- DAY TO SECOND family type: Its storage size is 16 bytes.
  - INTERVAL DAY
  - INTERVAL HOUR
  - INTERVAL MINUTE
  - INTERVAL SECOND
  - INTERVAL DAY TO HOUR
  - INTERVAL DAY TO MINUTE
  - INTERVAL DAY TO SECOND
  - INTERVAL HOUR TO MINUTE
  - INTERVAL HOUR TO SECOND
  - INTERVAL MINUTE TO SECOND

If the number which is bigger than number of the specified digits is in the field to which the leading_prec ision is specified, then an error is returned.
If the number which is bigger than number of the specified digits is in the field to which the fractional_se conds_precision is specified, it is rounded off.

Table 16-1 Precisions and value range of the second or later field in INTERVAL * TO *

Field	Precision	Value range
MONTH	2	0 ~ 11
HOUR	2	0 ~ 23
MINUTE	2	0 ~ 59
SECOND (interger part)	2	0 ~ 59

For More Information

Refer to **Interval Literals**.

16.12 NATIVE_BIGINT

Syntax

```
NATIVE_BIGINT
```

Description

Signed 8-byte integer is stored.

It is as same as long long data type of C language (8 bytes integer).

- Value range: -9,223,372,036,854,775,808 ~ 9,223,372,036,854,775,807
- Storage size: 8 bytes

16.13 NATIVE_DOUBLE

Syntax

```
NATIVE_DOUBLE
```

Description

Double precision floating-point number (8 bytes) is stored.

It is as same as double data type of C language.

- Exponential range: 1E-307 ~ 1E+308
- Storage size: 8 bytes

16.14 NATIVE_INTEGER

Syntax

```
NATIVE_INTEGER
```

Description

Signed 4 byte integer is stored.

It is as same as integer data type of C language (4 bytes).

- Value range: -2,147,483,648 ~ +2,147,483,647
- Storage size: 4 bytes

16.15 NATIVE_REAL

Syntax

```
NATIVE_REAL
```

Description

Single precision floating-point number (4 bytes) is stored.

It is as same as float data type of C language.

- Exponential range: 1E-37 ~ 1E+37
- Storage size: 4 bytes

16.16 NATIVE_SMALLINT

Syntax

```
NATIVE_SMALLINT
```

Description

Signed 2 byte integer is stored.

It is as same as short data type of C language.

- Value range: -32,768 ~ 32,767
- Storage size: 2 bytes

16.17 NUMBER

Syntax

```
NUMBER  [ ( precision [ , scale ] ) ]
```

Syntax Rules and Parameters

- NUMBER: A floating point number without a precision and scale is stored.
  - The range of significant digits: 38
  - Exponential range: 1E-130 ~ 1E+125
  - It is as same as FLOAT (126).

- NUMBER(precision): The integer with significant digits of precision is stored.
  - Precision range: 1 ~ 38
  - The scale value: 0
  - It has a decimal precision value unlike **FLOAT** type.
  - It is as same as NUMBER(precision, 0), NUMERIC(precision, 0).

- NUMBER(precision, scale): A fixed point number with precision and scale is stored.
  - Precision range: 1 ~ 38
  - Scale range: -84 ~ 127
  - It has a decimal precision value unlike **FLOAT** type.
  - It is as same as NUMERIC (precision,scale).
  - Alias names: SMALLINT = NUMBER(5,0), INTEGER = NUMBER(10,0), BIGINT = NUMBER(19,0), I NT2 = NUMBER(5,0), INT4 = NUMBER(10,0), INT8 = NUMBER(19,0)

Description

NUMBER type is similar to NUMERIC type, but if both the precision and scale are omitted, NUMBER type s tores the floating point number whose precision and scale are not specified.

- NUMBER without precision, scale: Floating-point number
- NUMERIC without precision, scale: The fixed point number of NUMERIC(38, 0)
- Storage size: (number of digits in integer part + 1) / 2 + (number of digits in fractional part + 1) / 2 + 1(exponent, sign)

For More Information

Refer to the followings.

- FLOAT
- NUMERIC

16.18 NUMERIC

Syntax

```
NUMERIC  [ ( precision [ , scale ] ) ]
```

Syntax Rules and Parameters

- precision: It is the decimal precision of significant digits.
  - precision range: 1 ~ 38
  - Default value: 38

- scale: It is the decimal point range.
  - scale range: -84 ~ 127
  - Default value: 0

Description

A fixed point number with precision and scale is stored.

If the precision and scale are omitted, it means as follows.

- NUMERIC = NUMERIC(38,0)
- NUMERIC(p) = NUMERIC(p,0)

NUMBER type is similar to NUMERIC type, but if both the precision and scale are omitted, NUMBER type s tores the floating-point number whose precision and scale are not specified.

- NUMBER without precision, scale: Floating point number
- NUMERIC without precision, scale: Fixed point number of NUMERIC(38,0)
- Storage size: (number of digits in integer part + 1) / 2 + (number of digits in fractional part + 1) / 2 + 1(exponent, sign)

For More Information

Refer to the followings.

- FLOAT
- NUMBER

16.19 ROWID

Syntax

```
ROWID
```

Description

A record identifier (ROWID) is stored.
A record identifier (ROWID) is the identification information of each record in database.
When querying the ROWID pseudo column, each record identifier (ROWID) is obtained. This ROWID pseu do column has the ROWID data type information.

ROWID type consists of the followings in a stand-alone system.
- OBJECT_ID
- TABLESPACE_ID
- PAGE_ID
- OFFSET within PAGE

ROWID type consists of the followings in a cluster system.
- GRID_BLOCK_SEQUENCE
- GRID_BLOCK_ID
- MEMBER_ID
- SHARD_ID

ROWID is stored in the base 64 value, which can include A ~ Z, a ~ z, 0 ~ 9, +, /.
Each component information of ROWID is obtained using ROWID-related functions.

- Storage size: 16 bytes

For More Information

Refer to the followings.

- **ROWID Pseudo Column**
- **ROWID-related Functions**

16.20 TIME

Syntax

```
TIME [ ( fractional_seconds_precision ) ] [ WITH TIME ZONE ¦ WITHOUT TIME ZONE ]
```

Syntax Rules and Parameters

- fractional_seconds_precision: It is the number of significant digits in fractional seconds.
  - fractional_seconds_precision range: 0 ~ 6
  - Default value: 6

- [WITH TIME ZONE | WITHOUT TIME ZONE]: It specifies whether to store TIME ZONE value.
  - WITH TIME ZONE: The time which includes time zone
  - WITHOUT TIME ZONE: The time which does not include time zone
  - Default value: WITHOUT TIME ZONE

Description

The time which includes HOUR, MINUTE and SECOND is stored.

- Storage size
  - TIME WITHOUT TIME ZONE: 8 bytes
  - TIME WITH TIME ZONE: 12 bytes

For More Information

Refer to the followings.

- **Time Literals**
- **Time with Time Zone Literals**
- **DATE**
- **TIMESTAMP**

16.21 TIMESTAMP

Syntax

```
TIMESTAMP [ ( fractional_seconds_precision ) ] [ WITH TIME ZONE ¦ WITHOUT TIME ZONE ]
```

Syntax Rules and Parameters

- fractional_seconds_precision: It is the number of significant digits in the fractional seconds.
  - fractional_seconds_precision range: 0 ~ 6
  - Default value: 6

- [WITH TIME ZONE | WITHOUT TIME ZONE]: It specifies whether to store TIME ZONE value.
  - WITH TIME ZONE: The time which includes time zone.
  - WITHOUT TIME ZONE: The time which does not include time zone.
  - Default value: WITHOUT TIME ZONE

Description

The time which includes YEAR, MONTH, DATE, HOUR, MINUTE and SECOND is stored.

- Storage size
  - TIMESTAMP WITHOUT TIME ZONE: 8 bytes
  - TIMESTAMP WITH TIME ZONE: 12 bytes

For More Information

Refer to the followings.

- **Timestamp Literals**
- **Timestamp with Time Zone Literals**
- **DATE**
- **TIME**

17.

Built-in Function References

17.1 * (MULTIPLICATION)

Syntax

```
expr1 * expr2
```

Description

It returns the multiplication result of expr1 and expr2.

The multiplication types and result types are as follows.
For more information, refer to **Type Conversion**.

Table 17-1 Numeric * operation

expr1 (expr2)	expr2 (expr1)	Result type
NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_BIGINT
NUMBER	NUMBER	NUMBER
NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

Table 17-2 INTERVAL * operation

expr1 (expr2)	expr2 (expr1)	Result type
INTERVAL YEAR TO MONTH	Numeric type	INTERVAL YEAR TO MONTH (The result type is the interval type.)
INTERVAL DAY TO SECOND	Numeric type	INTERVAL DAY TO SECOND (The result type is the interval type.)
Refer to **INTERVAL type details which is included in INTERVAL type written in the following table**.		

Table 17-3 INTERVAL type details which is included in INTERVAL type written in the following table

INTERVAL YEAR TO MONTH	INTERVAL DAY TO SECOND
	• INTERVAL DAY • INTERVAL HOUR • INTERVAL MINUTE

INTERVAL YEAR TO MONTH	INTERVAL DAY TO SECOND
• INTERVAL YEAR • INTERVAL MONTH • INTERVAL YEAR TO MONTH	• INTERVAL SECOND • INTERVAL DAY TO HOUR • INTERVAL DAY TO MINUTE • INTERVAL DAY TO SECOND • INTERVAL HOUR TO MINUTE • INTERVAL HOUR TO SECOND • INTERVAL MINUTE TO SECOND

Example

```
gSQL> SELECT INTERVAL'1-2'YEAR TO MONTH * 2 AS RESULT FROM DUAL;
RESULT
----------
+000002-04
1 row selected.
gSQL> SELECT INTERVAL'1 01:02:03.400000'DAY TO SECOND * 2 AS RESULT
      FROM DUAL;
RESULT
-----------------------
+000002 02:04:06.800000
1 row selected.
```

17.2 + (ADDITION)

Syntax

```
expr1 + expr2
```

Description

It returns the addition result of expr1 and expr2.

The addition types and result types are as follows.
For more information, refer to **Type Conversion**.

Table 17-4 Numeric + operation

expr1 (expr2)	expr2 (expr1)	Result type
NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_BIGINT
NUMBER	NUMBER	NUMBER
NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

Table 17-5 (DATETIME/INTERVAL) + operation

expr1 (expr2)	expr2 (expr1)	Result type
DATE	NUMERIC	DATE
DATE	INTERVAL YEAR TO MONTH	DATE
DATE	INTERVAL DAY	DATE
DATE	INTERVAL DAY TO SECOND	TIMESTAMP
TIME	NUMERIC	TIME
TIME	INTERVAL YEAR TO MONTH	TIME
TIME	INTERVAL DAY TO SECOND	TIME
TIME WITH TIME ZONE	NUMERIC	TIME WITH TIME ZONE
TIME WITH TIME ZONE	INTERVAL YEAR TO MONTH	TIME WITH TIME ZONE
TIME WITH TIME ZONE	INTERVAL DAY TO SECOND	TIME WITH TIME ZONE
TIMESTAMP	NUMERIC	TIMESTAMP

expr1 (expr2)	expr2 (expr1)	Result type
TIMESTAMP	INTERVAL YEAR TO MONTH	TIMESTAMP
TIMESTAMP	INTERVAL DAY TO SECOND	TIMESTAMP
TIMESTAMP WITH TIME ZONE	NUMERIC	TIMESTAMP WITH TIME ZONE
TIMESTAMP WITH TIME ZONE	INTERVAL YEAR TO MONTH	TIMESTAMP WITH TIME ZONE
TIMESTAMP WITH TIME ZONE	INTERVAL DAY TO SECOND	TIMESTAMP WITH TIME ZONE
INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH (The result type includes all the interval range of expr1 and expr2.)
INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND (The result type includes all the interval range of expr1 and expr2.)
Refer to **INTERVAL type details which is included in INTERVAL type written in the following table**.		

Example

```
gSQL> SELECT TO_DATE( '2012-05-05', 'YYYY-MM-DD' ) + 5 AS RESULT FROM DUAL;
RESULT
----------
2012-05-10
1 row selected.
gSQL> SELECT
      TO_DATE( '2012-05-05', 'YYYY-MM-DD' ) + INTERVAL'01-01'YEAR TO MONTH
      AS RESULT
      FROM DUAL;
RESULT
----------
2013-06-05
1 row selected.
gSQL> SELECT
      INTERVAL'01-01'YEAR TO MONTH + INTERVAL'02-10'YEAR TO MONTH
      AS RESULT
      FROM DUAL;
RESULT
----------
+000003-11
1 row selected.
```

17.3 + (POSITIVE)

Syntax

```
+ expr
```

Description

The + sign is displayed in expr.

Example

```
gSQL> SELECT +3 AS RESULT1, +(-3) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
      3      -3
1 row selected.
```

17.4 - (NEGATIVE)

Syntax

```
- expr
```

Description

The - sign is displayed in expr.

Example

```
gSQL> SELECT -3 AS RESULT1, -(-3) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
     -3       3
1 row selected.
```

17.5 - (SUBTRACTION)

Syntax

```
expr1 - expr2
```

Description

It returns the subtraction result of expr1 and expr2.

The subtraction types and result types are as follows.
For more information, refer to **Type Conversion**.

Table 17-6 Numeric - operation

expr1	expr2	Result type
NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_BIGINT
NUMBER	NUMBER	NUMBER
NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

Table 17-7 (DATETIME/INTERVAL) - operation

expr1	expr2	Result type
DATE	DATE	NUMBER
DATE	Numeric type	DATE
DATE	INTERVAL YEAR TO MONTH	DATE
DATE	INTERVAL DAY	DATE
DATE	INTERVAL DAY TO SECOND	TIMESTAMP
TIME	TIME	INTERVAL DAY TO SECOND
TIME	Numeric type	TIME
TIME	INTERVAL YEAR TO MONTH	TIME
TIME	INTERVAL DAY TO SECOND	TIME
TIME WITH TIME ZONE	Numeric type	TIME WITH TIME ZONE
TIME WITH TIME ZONE	INTERVAL YEAR TO MONTH	TIME WITH TIME ZONE

expr1	expr2	Result type
TIME WITH TIME ZONE	INTERVAL DAY TO SECOND	TIME WITH TIME ZONE
TIMESTAMP	TIMESTAMP	INTERVAL DAY TO SECOND
TIMESTAMP	Numeric type	TIMESTAMP
TIMESTAMP	INTERVAL YEAR TO MONTH	TIMESTAMP
TIMESTAMP	INTERVAL DAY TO SECOND	TIMESTAMP
TIMESTAMP WITH TIME ZONE	TIMESTAMP WITH TIME ZONE	INTERVAL DAY TO SECOND
TIMESTAMP WITH TIME ZONE	Numeric type	TIMESTAMP WITH TIME ZONE
TIMESTAMP WITH TIME ZONE	INTERVAL YEAR TO MONTH	TIMESTAMP WITH TIME ZONE
TIMESTAMP WITH TIME ZONE	INTERVAL DAY TO SECOND	TIMESTAMP WITH TIME ZONE
INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH (The result type includes all the interval range of expr1 and expr2.)
INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND (The result type includes all the interval range of expr1 and expr2.)
Refer to **INTERVAL type details which is included in INTERVAL type written in the following table**.		

