.

The following is an example of using NO_UNNEST hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ NO_UNNEST */
                               l_orderkey
```

```
                      FROM   lineitem
                    GROUP BY l_orderkey
                    HAVING   sum(l_quantity) > 300
                  )
;
no rows selected.
>>>  start print plan
< Execution Plan >

```

〈unnest join operation hints〉

If 〈unnest join operation hints〉 is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join as specified by a hint.

UNNEST_NL

If UNNEST_NL hint is specified, an optimizer transforms the subquery into the join statement which guara ntees the same result, and performs the join by nested loop join method.

The following is an example of using UNNEST_NL hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ UNNEST_NL */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                                      |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                      |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                           |

     7  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
```

```
            MIN RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
            MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
          FETCH ONE ROW
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V4") and participates in NESTED JOIN.

UNNEST_NL_IN

If UNNEST_NL_IN hint is specified, an optimizer transforms the subquery into the join statement which gu arantees the same result, and performs the join by nested loop join method. Then, it places the subquery which is unnested to a table or a view, on the right of the join.

The following is an example of using UNNEST_NL_IN hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_NL_IN */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
=============================================================================

             LOGICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     7  -  READ INDEX COLUMN : LINEITEM.L_ORDERKEY
           READ TABLE COLUMN : LINEITEM.L_QUANTITY
             MIN RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
             MAX RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V5"), becomes a right child of NESTED J OIN and participates in the join.

UNNEST_NL_OUT

If UNNEST_NL_OUT hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by nested loop join method. Then, it places the subque ry which is unnested to a table or a view, on the left of the join.

The following is an example of using UNNEST_NL_OUT hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_NL_OUT */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan

           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V6"), becomes a right child of NESTED J OIN and participates in the join.

UNNEST_INL_OUT

If UNNEST_INL_OUT hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by instant nested loop join method. Then, it places the subquery which is unnested to a table or a view, on the left of the join.

The following is an example of using UNNEST_INL_OUT hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_INL_OUT */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
no rows selected.
>>>  start print plan
< Execution Plan >

             MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
     8  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V4"), becomes a left child of NESTED J OIN and participates in the join.

UNNEST_HASH

If UNNEST_HASH hint is specified, an optimizer transforms the subquery into the join statement which gu arantees the same result, and performs the join by hash join method.

The following is an example of using UNNEST_HASH hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
```

```
 WHERE o_orderkey IN (
                      SELECT   /*+ UNNEST_HASH */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan
< Execution Plan >
============================================================================

     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  HASH KEY : $V6.L_ORDERKEY
           READ KEY COLUMN : $V6.L_ORDERKEY
             HASH FILTER : $V6.L_ORDERKEY = ORDERS.O_ORDERKEY
           FETCH ONE ROW
     5  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     6  -  TARGET : LINEITEM.L_ORDERKEY
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V6") and participates in NESTED JOIN.

UNNEST_HASH(hash_bucket_count)

UNNEST_HASH(hash_bucket_count) hint is as same as UNNEST_HASH hint, but in addition to that it can specify the hash bucket count.
Therefore, if UNNEST_HASH(hash_bucket_count) hint is used, then it creates hash buckets as many as ha sh_bucket_count.

The following is an example of using UNNEST_HASH(hash_bucket_count) hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ UNNEST_HASH(3) */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      HASH JOIN (INNER JOIN)                                       |
|    3  |        TABLE ACCESS ("ORDERS")                                    |
|    4  |        HASH JOIN INSTANT                                          |
|    5  |          INLINE_VIEW ("$V6")                                      |
|    6  |            QUERY BLOCK ("$QB_IDX_6")                              |
|    7  |              GROUP HASH INSTANT                                   |
|    8  |                TABLE ACCESS ("LINEITEM")                          |
============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  HASH KEY : $V6.L_ORDERKEY
           READ KEY COLUMN : $V6.L_ORDERKEY
```

```
            HASH FILTER : $V6.L_ORDERKEY = ORDERS.O_ORDERKEY
          FETCH ONE ROW
     5  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     6  -  TARGET : LINEITEM.L_ORDERKEY
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
          RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
          READ KEY COLUMN : LINEITEM.L_ORDERKEY
          READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
            PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The execution plan is as same as the example of using UNNEST_HASH hint, but hash buckets are created in HASH JOIN INSTANT as many as hash bucket count when using the hint above. Therefore, use this hint to adjust hash bucket count if the performance gets slower because hash bucket count is estimated too b ig or too small while performing cost estimation.

UNNEST_HASH_IN

If UNNEST_HASH_IN hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by hash join method. Then, it places the subquery whi ch is unnested to a table or a view, on the right of the join.

The following is an example of using UNNEST_HASH_IN hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_HASH_IN */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
================================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                     ¦
--------------------------------------------------------------------------------
```

```
|    0  |  SELECT STATEMENT                                          |

     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V4"), becomes a right child of NESTED J OIN and participates in the join.

UNNEST_HASH_IN(hash_bucket_count)

UNNEST_HASH_IN(hash_bucket_count) hint is as same as UNNEST_HASH_IN hint, but in addition to that it can specify the hash bucket count.
Therefore, if UNNEST_HASH_IN(hash_bucket_count) hint is used, then it creates hash buckets as many as hash_bucket_count.

The following is an example of using UNNEST_HASH_IN(hash_bucket_count) hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
```

```
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_HASH_IN(3) */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
============================================================================

           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The execution plan is as same as the example of using UNNEST_HASH_IN hint, but hash buckets are created in HASH JOIN INSTANT as many as hash bucket count when using the hint above. Therefore, use this hint to adjust hash bucket count if the performance gets slower because hash bucket count is estimated too big or too small while performing cost estimation.

UNNEST_HASH_OUT

If UNNEST_HASH_OUT hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by hash join method. Then, it places the subquery which is unnested to a table or a view, on the left of the join.

The following is an example of using UNNEST_HASH_OUT hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_HASH_OUT */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
=============================================================================

|    5  |            GROUP HASH INSTANT                                     |
|    6  |              TABLE ACCESS ("LINEITEM")                            |
|    7  |        HASH JOIN INSTANT                                          |
|    8  |          TABLE ACCESS ("ORDERS")                                  |
=============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
```

```
     3  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     4  -  TARGET : LINEITEM.L_ORDERKEY
     5  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     6  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     7  -  HASH KEY : ORDERS.O_ORDERKEY
           RECORD COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
           READ KEY COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
             HASH FILTER : ORDERS.O_ORDERKEY = $V4.L_ORDERKEY
           FETCH ONE ROW
     8  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V4"), becomes a left child of HASH JOI N and participates in the join.

UNNEST_HASH_OUT(hash_bucket_count)

UNNEST_HASH_OUT(hash_bucket_count) hint is as same as UNNEST_HASH_OUT hint, but in addition to that it can specify the hash bucket count.
Therefore, if UNNEST_HASH_OUT(hash_bucket_count) hint is used, then it creates hash buckets as many as hash_bucket_count.

The following is an example of using UNNEST_HASH_OUT(hash_bucket_count) hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_HASH_OUT(3) */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
```

```
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      HASH JOIN (INNER JOIN)                                       |
|    3  |        INLINE_VIEW ("$V4")                                        |
|    4  |          QUERY BLOCK ("$QB_IDX_6")                                |
|    5  |            GROUP HASH INSTANT                                     |
|    6  |              TABLE ACCESS ("LINEITEM")                            |
|    7  |        HASH JOIN INSTANT                                          |
|    8  |          TABLE ACCESS ("ORDERS")                                  |
============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     4  -  TARGET : LINEITEM.L_ORDERKEY
     5  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     6  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     7  -  HASH KEY : ORDERS.O_ORDERKEY
           RECORD COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
           READ KEY COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
             HASH FILTER : ORDERS.O_ORDERKEY = $V4.L_ORDERKEY
           FETCH ONE ROW
     8  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
<<<  end print plan
```

The execution plan is as same as the example of using UNNEST_HASH_OUT hint, but hash buckets are cr eated in HASH JOIN INSTANT as many as hash bucket count when using the hint above. Therefore, use th is hint to adjust hash bucket count if the performance gets slower because hash bucket count is estimate d too big or too small while performing cost estimation.

UNNEST_MERGE

If UNNEST_MERGE hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by merge join method.

The following is an example of using UNNEST_MERGE hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_MERGE */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      MERGE JOIN (INNER JOIN)                                      |
|    3  |        INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")                 |
|    4  |        SORT JOIN INSTANT                                          |
|    5  |          INLINE_VIEW ("$V6")                                      |
|    6  |            QUERY BLOCK ("$QB_IDX_6")                              |
|    7  |              GROUP HASH INSTANT                                   |
|    8  |                TABLE ACCESS ("LINEITEM")                          |
============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
           ON FILTER (Equi) : ORDERS.O_ORDERKEY = $V6.L_ORDERKEY
     3  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  SORT KEY : "$V6.L_ORDERKEY ASC NULLS LAST"
           READ KEY COLUMN : $V6.L_ORDERKEY
           MIN RANGE : $V6.L_ORDERKEY >= {ORDERS.O_ORDERKEY}
           MAX RANGE : $V6.L_ORDERKEY IS NOT NULL
     5  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     6  -  TARGET : LINEITEM.L_ORDERKEY
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
```

```
            READ KEY COLUMN : LINEITEM.L_ORDERKEY
            READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
              PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
      8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V6"), and participates in MERGE JOIN.

UNNEST_MERGE_IN

If UNNEST_MERGE_IN hint is specified, an optimizer transforms the subquery into the join statement whi ch guarantees the same result, and performs the join by merge join method. Then, it places the subquery which is unnested to a table or a view, on the right of the join.

The following is an example of using UNNEST_MERGE_IN hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ UNNEST_MERGE_IN */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      MERGE JOIN (INNER JOIN)                                      |
|    3  |        INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")                 |
|    4  |        SORT JOIN INSTANT                                          |
|    5  |          INLINE_VIEW ("$V6")                                      |
|    6  |            QUERY BLOCK ("$QB_IDX_6")                              |

|    8  |                TABLE ACCESS ("LINEITEM")                          |
```

```
=======================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
             ON FILTER (Equi) : ORDERS.O_ORDERKEY = $V6.L_ORDERKEY
     3  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  SORT KEY : "$V6.L_ORDERKEY ASC NULLS LAST"
           READ KEY COLUMN : $V6.L_ORDERKEY
             MIN RANGE : $V6.L_ORDERKEY >= {ORDERS.O_ORDERKEY}
             MAX RANGE : $V6.L_ORDERKEY IS NOT NULL
     5  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     6  -  TARGET : LINEITEM.L_ORDERKEY
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V6"), becomes a right child of MERGE JOIN and participates in the join.

UNNEST_MERGE_OUT

If UNNEST_MERGE_OUT hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result, and performs the join by merge join method. Then, it places the subquery which is unnested to a table or a view, on the left of the join.

The following is an example of using UNNEST_MERGE_OUT hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ UNNEST_MERGE_OUT */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
```

```
;
>>>  start print plan
< Execution Plan >

¦    8  ¦        INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")               ¦
=============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
             ON FILTER (Equi) : $V5.L_ORDERKEY = ORDERS.O_ORDERKEY
     3  -  SORT KEY : "$V5.L_ORDERKEY ASC NULLS LAST"
           READ KEY COLUMN : $V5.L_ORDERKEY
     4  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     5  -  TARGET : LINEITEM.L_ORDERKEY
     6  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     7  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     8  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
             MIN RANGE : ORDERS.O_ORDERKEY >= {$V5.L_ORDERKEY}
             MAX RANGE : ORDERS.O_ORDERKEY IS NOT NULL
<<<  end print plan
```

In the example above, a subquery is unnested to INLINE_VIEW ("$V5"), becomes a left child of MERGE JO IN and participates in the join.

NL_SJ

If NL_SJ hint is specified, an optimizer unnests the subquery in semi join form, and performs the semi join in nested loop method.

It is operated in the same way as that of UNNEST_NL hint. However, UNNEST_NL hint is applied to both s emi join and anti-semi join, on the other hand, NL_SJ hint is applied only to semi join.
Therefore, if the hint above is specified on a subquery which is unnested with anti-semi join, then an opti mizer ignores it.

The following is an example of using NL_SJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ NL_SJ */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      NESTED JOIN (INNER JOIN)                                     |
|    3  |        TABLE ACCESS ("ORDERS")                                    |
|    4  |        INLINE_VIEW ("$V5")                                        |
|    5  |          QUERY BLOCK ("$QB_IDX_6")                                |
|    6  |            GROUP                                                  |
|    7  |              INDEX ACCESS ("LINEITEM", "LINEITEM_PK_INDEX")       |
=============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     5  -  TARGET : LINEITEM.L_ORDERKEY
```

```
     6  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             LOGICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     7  -  READ INDEX COLUMN : LINEITEM.L_ORDERKEY
           READ TABLE COLUMN : LINEITEM.L_QUANTITY
             MIN RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
             MAX RANGE : LINEITEM.L_ORDERKEY = {ORDERS.O_ORDERKEY}
<<<  end print plan
```

In the example above, NL_SJ hint is applied so a subquery is unnested with semi join and nested loop join is performed. Also, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

The following is an example of using NL_SJ hint on a subquery which can be unnested only in anti-semi j oin form.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey NOT IN (
                           SELECT   /*+ NL_SJ */
                                    l_orderkey
                             FROM   lineitem

     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The hint is ignored so it is unnested by anti-semi join method, then performed in hash join method.

NL_ISJ

If NL_ISJ hint is specified, an optimizer unnests the subquery in inverted semi join form, and performs the semi join in nested loop method. Then, it places the subquery which is unnested to a table or a view, on t he left of the join because it is an inversted semi join.

It is operated in the same way as that of UNNEST_NL_OUT hint. However, UNNEST_NL_OUT hint is applie d to both semi join and anti-semi join, on the other hand, NL_ISJ hint is applied only to semi join. Therefore, if the hint above is specified on a subquery which is unnested with anti-semi join, then an opti mizer ignores it.