Example

```
gSQL> SELECT
      TO_DATE( '2012-05-05' ) - TO_DATE( '2012-05-01' ) AS RESULT
      FROM DUAL;
RESULT
------
     4
1 row selected.
gSQL> SELECT TO_DATE( '2012-05-05' ) - 3 AS RESULT FROM DUAL;
RESULT
----------
2012-05-02
1 row selected.
gSQL> SELECT
      TO_DATE( '2012-05-05' ) - INTERVAL'01-02'YEAR TO MONTH AS RESULT
      FROM DUAL;
RESULT
----------
2011-03-05
1 row selected.
```

```
gSQL> SELECT
      INTERVAL'05-01'YEAR TO MONTH - INTERVAL'02-01'YEAR TO MONTH
      AS RESULT
      FROM DUAL;
RESULT
----------
+000003-00
1 row selected.
gSQL> SELECT INTERVAL'15 23:59:59.999999'DAY TO SECOND
           - INTERVAL'10 23:59:59.999999'DAY TO SECOND AS RESULT
      FROM DUAL;
RESULT
----------------------
+000005 00:00:00.000000
1 row selected.
```

17.6 / (DIVISION)

Syntax

```
expr1 / expr2
```

Description

It returns the division result of expr1 and expr2.

The division types and result types are as follows.
For more information, refer to **Type Conversion**.

Table 17-8 Numeric / operation

expr1	expr2	Result type
NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER	NUMBER
NATIVE_DOUBLE	NATIVE_DOUBLE	NATIVE_DOUBLE

Table 17-9 (DATETIME/INTERVAL) / operation

expr1	expr2	Result type
INTERVAL YEAR TO MONTH	Numeric type	INTERVAL YEAR TO MONTH (The result type is interval type.)
INTERVAL DAY TO SECOND	Numeric type	INTERVAL DAY TO SECOND (The result type is interval type.)
Refer to **INTERVAL type details which is included in INTERVAL type written in the following table**.		

Example

```
gSQL> SELECT INTERVAL'20-10'YEAR TO MONTH / 2 AS RESULT FROM DUAL;
RESULT
----------
```

```
+000010-05
1 row selected.
gSQL> SELECT   INTERVAL'02 02:04:06.800000'DAY TO SECOND / 2 AS RESULT
      FROM DUAL;
RESULT
----------------------
+000001 01:02:03.400000
1 row selected.
```

17.7 || (CONCATENATE)

Syntax

```
str1 || str2
```

Description

CONCATENATE returns the string concatenating str1 and str2.

If either str1 or str2 is NULL, the string except NULL is returned. If both of str1 and str2 are NULL, NULL is returned.

The argument can be a type which can be converted to either character string type or binary string type. For more information, refer to **Type Conversion**.

It is an alias of **CONCAT**, **CONCATENATE**.

The result types are as follows.

Table 17-10 The result types of || (CONCATENATE)

Data type	CHAR	VARCHAR	LONG VARCHAR
CHAR	CHAR	VARCHAR	LONG VARCHAR
VARCHAR	VARCHAR	VARCHAR	LONG VARCHAR
LONG VARCHAR	LONG VARCHAR	LONG VARCHAR	LONG VARCHAR
Data type	**BINARY**	**VARBINARY**	**LONG VARBINARY**
BINARY	BINARY	VARBINARY	LONG VARBINARY
VARBINARY	VARBINARY	VARBINARY	LONG VARBINARY
LONG VARBINARY	LONG VARBINARY	LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT 'DATA' || 'BASE' AS RESULT1,
             'DATA' || NULL   AS RESULT2,
               NULL || NULL   AS RESULT3
       FROM DUAL;
```

```
RESULT1  RESULT2 RESULT3
-------- ------- -------
DATABASE DATA    null
1 row selected.
```

17.8 ABS

Syntax

```
ABS( num )
```

Description

ABS returns the absolute value of num.

The num argument can be a numeric type or types which can be converted to number.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT ABS(-1) AS RESULT1, ABS(1) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
      1       1
1 row selected.
```

17.9 ACOS

Syntax

```
ACOS( num )
```

Description

ACOS returns the arc cosine value of num.
The num argument should be in the range of -1 to 1.
If num is NULL, then it returns NULL.
It returns the radians value in the range of 0 and pi.

Example

```
gSQL> SELECT ACOS( 1 ) FROM DUAL;
ACOS( 1 )
---------
        0
1 row selected.
```

17.10 ADDDATE

Syntax

```
ADDDATE( date, INTERVAL expr unit  )
ADDDATE( expr, days )
```

Description

ADDDATE adds the second argument to the first argument, then returns the result.
If any of the input argument value is NULL, the result is also NULL.
The first argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, and the second argument data type can be INTERVAL or numeric.

The result type is as same as **(DATETIME/INTERVAL) + operation**.

Example

```
gSQL> SELECT ADDDATE( TO_DATE( '2012-12-12', 'YYYY-MM-DD' ), 1 ) AS RESULT
        FROM DUAL;
RESULT
----------
2012-12-13
1 row selected.
gSQL> SELECT ADDDATE( TO_DATE( '2012-11-11', 'YYYY-MM-DD' ),
                      INTERVAL'01-01'YEAR TO MONTH ) AS RESULT
      FROM DUAL;
RESULT
----------
2013-12-11
1 row selected.
```

17.11 ADDTIME

Syntax

```
ADDTIME( expr1, expr2 )
```

Description

ADDTIME adds expr2 to expr1, then returns the result.

expr1 data type can be TIME, TIME WITH TIME ZONE, TIMESTAMP, TIMESTAMP WITH TIME ZONE TYPE, and expr2 data type can be INTERVAL DAY TO SECOND TYPE.
If expr1 or expr2 is NULL, the result is NULL.

The result type is as same as **(DATETIME/INTERVAL) + operation**.

Example

```
gSQL> SELECT
      ADDTIME( TO_TIMESTAMP( '2001-05-05 06:00:00',
                             'YYYY-MM-DD HH24:MI:SS' ),
               INTERVAL'0 00:06:06.666666'DAY TO SECOND ) AS RESULT
      FROM DUAL;
RESULT
--------------------------
2001-05-05 06:06:06.666666
1 row selected.
```

17.12 ADD_MONTHS

Syntax

```
ADD_MONTHS( date, number )
```

Description

ADD_MONTHS adds as many month as the number to the date, then returns the result.
After ADD_MONTHS operation, if the date is bigger than the last day of the month, it is adjusted to the l ast day of the month.

The data type of date argument can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, and the num ber argument can be a numeric type.
If any of the input argument is NULL, the result is also NULL.

The result type is always DATE regardless of the input argument date type.

Example

```
gSQL> SELECT
      ADD_MONTHS( TO_DATE( '2001-07-31', 'YYYY-MM-DD' ), 1 ) AS RESULT1,
      ADD_MONTHS( TO_DATE( '2001-07-31', 'YYYY-MM-DD' ), 2 ) AS RESULT2
      FROM DUAL;
RESULT1    RESULT2
---------- ----------
2001-08-31 2001-09-30
1 row selected.
```

17.13 ASCII

Syntax

```
ASCII( char )
```

Description

It returns the database character set code of the first character of char in decimal form.
The data type of char can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING or can be a type which can be converted to a character type, and the return type is NUMBER.
If char is NULL, then it returns NULL.

Example

```
gSQL> SELECT ASCII( 'G' ) AS RESULT FROM DUAL;
RESULT
------
    71
1 row selected.
```

17.14 ASIN

Syntax

```
ASIN( num )
```

Description

ASIN returns the arc sin value of num.

The num argument should be in the range of -1 to 1.
If num is NULL, then it returns NULL.

It returns the radians value in the range of -pi/2 and pi/2.

Example

```
gSQL> SELECT ASIN( 0 ) FROM DUAL;
ASIN( 0 )
---------
        0
1 row selected.
```

17.15 ATAN

Syntax

```
ATAN( num )
```

Description

ATAN returns the arc tangent value of num.

The num value range is not limited. It returns the radians value in the range of -pi/2 and pi/2.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT ATAN(0.5) FROM DUAL;
       ATAN(0.5)
----------------
.463647609000806
1 row selected.
```

17.16 ATAN2

Syntax

```
ATAN2( num1, num2 )
```

Description

ATAN2 returns the arc tangent value of num1 and num2.

The num1 argument value range is not limited. It returns the radians value in the range of -pi and pi. Either num1 or num2 is NULL, then it returns NULL.

Example

```
gSQL> SELECT ATAN2(1,2) FROM DUAL;
      ATAN2(1,2)
----------------
.463647609000806
1 row selected.
```

17.17 AVG

Syntax

```
AVG( [ ALL ¦ DISTINCT ] num )
```

Description

It is an aggregate function, and it obtains average value of exprs.

If ALL is explicitly specified, aggregation is executed for all values.
If DISTINCT is explicitly specified, aggregation is executed for the values which exclude duplicate values.
If ALL or DISTINCT is not explicitly specified, it is processed in the same way as when ALL is specified.

Example

```
gSQL> SELECT AVG(c1) FROM t1;
AVG(C1)
-------
      2
1 row selected.
```

17.18 AVG() OVER

Syntax

```
AVG ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function AVG calculates the average value of expr.
NULL is excluded from the calculation.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , AVG( min_price ) OVER ( ORDER BY min_price ) AS "AVG"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE              AVG
--------- ----------------
       73               73
      247              160
      731 350.333333333333
     null 350.333333333333
     null 350.333333333333
5 rows selected.
```

17.19 BITAND

Syntax

```
BITAND( num1, num2 )
```

Description

It returns the AND operation result for the bits of num1 and num2.

The input argument data type can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT or a data type which can be converted to NATIVE_BIGINT.
When converting to NATIVE_BIGINT type, the decimal point is truncated.
If any of the input argument value is NULL, the result is also NULL.

The result type is NATIVE_BIGINT.

Example

```
gSQL> SELECT BITAND( 5, 3 ) AS RESULT FROM DUAL;
RESULT
------
     1
1 row selected.
```

17.20 BITNOT

Syntax

```
BITNOT( num )
```

Description

It returns the NOT operation result for the num bit.

The input argument data type can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT or a data type which can be converted to NATIVE_BIGINT.
When converting to NATIVE_BIGINT type, the decimal point is truncated.
If the input argument is NULL, the result is also NULL.

The result type is as follows.

- If the input argument is NATIVE_SMALLINT type, its result type is NATIVE_SMALLINT type.
- If the input argument is NATIVE_INTEGER type, its result type is NATIVE_INTEGER type.
- If the input argument is NATIVE_BIGINT type, its result type is NATIVE_BIGINT type.

Example

```
gSQL> SELECT BITNOT( 5 ) AS RESULT FROM DUAL;
RESULT
------
    -6
1 row selected.
```

17.21 BITOR

Syntax

```
BITOR( num1, num2 )
```

Description

It returns the OR operation result for the bits of num1 and num2.

The input argument data type can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT types or a d ata type which can be converted to NATIVE_BIGINT type.
When converting to NATIVE_BIGINT type, the decimal point is truncated.
If any of the input argument value is NULL, the result is NULL.

The result type is NATIVE_BIGINT type.

Example

```
gSQL> SELECT BITOR( 5, 3 ) FROM DUAL;
BITOR( 5, 3 )
-------------
            7
1 row selected.
```

17.22 BITXOR

Syntax

```
BITXOR( num1, num2 )
```

Description

It returns the XOR operation result for the bits of num1 and num2.

The input argument data type can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT or a data type which can be converted to NATIVE_BIGINT.
When converting to NATIVE_BIGINT type, the decimal point is truncated.
If any of the input argument value is NULL, the result is NULL.

The result type is NATIVE_BIGINT.

Example

```
gSQL> SELECT BITXOR( 5, 3 ) FROM DUAL;
BITXOR( 5, 3 )
--------------
             6
1 row selected.
```

17.23 BIT_LENGTH

Syntax

```
BIT_LENGTH( str )
```

Description

BIT_LENGTH returns the number of bits for str.
If str is NULL, then it returns NULL.

Example

```
gSQL> SELECT BIT_LENGTH( 'LIKE' ) AS RESULT FROM DUAL;
     RESULT
     ---------------
             32
    1 row selected.
```

17.24 BYTE_LENGTH

Syntax

```
BYTE_LENGTH( str )
```

Description

It is an alias of OCTET_LENGTH.
For more information, refer to **OCTET_LENGTH**, **LENGTHB**.

Example

- Multi byte character set (e.g. UTF8): 1 byte character

```
gSQL> SELECT BYTE_LENGTH( 'OCTET_LENGTH' ) AS RESULT_1BYTE_CHARACTERS
        FROM DUAL;
RESULT_1BYTE_CHARACTERS
-----------------------
                     12
1 row selected.
```

- Multi byte character set (e.g. UTF8): 2 byte character

```
gSQL> SELECT BYTE_LENGTH( 'αβ' ) AS RESULT_2BYTE_CHARACTERS FROM DUAL;
RESULT_2BYTE_CHARACTERS
-----------------------
                      4
1 row selected.
```

17.25 CASE2

Syntax

```
CASE2( condition1, result1
      [, condition2, result2
       , ...
       , conditionN, resultN ]
      [, default ] )
```

Description

CASE2 evaluates the condition in the described order.
If the comparison result is FALSE, it continues evaluating until TRUE comes up.
If the comparison result is TRUE, it returns the corresponding result, and does not evaluate any more.
If all the evaluation results are FALSE, it returns the default value. If the default is omitted, it returns NULL.

If multiple types are used in result, then the result type is determined according to **Result Type Combinati on Rule**.

CASE2 can be expressed by using CASE as follows.

- CASE2(condition1, res1, condition2, res2)

```
CASE WHEN condition1 THEN res1
     WHEN condition2 THEN res2
     ELSE NULL
  END
```

- CASE2(condition1, res1, condition2, res2, default)

```
CASE WHEN condition1 THEN res1
     WHEN condition2 THEN res2
     ELSE default
  END
```

Example

```
gSQL> SELECT I1,
        CASE2( I1 = 1, 'ONE', I1 = 2, 'TWO' ) AS CASE2_RESULT1,
        CASE2( I1 = 1, 'ONE', I1 = 2, 'TWO', 'NUMBER' ) AS CASE2_RESULT2
      FROM T1;
I1 CASE2_RESULT1 CASE2_RESULT2
-- ------------- -------------
 1 ONE           ONE
 2 TWO           TWO
 3 null          NUMBER
3 rows selected.
```

17.26 CBRT

Syntax

```
CBRT( num )
```

Description

It returns the cube root of num.
If num is NULL, the result is also NULL.

Example

```
gSQL> SELECT CBRT( 27 ) FROM DUAL;
CBRT( 27 )
----------
         3
1 row selected.
```

17.27 CEIL

Syntax

```
CEIL( num )
CEILING( num )
```

Description

CEIL returns the smallest integer which is equal to or bigger than num.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT CEIL( 3.5 ) AS RESULT1, CEIL( -3.5 ) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
      4      -3
1 row selected.
```

17.28 CHAR_LENGTH

Syntax

```
CHAR_LENGTH( str )
CHARACTER_LENGTH( str )
```

Description

CHAR_LENGTH returns the number of character for str according to the character set.

The str can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYIN G, or it can be a data type which can be converted to character type. The return type is NATIVE_BIGINT.

If the data type of str is CHARACTER, the trailing blanks are included in the calculation.
If str is NULL, it returns NULL.

It is an alias of **LENGTH**.

Example

Multi byte character set: (e.g. UTF8)

```
gSQL> SELECT CHAR_LENGTH( 'αβ-SUMMER' ) AS RESULT FROM DUAL;
     RESULT
     ---------------
              9
    1 row selected.
```

17.29 CHR

Syntax

```
CHR( num )
```

Description

It returns a character in the database character set code corresponding to num.

num is a numeric type.
If num is NULL, then it returns NULL.
The return type is VARCHAR.

Example

```
gSQL> SELECT CHR(71) FROM DUAL;
CHR(71)
-------
G
1 row selected.
```

17.30 CLOCK_DATE

Syntax

```
CLOCK_DATE()
```

Description

Whenever the CLOCK_DATE function is called, the current date (DATE type) value is obtained.

The differences among the functions to obtain the current date are as follows.