The following is an example of using NL_ISJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ NL_ISJ */
                               l_orderkey
                        FROM   lineitem
```

```
                    GROUP BY l_orderkey
                    HAVING   sum(l_quantity) > 300
                  )
;
>>>  start print plan
< Execution Plan >
============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                 ¦

           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     6  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     7  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
             MIN RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
             MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
           FETCH ONE ROW
<<<  end print plan
```

In the example above, NL_ISJ hint is applied so a subquery is unnested with inverted semi join and nested loop join is performed. Also, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

The following is an example of using NL_ISJ hint in a subquery which can be unnested only in anti-semi jo in form.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey NOT IN (
                          SELECT   /*+ NL_ISJ */
                                   l_orderkey
                            FROM   lineitem
                           GROUP BY l_orderkey
                           HAVING   sum(l_quantity) > 300
                         )
;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      HASH JOIN (ANTI SEMI)                                        |
|    3  |        TABLE ACCESS ("ORDERS")                                    |
|    4  |        HASH JOIN INSTANT (UNIQUE)                                 |
|    5  |          INLINE_VIEW ("$V6")                                      |
|    6  |            QUERY BLOCK ("$QB_IDX_6")                              |
|    7  |              GROUP HASH INSTANT                                   |
|    8  |                TABLE ACCESS ("LINEITEM")                          |
=============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  READ COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
     4  -  HASH KEY : $V6.L_ORDERKEY
           READ KEY COLUMN : $V6.L_ORDERKEY
             HASH FILTER : $V6.L_ORDERKEY = ORDERS.O_ORDERKEY
           FETCH ONE ROW
     5  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     6  -  TARGET : LINEITEM.L_ORDERKEY
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
```

```
            PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The hint is ignored so it is unnested by anti-semi join method, performed in hash join method, and the un nested subquery is located on the right.

INL_SJ

If INL_SJ hint is specified, an optimizer unnests the subquery in semi join form, and performs the semi join in instant nested loop method.

It is operated in the same way as that of UNNEST_INL hint. However, UNNEST_INL hint is applied to both semi join and anti-semi join, on the other hand, INL_SJ hint is applied only to semi join. Therefore, if the h int above is specified on a subquery which is unnested with anti-semi join, then an optimizer ignores it.

The following is an example of using INL_SJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ INL_SJ */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                      )
;
>>>  start print plan
< Execution Plan >

<<<  end print plan
```

The hint is ignored so it is unnested by anti-semi join method, then performed in hash join method.

MERGE_SJ

If MERGE_SJ hint is specified, an optimizer unnests the subquery in semi join form, and performs the sem i join in merge join method.

It is operated in the same way as that of UNNEST_MERGE hint. However, UNNEST_MERGE hint is applied to both semi join and anti-semi join, on the other hand, MERGE_SJ hint is applied only to semi join. Therefore, if the hint above is specified on a subquery which is unnested with anti-semi join, then an opti mizer ignores it.

The following is an example of using MERGE_SJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ MERGE_SJ */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan

```
     7  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the example above, MERGE_SJ hint is applied so a subquery is unnested with semi join and merge join is performed. Also, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

The following is an example of using MERGE_SJ hint in a subquery which can be unnested only in anti-se mi join form.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey NOT IN (
                          SELECT   /*+ MERGE_SJ */
                                   l_orderkey
                            FROM   lineitem
                           GROUP BY l_orderkey
                           HAVING   sum(l_quantity) > 300
                         )
;
>>>  start print plan
< Execution Plan >

```

The hint is ignored so it is unnested by anti-semi join method, then performed in hash join method.

HASH_SJ

If HASH_SJ hint is specified, an optimizer unnests the subquery in semi join form, and performs the semi j oin in hash join method.

It is operated in the same way as that of UNNEST_HASH hint. However, UNNEST_HASH hint is applied to both semi join and anti-semi join, on the other hand, HASH_SJ hint is applied only to semi join. Therefore, if the hint above is specified on a subquery which is unnested with anti-semi join, then an optimizer ignor es it.

The following is an example of using HASH_SJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ HASH_SJ */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
```

```
                    )

The hint is ignored so it is unnested by anti-semi join method, then performed in nested loop join metho d.

HASH_ISJ

If HASH_ISJ hint is specified, an optimizer unnests the subquery in inverted semi join form, and performs t he join in hash join method.

It is operated in the same way as that of UNNEST_HASH_OUT hint. However, UNNEST_HASH_OUT hint is applied to both semi join and anti-semi join, on the other hand, HASH_ISJ hint is applied only to semi join. Therefore, if the hint above is specified on a subquery which is unnested with anti-semi join, then an opti mizer ignores it.

The following is an example of using HASH_ISJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ HASH_ISJ */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan
```

```

```

The hint is ignored so it is unnested by semi join method, then performed in hash join method. Also, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

INL_AJ

If INL_AJ hint is specified, an optimizer unnests the subquery in anti-semi join form, and performs the join in instant nested loop join method.

It is operated in the same way as that of UNNEST_INL hint. However, UNNEST_INL hint is applied to both semi join and anti-semi join, on the other hand, INL_AJ hint is applied only to anti-semi join. Therefore, if the hint above is specified on a subquery which is unnested with semi join, then an optimizer ignores it.

The following is an example of using INL_AJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey NOT IN (
                          SELECT   /*+ INL_AJ */
```

```
                              l_orderkey
                       FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >

             MIN RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
             MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
```

```
           FETCH ONE ROW
<<<  end print plan
```

The hint is ignored so it is unnested by semi join method, then performed in nested loop join method. Als o, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

MERGE_AJ

If MERGE_AJ hint is specified, an optimizer unnests the subquery in anti-semi join form, and performs the join in merge join method.

It is operated in the same way as that of UNNEST_MERGE hint. However, UNNEST_MERGE hint is applied to both semi join and anti-semi join, on the other hand, MERGE_AJ hint is applied only to anti-semi join. Therefore, if the hint above is specified on a subquery which is unnested with semi join, then an optimize r ignores it.

The following is an example of using MERGE_AJ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey NOT IN (
                           SELECT   /*+ MERGE_AJ */
                                    l_orderkey
                             FROM   lineitem
                            GROUP BY l_orderkey
                            HAVING   sum(l_quantity) > 300
                          )
;
>>>  start print plan

     8  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

The following is an example of using HASH_AJ hint in a subquery which can be unnested only in semi join form.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ HASH_AJ */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                    )
;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      NESTED JOIN (INNER JOIN)                                     |
|    3  |        INLINE_VIEW ("$V4")                                        |
|    4  |          QUERY BLOCK ("$QB_IDX_6")                                |
|    5  |            GROUP HASH INSTANT                                     |
|    6  |              TABLE ACCESS ("LINEITEM")                            |
|    7  |        INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")                 |
=============================================================================
     1  -  TARGET : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     2  -  JOINED COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_TOTALPRICE
     3  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     4  -  TARGET : LINEITEM.L_ORDERKEY
     5  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
```

```
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
     6  -  READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
     7  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_TOTALPRICE, ORDERS.O_ORDERDATE
             MIN RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
             MAX RANGE : ORDERS.O_ORDERKEY = {$V4.L_ORDERKEY}
           FETCH ONE ROW
<<<  end print plan
```

The hint is ignored so it is unnested by semi join method, then performed in nested loop join method. Als o, the semi join is converted into an inner join because both o_orderkey and l_orderkey are primary keys.

〈unnest join driver hints〉

Those hints are available when performing subquery unnesting in the cluster system. They are ignored in the standalone system.

LOCAL_UNNEST

If LOCAL_UNNEST hint is specified, an optimizer transforms the subquery into the join statement which g uarantees the same result, then performs the join in a local. In other words, it performs the join by bring r esults of both a left child and a right child to the local.

The following is an example of using LOCAL_UNNEST hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ LOCAL_UNNEST */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                       HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >

           READ KEY COLUMN : $V8.L_ORDERKEY
             HASH FILTER : $V8.L_ORDERKEY = ORDERS.O_ORDERKEY
     6  -  SQL : SELECT /*+ NO_MERGE( _A1 ) */ * FROM ( SELECT /*+ USE_GROUP_HASH(10) FULL(
_A2 ) */ "_A2"."L_ORDERKEY" FROM "PUBLIC"."LINEITEM"@LOCAL AS "_A2" GROUP BY
"_A2"."L_ORDERKEY" HAVING SUM( "_A2"."L_QUANTITY" ) > :_V0 ) AS "_A1"("L_ORDERKEY")
           TARGET DOMAIN : G1(G1N1,G1N2) 0 rows, G2(G2N1,G2N2) 0 rows, G3(G3N1,G3N2) 0 rows
     7  -  COLUMN : LINEITEM.L_ORDERKEY AS L_ORDERKEY
     8  -  TARGET : LINEITEM.L_ORDERKEY
     9  -  GROUP KEY : LINEITEM.L_ORDERKEY
           RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
           READ KEY COLUMN : LINEITEM.L_ORDERKEY
           READ RECORD COLUMN : SUM( LINEITEM.L_QUANTITY )
             PHYSICAL FILTER : SUM( LINEITEM.L_QUANTITY ) > 300
    10  -  HASH SHARD ( # 3 )
           READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_QUANTITY
<<<  end print plan
```

In the execution plan above, HASH JOIN (INNER JOIN) is performed in local by bringing TABLE ACCESS ("ORDERS") result from PLAN BASED CLUSTER of IDX 3 and bringing INLINE_VIEW ("$V8") result from PL AN BASED CLUSTER of IDX 6.

REMOTE_UNNEST

If REMOTE_UNNEST hint is specified, an optimizer transforms the subquery into the join statement which guarantees the same result. Then it performs the join in remote. In other words, it performs the join in ea ch group.

The following is an example of using REMOTE_UNNEST hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
  FROM orders
 WHERE o_orderkey IN (
                      SELECT   /*+ REMOTE_UNNEST */
                               l_orderkey
                        FROM   lineitem
                      GROUP BY l_orderkey
                      HAVING   sum(l_quantity) > 300
                     )
;
>>>  start print plan
< Execution Plan >
=============================================================================

             MAX RANGE : ORDERS.O_ORDERKEY = {$V5.L_ORDERKEY}
           FETCH ONE ROW
<<<  end print plan
```

In the execution plan above, the join is performed in each group and join results are collected from PLAN BASED CLUSTER of IDX 2, then returned.

〈unnest join pusher hints〉

Those hints are available when performing subquery unnesting in the cluster system. They are ignored in the standalone system.

PUSHER_SUBQ

If PUSHER_SUBQ hint is specified, an optimizer transforms the subquery into the join statement which gu arantees the same result. Then, it builds the view or the table which was created by unnesting the subqu ery as a pusher table when performing the join in a remote.

The following is an example of using PUSHER_SUBQ hint.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ PUSHER_SUBQ */
                             l_partkey
                        FROM lineitem
                       WHERE l_shipdate = date'1998-12-01'
                    );
```

```
< Execution Plan >

<<<  end print plan
```

In [IDX 3] of the execution plan above, l_partkey creates a pusher table which is a shard key and the data read from [IDX 4] is stored. Then, remote semi joined is performed for part and the pusher table.

NO_PUSHER_SUBQ

If NO_PUSHER_SUBQ hint is specified, an optimizer transforms the subquery into the join statement whic h guarantees the same result. Then, it prevents to build the view or the table which was created by unnes ting the subquery as a pusher table when performing the join in a remote.

Therefore, the remote unnest may not be available, and a sibling table can be built as a pusher table.

The following is an example of using NO_PUSHER_SUBQ hint.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ NO_PUSHER_SUBQ */
                              l_partkey
                        FROM lineitem
                       WHERE l_shipdate = date'1998-12-01'
```

```
                    );
>>>  start print plan
< Execution Plan >

```

In the execution above, remote unnest is not performed, but local unnest is performed. In other words, it reads the data satisfying conditions from part and lineitem to G1, G2 and G3, then performs semi join in the current driver server.

The following is an example of using REMOTE_UNNEST hint and NO_PUSHER_SUBQ hint together.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ REMOTE_UNNEST NO_PUSHER_SUBQ */
                              l_partkey
                       FROM lineitem
                      WHERE l_shipdate = date'1998-12-01'
                    );
>>>  start print plan
< Execution Plan >

```

In the execution plan above, it can not accumulate a subquery in a pusher table, so it creates part as a clo ned pusher table, then performs remote join.

PUSHER_OUTQ

If PUSHER_OUTQ hint is specified, an optimizer transforms the subquery into the join statement which gu arantees the same result. Then, it accumulates a subquery of an outer table in a pusher table when perfor ming the join in a remote.

The following is an example of using PUSHER_OUTQ hint.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ PUSHER_OUTQ */
                              l_partkey
                       FROM lineitem
                      WHERE l_shipdate = date'1998-12-01'
                    );
< Execution Plan >

<<<  end print plan
```

PUSHER_OUTQ hint is applied when it is remote semi join.
If the cost of local semi join is better than that of remote semi join to which PUSHER_OUTQ was applied, then local semi join is selected. Therefore, whether the hint is applied can not be checked in the executio n plan.

Therefore, use REMOTE_UNNEST hint and PUSHER_OUTQ hint together as follows to check whether the hint is applied.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ REMOTE_UNNEST PUSHER_OUTQ */
                              l_partkey
                         FROM lineitem
                        WHERE l_shipdate = date'1998-12-01'
                      );
>>>  start print plan
< Execution Plan >

<<<  end print plan
```

In the execution plan above, it performs remote semi join and builds part which is a table of an outer que ry as a pusher table.

NO_PUSHER_OUTQ

If NO_PUSHER_OUTQ hint is specified, an optimizer transforms the subquery into the join statement whic h guarantees the same result. Then, it should not build an outer table of a subquery as a pusher table wh en performing the join in a remote.

The following is an example of using NO_PUSHER_OUTQ hint.

```
\EXPLAIN PLAN
SELECT p_name
  FROM part
 WHERE p_partkey IN ( SELECT /*+ NO_PUSHER_OUTQ */
                              l_partkey
                        FROM lineitem
                       WHERE l_shipdate = date'1998-12-01'
                    );
```

```
>>>  start print plan
< Execution Plan >

<<<  end print plan
```

In the execution plan above, it does not build part which is a table of an outer query as a pusher table, bu t it builds lineitem which is a table whose subquery is unnested as a pusher table.

〈unnest merge hints〉

If a subquery is unnested as a view, then the hint defines whether to merge the view.

MERGE_SUBQ

If a subquery is unnested as a view, then the hint merges the view.

The following is an example of using MERGE_SUBQ hint.

```
\EXPLAIN PLAN
SELECT
       o_orderdate,
       o_totalprice
```

```
  FROM orders
 WHERE o_orderkey IN (
                       SELECT   /*+ MERGE_SUBQ */
                                l_orderkey
                         FROM   lineitem
                       GROUP BY l_orderkey
                     )
;
no rows selected.
>>>  start print plan
< Execution Plan >
============================================================================

          FETCH ONE ROW
<<<  end print plan
```

In the execution plan above, if a subquery is unnested as a view, then the nested join is performed for the view as it is.

〈transitive closure hints〉

Those hints determine whether to apply the join transitive closure method.
For more information about join transitive closure, refer to **Join Transitive Closure**.

TRANSITIVE_CLOSURE

If TRANSITIVE_CLOSURE hint is specified, join transitive closure is applied during the rewriter process.

The following is an example of using TRANSITIVE_CLOSURE hint.

```
\EXPLAIN PLAN
SELECT /*+ TRANSITIVE_CLOSURE */
       l_extendedprice * (1 - l_discount) - ps_supplycost * l_quantity as amount
  FROM part,
       lineitem,
       partsupp
 WHERE ps_suppkey = l_suppkey
   AND ps_partkey = l_partkey
   AND p_partkey = l_partkey
   AND p_name like '%green%';
>>>  start print plan
< Execution Plan >
================================================================================

     5  -  READ INDEX COLUMN : PARTSUPP.PS_PARTKEY
           READ TABLE COLUMN : PARTSUPP.PS_SUPPKEY, PARTSUPP.PS_SUPPLYCOST
             MIN RANGE : PARTSUPP.PS_PARTKEY = {PART.P_PARTKEY}
             MAX RANGE : PARTSUPP.PS_PARTKEY = {PART.P_PARTKEY}
     6  -  READ INDEX COLUMN : LINEITEM.L_PARTKEY, LINEITEM.L_SUPPKEY
           READ TABLE COLUMN : LINEITEM.L_QUANTITY, LINEITEM.L_EXTENDEDPRICE,
LINEITEM.L_DISCOUNT
             MIN RANGE : LINEITEM.L_PARTKEY = {PART.P_PARTKEY} AND LINEITEM.L_SUPPKEY =
{PARTSUPP.PS_SUPPKEY}
             MAX RANGE : LINEITEM.L_PARTKEY = {PART.P_PARTKEY} AND LINEITEM.L_SUPPKEY =
{PARTSUPP.PS_SUPPKEY}
<<<  end print plan
```

A join condition does not exist in *partsupp* and *part* in the example query above, but the join condition (*ps_partkey = p_partkey*) exists in *partsupp* and *part* in the execution plan.

The user does not specify ps_partkey = p_partkey, but it is created through the relation such as ps_partkey = l_partkey AND p_partkey = l_partkey. The method creating a join condition by using another join condition in this way is called as join transitive closure. Therefore, part and partsupp can be joined first, so the join whose intermediate result are relatively fewer is preferencially performed so that the performance is upgraded.

NO_TRANSITIVE_CLOSURE

If NO_TRANSITIVE_CLOSURE hint is specified, join transitive closure is not applied during the rewriter process.

The following is an example of using NO_TRANSITIVE_CLOSURE hint.

```
\EXPLAIN PLAN
SELECT /*+ NO_TRANSITIVE_CLOSURE */
       l_extendedprice * (1 - l_discount) - ps_supplycost * l_quantity as amount
  FROM part,
       lineitem,
       partsupp
 WHERE ps_suppkey = l_suppkey
   AND ps_partkey = l_partkey
```

```
   AND p_partkey = l_partkey
   AND p_name like '%green%';
>>>  start print plan
< Execution Plan >

           RECORD COLUMN : LINEITEM.L_EXTENDEDPRICE, LINEITEM.L_DISCOUNT, LINEITEM.L_QUANTITY
           READ KEY COLUMN : LINEITEM.L_PARTKEY, LINEITEM.L_SUPPKEY, LINEITEM.L_EXTENDEDPRICE,
LINEITEM.L_DISCOUNT, LINEITEM.L_QUANTITY
             HASH FILTER : LINEITEM.L_PARTKEY = PARTSUPP.PS_PARTKEY AND LINEITEM.L_SUPPKEY =
PARTSUPP.PS_SUPPKEY
     5  -  JOINED COLUMN : LINEITEM.L_PARTKEY, LINEITEM.L_SUPPKEY, LINEITEM.L_EXTENDEDPRICE,
LINEITEM.L_DISCOUNT, LINEITEM.L_QUANTITY
     6  -  READ COLUMN : PART.P_PARTKEY, PART.P_NAME
             LOGICAL FILTER : PART.P_NAME LIKE '%green%'
     7  -  READ INDEX COLUMN : LINEITEM.L_PARTKEY, LINEITEM.L_SUPPKEY
           READ TABLE COLUMN : LINEITEM.L_QUANTITY, LINEITEM.L_EXTENDEDPRICE,
LINEITEM.L_DISCOUNT
             MIN RANGE : LINEITEM.L_PARTKEY = {PART.P_PARTKEY}
             MAX RANGE : LINEITEM.L_PARTKEY = {PART.P_PARTKEY}
<<<  end print plan
```

In the example above, the example and the query are as same as those of TRANSITIVE_CLOSURE hint, bu t the execution plan is different from that of TRANSITIVE_CLOSURE hint. It is because the execution plan i s created with only the join condition described by the user.

If statistics information is correct, then the time to perform the query in the execution plan above may tak e longer than the time to perform the example of TRANSITIVE_CLOSURE hint. It is because its intermediat e results of join are more.

However, if the number of lineitem rows are much fewer due to an incorrect statistics information, then i t is more effected to create the execution plan with only the join condition specified by the user. Therefor e, use NO_TRANSITIVE_CLOSURE hint in this case.

〈view hints〉

〈view merge hints〉

Those hints determine whether to apply the view merging method during the rewriter process.

MERGE(view_name)

If MERGE(view_name) hint is specified, the view with view_name is merged with an outer query.

The following is an example of using MERGE(view_name) hint.

```
CREATE OR REPLACE VIEW v_nation
  (
     v_nationkey,
     v_nation_name,
     v_region_name
  )
AS SELECT n_nationkey,
          n_name,
          r_name
     FROM nation,
          region
    WHERE n_regionkey = r_regionkey;
\EXPLAIN PLAN
  SELECT /*+ MERGE(v_nation) */
         v_nation_name,
         count(*)
    FROM customer,
         v_nation
   WHERE c_nationkey = v_nationkey
     AND v_region_name = 'ASIA'
GROUP BY v_nation_name ;
>>>  start print plan
< Execution Plan >
```

```
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      GROUP HASH INSTANT                                           |
|    3  |        NESTED JOIN (INNER JOIN)                                   |
|    4  |          NESTED JOIN (INNER JOIN)                                 |
|    5  |            TABLE ACCESS ("REGION")                                |
|    6  |            INDEX ACCESS ("NATION", "NATION_REGIONKEY_FK")         |
|    7  |          INDEX ACCESS ("CUSTOMER", "CUSTOMER_NATIONKEY_FK")       |
=============================================================================
     1  -  TARGET : NATION.N_NAME, COUNT(*)
     2  -  GROUP KEY : NATION.N_NAME
           RECORD COLUMN : COUNT(*)
           READ KEY COLUMN : NATION.N_NAME
           READ RECORD COLUMN : COUNT(*)
     3  -  JOINED COLUMN : NATION.N_NAME
     4  -  JOINED COLUMN : NATION.N_NATIONKEY, NATION.N_NAME

             PHYSICAL FILTER : REGION.R_NAME = 'ASIA'
     6  -  READ INDEX COLUMN : NATION.N_REGIONKEY
           READ TABLE COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
             MIN RANGE : NATION.N_REGIONKEY = {REGION.R_REGIONKEY}
             MAX RANGE : NATION.N_REGIONKEY = {REGION.R_REGIONKEY}
     7  -  READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
             MIN RANGE : CUSTOMER.C_NATIONKEY = {NATION.N_NATIONKEY}
             MAX RANGE : CUSTOMER.C_NATIONKEY = {NATION.N_NATIONKEY}
<<<  end print plan
```

In the execution plan above, v_nation is merged with an outer query.

NO_MERGE(view_name)

If NO_MERGE(view_name) hint is specified, the view with view_name is not merged with an outer query.

The following is an example of using NO_MERGE(view_name) hint.

```
CREATE OR REPLACE VIEW v_nation
  (
    v_nationkey,
    v_nation_name,
    v_region_name
```

```
  )
AS SELECT n_nationkey,
          n_name,
          r_name
     FROM nation,
          region
    WHERE n_regionkey = r_regionkey;
```

- The view merging method is not applied.

```
\EXPLAIN PLAN
  SELECT /*+ NO_MERGE(v_nation) */
         v_nation_name,
         count(*)
    FROM customer,
         v_nation
   WHERE c_nationkey = v_nationkey
     AND v_region_name = 'ASIA'
GROUP BY v_nation_name ;
>>>  start print plan
< Execution Plan >
================================================================================

     1  -  TARGET : V_NATION.V_NATION_NAME, COUNT(*)
     2  -  GROUP KEY : V_NATION.V_NATION_NAME
           RECORD COLUMN : COUNT(*)
           READ KEY COLUMN : V_NATION.V_NATION_NAME
           READ RECORD COLUMN : COUNT(*)
     3  -  JOINED COLUMN : V_NATION.V_NATION_NAME
```

```
     4  -  COLUMN : V_NATIONKEY AS V_NATIONKEY, V_NATION_NAME AS V_NATION_NAME, V_REGION_NAME
AS V_REGION_NAME
     5  -  TARGET : NATION.N_NATIONKEY AS V_NATIONKEY, NATION.N_NAME AS V_NATION_NAME,
REGION.R_NAME AS V_REGION_NAME
     6  -  JOINED COLUMN : NATION.N_NATIONKEY, NATION.N_NAME, REGION.R_NAME
     7  -  READ COLUMN : REGION.R_REGIONKEY, REGION.R_NAME
             PHYSICAL FILTER : REGION.R_NAME = 'ASIA'
     8  -  READ INDEX COLUMN : NATION.N_REGIONKEY
           READ TABLE COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
             MIN RANGE : NATION.N_REGIONKEY = {REGION.R_REGIONKEY}
             MAX RANGE : NATION.N_REGIONKEY = {REGION.R_REGIONKEY}
     9  -  READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
             MIN RANGE : CUSTOMER.C_NATIONKEY = {V_NATION.V_NATIONKEY}
             MAX RANGE : CUSTOMER.C_NATIONKEY = {V_NATION.V_NATIONKEY}
<<<  end print plan
```

In the execution plan above, v_nation is not merged with an outer query, but it exists as it is in view form.

〈push view predicate hints〉

Those hints either push the view-related join predicate into the view or prevent the pushing.

PUSH_PRED

If PUSH_PRED hint is specified, it pushes all join predicates related to views listed in a from clause into the view.

The following is an example of using PUSH_PRED hint.

```
CREATE OR REPLACE VIEW v_nation
  (
     v_nationkey,
     v_nation_name,
     v_region_name
  )
AS SELECT n_nationkey,
          n_name,
          r_name
     FROM nation,
          region
    WHERE n_regionkey = r_regionkey;
\EXPLAIN PLAN
  SELECT /*+ PUSH_PRED */
         v_nation_name,
```

```
        count(*)
    FROM customer,
        v_nation
   WHERE c_nationkey = v_nationkey
     AND v_region_name = 'ASIA'
GROUP BY v_nation_name;
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      GROUP HASH INSTANT                                           |
|    3  |        NESTED JOIN (INNER JOIN)                                   |
|    4  |          INDEX ACCESS ("CUSTOMER", "CUSTOMER_NATIONKEY_FK")       |
|    5  |          VIEW ("V_NATION")                                        |
|    6  |            QUERY BLOCK ("$QB_IDX_7")                              |
|    7  |              NESTED JOIN (INNER JOIN)                             |
|    8  |                INDEX ACCESS ("NATION", "NATION_PK_INDEX")          |
|    9  |                INDEX ACCESS ("REGION", "REGION_PK_INDEX")          |
============================================================================
     1  -  TARGET : V_NATION.V_NATION_NAME, COUNT(*)
     2  -  GROUP KEY : V_NATION.V_NATION_NAME
           RECORD COLUMN : COUNT(*)
           READ KEY COLUMN : V_NATION.V_NATION_NAME
           READ RECORD COLUMN : COUNT(*)
     3  -  JOINED COLUMN : V_NATION.V_NATION_NAME
     4  -  READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
     5  -  COLUMN : V_NATIONKEY AS V_NATIONKEY, V_NATION_NAME AS V_NATION_NAME, V_REGION_NAME
AS V_REGION_NAME
     6  -  TARGET : NATION.N_NATIONKEY AS V_NATIONKEY, NATION.N_NAME AS V_NATION_NAME,
REGION.R_NAME AS V_REGION_NAME
     7  -  JOINED COLUMN : NATION.N_NATIONKEY, NATION.N_NAME, REGION.R_NAME
     8  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME, NATION.N_REGIONKEY
             MIN RANGE : NATION.N_NATIONKEY = {CUSTOMER.C_NATIONKEY}
             MAX RANGE : NATION.N_NATIONKEY = {CUSTOMER.C_NATIONKEY}
           FETCH ONE ROW
     9  -  READ INDEX COLUMN : REGION.R_REGIONKEY
           READ TABLE COLUMN : REGION.R_NAME
```

```
            MIN RANGE : REGION.R_REGIONKEY = {NATION.N_REGIONKEY}
            MAX RANGE : REGION.R_REGIONKEY = {NATION.N_REGIONKEY}
            PHYSICAL TABLE FILTER : REGION.R_NAME = 'ASIA'
          FETCH ONE ROW
<<<  end print plan
```

In the execution plan above, c_nationkey = v_nationkey is used by being pushed into the view.

NO_PUSH_PRED

If NO_PUSH_PRED hint is specified, it prevents pushing all join predicates related to views listed in a from clause into the view.