- TRANSACTION_DATE(): All date values in the transaction are same.
- STATEMENT_DATE(): All date values in an SQL statement are same.
- CLOCK_DATE(): Whenever the function is called, the current date value is obtained.

Example

Each row can have a different date value.

```
gSQL> SELECT CLOCK_DATE() FROM t1;
CLOCK_DATE()
------------
2013-12-12
2013-12-12
2013-12-13
3 rows selected.
```

17.31 CLOCK_LOCALTIME

Syntax

```
CLOCK_LOCALTIME()
```

Description

Whenever the CLOCK_LOCALTIME function is called, the current time value without TIME ZONE (TIME WITHOUT TIME ZONE type) is obtained.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_LOCALTIME(): All time values in the transaction are same.
- STATEMENT_LOCALTIME(): All time values in an SQL statement are same.
- CLOCK_LOCALTIME(): Whenever the function is called, the current time value is obtained.

Example

Each row can have a different time value.

```
gSQL> SELECT CLOCK_LOCALTIME() FROM t1;
CLOCK_LOCALTIME()
-----------------
14:42:05.470757
14:42:05.470759
14:42:05.470759
3 rows selected.
```

17.32 CLOCK_LOCALTIMESTAMP

Syntax

```
CLOCK_LOCALTIMESTAMP()
```

Description

Whenever the CLOCK_LOCALTIMESTAMP() function is called, the current TIMESTAMP value without TIM E ZONE (TIMESTAMP WITHOUT TIME ZONE type) is obtained.

The differences among the functions to obtain the current TIMESTAMP are as follows.

- TRANSACTION_LOCALTIMESTAMP(): All TIMESTAMP values in the transaction are same.
- STATEMENT_LOCALTIMESTAMP(): All TIMESTAMP values in an SQL statement are same.
- CLOCK_LOCALTIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

Each row can have a different timestamp value.

```
gSQL> SELECT CLOCK_LOCALTIMESTAMP() FROM t1;
CLOCK_LOCALTIMESTAMP()
--------------------------
2013-12-12 14:46:17.309206
2013-12-12 14:46:17.309209
2013-12-12 14:46:17.309209
```

17.33 CLOCK_TIME

Syntax

```
CLOCK_TIME()
```

Description

Whenever the CLOCK_TIME() function is called, the current time value with TIME ZONE (TIME WITH TIME ZONE type) is obtained.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_TIME(): All time values in the transaction are same.
- STATEMENT_TIME(): All time values in an SQL statement are same.
- CLOCK_TIME(): Whenever the function is called, the current time value is obtained.

Example

Each row can have a different time value.

```
gSQL> SELECT CLOCK_TIME() FROM t1;
CLOCK_TIME()
----------------------
14:48:21.052324 +09:00
14:48:21.052326 +09:00
14:48:21.052327 +09:00
3 rows selected.
```

17.34 CLOCK_TIMESTAMP

Syntax

```
CLOCK_TIMESTAMP()
```

Description

Whenever CLOCK_TIMESTAMP() function is called, the current TIMESTAMP value with TIME ZONE (TIME STAMP WITH TIME ZONE type) is obtained.

The differences among the functions to obtain the current TIMESTAMP are as follows.

- TRANSACTION_TIMESTAMP(): All TIMESTAMP values in the transaction are same.
- STATEMENT_TIMESTAMP(): All TIMESTAMP values in an SQL statement are same.
- CLOCK_TIMESTAMP(): Whenever the function is called, the current TIMESTAMP value is obtained.

Example

Each row can have a different timestamp value.

```
gSQL> SELECT CLOCK_TIMESTAMP() FROM t1;
CLOCK_TIMESTAMP()
-------------------------------
2013-12-12 14:49:45.051709 +09:00
2013-12-12 14:49:45.051714 +09:00
2013-12-12 14:49:45.051714 +09:00
3 rows selected.
```

17.35 COALESCE

Syntax

```
COALESCE( expr1, ..., exprN )
```

Description

It returns the first non null expr in the expr list.
If all expr in the expr list are null, it returns null.
In the expr list, there should be two or more expr.

If multiple types are in the expr list, the result type is determined by the **Result Type Combination Rule**.

- COALESCE can be expressed by using CASE as follows.
    - COALESCE(expr1, expr2)

```
CASE WHEN expr1 IS NOT NULL THEN expr1
       ELSE expr2
  END
```

    - COALESCE(expr1, expr2, ..., exprN)

```
CASE WHEN expr1 IS NOT NULL THEN expr1
       ELSE COALESCE( expr2, ..., exprN )
  END
```

Example

```
gSQL> SELECT COALESCE( NULL, 1, 2 ) FROM DUAL;
COALESCE( NULL, 1, 2 )
----------------------
                     1
1 row selected.
gSQL> SELECT COALESCE( NULL, NULL, NULL ) FROM DUAL;
```

```
COALESCE( NULL, NULL, NULL )
----------------------------
null
1 row selected.
```

17.36 CONCAT

Syntax

```
CONCAT( str1, str2, ... )
```

Description

It is an alias of || (CONCATENATE).
It is an argument of CONCAT function and 2 ~ 254 number of CONCATs can be set.
For more information, refer to **|| (CONCATENATE)**, **CONCATENATE**.

Example

```
gSQL> SELECT CONCAT( 'DATA', 'BASE' ) AS RESULT FROM DUAL;
RESULT
--------
DATABASE
1 row selected.
```

17.37 CONCATENATE

Syntax

```
CONCATENATE( str1, str2, ... )
```

Description

It is an alias of || (CONCATENATE).
It is an argument of CONCATENATE function and 2 ~ 254 number of CONCATENATEs can be set.
For more information, refer to **CONCAT**, **|| (CONCATENATE)**.

Example

```
gSQL> SELECT CONCATENATE( 'DATA', 'BASE' ) AS RESULT FROM DUAL;
RESULT
--------
DATABASE
1 row selected.
```

17.38 CORR() OVER

Syntax

```
CORR( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function CORR calculates the coefficient of correlation for the pair of exprs.

If expr1 or expr2 is NULL, then it is excluded from the calculation.
If the number of rows for the pair of exprs is one or less, then it returns NULL as a result.

Example

```
gSQL> SELECT employee_id, TO_CHAR( hire_date, 'YYYY' ) AS hire_date, salary,
             CORR( TO_CHAR( hire_date, 'YYYY' ), salary ) OVER ( ORDER BY employee_id ) AS
corr
      FROM employees
      WHERE department_id = 60;
EMPLOYEE_ID HIRE_DATE SALARY              CORR
----------- --------- ------ -----------------
        103 1990        9000              null
        104 1991        6000                -1
        105 1997        4800 -.805837379342809
        106 1998        4800 -.840210805972693
        107 1999        4200 -.875185734200534
5 rows selected.
```

17.39 COS

Syntax

```
COS(num)
```

Description

It returns the COSINE value of num.
If the num argument is NULL, the result is also NULL.

Example

```
gSQL> SELECT COS( 0 ) FROM DUAL;
COS( 0 )
--------
       1
1 row selected.
```

17.40 COT

Syntax

```
COT(num)
```

Description

It returns the COTANGENT value of num.
If the num argument is NULL, the result is also NULL.

Example

```
gSQL> SELECT COT( 1 ) FROM DUAL;
        COT( 1 )
----------------
.642092615934331
1 row selected.
```

17.41 COUNT

Syntax

```
COUNT( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregate function. It returns the number of row whose expr is not NULL.

If ALL is explicitly specified, aggregation is executed for all values.
If DISTINCT is explicitly specified, aggregation is executed for the values which exclude duplicate values.
If ALL or DISTINCT is not explicitly specified, it is processed in the same way as when ALL is specified.

Example

```
gSQL> SELECT COUNT(c1) FROM t1;
COUNT(C1)
---------
        3
1 row selected.
```

17.42 COUNT() OVER

Syntax

```
COUNT ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function COUNT counts the number of rows.
NULL is excluded from the calculation.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , COUNT( min_price ) OVER ( ORDER BY min_price ) AS "COUNT"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE COUNT
--------- -----
       73     1
      247     2
      731     3
     null     3
     null     3
5 rows selected.
```

17.43 COUNT(*)

Syntax

```
COUNT(*)
```

Description

It is an aggregate function, and the number of rows is obtained.
It has nothing to do with whether it is NULL or not because an expression is not explicitly specified.

Example

```
gSQL> SELECT COUNT(*) FROM t1;
COUNT(*)
--------
       4
1 row selected.
```

17.44 COUNT(*) OVER

Syntax

```
COUNT(*) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function COUNT(*) counts the number of rows.
It does not separately specify an expression, so it is irrelevant whether the value is NULL or not.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , COUNT(*) OVER ( ORDER BY min_price ) AS "COUNT(*)"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE COUNT(*)
--------- --------
       73        1
      247        2
      731        3
     null        5
     null        5
5 rows selected.
```

17.45 COVAR_POP() OVER

Syntax

```
COVAR_POP( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function COVAR_POP calculates the population covariance for the pair of exprs.

If expr1 or expr2 is NULL, then it is excluded from the calculation.
If the number of rows for the pair of exprs is one or less, then it returns 0 as a result.

Example

```
gSQL> SELECT employee_id, TO_CHAR( hire_date, 'YYYY' ) AS hire_date, salary,
             COVAR_POP( TO_CHAR( hire_date, 'YYYY' ), salary ) OVER ( ORDER BY employee_id )
AS covar_pop
      FROM employees
      WHERE department_id = 60;
EMPLOYEE_ID HIRE_DATE SALARY COVAR_POP
----------- --------- ------ ---------
        103 1990        9000         0
        104 1991        6000      -750
        105 1997        4800     -4400
        106 1998        4800     -5100
        107 1999        4200     -5640
5 rows selected.
```

17.46 COVAR_SAMP() OVER

Syntax

```
COVAR_SAMP( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function COVAR_SAMP calculates the sample covariance for the pair of exprs.

If expr1 or expr2 is NULL, then it is excluded from the calculation.
If the number of rows for the pair of exprs is one or less, then it returns NULL as a result.

Example

```
gSQL> SELECT employee_id, TO_CHAR( hire_date, 'YYYY' ) AS hire_date, salary,
             COVAR_SAMP( TO_CHAR( hire_date, 'YYYY' ), salary ) OVER ( ORDER BY employee_id )
AS covar_samp
      FROM employees
      WHERE department_id = 60;
EMPLOYEE_ID HIRE_DATE SALARY COVAR_SAMP
----------- --------- ------ ----------
        103 1990        9000       null
        104 1991        6000      -1500
        105 1997        4800      -6600
        106 1998        4800      -6800
        107 1999        4200      -7050
5 rows selected.
```

17.47 CUME_DIST() OVER

Syntax

```
CUME_DIST( ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function CUME_DIST calculates the cumulative distribution according to the relative position of t he current row's value.

The result of CUME_DIST function is the number between 0 and 1.
If the row values are same, then it returns the same result which is the biggest cumulative distribution val ue.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             CUME_DIST() OVER ( ORDER BY salary ) AS cume_dist
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY CUME_DIST
------------- ------ ---------
           60   4200        .2
           60   4800        .6
           60   4800        .6
           60   6000        .8
           60   9000         1
5 rows selected.
```

17.48 CURRENT_CATALOG

Syntax

```
CURRENT_CATALOG [()]
```

Description

The catalog name (database name) is obtained.

Example

```
gSQL> SELECT CURRENT_CATALOG FROM dual;
CURRENT_CATALOG
---------------
TEST_DB
1 row selected.
```

17.49 CURRENT_DATE

Syntax

```
CURRENT_DATE [()]
STATEMENT_DATE()
```

Description

The current date (DATE type) is obtained.

CURRENT_DATE is an SQL standard function.

The differences among the functions to obtain the current date are as follows.

- TRANSACTION_DATE(): All date values in the transaction are same.
- CURRENT_DATE, STATEMENT_DATE(): All date values in an SQL statement are same.
- CLOCK_DATE(): Whenever the function is called, the current date value is obtained.

Example

```
gSQL> SELECT CURRENT_DATE FROM t1;
CURRENT_DATE
------------
2013-12-12
2013-12-12
2013-12-12
3 rows selected.
```

17.50 CURRENT_SCHEMA

Syntax

```
CURRENT_SCHEMA [()]
```

Description

User's current SCHEMA is obtained.

Example

```
gSQL> SELECT CURRENT_SCHEMA FROM dual;
CURRENT_SCHEMA
--------------
PUBLIC
1 row selected.
```

17.51 CURRENT_TIME

Syntax

```
CURRENT_TIME [()]
STATEMENT_TIME()
```

Description

The current TIME WITH TIME ZONE type value based on the session time is obtained.

CURRENT_TIME is an SQL standard function.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_TIME(): All time values in the transaction are same.
- CURRENT_TIME, STATEMENT_TIME(): All time values in an SQL statement are same.
- CLOCK_TIME(): Whenever the function is called, the current time value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT CURRENT_TIME FROM t1;
CURRENT_TIME
----------------------
16:27:10.116396 +09:00
16:27:10.116396 +09:00
16:27:10.116396 +09:00
3 rows selected.
```

17.52 CURRENT_TIMESTAMP

Syntax

```
CURRENT_TIMESTAMP [()]
STATEMENT_TIMESTAMP()
```

Description

It obtains the TIMESTAMP WITH TIME ZONE type value based on the session time.

CURRENT_TIMESTAMP is an SQL standard function.

The differences among the functions to obtain the current TIMESTAMP are as follows.
• TRANSACTION_TIMESTAMP(): All TIMESTAMP values in the transaction are same.
• CURRENT_TIMESTAMP, STATEMENT_TIMESTAM(): All TIMESTAMP values in an SQL statement are sa me.
• CLOCK_TIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT CURRENT_TIMESTAMP FROM t1;
CURRENT_TIMESTAMP
-------------------------------
2013-12-12 16:34:55.649632 +09:00
2013-12-12 16:34:55.649632 +09:00
2013-12-12 16:34:55.649632 +09:00
3 rows selected.
```

17.53 CURRENT_USER

Syntax

```
CURRENT_USER [()]
```

Description

It returns the current user.

The user information is managed in three types as follows.

- Logon user: It is a user who performed login, and it is maintained until the connection is closed.
- Session user: It is as same as the first logon user, but it can be changed using the SET SESSION AUTH ORIZATION statement.
- Current user: It is generally as same as the session user, but it is temporarily changed internally in syst em to control access when using the PSM, view.
    - The session user and current user is similar to the difference between the unix system's real user and the effective user.

Example

```
% gsql sys gliese
gSQL> SET SESSION AUTHORIZATION test;
Session set.
gSQL> SELECT
        LOGON_USER() AS result1,
        SESSION_USER() AS result2,
        CURRENT_USER() AS result3
      FROM DUAL;
RESULT1 RESULT2 RESULT3
------- ------- -------
SYS     TEST    TEST
1 row selected.
```

17.54 CURRVAL

Syntax

```
seq_name.CURRVAL
CURRVAL(seq_name)
```

Description

The current value of the sequence object is obtained.

A sequence value should be set with NEXTVAL(seq_name) at least once.

Example

```
gSQL> SELECT seq.CURRVAL FROM dual;
SEQ.CURRVAL
-----------
          1
1 row selected.
```

17.55 DATEADD

Syntax

```
DATEADD( datepart, number, date )
```

Description

It adds number to the specified datepart of date, and returns the result.

If the number is decimal point, it is not rounded off.
The date data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIME, TIME WITH TIME ZONE.
If number or date is NULL, the result is also NULL.

The result type which is as same as the input date argument type is returned.