The following is an example of using NO_PUSH_PRED hint.

```
CREATE OR REPLACE VIEW v_nation
  (
     v_nationkey,
     v_nation_name,
     v_region_name
  )
AS SELECT n_nationkey,
          n_name,
          r_name
     FROM nation,
          region
    WHERE n_regionkey = r_regionkey;
\EXPLAIN PLAN
  SELECT /*+ NO_PUSH_PRED */
         v_nation_name,
         count(*)
    FROM customer,
         v_nation
   WHERE c_nationkey = v_nationkey
     AND v_region_name = 'ASIA'
GROUP BY v_nation_name;
>>>  start print plan
< Execution Plan >
=============================================================================

             MAX RANGE : CUSTOMER.C_NATIONKEY = {V_NATION.V_NATIONKEY}
<<<  end print plan
```

In the execution plan above, c_nationkey = v_nationkey is used outside of the view.

PUSH_PRED(view_name[[,] view_name])

If PUSH_PRED(view_name[[,] view_name]) hint is specified, it pushes all join predicates related to vie ws listed ina from clause into the view.

The following is an example of using PUSH_PRED(view_name[[,] view_name]) hint.

```
CREATE OR REPLACE VIEW v_nation
  (
    v_nationkey,
```

```
     v_nation_name,
     v_region_name
  )
AS SELECT n_nationkey,
          n_name,
          r_name
     FROM nation,
          region
    WHERE n_regionkey = r_regionkey;
\EXPLAIN PLAN
  SELECT /*+ PUSH_PRED(v_nation) */
         v_nation_name,
         count(*)
    FROM customer,
         v_nation
   WHERE c_nationkey = v_nationkey
     AND v_region_name = 'ASIA'
GROUP BY v_nation_name;
>>>  start print plan
< Execution Plan >
============================================================================

<<<  end print plan
```

Operation Hint

Those hints are applied per each relation.

〈access path hints〉

It defines how to access a single table.

FULL(table_name)

If FULL(table_name) hint is specified, then an optimizer performs the table full scan for the specified tabl e.
Only one table_name can be specified, and it should exist in 〈from clause〉.

The following is an example of using FULL(table_name) hint.

```
SELECT count(*) FROM nation;
COUNT(*)
--------
      25
1 row selected.
\EXPLAIN PLAN
SELECT /*+ FULL( nation ) */
       n_name
  FROM nation
 WHERE n_nationkey < 10;
>>>  start print plan
< Execution Plan >
============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                  ¦ ROWS ¦
----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                  ¦   10 ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                     ¦   10 ¦
¦    2  ¦      TABLE ACCESS ("NATION")                     ¦   10 ¦
============================================================================
     1  -  TARGET : NATION.N_NAME
     2  -  READ COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
             PHYSICAL FILTER : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, n_nationkey is a primary key column so the index access is available. However the

performance of the table access is better than that of the index access when selecting ten results from a s mall table whose nation table has 25 rows only.

INDEX(table_name [,] [index_name [[,] index_name]])

If INDEX(table_name [,] [index_name [[,] index_name]]) hint is specified, then an optimizer perfor ms the index scan for the specified table. In this case, the index with the best cost is selected among liste d indexes. If index_name is not specified, then the index with the best cost is selected among all indexes i n the table.
One or more table_name can be specified, and it should exist in <from clause>.

An index name can be specified one or more, or it can be omitted. And it should be index_name which e xists in the table corresponding to table_name.

The following is an example of using INDEX(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ INDEX( nation ) */
         n_nationkey,
         n_name
    FROM nation
   WHERE n_nationkey < 10
ORDER BY n_nationkey;

>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                      | ROWS |
-----------------------------------------------------------------------------
| 0 |  SELECT STATEMENT                                          |  10  |
| 1 |    QUERY BLOCK ("$QB_IDX_2")                               |  10  |
| 2 |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")            |  10  |
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
             MAX RANGE : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, a nation table is a small table which has 25 rows, and only 10 rows are selected a mong those. Therefore, the performance of the table access is better than that of the index access. Howe ver, the result of an index access is as if it is ordered by even though the order by is not separately perfor

med, so the order by can be omitted. Therefore, an index access may be better in this case.

NO_INDEX(table_name [,] [index_name [[,] index_name]])

If NO_INDEX(table_name [,] [index_name [[,] index_name]]) hint is specified, then an optimizer pr events using the specified index. If index_name is not specified, then none of the index is used. In other words, it does not perform the index scan.
Only one table_name can be specified, and it should exist in <from clause>.

An index name can be specified one or more, or it can be omitted. And it should be index_name which e xists in the table corresponding to table_name.

The following is an example of using NO_INDEX(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ NO_INDEX( nation ) */
         n_nationkey,
         n_name
    FROM nation
   WHERE n_nationkey < 10
ORDER BY n_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                  ¦ ROWS ¦
-----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                  ¦  10  ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                     ¦  10  ¦
¦    2  ¦      SORT INSTANT                                ¦  10  ¦
¦    3  ¦        TABLE ACCESS ("NATION")                   ¦  10  ¦
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  SORT KEY : "NATION.N_NATIONKEY ASC NULLS LAST"
           RECORD COLUMN : NATION.N_NAME
           READ KEY COLUMN : NATION.N_NATIONKEY
           READ RECORD COLUMN : NATION.N_NAME
     3  -  READ COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
             PHYSICAL FILTER : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, the table access is performed because using any index is prevented.

INDEX_FORWARD(table_name [,] [index_name [[,] index_name]])

INDEX_FORWARD(table_name [,] [index_name [[,] index_name]]) hint is as same as INDEX(table_name [,] [index_name[[,] index_name]]) hint.
It performs the forward scan for the index. Therefore, if the index was created in an ascending order, then it outputs the result in an ascending order. If the index was created in a descending order, then it outputs the result in a descending order.

The following is an example of using INDEX_FORWARD(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ INDEX_FORWARD( nation ) */
         n_nationkey,
         n_name
    FROM nation
   WHERE n_nationkey < 10
ORDER BY n_nationkey ASC;
>>>  start print plan
< Execution Plan >
=====================================================================
|  IDX  |  NODE DESCRIPTION                                 | ROWS |
---------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                 |  10  |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                      |  10  |
|    2  |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")   |  10  |
=====================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
             MAX RANGE : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, if NATION_PK_INDEX was created in an ascending order, then separate sorting for ORDER BY is not required when performing the forward scan for the index.

INDEX_BACKWARD(table_name [,] [index_name [[,] index_name]])

It performs the backward scan for the index. Therefore, if the index was created in an ascending order, then it outputs the result in a descending order. If the index was created in a descending order, then it outputs the result in an ascending order.
The syntax rule of INDEX_BACKWARD(table_name [,] [index_name [[,] index_name]]) is as same as that of INDEX(table_name [,] [index_name[[,] index_name]]) hint.

The following is an example of using INDEX_BACKWARD(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ INDEX_BACKWARD( nation ) */
         n_nationkey,
         n_name
    FROM nation
   WHERE n_nationkey < 10
ORDER BY n_nationkey DESC;
>>>  start print plan
< Execution Plan >
=================================================================
|  IDX  |  NODE DESCRIPTION                              | ROWS |
-----------------------------------------------------------------
|    0  |  SELECT STATEMENT                              |  10  |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |  10  |
|    2  |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")|  10  |
=================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
             MAX RANGE : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, if NATION_PK_INDEX was created in an ascending order, then separate sorting for ORDER BY is not required when performing the backward scan for the index.

INDEX_ASC(table_name [,] [index_name [[,] index_name]])

INDEX_ASC(table_name [,] [index_name [[,] index_name]]) hint is as same as INDEX(table_name [,] [index_name[[,] index_name]]) hint.
It performs the forward scan for the index. Therefore, if the index was created in an ascending order, the n it outputs the result in an ascending order. If the index was created in a descending order, then it outp uts the result in a descending order.

The following is an example of using INDEX_ASC(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ INDEX_ASC( nation ) */
         n_nationkey,
         n_name
    FROM nation
```

```
   WHERE n_nationkey < 10
ORDER BY n_nationkey ASC;
>>>  start print plan
< Execution Plan >
=================================================================
|  IDX  |  NODE DESCRIPTION                              | ROWS |
-----------------------------------------------------------------
|    0  |  SELECT STATEMENT                              |  10  |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                   |  10  |
|    2  |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")|  10  |
=================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
             MAX RANGE : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, if NATION_PK_INDEX was created in an ascending order, then separate sorting for ORDER BY is not required when performing the forward scan for the index.

INDEX_DESC(table_name [,] [index_name [[,] index_name]])

It performs the backward scan for the index. Therefore, if the index was created in an ascending order, th en it outputs the result in a descending order. If the index was created in a descending order, then it outp uts the result in an ascending order.
The syntax rule of INDEX_DESC(table_name [,] [index_name [[,] index_name]]) is as same as that o f INDEX(table_name [,] [index_name[[,] index_name]]) hint.

The following is an example of using INDEX_DESC(table_name) hint.

```
\EXPLAIN PLAN
  SELECT /*+ INDEX_DESC( nation ) */
         n_nationkey,
         n_name
    FROM nation
   WHERE n_nationkey < 10
ORDER BY n_nationkey DESC;
>>>  start print plan
< Execution Plan >
=================================================================
|  IDX  |  NODE DESCRIPTION                              | ROWS |
-----------------------------------------------------------------
```

```
¦    0  ¦  SELECT STATEMENT                                  ¦  10  ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                     ¦  10  ¦
¦    2  ¦      INDEX ACCESS ("NATION", "NATION_PK_INDEX")  ¦  10  ¦
=================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
             MAX RANGE : NATION.N_NATIONKEY < 10
<<<  end print plan
```

In the example above, if NATION_PK_INDEX was created in an ascending order, then separate sorting for ORDER BY is not required when performing the backward scan for the index.

INDEX_COMBINE(table_name [,] [index_name [[,] index_name]])

If INDEX_COMBINE(table_name [,] [index_name [[,] index_name]]) hint is specified, then an optimizer separates OR statements in the specified table, performs the index scan and merges the results. In this case, the index with the best cost is selected among listed indexes when determining each index scan. If index_name is not specified, then the index with the best cost is selected among all indexes in the table. Therefore, each different index can be used according to OR statements.

When specifying INDEX_COMBINE hint, a table name should exists in <from clause> and the index name should be the one existing in the table.

The or statement should exist in the condition to scan the table for performing INDEX_COMBINE hint. If the or statement does not exist, then the optimizer ignores the hint.

The following is an example of using INDEX_COMBINE(table_name) hint.

```
\EXPLAIN PLAN
SELECT /*+ INDEX_COMBINE( orders ) */
       o_orderstatus
  FROM orders
 WHERE o_orderkey = 1 OR o_custkey = 1;
>>>  start print plan
< Execution Plan >
=========================================================================
¦  IDX  ¦  NODE DESCRIPTION                                    ¦ ROWS ¦
-------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                    ¦   7  ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                       ¦   7  ¦
¦    2  ¦      CONCAT (Compare RID)                          ¦   7  ¦
¦    3  ¦        INDEX ACCESS ("ORDERS", "ORDERS_PK_INDEX")  ¦   1  ¦
¦    4  ¦        INDEX ACCESS ("ORDERS", "ORDERS_CUSTKEY_FK")¦   6  ¦
```

```
================================================================================
     1  -  TARGET : ORDERS.O_ORDERSTATUS
     2  -  CONCAT COLUMN : ORDERS.$PHYSICAL_ROWID, ORDERS.O_ORDERSTATUS
     3  -  READ INDEX COLUMN : ORDERS.O_ORDERKEY
           READ TABLE COLUMN : ORDERS.O_ORDERSTATUS
             MIN RANGE : ORDERS.O_ORDERKEY = 1
             MAX RANGE : ORDERS.O_ORDERKEY = 1
           FETCH ONE ROW
     4  -  READ INDEX COLUMN : ORDERS.O_CUSTKEY
           READ TABLE COLUMN : ORDERS.O_ORDERSTATUS
             MIN RANGE : ORDERS.O_CUSTKEY = 1
             MAX RANGE : ORDERS.O_CUSTKEY = 1
<<<  end print plan
```

In the example above, the index scan is not available with the entire o_orderkey = 1 OR o_custkey = 1 co ndition, so the performance may become slow. Therefore, separate OR statement and perform the index scan for each condition (o_orderkey = 1 and o_custkey = 1), then merge the results to upgrade the perfo rmance.

IN_KEY_RANGE(table_name [,] [index_name [[,] index_name]])

If IN_KEY_RANGE(table_name [,] [index_name [[,] index_name]]) hint is specified, then an optimiz er performs the IN key range scan for the specified table. In this case, the index with the best cost is select ed among specified indexes. If index_name is not specified, then the index with the best cost is selected a mong all indexes in the table.
However, a filter which is capable of the IN key range is required for applying IN_KEY_RANGE(table_nam e [,] [index_name [[,] index_name]]) hint.

Filter conditions for IN key range are as follows.

e.g. (col1, col2) IN ((val1, val2), (val3, val4))

- *IN* or *=ANY List Function Filter* should exist in WHERE clause.
- col1 and col2 should be base columns. In other words, they should not be operations nor are functions.
- (val1, val3) corresponding to col1 can be converted to a single data type,
  (val2, val4) corresponding to col2 can be converted to a single data type.

The following is an example of using IN_KEY_RANGE hint.

```
\EXPLAIN PLAN
  SELECT /*+ IN_KEY_RANGE( orders ) */
         o_orderstatus
    FROM orders
```

```
   WHERE o_orderkey > 500 AND o_custkey IN ( 1, 10, 100, 1000, 10000 );
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                        | ROWS |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                        |   91 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                             |   91 |
|    2  |      INDEX ACCESS ("ORDERS", "ORDERS_CUSTKEY_FK")        |   91 |
============================================================================
     1  -  TARGET : ORDERS.O_ORDERSTATUS
     2  -  READ INDEX COLUMN : ORDERS.O_CUSTKEY
           READ TABLE COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_ORDERSTATUS
           IN KEY RANGE
             MIN RANGE : ORDERS.O_CUSTKEY = ?
             MAX RANGE : ORDERS.O_CUSTKEY = ?
             PHYSICAL TABLE FILTER : ORDERS.O_ORDERKEY > 500
<<<  end print plan
```

In the execution plan above, the IN key range scan is performed.

ROWID(table_name)

If ROWID(table_name) hint is specified, then an optimizer performs the rowid scan for the specified tabl e. The table name should exist in <from clause> when specifying ROWID hint.

The equal condition using ROWID should exist in the table to apply ROWID hint. If this condition does not exist, then an optimizer ignores this hint.

The following is an example of using ROWID hint.