Table 17-11 Available string format in datepart

datepart	Description
YEAR	Year
QUARTER	Quarter
MONTH	Month
DAYOFYEAR	Day of year
DAY	Day
WEEK	Week
WEEKDAY	Weekday
HOUR	Hour
MINUTE	Minute
SECOND	Second
MILLISECOND	Millisecond
MICROSECOND	Microsecond

Example

```
gSQL> SELECT
      DATEADD( YEAR, 1, TO_DATE( '2013-05-14', 'YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
RESULT
----------
2014-05-14
1 row selected.
gSQL> SELECT
      DATEADD( MONTH, 13, TO_DATE('2013-05-14', 'YYYY-MM-DD') ) AS RESULT
      FROM DUAL;
RESULT
----------
2014-06-14
1 row selected.
gSQL> SELECT
      DATEADD( DAY, 397, TO_DATE('2013-05-14', 'YYYY-MM-DD') ) AS RESULT
      FROM DUAL;
RESULT
----------
2014-06-15
1 row selected.
```

17.56 DATEDIFF

Syntax

```
DATEDIFF( datepart, startdate, enddate )
```

Description

It substracts startdate from enddate, then returns the result to the specified datepart.

If the startdate or enddate is NULL, the result is also NULL.
The data type of startdate and enddate can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIME.

The result type is NUMBER.

Table 17-12 Available string format in datepart

datepart	Description
YEAR	Year
QUARTER	Quarter
MONTH	Month
DAYOFYEAR	Day of year
DAY	Day
HOUR	Hour
MINUTE	Minute
SECOND	Second
MILLISECOND	Millisecond
MICROSECOND	Microsecond

Example

```
gSQL> SELECT
      DATEDIFF( YEAR,
                TO_DATE( '2013-05-14', 'YYYY-MM-DD' ),
                TO_DATE( '2014-06-15', 'YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
```

```
RESULT
------
     1
1 row selected.
gSQL> SELECT
      DATEDIFF( MONTH,
                TO_DATE( '2013-05-14', 'YYYY-MM-DD' ),
                TO_DATE( '2014-06-15', 'YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
RESULT
------
    13
1 row selected.
gSQL> SELECT
      DATEDIFF( DAY,
                TO_DATE( '2013-05-14', 'YYYY-MM-DD' ),
                TO_DATE( '2014-06-15', 'YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
RESULT
------
   397
1 row selected.
```

17.57 DATE_ADD

Syntax

```
DATE_ADD( date, INTERVAL expr unit  )
```

Description

It is the same function as **ADDDATE** (date, INTERVAL expr unit).

Example

```
gSQL> SELECT
      DATE_ADD( TO_DATE( '2012-01-02', 'YYYY-MM-DD' ),
                INTERVAL '2-2' YEAR TO MONTH ) AS RESULT
      FROM DUAL;
RESULT
----------
2014-03-02
1 row selected.
```

17.58 DATE_PART

Syntax

```
DATE_PART( field, datetime )
```

Description

The result of DATE_PART is as same as the result of the EXTRACT function. It searches for the specified fi eld from the input datetime type, and returns it.

The field argument should be text literal, and YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, TIMEZONE _HOUR, TIMEZONE_MINUTE can be specified to text literal.
The datetime argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIME, TIME WITH TIME ZONE, INTERVAL.

If field is not in the range of datetime, an error is returned.
For DATE type, field should be YEAR, MONTH, DAY, otherwise an error is returned.
If datatime is NULL, then it returns NULL.

The return type is NUMBER.

For more information, refer to **EXTRACT**.

Example

```
gSQL> SELECT
      DATE_PART( 'DAY', TO_DATE( '2012-01-02', 'YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
RESULT
------
     2
1 row selected.
gSQL> SELECT
      DATE_PART( 'YEAR', INTERVAL'9-11'YEAR TO MONTH ) AS RESULT
      FROM DUAL;
```

```
RESULT
------
     9
1 row selected.
```

17.59 DECODE

Syntax

```
DECODE( expr, comparison_expr1, result1
          [, comparison_expr2, result2
           , ...
           , comparison_exprN, resultN ]
          [, default ] )
```

Description

It evaluates expr and comparison_expr in the described order in DECODE statement using equal operation.
If the comparison result is FALSE, it continues evaluating until TRUE comes up.
If the comparison result is TRUE, it returns the corresponding result, and does not evaluate any more.

If expr and comparison_expr are equal, or if both expr and comparison_expr are NULL(null = null), it is evaluated as TRUE, and returns the corresponding result.
If all of the evaluated results are FALSE, it returns default. If the default is omitted, it returns NULL.

- Comparing expr and comparison_expr
  All expr, comparison_expr1, ..., comparison_exprN are converted to the data type of comparison_expr1 (the first comparison_expr), then they are compared.
  If comparison_expr1 (the first comparison_expr) is a character type and a numeric type then it becomes the type including the range of types described in each *expr, comparison_expr1, ..., comparison_exprN*.
  If all types described in *expr, comparison_expr1, ..., comparison_exprN* are CHAR, then VARCHAR type comparison is performed.

- Result type
  The result type becomes the data type of result1 (the first result).
  If the data type of result1 (the first result) is a character type and a numeric type then it becomes the type including the range of types described in result1, ..., resultN each.
  If result1 (the first result) is CHAR or NULL, then the result type is VARCHAR.

DECODE can be expressed by using CASE as follows.

- DECODE(expr, comp_expr1, res1, comp_expr2, res2)

```
CASE WHEN (expr = comp_expr1) OR (expr IS NULL AND comp_expr1 IS NULL ) THEN res1
     WHEN (expr = comp_expr2) OR (expr IS NULL AND comp_expr2 IS NULL ) THEN res2
     ELSE NULL
  END
```

- DECODE(expr, comp_expr1, res1, comp_expr2, res2, default)

```
CASE WHEN (expr = comp_expr1) OR (expr IS NULL AND comp_expr1 IS NULL ) THEN res1
     WHEN (expr = comp_expr2) OR (expr IS NULL AND comp_expr2 IS NULL ) THEN res2
     ELSE default
  END
```

Example

```
gSQL> SELECT I1,
             DECODE( I1, 1, 'ONE',
                         2, 'TWO',
                         NULL, 'NULL VALUE',
                         'DEFAULT VALUE' ) AS DECODE_RESULT
      FROM T1;
  I1 DECODE_RESULT
---- -------------
   1 ONE
   2 TWO
null NULL VALUE
   3 DEFAULT VALUE
4 rows selected.
```

17.60 DEGREES

Syntax

```
DEGREES( radians )
```

Description

It converts a degree radians to a value in degrees, and returns the converted value.
If radians is NULL, then it returns NULL.

Example

```
gSQL> SELECT DEGREES( PI() ) AS RESULT FROM DUAL;
RESULT
------
   180
1 row selected.
```

17.61 DENSE_RANK() OVER

Syntax

```
DENSE_RANK( ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function DENSE_RANK calculates the ranking.

The ranking is a consecutive integer starting from 1, and rows with the same value have the same rank. However, unlike RANK, even when rows with the same value appear, the ranking is not skipped.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             DENSE_RANK() OVER ( ORDER BY salary ) AS d_rank
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY D_RANK
------------- ------ ------
           60   4200      1
           60   4800      2
           60   4800      2
           60   6000      3
           60   9000      4
5 rows selected.
```

17.62 DIGEST

Syntax

```
DIGEST( data, type )
```

Description

It hashes the data to the given type, and returns the result in VARBINARY type.

An implicit conversion may occur when inputting data type based on the following rules.

- Input the BINARY, VARBINARY type data in VARBINARY type.
- Input LONG VARBINARY type data in LONG VARBINARY type.
- Input LONG VARCHAR type data in LONG VARCHAR type.
- Input all other type of data after implicitly converting it to VARCHAR type.

DIGEST function supports the following hash types.

- The result of 'SHA1' is 20 byte varbinary.
- The result of 'SHA224' is 28 byte varbinary.
- The result of 'SHA256' is 32 byte varbinary.
- The result of 'SHA384' is 48 byte varbinary.
- The result of 'SHA512' is 64 byte varbinary.

Use HEX function to view the result in hexadecimal character because the result is returned in VARBINAR Y type. In this case, the length becomes double of the original.

Example

```
gSQL> SELECT HEX( DIGEST( 'my password', 'SHA256' ) ) AS RESULT FROM DUAL;
RESULT
----------------------------------------------------------------
BB14292D91C6D0920A5536BB41F3A50F66351B7B9D94C804DFCE8A96CA1051F2
1 row selected.
```

17.63 DUMP

Syntax

```
DUMP( expr )
```

Description

It returns internal representation information of expr.
Internal representation information is displayed as the data type, byte length and data information.

expr can be any data types.
If expr is NULL, then it returns NULL.
The return type is CHARACTER VARYING.

Example

```
gSQL> SELECT DUMP( 'DUMP' ) AS RESULT FROM DUAL;
RESULT
--------------------------------
Type=CHAR Len=4 : Str=68,85,77,80
1 row selected.
```

17.64 EXP

Syntax

```
EXP( num )
```

Description

It returns squared value of e (base of natural logarithm)'s num.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT EXP( 1 ) AS RESULT FROM DUAL;
          RESULT
----------------
2.71828182845905
1 row selected.
```

17.65 EXTRACT

Syntax

```
EXTRACT( <field> FROM datetime )
<field> ::=
        YEAR
      ¦ MONTH
      ¦ DAY
      ¦ HOUR
      ¦ MINUTE
      ¦ SECOND
      ¦ TIMEZONE_HOUR
      ¦ TIMEZONE_MINUTE
```

Description

It searches for the specified field from an input datetime type, and returns it.

The datetime argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIME, TIME WITH TIME ZONE, INTERVAL.

If field is not in the range of datetime, an error is returned.
For DATE type, the field should be YEAR, MONTH, DAY, otherwise an error is returned.
The return type is NUMBER.

Result of EXTRACT is as same as the result of the **DATE_PART** function.

Example

```
gSQL> SELECT
      EXTRACT( SECOND FROM TO_TIMESTAMP( '2012-12-13 01:23:44.5',
                                         'YYYY-MM-DD HH24:MI:SS.FF1' )  )
              AS RESULT
      FROM DUAL;
RESULT
```

```
------
  44.5
1 row selected.
gSQL> SELECT
      EXTRACT( YEAR FROM CAST('2-3' AS INTERVAL YEAR TO MONTH) ) AS RESULT
      FROM DUAL;
RESULT
------
     2
1 row selected.
```

17.66 FACTORIAL

Syntax

```
FACTORIAL( num )
```

Description

It multiplies the successive natural numbers from 1 to num in order, and returns the result.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT FACTORIAL( 5 ) AS RESULT FROM DUAL;
RESULT
------
   120
1 row selected.
```

17.67 FIRST() OVER

Syntax

```
aggregation_function KEEP ( DENSE_RANK FIRST ORDER BY <sort specification list> ) OVER <
window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function FIRST sorts the sort specification list written in *order by* within KEEP clause, then return s the aggregation function value of rows whose DENSE_RANK is 1.

aggregation_functions are AVG, COUNT, COUNT(*), SUM, MAX, MIN, STDDEV, VARIANCE.

order by is not available within the window clause.
window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
           DENSE_RANK() OVER ( ORDER BY department_id ) AS "DENSE_RANK",
           MAX( salary ) KEEP ( DENSE_RANK FIRST ORDER BY department_id ) OVER () AS
"MAX_FIRST"
  FROM employees
 WHERE department_id BETWEEN 90 AND 100;

DEPARTMENT_ID SALARY DENSE_RANK MAX_FIRST
------------- ------ ---------- ---------
           90  24000          1     24000
           90  17000          1     24000
           90  17000          1     24000
          100  12000          2     24000
          100   9000          2     24000
          100   8200          2     24000
```

```
          100   7700          2     24000
          100   7800          2     24000
          100   6900          2     24000
9 rows selected.
```

17.68 FIRST_VALUE() OVER

Syntax

```
FIRST_VALUE ( expr ) [ RESPECT NULLS ¦ IGNORE NULLS ] OVER < window name or specification >
FIRST_VALUE ( expr [ RESPECT NULLS ¦ IGNORE NULLS ] ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function FIRST_VALUE returns the first value of expr.

RESPECT NULLS returns the first value of rows including NULL.
IGNORE NULLS returns the first value of row except for NULL.
If it is not specified, the default value is RESPECT NULLS.

order by is not available in window clause.
window frame is not available.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , FIRST_VALUE( min_price ) OVER ( ORDER BY min_price NULLS FIRST ) AS
"FIRST_VALUE"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE FIRST_VALUE
--------- -----------
     null        null
     null        null
       73        null
      247        null
      731        null
5 rows selected.
```

The following is an example of specifying IGNORE NULLS in null_treatment.

```
gSQL> SELECT min_price AS "MIN_PRICE"
            , FIRST_VALUE( min_price IGNORE NULLS ) OVER ( ORDER BY min_price NULLS FIRST )
                                                          AS "FIRST_VALUE"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE FIRST_VALUE
--------- -----------
     null        null
     null        null
       73          73
      247          73
      731          73
5 rows selected.
```

17.69 FLOOR

Syntax

```
FLOOR( num )
```

Description

It returns the biggest integer which is equal to or smaller than num.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT FLOOR(42.8) AS RESULT1, FLOOR(-42.8) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
     42     -43
1 row selected.
```

17.70 FROM_BASE64

Syntax

```
FROM_BASE64( str )
```

Description

The converted character by base 64 encoding is input to FROM_BASE64, then the decoded binary string i s returned.

The input argument data type can be a character type such as CHARACTER VARYING, CHARACTER LON G VARYING, and the result type is a binary character such as BINARY VARYING, or BINARY LONG VARYI NG.

If str is NULL, then the result value is also NULL.
If str includes characters which are not in the range of base64 character, then it returns an error.
A newline, carriage return, tab, and space of str is ignored when decoding.

For more information, refer to **TO_BASE64**.

Example

```
gSQL> SELECT FROM_BASE64( TO_BASE64( 'abc' ) ),
             FROM_BASE64( TO_BASE64( 'abcd' ) )
        FROM DUAL;
FROM_BASE64( TO_BASE64( 'abc' ) ) FROM_BASE64( TO_BASE64( 'abcd' ) )
--------------------------------- ---------------------------------
616263                            61626364
1 row selected.
```

17.71 FROM_TZ

Syntax

```
FROM_TZ( timestamp, timezone )
```

Description

FROM_TZ function converts the timestamp and the timezone in the specified format to TIMESTAMP WIT H TIME ZONE type, then returns it.

The timestamp argument should be TIMESTAMP type or the type convertible to TIMESTAMP type.
If the timestamp argument is NULL, then the result value is also NULL.

The timezone argument should be CHARACTER type such as CHARACTER and CHARACTER VARYING, a nd the format is 'TZH:TZM'.
If the timezone argument is NULL, then the result is also NULL.

The result type is TIMESTAMP(6) WITH TIME ZONE.

Example

```
gSQL> SELECT
      FROM_TZ( TIMESTAMP'2021-01-01 10:10:20.000000', '+06:00' ) AS RESULT
        FROM DUAL;
RESULT
---------------------------------
2021-01-01 10:10:20.000000 +06:00
1 row selected.
```

17.72 GREATEST

Syntax

```
GREATEST( expr1 [, expr2, ... exprn ] )
```

Description

It returns the largest value among the received expr argument.

If any expr argument is NULL, the result value is NULL.

The result type becomes the data type of expr1 (the first expr).
If the data type of expr1 (the first expr) is a character type and a numeric type then it becomes the type in cluding the range of expr1, ..., exprN each.
If all of expr1, ..., exprN is described in CHAR type, then all exprs are compared in VARCHAR type and the result type is VARCHAR.

Example

```
gSQL> SELECT GREATEST( 100, 0, 200, 150, 1 ) AS RESULT FROM DUAL;
RESULT
------
   200
1 row selected.
```

17.73 HEX

Syntax

```
HEX( str )
```

Description

It returns a str argument in hexadecimal character.
A str argument data type can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, a type which can be converted to a character type, or a binary character type such as BINARY, BINARY VARYING, BINARY LONG VARYING.
The result type is a character type such as CHARACTER VARYING or CHARACTER LONG VARYING.

If str is NULL, then the result value is also NULL.

If an argument of HEX function is a numeric type, then it returns an error.
To convert a decimal number to a hexadecimal number, use TO_CHAR() function by using 'X' number format.
e.g. TO_CHAR(255, 'XX')

For more information, refer to **UNHEX**.

Example

```
gSQL> SELECT HEX( 'abc' ) FROM DUAL;
HEX( 'abc' )
------------
616263
1 row selected.
```

17.74 INITCAP

Syntax

```
INITCAP( str )
```

Description

It converts the first letter in each word of string str into uppercase, and converts all other letters into lowe rcase, then it returns the result.

str data type can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG V ARYING.

Each word in string is classified by white space or characters which are not alphanumeric.
If str is NULL, the result is also NULL.

The return type is as same as str argument datatype.

Example

```
gSQL> SELECT INITCAP( 'hi GLIESE' ) AS RESULT FROM DUAL;
RESULT
---------
Hi Gliese
1 row selected.
```

17.75 INSTR

Syntax

```
INSTR( str, substr [, position [, occurrence ] ] )
```

Description

It search for occurrenceth substr starting from str's position, and returns its location.

The data types of str arguments and substr arguments can be a character type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING, or a binary character type such as BINARY, BINARY VA RYING, BINARY LONG VARYING.

The position argument and the occurrence argument can be numeric data type.

If position and occurrence are omitted, the default is 1.
The position and occurrence start from 1, and they are calculated in character unit according to character set (not in byte unit).

The position means the first position to search substr in str, it should not be zero, but an integer value.

- If the position is positive: It compares forwards (toward the right) from the beginning of str until it finds the position of substr.
- If the position is negative: It compares backwards (toward the left) from the end of str it finds the position of substr.
- If the position is 0: The result is 0.

The occurrence means the number of repeating the subtr in the str, and it should be a positive integer.

If any of the input argument is NULL, the result is also NULL.

Example

```
gSQL> SELECT INSTR( 'ABCD ABCD ABCDABCD', 'BC' ) AS RESULT1,
             INSTR( 'ABCD ABCD ABCDABCD', 'BC', 4 ) AS RESULT2
      FROM DUAL;
RESULT1 RESULT2
```

```
------- -------
      2       7
1 row selected.
gSQL> SELECT INSTR( 'ABCD ABCD ABCDABCD', 'BC', 5 , 3 ) AS RESULT1,
             INSTR( 'ABCD ABCD ABCDABCD', 'BC', -5,  3 ) AS RESULT2
      FROM DUAL;
RESULT1 RESULT2
------- -------
     16       2
1 row selected.
```

17.76 LAG() OVER

Syntax

```
LAG ( expr [, offset [, default ] ] ) [ RESPECT NULLS ¦ IGNORE NULLS ] OVER < window name or specification >
LAG ( expr [ RESPECT NULLS ¦ IGNORE NULLS ] [, offset [, default ] ] ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function LAG returns the row value ahead from the current row as far as offset.
If offset is out of window range, then it returns the default value.

If offset and default values are not specified, then it is set to the default value.
The default value of offset is 1 and the the default value of default is NULL.

RESPECT NULLS returns the row value ahead as far as offset including NULL.
IGNORE NULLS returns the row value ahead as far as offset except for NULL.
If it is not specified, the default value is RESPECT NULLS.

window frame is not available.

Example

```
gSQL> SELECT department_id, employee_id, manager_id,
             LAG( manager_id ) OVER ( ORDER BY employee_id ) AS lag
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID  LAG
------------- ----------- ---------- ----
           90         100       null null
           90         101        100 null
           90         102        100  100
```

```
3 rows selected.
```

The following is an example of specifying offset.

```
gSQL> SELECT department_id, employee_id, manager_id,
             LAG( manager_id, 2 ) OVER ( ORDER BY employee_id ) AS lag
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID  LAG
------------- ----------- ---------- ----
           90         100       null null
           90         101        100 null
           90         102        100 null
3 rows selected.
```

The following is an example of specifying offset and default.

```
gSQL> SELECT department_id, employee_id, manager_id,
             LAG( manager_id, 2, 0 ) OVER ( ORDER BY employee_id ) AS lag
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID  LAG
------------- ----------- ---------- ----
           90         100       null    0
           90         101        100    0
           90         102        100 null
3 rows selected.
```

17.77 LAST() OVER

Syntax

```
aggregation_function KEEP ( DENSE_RANK LAST ORDER BY <sort specification list> ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function LAST sorts the sort specification list written in *order by* within KEEP clause, then returns the aggregation function value of rows whose DENSE_RANK is the last.

aggregation_functions are AVG, COUNT, COUNT(*), SUM, MAX, MIN, STDDEV, VARIANCE.

order by is not available within the window clause.
window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
           DENSE_RANK() OVER ( ORDER BY department_id ) AS "DENSE_RANK",
           MAX( salary ) KEEP ( DENSE_RANK LAST ORDER BY department_id ) OVER () AS "MAX_LAST"
  FROM employees
 WHERE department_id BETWEEN 90 AND 100;
DEPARTMENT_ID SALARY DENSE_RANK MAX_LAST
------------- ------ ---------- --------
           90  24000          1    12000
           90  17000          1    12000
           90  17000          1    12000
          100  12000          2    12000
          100   9000          2    12000
          100   8200          2    12000
          100   7700          2    12000
          100   7800          2    12000
```

```
          100   6900          2    12000
9 rows selected.
```

17.78 LAST_DAY

Syntax

```
LAST_DAY( date )
```

Description

It returns the last day of the month which is included in date.

The date argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE.
The return type is always DATE regardless of the date argument data type.
If date is NULL, then it returns NULL.

Example

```
gSQL> SELECT
      LAST_DAY( TO_DATE( '2012-07-10', 'YYYY-MM-DD' ) ) AS RESULT FROM DUAL;
RESULT
----------
2012-07-31
1 row selected.
```

17.79 LAST_IDENTITY_VALUE

Syntax

```
LAST_IDENTITY_VALUE()
```

Description

It is the recent value automatically created for an identity column in the current session, and the result type is NATIVE_BIGINT.

If there is not an automatically created value, then it returns null.

This function is similar to @@IDENTITY of MS-SQL and LAST_INSERT_ID() of MySQL. Be cautious when using it because the last altered table determines the value when performing DML for multiple tables as follows.

```
gSQL> INSERT INTO t1(name) VALUES ( 'leekmo' );
1 row created.
gSQL> SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                   12
1 row selected.
gSQL> INSERT INTO t2(name) VALUES ( 'leekmo' );
1 row created.
gSQL> SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                    2
1 row selected.
```

To obtain an identity column value created when performing the INSERT, use **INSERT INTO name RETURNING .. INTO** statement as follows.

```
gSQL> CREATE TABLE t1 ( id INTEGER GENERATED BY DEFAULT AS IDENTITY, name VARCHAR(32) );
Table created.
gSQL> \var v1 integer
```

```
gSQL> INSERT INTO t1(name) VALUES ( 'leekmo' ) RETURN id INTO :v1;
V1
--
 1
1 row created.
```

Example

The following is an example of using LAST_IDENTITY_VALUE() function.

```
gSQL> CREATE TABLE t1 ( id   INTEGER GENERATED BY DEFAULT AS IDENTITY,
                        name VARCHAR(32) );
Table created.
gSQL> COMMIT;
Commit complete.
```

- There is not an identity value created in the current session.

```
gSQL> SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                null
1 row selected.
```

- Identity value (1) is automatically created.

```
gSQL> INSERT INTO t1(name) VALUES ( 'leekmo' );
1 row created.
```

- Result: 1

```
gSQL> SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                   1
1 row selected.
```

- Identity value (2) is automatically created as a default value.

```
gSQL> UPDATE t1 SET id = DEFAULT;
1 row updated.
```

- Result: 2

```
gSQL> SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                    2
1 row selected.
```

- The user input value does not automatically create an identity value.

```
INSERT INTO t1 VALUES ( 100, 'jhkim' );
1 row updated.
```

- Result: 2

```
SELECT LAST_IDENTITY_VALUE() FROM dual;
LAST_IDENTITY_VALUE()
---------------------
                    2
1 row selected.
```

17.80 LAST_VALUE() OVER

Syntax

```
LAST_VALUE ( expr ) [ RESPECT NULLS ¦ IGNORE NULLS ] OVER < window name or specification >
LAST_VALUE ( expr [ RESPECT NULLS ¦ IGNORE NULLS ] ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function LAST_VALUE returns the last value of expr.

RESPECT NULLS returns the last value of rows including NULL.
IGNORE NULLS returns the last value of row except for NULL.
If it is not specified, the default value is RESPECT NULLS.

order by is not available in window clause.
window frame is not available.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , LAST_VALUE( min_price ) OVER ( ORDER BY min_price ) AS "LAST_VALUE"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE LAST_VALUE
--------- ----------
       73         73
      247        247
      731        731
     null       null
     null       null
5 rows selected.
```

The following is an example of specifying IGNORE NULLS in null_treatment.

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , LAST_VALUE( min_price IGNORE NULLS ) OVER ( ORDER BY min_price ) AS
"LAST_VALUE"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE LAST_VALUE
--------- ----------
       73         73
      247        247
      731        731
     null        731
     null        731
5 rows selected.
```

17.81 LEAD() OVER

Syntax

```
LEAD ( expr [, offset [, default ] ] ) [ RESPECT NULLS ¦ IGNORE NULLS ] OVER < window name or specification >
LEAD ( expr [ RESPECT NULLS ¦ IGNORE NULLS ] [, offset [, default ] ] ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function LEAD returns the row value behind from the current row as far as offset.
If offset is out of window range, then it returns the default value.

If offset and default values are not specified, then it is set to the default value.
The default value of offset is 1 and the the default value of default is NULL.

RESPECT NULLS returns the row value behind as far as offset including NULL.
IGNORE NULLS returns the row value behind as far as offset except for NULL.
If it is not specified, the default value is RESPECT NULLS.

window frame is not available.

Example

```
gSQL> SELECT department_id, employee_id, manager_id,
             LEAD( manager_id ) OVER ( ORDER BY employee_id DESC ) AS lead
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID LEAD
------------- ----------- ---------- ----
           90         102        100  100
           90         101        100 null
           90         100       null null
```

```
3 rows selected.
```

The following is an example of specifying offset.

```
gSQL> SELECT department_id, employee_id, manager_id,
             LEAD( manager_id, 2 ) OVER ( ORDER BY employee_id DESC ) AS lead
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID LEAD
------------- ----------- ---------- ----
           90         102        100 null
           90         101        100 null
           90         100       null null
3 rows selected.
```

The following is an example of specifying offset and default.

```
gSQL> SELECT department_id, employee_id, manager_id,
             LEAD( manager_id, 2, 0 ) OVER ( ORDER BY employee_id DESC ) AS lead
        FROM employees
       WHERE department_id = 90;
DEPARTMENT_ID EMPLOYEE_ID MANAGER_ID LEAD
------------- ----------- ---------- ----
           90         102        100 null
           90         101        100    0
           90         100       null    0
3 rows selected.
```

17.82 LEAST

Syntax

```
LEAST( expr1 [, expr2, ... exprn ] )
```

Description

It returns the smallest value among received expr arguments.

If any of expr is NULL, the result is NULL.

The result type is determined according to the data type of expr1 (the first expr).
If the data type of expr1 (the first expr) is a character type and a numeric type then it becomes the type in cluding the range of expr1, ..., exprN each.
If all of expr1, ..., exprN is described in CHAR type, then all exprs are compared in VARCHAR type and the result type is VARCHAR.

Example

```
gSQL> SELECT LEAST( 100, 0, 200, 150, 1 ) AS RESULT FROM DUAL;
RESULT
------
     0
1 row selected.
```

17.83 LENGTH

Syntax

```
LENGTH( str )
```

Description

It is an alias of **CHAR_LENGTH**.

Example

Multi byte character set: (e.g.UTF8)

```
gSQL> SELECT LENGTH( 'αβ-SUMMER' ) AS RESULT FROM DUAL;
     RESULT
     ---------------
               9
    1 row selected.
```

17.84 LENGTHB

Syntax

```
LENGTHB( str )
```

Description

It is an alias of **OCTET_LENGTH**.
For more information, refer to **BYTE_LENGTH**.

Example

- Multi byte character set (e.g.UTF8): 1 byte character

```
gSQL> SELECT LENGTHB( 'OCTET_LENGTH' ) AS RESULT_1BYTE_CHARACTERS
        FROM DUAL;
RESULT_1BYTE_CHARACTERS
-----------------------
                     12
1 row selected.
```

- Multi byte character set (e.g.UTF8): 2 byte character

```
gSQL> SELECT LENGTHB( 'αβ' ) AS RESULT_2BYTE_CHARACTERS FROM DUAL;
RESULT_2BYTE_CHARACTERS
-----------------------
                      4
1 row selected.
```

17.85 LISTAGG() OVER

Syntax

```
LISTAGG( str [, delimiter] ) WITHIN GROUP ( ORDER BY <sort specification list> ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function LISTAGG connects str in its order sorted within each group.

Only PARTITION BY clause is available in OVER() clause of LISTAGG.
It divides the query result sets into groups by using OVER() clause.

It sorts the records within the group with WITHIN GROUP (ORDER BY <sort specification list>).

It connects str in the order of the record sorted within each group.
If str is NULL, then it is excluded.

A delimiter is str connection delimiter, and if it is omitted the default value is NULL.

str can be a character string or a binary string.
If str is a character string, then the result type is varchar.
If str is a binary string, then the result type is varbinary.

Example

```
gSQL>
SELECT regionkey,
       name,
       LISTAGG( name ) WITHIN GROUP ( ORDER BY nationkey )
                       OVER ( PARTITION BY regionkey )
       AS "LISTAGG( name ) RESULT",
       LISTAGG( name, ', ' ) WITHIN GROUP ( ORDER BY nationkey )
```

```
                           OVER ( PARTITION BY regionkey )
       AS "LISTAGG( name, ', ' ) RESULT"
  FROM nation;
REGIONKEY NAME    LISTAGG( name ) RESULT    LISTAGG( name, ', ' ) RESULT
--------- ------- ------------------------- ----------------------------
        1 BRAZIL  BRAZILCANADAPERU          BRAZIL, CANADA, PERU
        1 CANADA  BRAZILCANADAPERU          BRAZIL, CANADA, PERU
        1 PERU    BRAZILCANADAPERU          BRAZIL, CANADA, PERU
        1 null    BRAZILCANADAPERU          BRAZIL, CANADA, PERU
        2 null    INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 INDIA   INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 null    INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 null    INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 JAPAN   INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 CHINA   INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 null    INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        2 VIETNAM INDIAJAPANCHINAVIETNAM    INDIA, JAPAN, CHINA, VIETNAM
        3 EGYPT   EGYPTIRANIRAQ             EGYPT, IRAN, IRAQ
        3 IRAN    EGYPTIRANIRAQ             EGYPT, IRAN, IRAQ
        3 IRAQ    EGYPTIRANIRAQ             EGYPT, IRAN, IRAQ
15 rows selected.
```

17.86 LN

Syntax

```
LN( num )
```

Description

It returns the natural logarithm value of num.
num should be a value which is bigger than 0.
If num is NULL, then it returns NULL.

Example

```
gSQL> SELECT LN( 2.71828182845905 ) AS RESULT FROM DUAL;
RESULT
------
     1
1 row selected.
```

17.87 LNNVL

Syntax

```
LNNVL( expr )
```

Description

Logical Not Null VaLue (LNNVL) function is similar to NOT logical operator, but the difference is that it ret urns TRUE as in the following example when the input value is null.

Example

```
gSQL> SELECT c1, c2, (c1 = c2), NOT(c1 = c2), LNNVL(c1 = c2) FROM t1;
C1   C2 (C1 = C2) NOT(C1 = C2) LNNVL(C1 = C2)
-- ---- --------- ------------ --------------
 1    1 TRUE      FALSE        FALSE
 1    2 FALSE     TRUE         TRUE
 1 null null      null         TRUE
3 rows selected.
```

17.88 LOCALTIME

Syntax

```
LOCALTIME [()]
STATEMENT_LOCALTIME()
```

Description

The current TIME WITHOUT TIME ZONE type value based on the session time is obtained.

LOCALTIME is an SQL standard function.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_LOCALTIME(): All time values in the transaction are same.
- LOCALTIME, STATEMENT_LOCALTIME(): All time values in an SQL statement are same.
- CLOCK_LOCALTIME(): Whenever the function is called, the current time value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT LOCALTIME FROM t1;
LOCALTIME
---------------
16:17:08.592459
16:17:08.592459
16:17:08.592459
3 rows selected.
```

17.89 LOCALTIMESTAMP

Syntax

```
LOCALTIMESTAMP [()]
STATEMENT_LOCALTIMESTAMP()
```

Description

The current TIMESTAMP WITHOUT TIME ZONE type value based on the session time is obtained.