```
\EXPLAIN PLAN
  SELECT /*+ ROWID( orders ) */
         o_orderstatus
    FROM orders
   WHERE rowid = 'AAAAAAAAYfAAACAAACGjAAA';
>>>  start print plan
< Execution Plan >
============================================================================
|  IDX  |  NODE DESCRIPTION                                        | ROWS |
----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                        |    1 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                             |    1 |
```

```
|    2  |      ROWID ACCESS ("ORDERS")                              |    1 |
=========================================================================

     1  -  TARGET : ORDERS.O_ORDERSTATUS
     2  -  READ COLUMN : ORDERS.O_ORDERSTATUS
             ROWID FILTER : ORDERS.ROWID = 'AAAAAAAAYfAAACAAACGjAAA'
<<<  end print plan
```

〈join hints〉

〈join order hints〉

Those hints define how to perform the join ordering.

ORDERED

If ORDERED hint is specified, then an optimizer orders to perform joining in an order described in 〈from clause〉 when performing the join ordering.

If a user knows how many number of rows satisfying the join conditions and the best join order, then the user can decrease the join ordering cost by using ORDERED hint.

The following is an example of using ORDERED hint.

```
\EXPLAIN PLAN
  SELECT  /*+ ORDERED */

ORDERING(table_name [, table_name [, table_name [LEFT | RIGHT]]])

If ORDERING(table_name [, table_name [, table_name [LEFT | RIGHT]]]) hint is specified, then an opt imizer orders to perform joining in an order described in the hint when performing the join ordering.

A locating option can not be specified for the first and the second tables, but it can be specified from the third table. Location options are LEFT and RIGHT. LEFT places the table on the left node (outer node) of t

he join, and RIGHT places the table on the right node (inner node) of the join. If a locating option is not u sed, then the location is determined by the cost estimation.

The following is an example of using ORDERING hint.

```
\EXPLAIN PLAN
  SELECT  /*+ ORDERING( customer, orders, lineitem RIGHT ) */
          l_orderkey,
          ROUND( sum(l_extendedprice*(1-l_discount)), 2) as revenue,

LEADING(table_name [[,] table_name])

If LEADING(table_name [[,] table_name]) hint is specified, then an optimizer orders to perform joinin g in an order described in the hint when performing the join ordering. Unlike an ORDERING hint, LEADIN G(table_name [[,] table_name]) hint can not specify the location of tables, but it can only specify the order of tables participating in the join ordering.

The following is an example of using LEADING hint.

```
\EXPLAIN PLAN
  SELECT  /*+ LEADING( customer, orders, lineitem ) */
          l_orderkey,
          ROUND( sum(l_extendedprice*(1-l_discount)), 2) as revenue,
          o_orderdate,
          o_shippriority
   FROM   lineitem,
          orders,
          customer
  WHERE   c_mktsegment = 'BUILDING'
    AND   c_custkey = o_custkey
    AND   l_orderkey = o_orderkey
    AND   o_orderdate < date '1995-03-15'
    AND   l_shipdate > date '1995-03-15'
GROUP BY  l_orderkey,
```

```
          o_orderdate,
          o_shippriority;
>>>  start print plan
< Execution Plan >

〈join operation hints〉

USE_HASH(table_name [[,] table_name])

If USE_HASH(table_name [[,] table_name]) hint is specified, then an optimizer selects hash join when determining the join operation of the join in which table_name participates.

One or more table should be specified, and the same tables can not be specified more than two. If 〈join operation hints〉 already exists in the specified table, then the hint is ignored. Also, if each different join operation hint is specified in two tables participating in join, then the hint specified in a right node(inner node) is preferentially applied.

The hint is applied only when a equi-join condition exists even though USE_HASH hint is specified. If a join condition which is capable of hash join does not exist, then an optimizer selects the best join operation through a cost estimation.

The following is an example of using USE_HASH(table_name [[,] table_name]) hint.

```
\EXPLAIN PLAN
  SELECT  /*+ USE_HASH( orders ) */
          c_name,
          o_orderdate,
          o_orderstatus
    FROM  customer,
          orders
   WHERE  c_custkey = o_custkey
     AND  o_orderdate >= date '1995-03-15'
     AND  o_orderdate < date '1995-03-15' + interval '1' month;
>>>  start print plan
< Execution Plan >
================================================================================

INTERVAL(MONTH) ) AND ORDERS.O_ORDERDATE >= DATE'1995-03-15'
<<<  end print plan
```

USE_HASH(table_name [[,] table_name] , hash_bucket_count)

USE_HASH(table_name [[,] table_name] , hash_bucket_count) hint is as same as UNNEST_HASH hint, but in addition to that it can specify the hash bucket count.

If statistics information is incorrect, then hash bucket count of hash instants created for hash join may be too many or too little so it may degrade the performance. In this case, specify the hash bucket count by u sing the hint to prevent the performance from degrading.

The following is an example of using USE_HASH(table_name [[,] table_name], hash_bucket_count) hi nt.

```
SELECT COUNT(DISTINCT o_custkey)
  FROM orders
 WHERE o_orderdate >= date '1995-03-15'
   AND o_orderdate < date '1995-03-15' + interval '1' month;
COUNT(DISTINCT O_CUSTKEY)
-------------------------
                    17430
1 row selected.
\EXPLAIN PLAN VERBOSE
  SELECT  /*+ USE_HASH( orders, 17430 ) */
          c_name,
          o_orderdate,
          o_orderstatus
    FROM  customer,
          orders
   WHERE  c_custkey = o_custkey
     AND  o_orderdate >= date '1995-03-15'
     AND  o_orderdate < date '1995-03-15' + interval '1' month;
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                              |  ROWS | Ellipsis  |

```

```
|  0  |  SELECT STATEMENT                                |  19343 | ... |
|  1  |    QUERY BLOCK ("$QB_IDX_2")                     |  19343 | ... |
|  2  |      HASH JOIN (INNER JOIN)                      |  19343 | ... |
|  3  |        TABLE ACCESS ("CUSTOMER")                 | 150000 | ... |
|  4  |        HASH JOIN INSTANT                         |  19343 | ... |
|  5  |          TABLE ACCESS ("ORDERS")                 |  19343 | ... |
=============================================================================
     1  -  TARGET : CUSTOMER.C_NAME, ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
     2  -  JOINED COLUMN : CUSTOMER.C_NAME, ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
     3  -  READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_NAME
     4  -  HASH KEY : ORDERS.O_CUSTKEY
           RECORD COLUMN : ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
           READ KEY COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_ORDERDATE, ORDERS.O_ORDERSTATUS
             HASH FILTER : ORDERS.O_CUSTKEY = CUSTOMER.C_CUSTKEY
           HASH BUCKET COUNT : 17430
     5  -  READ COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_ORDERSTATUS, ORDERS.O_ORDERDATE
             PHYSICAL FILTER : ORDERS.O_ORDERDATE < DATE'1995-03-15' + CAST( '1' AS
INTERVAL(MONTH) ) AND ORDERS.O_ORDERDATE >= DATE'1995-03-15'
<<<  end print plan
```

In the example above, the hash bucket count in an output of orders participating in the join is specified a s many as the number of distinct values.

USE_HASH_IN(alias)

If USE_HASH_IN(alias) hint is specified, then an optimizer selects hash join when determining the join o peration of the join in which the alias participates. Then it places the alias on the right(inner) of the join.

If <join operation hints> already exists in the specified alias, then the hint is ignored. Also, if each differen t join operation hint is specified in two tables participating in join, then the hint specified in a right node(i nner node) is preferentially applied.

A table name, a table alias name, a view name, a view alias name and a join alias name can be an alias.

The following is an example of using USE_HASH_IN(alias) hint.

```
--# hash join
\EXPLAIN PLAN
  SELECT  /*+ USE_HASH_IN( orders ) */
          c_name,
          o_orderdate,
          o_orderstatus
    FROM  customer,
```

```
          orders
   WHERE  c_custkey = o_custkey
     AND  o_orderdate >= date '1995-03-15'
     AND  o_orderdate < date '1995-03-15' + interval '1' month;
>>>  start print plan
< Execution Plan >

In the execution plan above, join alias j10| is located on the right of the hash join.

USE_HASH_OUT(alias)

If USE_HASH_OUT(alias) hint is specified, then an optimizer selects hash join when determining the join operation of the join in which the alias participates. Then it places the alias on the left(outer) of the join.

If <join operation hints> already exists in the specified alias, then the hint is ignored. Also, if each differen t join operation hint is specified in two tables participating in join, then the hint specified in a right node(i nner node) is preferentially applied.

A table name, a table alias name, a view name, a view alias name and a join alias name can be an alias.

The following is an example of using USE_HASH_OUT(alias) hint.

```
\EXPLAIN PLAN
  SELECT  /*+ USE_HASH_OUT( orders ) */
          c_name,
          o_orderdate,
          o_orderstatus
    FROM  customer,
          orders
   WHERE  c_custkey = o_custkey
     AND  o_orderdate >= date '1995-03-15'
     AND  o_orderdate < date '1995-03-15' + interval '1' month;
>>>  start print plan
< Execution Plan >

USE_JOIN_COMBINE(alias)

If USE_JOIN_COMBINE(alias) hint is specified, then an optimizer selects join combine when determining the join operation of the join in which the alias participates.

A table name, a table alias name, a view name, a view alias name and a join alias name can be an alias.

The following is an example of using USE_JOIN_COMBINE(alias) hint.

```
\EXPLAIN PLAN
SELECT /*+ USE_JOIN_COMBINE(part) */
        sum(l_extendedprice * (1 - l_discount) ) as revenue
  FROM lineitem,
       part
 WHERE
       (
            p_partkey = l_partkey
        and p_brand = 'Brand#12'
        and p_container in ( 'SM CASE', 'SM BOX', 'SM PACK', 'SM PKG')
        and l_quantity >= 1 and l_quantity <= 1 + 10
        and p_size between 1 and 5
        and l_shipmode in ('AIR', 'AIR REG')
        and l_shipinstruct = 'DELIVER IN PERSON'
       )
       or
       (
            p_partkey = l_partkey
        and p_brand = 'Brand#23'
        and p_container in ('MED BAG', 'MED BOX', 'MED PKG', 'MED PACK')
        and l_quantity >= 10 and l_quantity <= 10 + 10
        and p_size between 1 and 10
        and l_shipmode in ('AIR', 'AIR REG')
        and l_shipinstruct = 'DELIVER IN PERSON'
       )
```

```
      or
      (
            p_partkey = l_partkey
        and p_brand = 'Brand#34'
        and p_container in ( 'LG CASE', 'LG BOX', 'LG PACK', 'LG PKG')
        and l_quantity >= 20 and l_quantity <= 20 + 10
        and p_size between 1 and 15
        and l_shipmode in ('AIR', 'AIR REG')
        and l_shipinstruct = 'DELIVER IN PERSON'
      );
>>>  start print plan

```

〈join driver hints〉

Those hints are available when performing the join in the cluster system. They are ignored in the standalone system.

LOCAL_JOIN(alias)

It performs the join in the current server when an alias participates in the join. If both a left child and a right child are sharded tables, it brings all subordinate rows to a local, then performs the join.

The following is an example of using LOCAL_JOIN hint.

```
\EXPLAIN PLAN
SELECT /*+ LOCAL_JOIN(lineitem) */
       l_orderkey, p_partkey
  FROM part, lineitem
 WHERE p_partkey = l_partkey;
>>>  start print plan
< Execution Plan >

           READ INDEX COLUMN : PART.P_PARTKEY
     5  -  HASH KEY : LINEITEM.L_PARTKEY
           RECORD COLUMN : LINEITEM.L_ORDERKEY
```

```
          READ KEY COLUMN : LINEITEM.L_PARTKEY, LINEITEM.L_ORDERKEY
            HASH FILTER : LINEITEM.L_PARTKEY = PART.P_PARTKEY
    6  -  SQL : SELECT /*+ FULL( _A1 ) */
                       "_A1"."L_ORDERKEY", "_A1"."L_PARTKEY"
                  FROM "PUBLIC"."LINEITEM"@LOCAL AS "_A1"
                 WHERE "_A1"."L_SHIPDATE" = :_V0
          TARGET DOMAIN : G1(G1N1,G1N2) 840 rows,
                          G2(G2N1,G2N2) 824 rows,
                          G3(G3N1,G3N2) 864 rows
    7  -  HASH SHARD ( # 3 )
          READ COLUMN : LINEITEM.L_ORDERKEY, LINEITEM.L_PARTKEY, LINEITEM.L_SHIPDATE
            PHYSICAL FILTER : LINEITEM.L_SHIPDATE = DATE'1995-03-15'
<<<  end print plan
```

Both part and lineitem are hash sharded tables. In the execution plan above, it brings both tables to G1, G2 and G3, then performs the join in a local.

REMOTE_JOIN(alias)

It performs the join in each server when an alias participates in the join.

The following is an example of using REMOTE_JOIN hint.

```
\EXPLAIN PLAN
SELECT /*+ REMOTE_JOIN(lineitem) */
       l_orderkey, p_partkey
  FROM part, lineitem
 WHERE p_partkey = l_partkey
   AND l_shipdate = date '1995-03-15';
>>>  start print plan
< Execution Plan >

           FETCH ONE ROW
<<<  end print plan
```

In the execution plan above, it performs the remote join by creating lineitem as a pusher table whose sha rd key is l_partkey, then transferring SQL to each server.

〈join pusher hints〉

Those hints are used when performing the remote join in a cluster system. It is ignored in a standalone sy stem.

PUSHER(alias)

It builds a table or a view corresponding to an alias as a pusher table when an alias participates in a remot e join.
The hint is not applied when the remote join is available without a pusher table.

The following is an example of using PUSHER hint.

```
\EXPLAIN PLAN
SELECT /*+ PUSHER(lineitem) */
       l_orderkey, p_partkey
  FROM part, lineitem
 WHERE p_partkey = l_partkey
   AND l_shipdate = date '1995-03-15';
>>>  start print plan
< Execution Plan >

          FETCH ONE ROW
<<<  end print plan
```

In the execution plan above, it performs the remote join by creating lineitem as a pusher table whose sha rd key is l_partkey, then transferring SQL to each server.