LOCALTIMESTAMP is an SQL standard function.

The differences among the functions to obtain the current TIMESTAMP are as follows.
- TRANSACTION_LOCALTIMESTAMP(): All TIMESTAMP values in the transaction are same.
- LOCALTIMESTAMP, STATEMENT_LOCALTIMESTAMP(): All TIMESTAMP values in an SQL statement ar e same.
- CLOCK_LOCALTIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT LOCALTIMESTAMP FROM t1;
LOCALTIMESTAMP
--------------------------
2013-12-12 16:21:51.790614
2013-12-12 16:21:51.790614
2013-12-12 16:21:51.790614
3 rows selected.
```

17.90 LOCAL_GROUP_ID

Syntax

```
LOCAL_GROUP_ID()
```

Description

It returns a cluster group ID for a server which processes a query from a user.

It is a valid information in a cluster system.

Example

All rows have the same value.

```
gSQL> SELECT LOCAL_GROUP_ID() FROM DUAL;
LOCAL_GROUP_ID()
----------------
               1
1 row selected.
```

17.91 LOCAL_GROUP_NAME

Syntax

```
LOCAL_GROUP_NAME()
```

Description

It returns a cluster group name for a server which processes a query from a user.

It is a valid information in a cluster system.

Example

All rows have the same value.

```
gSQL> SELECT LOCAL_GROUP_NAME() FROM DUAL;
LOCAL_GROUP_NAME()
------------------
G1
1 row selected.
```

17.92 LOCAL_MEMBER_ID

Syntax

```
LOCAL_MEMBER_ID()
```

Description

It returns a cluster member ID for a server which processes a query from a user.

It is a valid information in a cluster system.

Example

All rows have the same value.

```
gSQL> SELECT LOCAL_MEMBER_ID() FROM DUAL;
LOCAL_MEMBER_ID()
-----------------
                1
1 row selected.
```

17.93 LOCAL_MEMBER_NAME

Syntax

```
LOCAL_MEMBER_NAME()
```

Description

It returns a cluster member name for a server which processes a query from a user.

It is a valid information in a cluster system.

Example

All rows have the same value.

```
gSQL> SELECT LOCAL_MEMBER_NAME() FROM DUAL;
LOCAL_MEMBER_NAME()
-------------------
G1N1
1 row selected.
```

17.94 LOG

Syntax

```
LOG( num2 )
LOG( num1, num2 )
```

Description

It returns the logarithm of num2 in the num1 base.
If num1 is omitted, it returns the logarithm value whose base is 10.

num1 should be a positive number except 1 and 0, and num2 should be a positive number.

If num1 or num2 is NULL, then it returns NULL.

Example

```
gSQL> SELECT LOG( 100 ) AS RESULT1, LOG( 4, 16 ) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
      2       2
1 row selected.
```

17.95 LOGON_USER

Syntax

```
LOGON_USER()
```

Description

It returns the logged-in user.

The user information is managed in three types as follows.

- Logon user: It is a user who performed login, and it is maintained until the connection is closed.
- Session user: It is as same as the first logon user, but it can be changed using the SET SESSION AUTH ORIZATION statement.
- Current user: It is generally as same as the session user, but it is temporarily changed internally in syst em to control access when using the PSM, view.
    - The session user and current user is similar to the difference between the unix system's real user and the effective user.

Example

```
% gsql test test
gSQL> SELECT LOGON_USER() AS result FROM DUAL;
RESULT
------
TEST
1 row selected.
```

17.96 LOWER

Syntax

```
LOWER( str )
```

Description

It returns lowercases of str.

The str argument data type can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.
If str is NULL, the result is also NULL.

The return type is the same datatype as the str argument.

Example

```
gSQL> SELECT LOWER( 'SPRING' ) AS RESULT FROM DUAL;
RESULT
------
spring
1 row selected.
```

17.97 LPAD

Syntax

```
LPAD( str, length, [, fill] )
```

Description

It adds character string fill to the left side of str until the string length becomes length, then returns the re sult.

The str argument data type can be character type such as CHARACTER, CHARACTER VARYING, CHARAC TER LONG VARYING, and a binary character type such as BINARY, BINARY VARYING, BINARY LONG VAR YING.

The length argument is numeric type.

length means the number of characters, and its maximum range is the maximum precision of the result t ype.
If fill is omitted, a white space is added.
If str is longer than the length, it cuts the str as long as the length, then returns it.
If any of str, length, fill is NULL, the result is also NULL.
If length is 0 or a negative number, the result is NULL.

The following table describes the result types.

Table 17-13 Result type of LPAD

str type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT LPAD('AA', 5) AS RESULT1,
             LPAD('AA', 5, 'X' ) AS RESULT2,
             LPAD('AA', 1 ) AS RESULT3
      FROM DUAL;
RESULT1 RESULT2 RESULT3
------- ------- -------
   AA   XXXAA   A
1 row selected.
```

17.98 LTRIM

Syntax

```
LTRIM( trim_source [, trim_character ] )
```

Description

It removes the matching characters by comparing from the left side of trim_character in trim_source until the matching character does not exist. Then it returns the result.

The data type of trim_character argument and trim_source argument can be a character type such as CH ARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, and a binary character type such as BIN ARY, BINARY VARYING, BINARY LONG VARYING.

If any of trim_character, trim_source is NULL, the result is NULL.
If trim_character is omitted, a single blank space (' ') is specified by default.

The following table describes the result types.

Table 17-14 Result type of LTRIM

trim_source, trim_character type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT LTRIM( '_____LTRIM', '_' ) AS RESULT FROM DUAL;
RESULT
------
LTRIM
1 row selected.
```

17.99 MAX

Syntax

```
MAX( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregate function and the maximum value among rows' exprs is obtained.

If ALL is explicitly specified, aggregation is executed for all values.
If DISTINCT is explicitly specified, aggregation is executed for the values which exclude duplicate values.
If ALL or DISTINCT is not explicitly specified, it is processed in the same way as when ALL is specified.

MAX function returns the same result without being affected by the ALL and DISTINCT.

Example

```
gSQL> SELECT MAX(c1) FROM t1;
MAX(C1)
-------
      3
1 row selected.
```

17.100 MAX() OVER

Syntax

```
MAX ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function MAX obtains the maximum value of exprs.
NULL is excluded from the calculation.

Example

```
gSQL> SELECT product_id AS "PRODUCT_ID", min_price AS "MIN_PRICE"
             , MAX( min_price ) OVER ( ORDER BY product_id ) AS "MAX"
        FROM product_information
       WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE  MAX
---------- --------- ----
      1769      null null
      1770        73   73
      2378       247  247
      2382       731  731
      3355      null  731
5 rows selected.
```

17.101 MEDIAN() OVER

Syntax

```
MEDIAN ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function MEDIAN returns the median value of row.
NULL is excluded from the calculation.

order by is not available within the window clause.
window frame is not available.

Example

```
gSQL> SELECT supplier_id, min_price
             , MEDIAN( min_price ) OVER ( PARTITION BY supplier_id ) AS "MEDIAN"
        FROM product_information
       WHERE supplier_id = 102050;
SUPPLIER_ID MIN_PRICE MEDIAN
----------- --------- ------
     102050        73    247
     102050       247    247
     102050       731    247
     102050      null    247
     102050      null    247
5 rows selected.
```

17.102 MIN

Syntax

```
MIN( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregate function and the minimum value among rows' exprs is obtained.

If ALL is explicitly specified, aggregation is executed for all values.
If DISTINCT is explicitly specified, aggregation is executed for the values which exclude duplicate values.
If ALL or DISTINCT is not explicitly specified, it is processed in the same way as when ALL is specified.

MIN function returns the same result without being affected by the ALL and DISTINCT.

Example

```
gSQL> SELECT MIN(c1) FROM t1;
MIN(C1)
-------
      1
1 row selected.
```

17.103 MIN() OVER

Syntax

```
MIN ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function MIN obtains the minimum value of exprs.
NULL is excluded from the calculation.

Example

```
gSQL> SELECT product_id AS "PRODUCT_ID", min_price AS "MIN_PRICE"
             , MIN( min_price ) OVER ( ORDER BY product_id DESC ) AS "MIN"
        FROM product_information
       WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE  MIN
---------- --------- ----
      3355      null null
      2382       731  731
      2378       247  247
      1770        73   73
      1769      null   73
5 rows selected.
```

17.104 MOD

Syntax

```
MOD( num1, num2 )
```

Description

It divides num1 by num2, and returns the remainder.
The num1 argument and num2 argument can be a numeric data type.
If num2 is 0, an error is returned.
If the num1 argument or num2 argument is NULL, then NULL is returned.

Example

```
gSQL> SELECT MOD(5, 4) AS RESULT1, MOD(-5, 4) AS RESULT2 FROM DUAL;
RESULT1 RESULT2
------- -------
      1      -1
1 row selected.
```

17.105 MONTHS_BETWEEN

Syntax

```
MONTHS_BETWEEN( date1, date2 )
```

Description

MONTHS_BETWEEN returns the number of months of which days between date2 and date1 are devided by 31.

If date1 or date2 is NULL, then the result is also NULL.
The date1 argument and date2 argument can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE type.

The result type is NUMBER.

If the same date (e.g. 2014-01-15 and 2014-02-15), or the last day of the month (e.g. 2014-08-31 and 2014-09-30) is included both in date1 and date2, then it returns the integer result regardless of the agreement of timestamp section (if it exists).

Example

```
gSQL> SELECT
        MONTHS_BETWEEN('2018-01-18', '2018-01-17')
  FROM DUAL;
MONTHS_BETWEEN('2018-01-18', '2018-01-17')
------------------------------------------
                     3.225806451612903E-2
1 row selected.
gSQL> SELECT
        MONTHS_BETWEEN('2018-02-17', '2018-01-17')
  FROM DUAL;
MONTHS_BETWEEN('2018-02-17', '2018-01-17')
------------------------------------------
```

```
                                        1
1 row selected.
gSQL> SELECT
        MONTHS_BETWEEN('2018-02-28', '2018-01-31')
  FROM DUAL;
MONTHS_BETWEEN('2018-02-28', '2018-01-31')
------------------------------------------
                                        1
1 row selected.
```

17.106 NEXT_DAY

Syntax

```
NEXT_DAY( date, day )
```

Description

It obtains a date of the day (day of week) which comes first after the given date (an argument).

The second day argument can be a string or a number which indicates the day.
- String: SUNDAY ~ SATURDAY or SUN ~ SAT
- Number: 1 (sunday) ~ 7 (saturday)

If any of the input argument is NULL, the result is also NULL.

The return type is always DATE regardless of the input type of the date.
The hour, minute and second of the result value returns the same hour, minute and second of the input a rgument date.

Example

- 2020-08-11 is Tuesday.

```
gSQL> SELECT NEXT_DAY( TO_DATE( '2020-08-11', 'YYYY-MM-DD'),
                       'SUNDAY' ) AS RESULT1
      FROM DUAL;
RESULT1
----------
2020-08-16
1 row selected.
gSQL> SELECT NEXT_DAY( TO_DATE( '2020-08-11', 'YYYY-MM-DD' ),
                       'SUN' ) AS RESULT1
FROM DUAL;
RESULT1
----------
2020-08-16
```

```
1 row selected.
gSQL> SELECT NEXT_DAY( TO_DATE( '2020-08-11', 'YYYY-MM-DD' ),
                       1 ) AS RESULT1
FROM DUAL;
RESULT1
----------
2020-08-16
1 row selected.
gSQL> SELECT TO_CHAR( NEXT_DAY( TO_DATE( '2020-08-11', 'YYYY-MM-DD' ),
                                'SUNDAY' ),
                     'YYYY-MM-DD HH24:MI:SS' ) AS RESULT1
FROM DUAL;
RESULT1
-------------------
2020-08-16 00:00:00
1 row selected.
```

17.107 NEXTVAL

Syntax

```
seq_name.NEXTVAL
NEXTVAL( seq_name )
NEXT VALUE FOR seq_name
```

Description

It obtains the next value of the sequence object.

Example

```
gSQL> CREATE SEQUENCE seq;
Sequence created.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT seq.NEXTVAL FROM dual;
SEQ.NEXTVAL
-----------
          1
1 row selected.
gSQL> SELECT NEXTVAL( seq ) FROM dual;
NEXTVAL( SEQ )
--------------
             2
1 row selected.
gSQL> SELECT NEXT VALUE FOR seq FROM dual;
NEXT VALUE FOR SEQ
------------------
                 3
1 row selected.
```

17.108 NTH_VALUE() OVER

Syntax

```
NTH_VALUE ( expr, n ) [ FROM { FIRST ¦ LAST } ][ { RESPECT ¦ IGNORE } NULLS ] OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function NTH_VALUE returns the expr value of the n-th row.
If the number of window's rows are less than n, then it returns NULL.

The n argument can be a numeric type or types which can be converted to number.

FROM FIRST points to the n-th row from the first row.
FROM LAST points to the n-th row from the last row.
If it is not specified, the default value is FROM FIRST.

RESPECT NULLS returns the value of the n-th row including NULL.
IGNORE NULLS returns the value of the n-th row except for NULL.
If it is not specified, the default value is RESPECT NULLS.

Example

```
gSQL> SELECT product_id, min_price,
             NTH_VALUE( min_price, 2 ) OVER ( ORDER BY product_id ) AS nth_value
      FROM product_information
      WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE NTH_VALUE
---------- --------- ---------
      1769      null      null
      1770        73        73
      2378       247        73
      2382       731        73
```

```
      3355      null        73
5 rows selected.
```

The following is an example of when FROM LAST is specified.

```
gSQL> SELECT product_id, min_price,
              NTH_VALUE( min_price, 2 ) FROM LAST OVER ( ORDER BY product_id ) AS nth_value
      FROM product_information
      WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE NTH_VALUE
---------- --------- ---------
      1769      null      null
      1770        73      null
      2378       247        73
      2382       731       247
      3355      null       731
5 rows selected.
```

The following is an example of when IGNORE NULLS is specified.

```
gSQL> SELECT product_id, min_price,
              NTH_VALUE( min_price, 2 ) IGNORE NULLS OVER ( ORDER BY product_id ) AS nth_value
      FROM product_information
      WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE NTH_VALUE
---------- --------- ---------
      1769      null      null
      1770        73      null
      2378       247       247
      2382       731       247
      3355      null       247
5 rows selected.
```

17.109 NTILE() OVER

Syntax

```
NTILE( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function NTILE returns the bucket number corresponding to each row.

The bucket number is a consecutive integer starting from 1, and the number of buckets are as same as th e number of expr.
If the number of buckets are bigger than that of rows, a bucket is given to each row and other buckets re mains empty.

expr should be a positive constant. If expr is not a fixed number, then expr should be the target of *windo w partition by*.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             NTILE(3) OVER ( ORDER BY salary ) AS ntile
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY NTILE
------------- ------ -----
           60   4200     1
           60   4800     1
           60   4800     2
           60   6000     2
           60   9000     3
5 rows selected.
```

The following is an example of when the number of buckets (the number of expr) is bigger than the num ber of rows.

```
gSQL> SELECT department_id, salary,
             NTILE(6) OVER ( ORDER BY salary ) AS ntile
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY NTILE
------------- ------ -----
           60   4200     1
           60   4800     2
           60   4800     3
           60   6000     4
           60   9000     5
5 rows selected.
```

17.110 NULLIF

Syntax

```
NULLIF( expr1, expr2 )
```

Description

If expr1 is equal to expr2, it returns NULL. If it is not equal it returns expr1 which is the first argument.

If the data types of expr1 and expr2 are different, the result type is determined by **Result Type Combinati on Rule**.

NULLIF can be expressed by using CASE as follows.

- NULLIF(expr1, expr2)

```
CASE WHEN expr1 = expr2 THEN NULL
       ELSE expr1
  END
```

Example

```
gSQL> SELECT NULLIF( 'SUN', 'SUN' ) AS RESULT1,
             NULLIF( 'SUN', 'MOON' ) AS RESULT2
       FROM DUAL;
RESULT1 RESULT2
------- -------
null    SUN
1 row selected.
```

17.111 NUMTODSINTERVAL

Syntax

```
NUMTODSINTERVAL( num, interval_indicator )
```

Description

It converts the number in interval_indicator unit to interval day to second type, then returns it.

The argument *number* is a numeric type.

The argument interval_indicator is the same character type as that of CHAR and VARCHAR, and it should be one of 'DAY', 'HOUR', 'MINUTE', 'SECOND' which is case insensitive.

If any argument is NULL, then NULL is returned as a result.

interval day(6) to second(6) type is returned as a result, and a user can not arbitrarily modify the precision. If the leading precision of the converted result exceeds the default precision, then an error is returned. If t he fraction precision exceeds the default precision, then the rounded value is returned as a result.

Example

- It converts *1 Day* to interval day to second type.

```
gSQL> SELECT NUMTODSINTERVAL(1, 'DAY') FROM DUAL;
NUMTODSINTERVAL(1, 'DAY')
-------------------------
+000001 00:00:00.000000
1 row selected.
```

- It converts *36 Hour* to interval day to second type.

```
gSQL> SELECT NUMTODSINTERVAL(36, 'HOUR') FROM DUAL;
NUMTODSINTERVAL(36, 'HOUR')
---------------------------
+000001 12:00:00.000000
1 row selected.
```

- It converts *1530 Minute* to interval day to second type.

```
gSQL> SELECT NUMTODSINTERVAL(1530, 'MINUTE') FROM DUAL;
NUMTODSINTERVAL(1530, 'MINUTE')
------------------------------
+000001 01:30:00.000000
1 row selected.
```

- It converts *90100.1234567 Second* to interval day to second type.

```
gSQL> SELECT NUMTODSINTERVAL(90100.1234567, 'SECOND') FROM DUAL;
NUMTODSINTERVAL(90100.1234567, 'SECOND')
---------------------------------------
+000001 01:01:40.123457
1 row selected.
```

17.112 NUMTOYMINTERVAL

Syntax

```
NUMTOYMINTERVAL( num, interval_indicator )
```

Description

It converts the number in interval_indicator unit to interval year to month type, then returns it.

The argument *number* is a numeric type.

The argument interval_indicator is the same character type as that of CHAR and VARCHAR, and it should be one of 'YEAR', 'MONTH' which is case insensitive.

If any argument is NULL, then NULL is returned as a result.

interval year(6) to month type is returned as a result, and a user can not arbitrarily modify the precision. If the leading precision of the converted result exceeds the default precision, then an error is returned.

Example

- It converts *1 Year* to interval year to month type.

```
gSQL> SELECT NUMTOYMINTERVAL(1, 'YEAR') FROM DUAL;
NUMTOYMINTERVAL(1, 'YEAR')
--------------------------
+000001-00
1 row selected.
```

- It converts *13.5 Month* to interval year to month type.

```
gSQL> SELECT NUMTOYMINTERVAL(13.5, 'MONTH') FROM DUAL;
NUMTOYMINTERVAL(13.5, 'MONTH')
------------------------------
+000001-02
1 row selected.
```

17.113 NVL

Syntax

```
NVL( expr1, expr2 )
```

Description

If expr1 is not NULL, then it returns expr1. If expr1 is NULL, it returns expr2.

The result type is determined according to the data type of expr1.
If NULL is described in expr1, then the result type is determined according to the data type of expr2.
If the data type of expr1 is a character type and a numeric type then it becomes the type including the ra nge of expr1 and expr2 each.
If the data type of both expr1 and expr2 is CHAR type, then the result type is VARCHAR.

Example

```
gSQL> SELECT I1, NVL( I1, 0 ) FROM T1;
  I1 NVL( I1, 0 )
---- ------------
   1            1
null            0
2 rows selected.
```

17.114 NVL2

Syntax

```
NVL2( expr1, expr2, expr3 )
```

Description

If expr1 is not null, then it returns expr2. If expr1 is NULL, it returns expr3.

The result type is determined according to the data type of expr2.
If NULL is described in expr2, then the result type is determined according to the data type of expr3.
If the data type of expr2 is a character type and a numeric type then it becomes the type including the ra nge of expr2 and expr3 each.
If the data type of both expr2 and expr3 is CHAR type, then the result type is VARCHAR.

Example

```
gSQL> SELECT I1, NVL2( I1, I1 * 1000, 0 ) FROM T1;
  I1 NVL2( I1, I1 * 1000, 0 )
---- ------------------------
   1                    1000
null                       0
2 rows selected.
```

17.115 OCTET_LENGTH

Syntax

```
OCTET_LENGTH( str )
BYTE_LENGTH( str )
LENGTHB( str )
```

Description

It returns the number of bytes in str.

The str argument data type can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, or a binary character type such as BINARY, BINARY VARYING, BINARY LONGVARYING.

If the str data type is CHARACTER, the white spaces are included in the calculation.
If str is NULL, the result is also NULL.

It is an alias of **BYTE_LENGTH** and **LENGTHB**.

Example

- Multi byte character set (e.g. UTF8): 1 byte character

```
gSQL> SELECT OCTET_LENGTH( 'OCTET_LENGTH' ) AS RESULT_1BYTE_CHARACTERS
        FROM DUAL;
RESULT_1BYTE_CHARACTERS
-----------------------
                     12
1 row selected.
```

- Multi byte character set (e.g. UTF8): 2 byte character

```
gSQL> SELECT OCTET_LENGTH( 'αβ' ) AS RESULT_2BYTE_CHARACTERS FROM DUAL;
RESULT_2BYTE_CHARACTERS
```

```
------------------------
                       4

1 row selected.
```

17.116 OVERLAY

Syntax

```
OVERLAY( str1 PLACING str2 FROM start_position  [ FOR string_length ] )
```

Description

It overlays the characters in the range between str1's start_position and string_lenght with str2.

The data types of str1 argument and str2 argument can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, or a binary character type such as BINARY, BINARY VARYING, BINARY LONG VARYING
The start_position argument and string_length argument can be numeric data type.

- OVERLAY function has the following result.
  - When FOR is specified.
    SUBSTRING(str1 FROM 1 FOR (start_position - 1))
    || str2
    || SUBSTRING(str1 FROM (start_position + string_length)
  - When FOR is omitted.
    SUBSTRING(str1 FROM 1 FOR (start_position - 1))
    || str2
    || SUBSTRING(str1 FROM (start_position + CHAR_LENGTH(str2))

For more information, refer to **SUBSTRING**.

The following table describes the result types.

Table 17-15 Result type of OVERLAY

str1, str2 types	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT
         OVERLAY( 'RESULT_OF_XXX_FUNC' PLACING 'OVERLAY' FROM 11 )
         AS RESULT1,
         OVERLAY( 'RESULT_OF_XXX_FUNC' PLACING 'OVERLAY' FROM 11 FOR 3 )
         AS RESULT2
      FROM DUAL;
RESULT1            RESULT2
------------------ ----------------------
RESULT_OF_OVERLAYC RESULT_OF_OVERLAY_FUNC
1 row selected.
```

17.117 PERCENT_RANK() OVER

Syntax

```
PERCENT_RANK( ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function PERCENT_RANK calculates the ranking ratio of each row for the entire number of rows.

The result of PERCENT_RANK function is the number between 0 and 1, and the rows with the same valu e have the same ratio value.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             PERCENT_RANK() OVER ( ORDER BY salary ) AS p_rank
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY P_RANK
------------- ------ ------
           60   4200      0
           60   4800    .25
           60   4800    .25
           60   6000    .75
           60   9000      1
5 rows selected.
```

17.118 PERCENTILE_CONT() OVER

Syntax

```
PERCENTILE_CONT( expr ) WITHIN GROUP ( ORDER BY <sort specification> ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function PERCENTILE_CONT is an inverse distribution function assuming a consecutive distributi on model.

It calculates the value corresponding to the specified percentile score for *not null values* sorted within the group.
The calculation result may differ from the specific value sorted within the group.

expr should be the percentile score between 0 and 1.

Only PARTITION BY clause is available in OVER() clause.
It divides the query result sets into groups by using PARTITION BY clause.

It sorts the records within the group with WITHIN GROUP (ORDER BY <sort specification>).
It can specify only one <sort specification> in ORDER BY.

NULL is excluded from the sorted values.

The following is a calculation formula.

```
P : Percentile score
N : The number of the records of not null values sorted within the group
RN = ( 1 + ( P * (N-1) ) )
CRN = CEILING( RN )
FRM = FLOOR( RN )
* if ( CRN = FRN = RN )
     sort expression value of RN
* else
     sort expression value of ( CRN - RN ) * FRN + sort expression value of ( RN - FRN ) * CRN
```

MEDIAN window function is a specific case among PERCENTILE_CONT window functions, and its default value is percentile score 0.5.

For more information, refer to the followings.

- MEDIAN() OVER
- PERCENTILE_DISC() OVER

Example

```
gSQL>
SELECT item_no,
       sales,
       PERCENTILE_CONT( 0.5 ) WITHIN GROUP ( ORDER BY sales )
                              OVER ( PARTITION BY item_no )
       AS PERCENTILE_CONT
  FROM store;
ITEM_NO SALES PERCENTILE_CONT
------- ----- ---------------
    100    50             125
    100    90             125

```

17.119 PERCENTILE_DISC() OVER

Syntax

```
PERCENTILE_DISC( expr ) WITHIN GROUP ( ORDER BY <sort specification> ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function PERCENTILE_DISC is an inverse distribution function assuming a discrete distribution m odel.

It calculates the percentile score for *not null values* sorted within the group.
It determines the smallest value among the values same or over the arguments percentile score of calcula ted percentile scores.
It returns the determined percentile score.

expr should be the percentile score between 0 and 1.

Only PARTITION BY clause is available in OVER() clause.
It divides the query result sets into groups by using PARTITION BY clause.

It sorts the records within the group with WITHIN GROUP (ORDER BY <sort specification>).
It can specify only one <sort specification> in ORDER BY.

It calculates CUME_DIST for the sort expression value with the sorted record.
When calculating CUME_DIST, NULL is excluded.

It determines the smallest value among CUME_DIST which is same or over the percentile score specified a s expr.
It returns the determined CUME_DIST value.

The result type is as same as sort expression value type.

For more information, refer to **CUME_DIST() OVER**.

Example

```
gSQL>
SELECT item_no,
       sales,
       CUME_DIST() OVER ( PARTITION BY item_no ORDER BY sales )
       AS CUME_DIST,
       PERCENTILE_DISC( 0.5 ) WITHIN GROUP ( ORDER BY sales )
                              OVER ( PARTITION BY item_no )
       AS PERCENTILE_DISC
  FROM store;
ITEM_NO SALES CUME_DIST PERCENTILE_DISC
------- ----- --------- ---------------
    100    50        .1             120
    100    90        .3             120
    100    90        .3             120
    100   100        .4             120
    100   120        .5             120
    100   130        .6             120
    100   150        .8             120
    100   150        .8             120
    100   170        .9             120
    100   200         1             120
    235    50        .2              90
    235    70        .4              90
    235    90        .6              90
    235   130        .8              90
    235   190         1              90
15 rows selected.
```

17.120 PHYSICAL_LENGTH

Syntax

```
PHYSICAL_LENGTH( expr )
```

Description

PHYSICAL_LENGTH returns the number of internal expression information bytes in expr.

The expr argument can be any data type.

If an input argument is NULL, then the result is 0.

Example

- When an input argument is NULL

```
gSQL> SELECT PHYSICAL_LENGTH( NULL ) AS RESULT FROM DUAL;
RESULT
------
     0
1 row selected.
```

- The following example shows the number of NUMBER type bytes of 1, 123 and 12345.

```
gSQL> SELECT PHYSICAL_LENGTH( 1 ) AS RESULT FROM DUAL;
RESULT
------
     2
1 row selected.
gSQL> SELECT PHYSICAL_LENGTH( 123 ) AS RESULT FROM DUAL;
RESULT
------
     3
1 row selected.
gSQL> SELECT PHYSICAL_LENGTH( 12345 ) AS RESULT FROM DUAL;
```

```
RESULT
------
     4
1 row selected.
```

17.121 PI

Syntax

```
PI()
```

Description

It returns "π" constant.

Example

```
gSQL> SELECT PI() AS RESULT FROM DUAL;
              RESULT
--------------------
3.141592653589793E+0
1 row selected.
```

17.122 POSITION

Syntax

```
POSITION( str1 IN str2 )
```

Description

It searches for the first str1 within str2, then returns its location.

The data type of str1 argument and str2 argument can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, or a binary character type BINARY, BINARY VARYING, BINARY LONG VARYING.

If str1 can not be found within str2, the return value is 0.
If str1 is found within str2, the position of str1 is returned, and the return value starts from 1.
The returned position value is calculated in character unit (not in byte unit).
If str1 or str2 is NULL, the return value is also NULL.

Example

```
gSQL> SELECT POSITION( 'CHAR' IN 'LONG CHAR 2000' ) AS RESULT FROM DUAL;
RESULT
------
     6
1 row selected.
```

17.123 POWER

Syntax

```
POWER( num1, num2 )
```

Description

It squares num1 to num2, and returns the result.

The num1 argument and num2 argument can be a numeric data type.
If num1 is a negative number, num2 should be an integer.
If num1 or num2 is NULL, the result is also NULL.

Example

```
gSQL> SELECT POWER( 2, 3 ) AS RESULT FROM DUAL;
RESULT
------
     8
1 row selected.
```

17.124 RADIANS

Syntax

```
RADIANS( degrees )
```

Description

It returns the radians of degrees.
The degrees argument can be a numeric data type.
If the degrees argument is NULL, then NULL is returned.

Example

```
gSQL> SELECT RADIANS( 180 ) AS RESULT FROM DUAL;
          RESULT
----------------
3.14159265358979
1 row selected.
```

17.125 RANDOM

Syntax

```
RANDOM( min, max )
```

Description

It returns a random value in the range above min and below max.
The min argument and max argument can be a numeric data type.
If either min argument or the max argument is NULL, then NULL is returned.