NO_PUSHER(alias)

It does not build a table or a view corresponding to an alias as a pusher table when an alias participates in the join.

If the remote join cost of when building a sibling of an alias as a pusher table is big, then a local join can be selected.
In this case, if using it together with REMOTE_JOIN hint, then it performs the remote join by building a si bling of an alias as a pusher table.

The following is an example of using NO_PUSHER hint.

```
\EXPLAIN PLAN
SELECT /*+ NO_PUSHER(lineitem) */
       l_orderkey, p_partkey
  FROM part, lineitem
 WHERE p_partkey = l_partkey
   AND l_shipdate = date '1995-03-15';
>>>  start print plan

<<<  end print plan
```

In the execution plan above, it performs the remote join by building a sibling of an alias as a pusher table.

〈group hints〉

Those hints are related to *group by* processing, so they are valid only when *group by* clause exists.

〈group operation hints〉

USE_GROUP_HASH

If USE_GROUP_HASH hint is specified, then an optimizer uses a hash instant to process *group by*.

Generally, a hash instant is used to process *group by*. However, if rows on the subordinate nodes ascend by being sorted for the *group by* key column, then hash instants are not accumulated. Instead, *group by* i s processed by comparing the *group by* key column values of rows.

An optimizer does not accumulate hash instants when performing the cost estimation but guides the sub ordinate node to use an index. However, if the statistics information is incorrect, then the cost of this met hod can be more expensive. Therefore, use USE_GROUP_HASH hint in this case.

The following is an example of using USE_GROUP_HASH hint. Compare the execution plan before and af ter using the hint to figure out the process of USE_GROUP_HASH hint.

```
\EXPLAIN PLAN
   SELECT
          c_custkey,
          count(o_orderkey) as c_count
     FROM  customer LEFT OUTER JOIN orders
          ON  c_custkey = o_custkey
          AND o_comment not like '%special%requests%'
          AND c_mktsegment = 'BUILDING'
 GROUP BY   c_custkey;
>>>  start print plan
```

```
< Execution Plan >

USE_GROUP_HASH(hash_bucket_count)

USE_GROUP_HASH(hash_bucket_count) hint is as same as USE_GROUP_HASH hint, but in addition to t hat it can specify the hash bucket count.

If statistics information is incorrect, then then hash bucket count of hash instants created for GROUP BY may be too many or too little so it may degrade the performance. In this case, specify the hash bucket co unt by using the hint to prevent the performance from degrading.

The following is an example of using USE_GROUP_HASH(hash_bucket_count) hint.

```
\EXPLAIN PLAN VERBOSE
   SELECT  /*+ USE_GROUP_HASH(15000) */
           c_custkey,
           count(o_orderkey) as c_count
     FROM  customer LEFT OUTER JOIN orders
           ON  c_custkey = o_custkey
           AND o_comment not like '%special%requests%'
           AND c_mktsegment = 'BUILDING'
 GROUP BY   c_custkey;
>>>  start print plan
```

```
< Execution Plan >

             PHYSICAL FILTER : CUSTOMER.C_MKTSEGMENT = 'BUILDING'
           HASH BUCKET COUNT : 150000
     6  -  READ COLUMN : CUSTOMER.C_CUSTKEY, CUSTOMER.C_MKTSEGMENT
<<<  end print plan
```

In the example above, the hash bucket count is specified as many as the number of expected output row s of GROUP HASH INSTANT.

NO_USE_GROUP_HASH

If NO_USE_GROUP_HASH hint is specified, then an optimizer processes *group by* without using a hash in stant.

In other words, if the intermediate result is sorted for group key and ascends from the subordinate plan, t hen it is used. Otherwise, it processes *group by* by using the sort instant.

```
\EXPLAIN PLAN
   SELECT  /*+ NO_USE_GROUP_HASH */
           c_custkey,
           count(o_orderkey) as c_count
     FROM  customer LEFT OUTER JOIN orders
           ON  c_custkey = o_custkey
           AND o_comment not like '%special%requests%'
           AND c_mktsegment = 'BUILDING'
 GROUP BY   c_custkey;
>>>  start print plan

    4  -  JOINED COLUMN : CUSTOMER.C_CUSTKEY, ORDERS.O_ORDERKEY
    5  -  CLONED
        READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
        READ TABLE COLUMN : CUSTOMER.C_CUSTKEY
          MIN RANGE : CUSTOMER.C_NATIONKEY = 1
          MAX RANGE : CUSTOMER.C_NATIONKEY = 1
    6  -  HASH SHARD ( # 3 )
        READ INDEX COLUMN : ORDERS.O_CUSTKEY
        READ TABLE COLUMN : ORDERS.O_ORDERKEY, ORDERS.O_ORDERSTATUS, ORDERS.O_ORDERDATE,
ORDERS.O_ORDERPRIORITY
          MIN RANGE : ORDERS.O_CUSTKEY = {CUSTOMER.C_CUSTKEY}
          MAX RANGE : ORDERS.O_CUSTKEY = {CUSTOMER.C_CUSTKEY}
          PHYSICAL TABLE FILTER : ORDERS.O_ORDERSTATUS = 'F' AND ORDERS.O_ORDERDATE >=
DATE'1993-07-01' AND ORDERS.O_ORDERPRIORITY = '2-HIGH'
<<<  end print plan
```

In the execution plan above, it brings all join results from G1, G2 and G3, then performs *group by* in a loc al.

Generally, if it is a sharded table, it is recommended to process it with remote group if possible. It is beca use that it can process grouping in parallel and the intermediate results to be transferred are decreased.

However, if the target rows of group by is few, so the parallel processing effect is not expected, then it is recommended to process *group by* in a local.

REMOTE_GROUP

It performs *group by* in a server of each group.

The following is an example of using REMOTE_GROUP hint.

```
\EXPLAIN PLAN
SELECT /*+ REMOTE_GROUP */
       c_custkey, COUNT(o_orderkey)
  FROM customer, orders
 WHERE c_custkey = o_custkey
GROUP BY c_custkey;
>>>  start print plan
< Execution Plan >

          FETCH ONE ROW
    9  -  CLONED
          READ INDEX COLUMN : _A1.C_CUSTKEY
<<<  end print plan
```

In the execution plan above, it processes group by in each server. After processing the join in each server, it groups 500,000 data and outputs 100,000 intermediate results. In this way, it can process the groupin g in parallel and decrease intermediate results to be brought to the network.

If processing the example above in a local, then it should bring 1,500,000 join results and perform group by for 1,500,000 results. In this case, it cost for bring 1,500,000 data to the network and for grouping 1, 500,000 data at once.

〈group cluster regrouping hints〉

Those hints are available when performing *group by* in the cluster system. They are ignored in the standal one system.

MERGE_GROUP

MERGE_GROUP hint is available when it satisfies the following conditions.

- Group by clause exists.
- It can be performed with remote group.
- The intermediate results ascend from the subordinate node of a group in a state that the order for th e group by key column is guaranteed.

Using MERGE_GROUP hint guarantees the order even after fetching the intermediate results to the driver.

The following is an example of using MERGE_GROUP hint.

```
\EXPLAIN PLAN
SELECT /*+ MERGE_GROUP */
       o_custkey
  FROM orders
 WHERE o_custkey > 0
GROUP BY o_custkey;
O_CUSTKEY

```

In the execution result above, they are output in an order of group key col.

〈distinct hints〉

Those hints are related to *distinct* processing, so they are valid only when *distinct* clause exists.

〈distinct operation hints〉

USE_DISTINCT_HASH

If USE_DISTINCT_HASH hint is specified, then an optimizer uses a hash instant to process *distinct*.

Generally, a hash instant is used to process *distinct*. However, if rows on the subordinate nodes ascend b y being sorted for the distinct key column, then hash instants are not accumulated. Instead, *distinct* is pro cessed by comparing the distinct key column values of rows.

An optimizer does not accumulate hash instants when performing the cost estimation but guides the sub ordinate node to use an index. However, if the statistics information is incorrect, then the cost of this met hod can be more expensive. Therefore, use USE_DISTINCT_HASH hint in this case.

The following is an example of using USE_DISTINCT_HASH hint. Compare the execution plan before and after using the hint to figure out the process of USE_DISTINCT_HASH hint.

```
EXPLAIN PLAN
   SELECT
          DISTINCT
          c_nationkey
     FROM  customer
    WHERE  c_comment not like '%special%requests%'
      AND  c_nationkey > 5;
>>>  start print plan
< Execution Plan >
=============================================================================

     3  -  READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
           READ TABLE COLUMN : CUSTOMER.C_COMMENT
             MIN RANGE : CUSTOMER.C_NATIONKEY > 5
             MAX RANGE : CUSTOMER.C_NATIONKEY IS NOT NULL
             LOGICAL TABLE FILTER : CUSTOMER.C_COMMENT NOT LIKE '%special%requests%'
<<<  end print plan
```

USE_DISTINCT_HASH(hash__bucket_count)

USE_DISTINCT_HASH(hash__bucket_count) hint is as same as USE_DISTINCT_HASH hint, but in addition to that it can specify the hash bucket count.

If statistics information is incorrect, then hash bucket count of hash instants created for DISTINCT may be too many or too little so it may degrade the performance. In this case, specify the hash bucket count by u sing the hint to prevent the performance from degrading.

The following is an example of using USE_DISTINCT_HASH hint(hash_bucket_count).

```
\EXPLAIN PLAN VERBOSE
   SELECT  /*+ USE_DISTINCT_HASH(19) */
           DISTINCT
           c_nationkey
     FROM  customer
    WHERE  c_comment not like '%special%requests%'
      AND  c_nationkey > 5;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                  |  ROWS | Ellipsis |
-----------------------------------------------------------------------------
| 0 |SELECT STATEMENT                                        |    19 | ... |
| 1 |  QUERY BLOCK ("$QB_IDX_2")                             |    19 | ... |
| 2 |    GROUP HASH INSTANT                                  |    19 | ... |
| 3 |      INDEX ACCESS ("CUSTOMER", "CUSTOMER_NATIONKEY_FK")|111562 | ... |
=============================================================================
     1  -  TARGET : CUSTOMER.C_NATIONKEY
     2  -  GROUP KEY : CUSTOMER.C_NATIONKEY
           READ KEY COLUMN : CUSTOMER.C_NATIONKEY
           HASH BUCKET COUNT : 19
```

```
     3  -  READ INDEX COLUMN : CUSTOMER.C_NATIONKEY
           READ TABLE COLUMN : CUSTOMER.C_COMMENT
             MIN RANGE : CUSTOMER.C_NATIONKEY > 5
             MAX RANGE : CUSTOMER.C_NATIONKEY IS NOT NULL
             LOGICAL TABLE FILTER : CUSTOMER.C_COMMENT NOT LIKE '%special%requests%'
<<<  end print plan
```

In the example above, the hash bucket count is specified as many as the number of expected output rows of GROUP HASH INSTANT.

NO_USE_DISTINCT_HASH

If NO_USE_DISTINCT_HASH hint is specified, then an optimizer processes *distinct* without using a hash instant.

In other words, if the intermediate result is sorted for distinct key and ascends from the subordinate plan, then it is used. Otherwise, it processes *distinct* by using the sort instant.

```
\EXPLAIN PLAN
   SELECT  /*+ NO_USE_DISTINCT_HASH */
           DISTINCT
           c_nationkey
     FROM  customer
    WHERE  c_comment not like '%special%requests%'
      AND  c_nationkey > 5;
>>>  start print plan
< Execution Plan >

|    3  |        PLAN BASED CLUSTER                      | LOCAL/REMOTE 34 |
|    4  |          TABLE ACCESS ("ORDERS")               |              13 |
=============================================================================
     1  -  TARGET : ORDERS.O_CUSTKEY
     2  -  GROUP KEY : ORDERS.O_CUSTKEY
           READ KEY COLUMN : ORDERS.O_CUSTKEY
     3  -  SQL : SELECT /*+ FULL( _A1 ) */
                        "_A1"."O_CUSTKEY"
```

```
                  FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
                 WHERE "_A1"."O_ORDERSTATUS" = :_V0
                   AND "_A1"."O_ORDERDATE" = :_V1
                   AND "_A1"."O_ORDERPRIORITY" = :_V2
          TARGET DOMAIN : G1(G1N1,G1N2) 13 rows,
                          G2(G2N1,G2N2) 11 rows,
                          G3(G3N1,G3N2) 10 rows
     4  -  HASH SHARD ( # 3 )
          READ COLUMN : ORDERS.O_CUSTKEY, ORDERS.O_ORDERSTATUS, ORDERS.O_ORDERDATE,
ORDERS.O_ORDERPRIORITY
            PHYSICAL FILTER : ORDERS.O_ORDERSTATUS = 'F' AND ORDERS.O_ORDERDATE =
DATE'1995-03-15' AND ORDERS.O_ORDERPRIORITY = '2-HIGH'
<<<  end print plan
```

In the execution plan above, it brings intermediate results satisfying conditions from orders to a local, the n creates GROUP HASH INSTANT for distinct.

REMOTE_DISTINCT

It performs distinct in a server of each group.

The following is an example of using REMOTE_DISTINCT hint.

```
\EXPLAIN PLAN
SELECT /*+ REMOTE_DISTINCT */
       DISTINCT o_orderstatus
  FROM orders
 WHERE o_orderdate = date '1995-03-15';
>>>  start print plan
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                |          ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                |             3 |

          READ KEY COLUMN : _A1.O_ORDERSTATUS
    6  -  HASH SHARD ( # 3 )
          READ COLUMN : _A1.O_ORDERSTATUS, _A1.O_ORDERDATE
            PHYSICAL FILTER : _A1.O_ORDERDATE = :_V0
<<<  end print plan
```

In the execution plan above, it performs remote distinct by transferring SQL including DISTINCT.

〈distinct cluster regrouping hints〉

Those hints are available when performing the distinct clause in the cluster system. It is ignored in the sta ndalone system.

MERGE_DISTINCT

MERGE_DISTINCT hint is available when it satisfies the following conditions.

- A distinct clause exists.
- It can be performed with remote distinct.
- The intermediate result ascends from the subordinate node of the distinct node in a state that the or der for the distinct key column is guaranteed.

Using MERGE_DISTINCT hint guarantees the order even after fetching the intermediate result to the drive r.

The following is an example of using MERGE_DISTINCT hint.

```
\EXPLAIN PLAN
SELECT /*+ MERGE_DISTINCT */
       DISTINCT o_custkey
  FROM orders
 WHERE o_custkey > 0
```

```
ORDER BY o_custkey;
O_CUSTKEY
---------
        1
        2
        4
      ...
99996 rows selected.
>>>  start print plan
< Execution Plan >
================================================================================
¦IDX¦  NODE DESCRIPTION                                                        ¦
--------------------------------------------------------------------------------
¦ 0 ¦  SELECT STATEMENT                                                        ¦

¦ 5 ¦            GROUP                                                         ¦
¦ 6 ¦              INDEX ACCESS ("ORDERS" AS _A1, "ORDERS_CUSTKEY_FK")         ¦
================================================================================
     1  -  TARGET : ORDERS.O_CUSTKEY
     2  -  SQL : SELECT /*+ INDEX( _A1, "PUBLIC"."ORDERS_CUSTKEY_FK" ) */
                         DISTINCT "_A1"."O_CUSTKEY"
                    FROM "PUBLIC"."ORDERS"@LOCAL AS "_A1"
                   WHERE "_A1"."O_CUSTKEY" > :_V0
                ORDER BY "_A1"."O_CUSTKEY" ASC NULLS LAST
           TARGET DOMAIN : G1(G1N1,G1N2) 98218 rows,
                           G2(G2N1,G2N2) 98174 rows,
                           G3(G3N1,G3N2) 98138 rows
           MERGE GROUPING
             SORT KEY : ORDERS.O_CUSTKEY
             GROUP KEY : ORDERS.O_CUSTKEY
     4  -  TARGET : _A1.O_CUSTKEY
     5  -  GROUP KEY : _A1.O_CUSTKEY
     6  -  HASH SHARD ( # 3 )
           READ INDEX COLUMN : _A1.O_CUSTKEY
             MIN RANGE : _A1.O_CUSTKEY > :_V0
             MAX RANGE : _A1.O_CUSTKEY IS NOT NULL
<<<  end print plan
```

In the execution plan above, *MULTIPLE CLUSTER(IDX:2)* keeps the order for o_custkey. Therefore, SORT n ode for ORDER BY is useless, so it is dropped.

〈order hints〉

Those hints are related to *order by* processing, so they are valid only when *order by* clause exists.

〈order operation hints〉

USE_ORDER_SORT

If USE_ORDER_SORT hint is specified, then an optimizer uses a sort instant to process *order by*.

Generally, a sort instant is used to process *order by*. However, if rows on the subordinate nodes ascend b y being sorted for the sort key column, then *order by* is processed without accumulating sort instants.

An optimizer does not accumulate sort instants when performing the cost estimation but guides the subo rdinate node to use an index. However, if the statistics information is incorrect, then the cost of this meth od can be more expensive. Therefore, use USE_ORDER_SORT hint in this case.

The following is an example of using USE_ORDER_SORT hint. Compare the execution plan before and aft er using the hint to figure out the process of USE_ORDER_SORT hint.

```
\EXPLAIN PLAN
  SELECT n_nationkey,
         n_name
    FROM nation
ORDER BY n_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                 ¦
-----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                 ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                    ¦
¦    2  ¦      INDEX ACCESS ("NATION", "NATION_PK_INDEX")       ¦
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
<<<  end print plan
\EXPLAIN PLAN
  SELECT /*+ USE_ORDER_SORT */
         n_nationkey,
```

```
        n_name
    FROM nation
ORDER BY n_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      SORT INSTANT                                                 |
|    3  |        TABLE ACCESS ("NATION")                                    |
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  SORT KEY : "NATION.N_NATIONKEY ASC NULLS LAST"
           RECORD COLUMN : NATION.N_NAME
           READ KEY COLUMN : NATION.N_NATIONKEY
           READ RECORD COLUMN : NATION.N_NAME
     3  -  READ COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
<<<  end print plan
```

NO_USE_ORDER_SORT

If NO_USE_ORDER_SORT hint is specified, then an optimizer makes the row to be sorted for sort key colu mn and ascend from the subordinate node without accumulating sort instant.

```
\EXPLAIN PLAN
  SELECT /*+ NO_USE_ORDER_SORT */
        n_nationkey,
        n_name
    FROM nation
ORDER BY n_nationkey;
>>>  start print plan
< Execution Plan >
=============================================================================
|  IDX  |  NODE DESCRIPTION                                                 |
-----------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                                 |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                      |
|    2  |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")                   |
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
```

```
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
<<<  end print plan
```

SORT INSTANT does not exist in the execution plan above. Instead, it outputs the result which is sorted fo r n_nationkey by performing INDEX ACCESS.

USE_ORDER_LIMIT_SORT

If USE_ORDER_LIMIT_SORT hint is specified, then an optimizer sorts the results by using limit sort method. In this case, it is applicable only when LIMIT clause and ORDER BY clause are used together.

```
\EXPLAIN PLAN
  SELECT /*+ USE_ORDER_LIMIT_SORT */
         n_nationkey,
         n_name
    FROM nation
ORDER BY n_nationkey
   LIMIT 10,10;
>>>  start print plan
< Execution Plan >
=============================================================================
¦  IDX  ¦  NODE DESCRIPTION                                                  ¦
-----------------------------------------------------------------------------
¦    0  ¦  SELECT STATEMENT                                                  ¦
¦    1  ¦    QUERY BLOCK ("$QB_IDX_2")                                     ¦
¦    2  ¦      SORT INSTANT                                                ¦
¦    3  ¦        TABLE ACCESS ("NATION")                                   ¦
=============================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  LIMIT SORT
           SORT KEY : "NATION.N_NATIONKEY ASC NULLS LAST"
           RECORD COLUMN : NATION.N_NAME
           READ KEY COLUMN : NATION.N_NATIONKEY
           READ RECORD COLUMN : NATION.N_NAME
     3  -  READ COLUMN : NATION.N_NATIONKEY, NATION.N_NAME
<<<  end print plan
```

SORT INSTANT is performed with LIMIT SORT in the execution plan above.

NO_USE_ORDER_LIMIT_SORT

If NO_USE_ORDER_LIMIT_SORT hint is specified, then an optimizer does not apply limit sort method. The refore, it is processed by creating SORT INSTANT, or making the row to be sorted for sort key column and

to ascend from the subordinate node.

```
\EXPLAIN PLAN
  SELECT /*+ NO_USE_ORDER_LIMIT_SORT */
         n_nationkey,
         n_name
    FROM nation
ORDER BY n_nationkey
   LIMIT 10,10;
>>>  start print plan
< Execution Plan >
=========================================================================
|  IDX  |  NODE DESCRIPTION                                             |
-------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                             |
|    1  |    QUERY BLOCK ("$QB_IDX_2")                                  |
|    2  |      INDEX ACCESS ("NATION", "NATION_PK_INDEX")               |
=========================================================================
     1  -  TARGET : NATION.N_NATIONKEY, NATION.N_NAME
     2  -  READ INDEX COLUMN : NATION.N_NATIONKEY
           READ TABLE COLUMN : NATION.N_NAME
<<<  end print plan
```

LIMIT SORT method is not applied in the execution plan above.

<order driver hints>

Those hints are available when performing *order by* clause in the cluster system. They are ignored in the s tandalone system.

LOCAL_ORDER

It performs *order by* in the current server.

The following is an example of using LOCAL_ORDER hint.

```
\EXPLAIN PLAN
  SELECT /*+ LOCAL_ORDER */
         o_orderdate, o_orderstatus
    FROM orders
   WHERE o_orderdate >= date '1993-07-01'
     AND o_orderdate < date '1993-07-01' + interval '1' month
ORDER BY o_orderdate;
>>>  start print plan
```

```
< Execution Plan >
============================================================================

<<<  end print plan
```

〈aggregation hints〉

Those hints are available when performing single-row aggregation.

〈aggregation driver hints〉

Those hints are available when performing single-row aggregation in the cluster system. It is ignored in th e standalone system.

LOCAL_AGGR

It performs aggregation in the current server.

The following is an example of using LOCAL_AGGR hint.

```
\EXPLAIN PLAN
SELECT /*+ LOCAL_AGGR */
       sum(ps_supplycost * ps_availqty) * 0.0001
  FROM partsupp,
       supplier,
       nation
 WHERE ps_suppkey = s_suppkey
   AND s_nationkey = n_nationkey
   AND n_name = 'GERMANY';
>>>  start print plan
< Execution Plan >

          MAX RANGE : _A1.PS_SUPPKEY = {_A2.S_SUPPKEY}
<<<  end print plan
```

In the execution plan above, it performs aggregation in each server, then performs re-aggregation by brin g the result to a local.

15.7 SQL Trace Log

Overview

SQL trace log records the information about performing a user query which can is analyzable. SQL trace log is created in $GOLDILOCKS_DATA/trc directory being separated as independent files such as process ID and a session ID. SQL trace log consists of various information such as a user query, SQL execution plan, and SQL execution time per each SQL process phase, then output.

Output

TRACE_LOG_ID value should be set by using ALTER SESSION statement or ALTER SYSTEM statement to output SQL trace log . For more information about the set value, refer to **TRACE_LOG_ID** of server property.

Trace log can record both successful SQL query and failed SQL query, and it can be set by combining flag values of TRACE_LOG_ID.

SQL query which failed on execution phase of **SQL Processing** is called as a failed SQL query. Therefore, SQL queries failed on a parser, a validator, a rewriter, an enumerator, a code planner, a data planner phases are not recorded on a trace log.

The following is an example of outputting SQL trace log by using TRACE_LOG_ID property.

- It outputs both successful SQL statement and failed SQL statement.

```
gSQL> ALTER SESSION SET TRACE_LOG_ID = 110000;
Session altered.
```

- It outputs both successful SQL statement and the bind value.

```
gSQL> ALTER SYSTEM SET TRACE_LOG_ID = 100010;
System altered.
```

When set TRACE_LOG_ID, which is a property to output SQL trace log, to ALTER SESSION, then it is applied only to the corresponding session and operated in it. If it is set to ALTER SYSTEM, then it is applied to all sessions of all processes connected to the server then operated in them. Therefore, use ALTER SESSIO

N to see the SQL trace log of the current session, and use ALTER SYSTEM to see SQL trace log of other pr ocesses and other sessions.

> ⚠ If the number of processes and sessions connected to the server when it is set to ALTER SYSTE M, then SQL trace log files are created a s many, so be cautious to use it.

SQL trace log file is created under trc directory, and the file name is created as follows.

```
opt_p[process ID]_s[session ID].trc
```

It specifies opt in front of a file name, then identifier p together with process ID, then session ID together with identifier s. The delimiter is_, and extension is trc. If the data created in the same session of the sam e process is bigger than the maximum size of SQL trace log file, then the file name is changed by adding t he current time at the end of the existing file name. Then, it creates a new file with the current file name and keep recording.

The following is an example of SQL trace log file name.

```
opt_p17104_s12.trc
```

Output Format

SQL trace log are divided into <SQL query string>, <Execution plan>, <Execution type>, <Bind param value > and <Time info>.

SQL Query String

It outputs the query input by a user including the current time, whether it is successful and the query proc essing time, and the output format is as follows.

```
[current time] [whether it is successful][query processing time] SQL statement
```

The date and time in us unit is input in [current time], and if it is successful S is input in [*whether it is succ essful*], if it is failed, then F is output. The query processing time is output in us unit, and SQL statement is input by a user.

The query processing time is measure in 10 ms when **TRACE_LOG_TIME_DETAIL** property is not set to *O N*. However, if this property is set to *ON*, then the query processing performance may be degraded.

Execution Plan

It outputs the execution plan of SQL statement. The form is similar to **Execution Plan**, and the total time c olumn is additionally output on the execution plan node table. The total time output on the statement is the time of processing the entire query, and the total time output on other nodes is the processing time o n each node. In this case, the total time is output in 10 ms unit.

Use **TRACE_LOG_TIME_DETAIL** property to output the detailed time. However, if this property is set to *O N*, then the then the query processing performance may be degraded.

Execution Type

When it directly performs the query by executing SQL statement, then it outputs *DIRECT EXECUTE*. When it performs the query by using prepare, it outputs *PREPARE EXECUTE*.

Bind Param Value

When a bind param value is used in SQL statement, then it outputs the information about the bind para m value. When a bind param value is not used in SQL statement, it outputs *No Bind Param*.

Time Info

It outputs the execution time per each phase of SQL processing. Time info is output being divided into m odule, time, rate and call. Module outputs the phase name such as parse and validate, and time output t he actual execution time, and rate outputs the ratio of execution time of each phase to the total executio n time. Call outputs how may times each phase is called.

Module consists of 7 phases such as parse, validate, code opt, optimizer, data opt, execute, fetch and tot al phase. A query is parsed on parse phase, and the parsed query is validated on phase. it is preprocessed to perform SQL optimizer on code opt phase, and SQL optimizer is actually executed on optimizer phase. It is prepared to execute the SQL execution plan on data opt phase, then SQL execution plan is executed on execute phase. Query results are collected like as SELECT statement and the result is returned on fetch phase.

When a plan cache is used, validate, code opt, optimizer may not be called. Time is output in 10 ms unit, so the execution time shorter than 10 ms is output as 0. Also, rate is the ratio of execution time of each p hase to the total execution time, so the total is 100%, and the ratio of dividing the execution time of eac h phase to total is output. In this case, of the execution time of each phase is 0, then it is output as 0%.

Use **TRACE_LOG_TIME_DETAIL** property to output the detailed time. However, if this property is set to *O N*, then the then the query processing performance may be degraded.

Examples

The following is SQL statement which does not have a bind param value.

```
SELECT O_TOTALPRICE, O_ORDERDATE, L_QUANTITY
  FROM ORDERS, LINEITEM
 WHERE O_ORDERKEY = L_ORDERKEY
   AND O_ORDERDATE >= DATE '1996-01-01'
   AND L_SHIPMODE = 'AIR';
```

The following SQL trace log is output when executing the SQL statement above after setting TRACE_LOG _ID to 101111.

```
[2017-05-25 12:27:59.199657] [S][0.000000] SELECT O_TOTALPRICE, O_ORDERDATE, L_QUANTITY
  FROM ORDERS, LINEITEM
 WHERE O_ORDERKEY = L_ORDERKEY
   AND O_ORDERDATE >= DATE '1996-01-01'
   AND L_SHIPMODE = 'AIR'
< Execution Plan >

16.

Built-in Data Type References

16.1 Aliases of Built-in Data Types

- BIGINT
  - It is as same as NUMBER(19,0).
  - Refer to **NUMBER**.
- BINARY
  - Refer to **BINARY**.
- BINARY VARYING
  - Refer to **BINARY VARYING** .
- BINARY LONG VARYING
  - Refer to **BINARY LONG VARYING** .
- BOOLEAN
  - Refer to **BOOLEAN**.
- CHAR
  - It is as same as CHARACTER.
  - Refer to **CHARACTER**.
- CHARACTER
  - Refer to **CHARACTER**.
- CHARACTER VARYING
  - Refer to **CHARACTER VARYING**.
- CHARACTER LONG VARYING
  - Refer to **CHARACTER LONG VARYING**.
- DATE
  - Refer to **DATE**.
- DEC
  - It is as same as NUMERIC.
  - Refer to **NUMERIC**.
- DECIMAL
  - It is as same as NUMERIC.
  - Refer to **NUMERIC**.
- DOUBLE
  - It is as same as FLOAT(53).
  - Refer to **FLOAT**.
- DOUBLE PRECISION
  - It is as same as FLOAT(53).
  - Refer to **FLOAT**.
- FLOAT
  - Refer to **FLOAT**.
- FLOAT4
  - It is as same as FLOAT(24).

    - Refer to **FLOAT**.
- FLOAT8
    - It is as same as FLOAT(53).
    - Refer to **FLOAT**.
- INT
    - It is as same as NUMBER(10,0).
    - Refer to **NUMBER**.
- INT2
    - It is as same as NUMBER(5,0).
    - Refer to **NUMBER**.
- INT4
    - It is as same as NUMBER(10,0).
    - Refer to **NUMBER**.
- INT8
    - It is as same as NUMBER(19,0).
    - Refer to **NUMBER**.
- INTEGER
    - It is as same as NUMBER(10,0).
    - Refer to **NUMBER**.
- INTERVAL
    - Refer to **INTERVAL**.
- LONG BINARY VARYING
    - It is as same as BINARY LONG VARYING.
    - Refer to **BINARY LONG VARYING**.
- LONG CHAR VARYING
    - It is as same as CHARACTER LONG VARYING.
    - Refer to **CHARACTER LONG VARYING**.
- LONG CHARACTER VARYING
    - It is as same as CHARACTER LONG VARYING.
    - Refer to **CHARACTER LONG VARYING**.
- LONG VARCHAR
    - It is as same as CHARACTER LONG VARYING.
    - Refer to **CHARACTER LONG VARYING**.
- NATIVE_BIGINT
    - Refer to **NATIVE_BIGINT**.
- NATIVE_DOUBLE
    - Refer to **NATIVE_DOUBLE**.
- NATIVE_INTEGER
    - Refer to **NATIVE_INTEGER**.
- NATIVE_REAL
    - Refer to **NATIVE_REAL**.

- NATIVE_SMALLINT
  - Refer to **NATIVE_SMALLINT**.
- NUMBER
  - Refer to **NUMBER**.
- NUMERIC
  - Refer to **NUMERIC**.
- ROWID
  - Refer to **ROWID**.
- SMALLINT
  - It is as same as NUMBER(5,0).
  - Refer to **NUMBER**.
- TIME
  - Refer to **TIME**.
- TIMESTAMP
  - Refer to **TIMESTAMP**.
- VARBINARY
  - It is as same as BINARY VARYING.
  - Refer to **BINARY VARYING**.
- VARCHAR
  - It is as same as CHARACTER VARYING.
  - Refer to **CHARACTER VARYING**.
- VARCHAR2
  - It is as same as CHARACTER VARYING.
  - Refer to **CHARACTER VARYING**.

16.2 BINARY

Syntax

```
BINARY [ (length) ]
```

Syntax Rules and Parameters

- length: It is the binary string length.
  - Range: 1 ~ 2000
  - Default value: 1

Description

A fixed-length binary string is stored.
If the binary string length to be stored is shorter than the specified length, X'00 ' is stored in the remaini ng part.

- Storage size: Bytes of the length value

For More Information

Refer to the followings.

- **BINARY VARYING**
- **BINARY LONG VARYING**

16.3 BINARY VARYING

Syntax

```
BINARY VARYING (length)
```

Syntax Rules and Parameters

- length: It is the maximum length of binary string.
  - Range: 1 ~ 4000

Description

The variable-length binary string is stored.

- Storage size: Bytes of the binary string to be stored
- Alias names: VARBINARY

For More Information

Refer to the followings.

- **BINARY**
- **BINARY LONG VARYING**

16.4 BINARY LONG VARYING

Syntax

```
BINARY LONG VARYING
```

Description

The value of the long variable binary string is stored.

- Maximum storage size: 100 megabytes
- Storage size: Bytes of the binary string to be stored
- Alias names: LONG BINARY VARYING, LONG VARBINARY

It can not be used as a column of the key, so there are limitations as follows.

- It can not be used as a key column of an index.
- It can not be used as the expression of ORDER BY clause.
- It can not be used as the expression of GROUP BY clause.
- It can not be used as the expression of DISTINCT clause.
- It can not be used as the expression of UNION, INTERSECT, EXCEPT clauses.

For More Information

Refer to the followings.

- **BINARY**
- **BINARY VARYING**

16.5 BOOLEAN

Syntax

```
BOOLEAN
```

Description

TRUE or FALSE is stored.

- Storage size: 1 byte.

16.6 CHARACTER

Syntax

```
CHARACTER [ (length [ CHARACTERS ¦ OCTETS ¦ CHAR ¦ BYTE ] ) ]
```

Syntax Rules and Parameters

- length: It is the string length.
  - Range: 1 ~ 2000
  - Default value: 1

- [CHARACTERS | OCTETS | CHAR | BYTE]: It is unit of length.
  - CHARACTERS
    - The number of characters
    - CHAR is as same as CHARACTERS.
  - OCTETS
    - The number of bytes
    - BYTE is as same as OCTETS.
  - If omitted, the default is the property value of **CHAR_LENGTH_UNITS** which is set when creating database.

Description

A fixed-length string is stored.
If the length of the string to be stored is shorter than the specified length, white spaces are stored in the r emaining part.

- Storage size: Bytes of the length value
- Alias name: CHAR

For More Information

Refer to the followings.

- CHARACTER VARYING
- CHARACTER LONG VARYING

16.7 CHARACTER VARYING

Syntax

```
CHARACTER VARYING ( length [ CHARACTERS ¦ OCTETS ¦ CHAR ¦ BYTE ] )
```

Syntax Rules and Parameters

- length: It is the string length.
  - Range: 1 ~ 4000

- [CHARACTERS | OCTETS | CHAR | BYTE]: It is unit of length.
  - CHARACTERS
    - The number of characters
    - CHAR is as same as CHARACTERS.
  - OCTETS
    - The number of bytes
    - BYTE is as same as OCTETS.
  - If omitted, the default is the property value of **CHAR_LENGTH_UNITS** which is set when creating database.

Description

The variable-length string is stored.

- Storage size: Bytes of the string to be stored
- Alias names: VARCHAR, VARCHAR2

For More Information

Refer to the followings.

- **CHARACTER**
- **CHARACTER LONG VARYING**

16.8 CHARACTER LONG VARYING

Syntax

```
CHARACTER LONG VARYING
```

Description

The value of the long variable-length string is stored.

- Maximum storage size: 100 megabytes
- Storage size: Bytes of the string to be stored
- Alias names: LONG CHARACTER VARYING, LONG CHAR VARYING, LONG VARCHAR

It can not be used as a column of the key, so there are limitations as follows.

- It can not be used as a key column of an index.
- It can not be used as the expression of ORDER BY clause.
- It can not be used as the expression of GROUP BY clause.
- It can not be used as the expression of DISTINCT clause.
- It can not be used as the expression of UNION, INTERSECT, EXCEPT clauses.

For More Information

Refer to the followings.

- CHARACTER
- CHARACTER VARYING

16.9 DATE

Syntax

```
DATE
```

Description

It is the date type including YEAR, MONTH, DAY, HOUR, MINUTE and SECOND (excluding fractional seconds).

- Value range: Date value between '4714-11-24 BC' and '9999-12-31 AD'
- Storage size: 8 bytes

For More Information

Refer to the followings.

- **Date Literals**
- **TIME**
- **TIMESTAMP**

16.10 FLOAT

Syntax

```
FLOAT[ ( precision ) ]
```

Syntax Rules and Parameters

- precision: It is the binary precision of significant digits.
  - Precision range: 1 ~ 126
  - Default value: 126

Description

The floating point value with a binary precision is stored.

- Exponential range: 1E-130 ~ 1E+125
- Storage size: (number of digits in integer part+ 1) / 2 + (number of digits in fractional part + 1) / 2 + 1(exponent, sign)

It has a binary precision value unlike **NUMBER**, **NUMERIC** types.

- Alias names: REAL = FLOAT(24), DOUBLE = FLOAT(53), DOUBLE PRECISION = FLOAT(53), FLOAT4 = FLOAT(24), FLOAT8 = FLOAT(53).

For More Information

Refer to the followings.

- **NUMBER**
- **NUMERIC**

16.11 INTERVAL

Syntax

```
<interval_type> ::=
      INTERVAL YEAR [ ( leading_precision ) ]
    ¦ INTERVAL MONTH [ ( leading_precision ) ]
    ¦ INTERVAL DAY [ ( leading_precision ) ]
    ¦ INTERVAL HOUR [ ( leading_precision ) ]
    ¦ INTERVAL MINUTE [ ( leading_precision ) ]
    ¦ INTERVAL SECOND [ ( leading_precision  [ , fractional_seconds_precision ] ) ]
    ¦ INTERVAL YEAR [ ( leading_precision ) ] TO MONTH
    ¦ INTERVAL DAY [ ( leading_precision ) ] TO HOUR
    ¦ INTERVAL DAY [ ( leading_precision ) ] TO MINUTE
    ¦ INTERVAL DAY [ ( leading_precision ) ] TO SECOND [ ( fractional_seconds_precision ) ]
    ¦ INTERVAL HOUR [ ( leading_precision ) ] TO MINUTE
    ¦ INTERVAL HOUR [ ( leading_precision ) ] TO SECOND [ ( fractional_seconds_precision ) ]
    ¦ INTERVAL MINUTE [ ( leading_precision ) ] TO SECOND [ ( fractional_seconds_precision ) ]
```

Syntax Rules and Parameters

- INTERVAL YEAR [(leading_precision)]: A period of YEAR is stored.
  - leading_precision
    - The number of digits in YEAR
    - Value range: 2 ~ 6
    - Default value: 2

- INTERVAL MONTH [(leading_precision)]: A period of MONTH is stored.
  - leading_precision
    - The number of digits in MONTH
    - Value range: 2 ~ 6
    - Default value: 2

- INTERVAL YEAR [(leading_precision)] TO MONTH: A period of YEAR and MONTH is stored.
  - leading_precision
    - The number of digits in YEAR
    - Value range: 2 ~ 6

        - Default value: 2

- INTERVAL DAY [(leading_precision)]: A period of DAY is stored.
    - leading_precision
        - The number of digits in DAY
        - Value range: 2 ~ 6
        - Default value: 2

- INTERVAL HOUR [(leading_precision)]: A period of HOUR is stored.
    - leading_precision
        - The number of digits in HOUR
        - Value range: 2 ~ 6
        - Default value: 2

- INTERVAL MINUTE [(leading_precision)]: A period of MINUTE is stored.
    - leading_precision
        - The number of digits in MINUTE
        - Value range: 2 ~ 6
        - Default value: 2

- INTERVAL SECOND [(leading_precision [, fractional_seconds_precision])]: A period of SECOND is stored.
    - leading_precision
        - The number of digits in SECOND
        - Value range: 2 ~ 6
        - Default value: 2
    - fractional_seconds_precision
        - The number of digits in fractional seconds
        - Value range: 0 ~ 6
        - Default value: 6

- INTERVAL DAY [(leading_precision)] TO HOUR: A period of DAY and HOUR is stored.
    - leading_precision
        - The number of digits in DAY
        - Value range: 2 ~ 6
        - Default value: 2

- INTERVAL DAY [(leading_precision)] TO MINUTE: A period of DAY, HOUR, and MINUTE is stored.
    - leading_precision
        - The number of digits in DAY
        - Value range: 2 ~ 6
        - Default value: 2

- INTERVAL DAY [(leading_precision)] TO SECOND [(fractional_seconds_precision)]: A period of DAY, HOUR, MINUTE, and SECOND is stored.
  - leading_precision
    - The number of digits in DAY
    - Value range: 2 ~ 6
    - Default value: 2
  - fractional_seconds_precision
    - The number of digits in fractional seconds
    - Value range: 0 ~ 6
    - Default value: 6

- INTERVAL HOUR [(leading_precision)] TO MINUTE: A period of HOUR and MINUTE is stored.
  - leading_precision
    - The number of digits in HOUR
    - Value range: 2 ~ 6
    - Default value: 2

- INTERVAL HOUR [(leading_precision)] TO SECOND [(fractional_seconds_precision)]: A period of HOUR, MINUTE and SECOND is stored.
  - leading_precision
    - The number of digits in HOUR
    - Value range: 2 ~ 6
    - Default value: 2
  - fractional_seconds_precision
    - The number of digits in fractional seconds
    - Value range: 0 ~ 6
    - Default value: 6

- INTERVAL MINUTE [(leading_precision)] TO SECOND [(fractional_seconds_precision)]: A period of MINUTE and SECOND is stored.
  - leading_precision
    - The number of digits in MINUTE
    - Value range: 2 ~ 6
    - Default value: 2
  - fractional_seconds_precision
    - The number of digits in fractional seconds
    - Value range: 0 ~ 6
    - Default value: 6

Description

INTERVAL types are classified into YEAR TO MONTH family type and DAY TO SECOND family type depen ding on the range of value representation as follows.

- YEAR TO MONTH family type: Its storage size is 8 bytes.
  - INTERVAL YEAR
  - INTERVAL MONTH
  - INTERVAL YEAR TO MONTH