Example

```
gSQL> SELECT RANDOM( 1, 100 ) AS RESULT FROM DUAL;
          RESULT
----------------
34.1870528003201
1 row selected.
```

17.126 RANK() OVER

Syntax

```
RANK( ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function RANK calculates the ranking.

The ranking is an integer starting from 1, and rows with the same value have the same rank.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             RANK() OVER ( ORDER BY salary ) AS rank
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY RANK
------------- ------ ----
           60   4200    1
           60   4800    2
           60   4800    2
           60   6000    4
           60   9000    5
5 rows selected.
```

17.127 RATIO_TO_REPORT() OVER

Syntax

```
RATIO_TO_REPORT ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function RATIO_TO_REPORT calculates the ratio of each row value for the total sum of expr valu es.
If the row value is NULL, then it returns NULL as a result.

order by is not available in window clause.
window frame is not available.

Example

```
gSQL> SELECT supplier_id, min_price
             , RATIO_TO_REPORT( min_price ) OVER ( PARTITION BY supplier_id ) AS "RATIO"
        FROM product_information
       WHERE supplier_id = 102050;
SUPPLIER_ID MIN_PRICE             RATIO
----------- --------- -----------------
     102050       731  .695528068506185
     102050      null              null
     102050        73 .0694576593720266
     102050       247  .235014272121789
     102050      null              null
5 rows selected.
```

17.128 REGR_AVGX() OVER

Syntax

```
REGR_AVGX( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_AVGX is a linear regression function.
It calculates the average value of the independent variable expr2 of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
AVG( expr2 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns NULL.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       REGR_AVGX( price, year ) OVER ( PARTITION BY item_no )
       AS "REGR_AVGX(price,year)"
```

```
  FROM store;
ITEM_NO PRICE YEAR REGR_AVGX(price,year)
------- ----- ---- --------------------
   3758 15000 2000                 2003
   3758 14700 2001                 2003
   3758 15300 2002                 2003
   3758 15200 2003                 2003
   3758 15100 2004                 2003
   3758 15300 2005                 2003
   3758 15350 2006                 2003
7 rows selected.
```

17.129 REGR_AVGY() OVER

Syntax

```
REGR_AVGY( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_AVGY is a linear regression function.
It calculates the average value of the dependent variable expr1 of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
AVG( expr1 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns NULL.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       round( REGR_AVGY( price, year ) OVER ( PARTITION BY item_no ), 5 )
       AS "REGR_AVGY(price,year)"
```

```
  FROM store;
ITEM_NO PRICE YEAR REGR_AVGY(price,year)
------- ----- ---- --------------------
   3758 15000 2000           15135.71429
   3758 14700 2001           15135.71429
   3758 15300 2002           15135.71429
   3758 15200 2003           15135.71429
   3758 15100 2004           15135.71429
   3758 15300 2005           15135.71429
   3758 15350 2006           15135.71429
7 rows selected.
```

17.130 REGR_COUNT() OVER

Syntax

```
REGR_COUNT( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_COUNT is a linear regression function.
It calculates the least-squares-fit linear equation of (X, Y) set.

It returns the number of (X, Y) pairs, the execution targets of the linear equation and both of which are not NULL.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The returned type is a numeric type.

It returns the number of pairs both of whose expr1 and expr2 are not NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns 0.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       REGR_COUNT( price, year ) OVER ( PARTITION BY item_no )
       AS "REGR_COUNT(price,year)"
  FROM store;
ITEM_NO PRICE YEAR REGR_COUNT(price,year)
------- ----- ---- ----------------------
```

```
   3758 15000 2000                    7
   3758 14700 2001                    7
   3758 15300 2002                    7
   3758 15200 2003                    7
   3758 15100 2004                    7
   3758 15300 2005                    7
   3758 15350 2006                    7
7 rows selected.
```

17.131 REGR_INTERCEPT() OVER

Syntax

```
REGR_INTERCEPT( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_INTERCEPT is a linear regression function.
It calculates the y intercept of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
AVG( expr1 ) - REGR_SLOPE( expr1, expr2 ) * AVG( expr2 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.

It returns NULL in the following cases.
- When all records are excluded from the target because expr1 or expr2 is NULL
- When the result of REGR_SLOPE is null

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       REGR_INTERCEPT( price, year ) OVER ( PARTITION BY item_no )
```

```
       AS "REGR_INTERCEPT(price,year)"
  FROM store;
ITEM_NO PRICE YEAR REGR_INTERCEPT(price,year)
------- ----- ---- --------------------------
   3758 15000 2000                  -131512.5
   3758 14700 2001                  -131512.5
   3758 15300 2002                  -131512.5
   3758 15200 2003                  -131512.5
   3758 15100 2004                  -131512.5
   3758 15300 2005                  -131512.5
   3758 15350 2006                  -131512.5
7 rows selected.
```

17.132 REGR_R2() OVER

Syntax

```
REGR_R2( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_R2 is a linear regression function.
It calculates the coefficient of determination (R-squared or fitness) of (X, Y) set's least-squares-fit linear e quation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
If VAR_POP( expr2 ) = 0, then it is NULL.
If VAR_POP( expr1 ) = 0 and VAR_POP( expr2 ) != 0, then it is 1.
If VAR_POP( expr1 ) > 0 and VAR_POP( expr2 ) != 0, then it is POWER( CORR( expr1, expr2), 2 ).
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.

It returns NULL in the following cases.
- When all records are excluded from the target because expr1 or expr2 is NULL
- When the result of VAR_POP (expr2) is 0

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       round( REGR_R2( price, year ) OVER ( PARTITION BY item_no ), 10 )
       AS "REGR_R2(price,year)"
  FROM store
 WHERE item_no = 3758;
ITEM_NO PRICE YEAR REGR_R2(price,year)
------- ----- ---- --------------------
   3758 15000 2000          .4786446469
   3758 14700 2001          .4786446469
   3758 15300 2002          .4786446469
   3758 15200 2003          .4786446469
   3758 15100 2004          .4786446469
   3758 15300 2005          .4786446469
   3758 15350 2006          .4786446469
7 rows selected.
```

17.133 REGR_SLOPE() OVER

Syntax

```
REGR_SLOPE( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_SLOPE is a linear regression function.
It calculates the slope of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
COVAR_POP(expr1, expr2) / VAR_POP(expr2)
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.

It returns NULL in the following cases.
- When all records are excluded from the target because expr1 or expr2 is NULL
- When the result of VAR_POP is 0

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       round( REGR_SLOPE( price, year ) OVER ( PARTITION BY item_no ), 10 )
```

```
       AS "REGR_SLOPE(price,year)"
  FROM store;
ITEM_NO PRICE YEAR REGR_SLOPE(price,year)
------- ----- ---- ----------------------
   3758 15000 2000          73.2142857143
   3758 14700 2001          73.2142857143
   3758 15300 2002          73.2142857143
   3758 15200 2003          73.2142857143
   3758 15100 2004          73.2142857143
   3758 15300 2005          73.2142857143
   3758 15350 2006          73.2142857143
7 rows selected.
```

17.134 REGR_SXX() OVER

Syntax

```
REGR_SXX( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_SXX is a linear regression function.
It is an auxiliary function calculating the diagnostic statistics of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
REGR_COUNT( expr1, expr2 ) * VAR_POP( expr2 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns NULL.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       REGR_SXX( price, year ) OVER ( PARTITION BY item_no )
       AS "REGR_SXX(price,year)"
  FROM store;
```

```
ITEM_NO PRICE YEAR REGR_SXX(price,year)
------- ----- ---- --------------------
   3758 15000 2000                   28
   3758 14700 2001                   28
   3758 15300 2002                   28
   3758 15200 2003                   28
   3758 15100 2004                   28
   3758 15300 2005                   28
   3758 15350 2006                   28
7 rows selected.
```

17.135 REGR_SXY() OVER

Syntax

```
REGR_SXY( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_SXY is a linear regression function.
It is an auxiliary function calculating the diagnostic statistics of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
REGR_COUNT( expr1, expr2 ) * COVAR_POP( expr1, expr2 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns NULL.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       REGR_SXY( price, year ) OVER ( PARTITION BY item_no )
       AS "REGR_SXY(price,year)"
  FROM store;
```

```
ITEM_NO PRICE YEAR REGR_SXY(price,year)
------- ----- ---- --------------------
   3758 15000 2000                 2050
   3758 14700 2001                 2050
   3758 15300 2002                 2050
   3758 15200 2003                 2050
   3758 15100 2004                 2050
   3758 15300 2005                 2050
   3758 15350 2006                 2050
7 rows selected.
```

17.136 REGR_SYY() OVER

Syntax

```
REGR_SYY( expr1, expr2 ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function REGR_SYY is a linear regression function.
It is an auxiliary function calculating the diagnostic statistics of (X, Y) set's least-squares-fit linear equation.

The arguments of expr1 and expr2 are numeral types.

expr1 is an dependent variable (y) and expr2 is a independent variable (x).

If expr1 is NULL or expr2 is NULL, then it is excluded from the target.

The following is a calculation formula.

```
REGR_COUNT( expr1, expr2 ) * VAR_POP( expr1 )
```

The returned type is a numeric type.

The returned value is the result from the calculation or NULL.
If all records are excluded from the target because expr1 or expr2 is NULL, then it returns NULL.

Example

```
gSQL>
SELECT item_no,
       price,
       year,
       round( REGR_SYY( price, year ) OVER ( PARTITION BY item_no ), 4 )
       AS "REGR_SYY(price,year)"
  FROM store;
```

```
ITEM_NO PRICE YEAR REGR_SYY(price,year)
------- ----- ---- --------------------
   3758 15000 2000          313571.4286
   3758 14700 2001          313571.4286
   3758 15300 2002          313571.4286
   3758 15200 2003          313571.4286
   3758 15100 2004          313571.4286
   3758 15300 2005          313571.4286
   3758 15350 2006          313571.4286
7 rows selected.
```

17.137 REPEAT

Syntax

```
REPEAT( str, num )
```

Description

The string repeats str as many times as specified in num, and returns the result.

The str argument can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, or a binary character type such as BINARY, BINARY VARYING, BINARY LONG VARYING.

The num argument can be a numeric data type.

If either str or num is NULL, the result is also NULL.
If num is 0 or a negative number, the result is also NULL.

The following table describes the result types.

Table 17-16 Result type of REPEAT

str type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT REPEAT( 'ab', 3 ) AS RESULT FROM DUAL;
RESULT
------
ababab
1 row selected.
```

17.138 REPLACE

Syntax

```
REPLACE( str, from, to )
```

Description

It replaces all *from* strings in str string with *to* strings, and returns the result.

The str argument, the from argument, and the to argument can be a character data types such as CHAR ACTER, CHARACTER VARYING, CHARACTER LONG VARYING.

If str is NULL, the result is also NULL.
If from is NULL, the str is returned without replacement.
If to value is omitted or NULL, the str value of which from is removed is returned.

The following table describes the result types.

Table 17-17 Result type of REPLACE

str type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR

Example

```
gSQL> SELECT REPLACE( 'HI GLIESE', 'HI', 'HELLO' ) AS RESULT FROM DUAL;
RESULT
------------
HELLO GLIESE
1 row selected.
```

17.139 REVERSE

Syntax

```
REVERSE( str )
```

Description

REVERSE returns characters of str in reverse order.

The str argument can be types which is convertible to a character string type or a binary string type.
A character string type is performed in a character unit, and a binary stringtype can be performed in a byte unit.

If str is NULL, then it returns NULL.

The following table describes the arguments and result types.

Table 17-18 Argument and result type of REVERSE

str	Result type
CHAR	CHAR
VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY	BINARY
VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT REVERSE( 'GOLDILOCKS' ) AS RESULT FROM DUAL;
RESULT
----------
SKCOLIDLOG
1 row selected.
gSQL> SELECT REVERSE( '선재소프트 2018' ) AS RESULT FROM DUAL;
```

```
RESULT
---------------
8102 트프소재선
1 row selected.
```

17.140 ROUND(number)

Syntax

```
ROUND( num [, scale ] )
```

Description

It rounds off num based on scale, and returns the result.

The num argument and scale argument can be a numeric data type.

If scale is omitted, the scale becomes 0 and is executed as if it is ROUND(num, 0).
If scale is a positive number, it is rounded off based on the number of right digit of the decimal point. If s cale is a negative number, it is rounded off based on the number of left digit of the decimal point.
If either num argument or the scale argument is NULL, then NULL is returned.

Example

```
gSQL> SELECT ROUND( 152.4282, 2 ) AS RESULT FROM DUAL;
RESULT
------
152.43
1 row selected.
gSQL> SELECT ROUND( 152.4282, -2 ) AS RESULT FROM DUAL;
RESULT
------
   200
1 row selected.
```

17.141 ROUND(date)

Syntax

```
ROUND( date [ , fmt ] )
```

Description

It rounds off the date in the specified fmt unit, and returns the result.

The data type of date argument can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE.
The fmt argument can be a character type such as CHARACTER, CHARACTER VARYING.
If either date argument or the fmt argument is NULL, then NULL is returned.
The result type is always DATE regardless of the date argument data type.

If fmt is omitted, the default is DAY.
The following table describes the available format strings.

Table 17-19 Available format sting of fmt

String	Description
CC, SCC	It is represented in four digit year by rounding off from 51 year. (e.g. XX01)
YYYY, YEAR, SYYYY, SYEAR, YYY, YY, Y	It is rounded off from July 1st.
IYYY, IYY, IY, I	It is the year embracing the calendar week defined by ISO 8601 standards, and it is rounded off from July 1st.
Q	It is rounded off from the 16th day in the second month of the quarter.
MONTH, MON, MM, RM	It is rounded off from the 16th day.
WW	A week starts from January 1st of the year, and it is rounded off on wednesday 12 p.m of WEEK.
IW	It is the calendar week defined by ISO 8601 standards (1 ~ 52 week or 1 ~ 53 weeks), and it is rounded off on thursday 12 p.m.
W	A week starts from the 1st day of the month, and it is rounded off on wednesday 12 p.m of WEEK.
DDD, DD, J	It is rounded off at 12 p.m.
DAY, DY, D	It is rounded off on wednesday 12 p.m of WEEK.
HH, HH12, HH24	It is rounded off from 30 minutes.
MI	It is rounded off from 30 seconds.

Example

```
gSQL> SELECT
      ROUND( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'CC' ) AS RESULT
      FROM DUAL;
RESULT
----------
2101-01-01
1 row selected.
gSQL> SELECT
      ROUND( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'YYYY' ) AS RESULT
      FROM DUAL;
RESULT
----------
2052-01-01
1 row selected.
gSQL> SELECT
      ROUND( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'MONTH' ) AS   RESULT
      FROM DUAL;
RESULT
----------
2051-08-01
1 row selected.
gSQL> SELECT
      ROUND( TO_TIMESTAMP( '2001-05-05 15:22:33.999999',
                           'YYYY-MM-DD HH24:MI:SS.FF6' ) ) AS RESULT
      FROM DUAL;
RESULT
----------
2001-05-06
1 row selected.
```

17.142 ROW_NUMBER() OVER

Syntax

```
ROW_NUMBER( ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function ROW_NUMBER assigns the unique number to each row.
The unique number is a consecutive integer starting from 1.

window frame is not available.

Example

```
gSQL> SELECT department_id, salary,
             ROW_NUMBER() OVER ( ORDER BY salary ) AS row_num
      FROM employees
      WHERE department_id = 60;
DEPARTMENT_ID SALARY ROW_NUM
------------- ------ -------
           60   4200       1
           60   4800       2
           60   4800       3
           60   6000       4
           60   9000       5
5 rows selected.
```

17.143 ROWID_GRID_BLOCK_ID

Syntax

```
ROWID_GRID_BLOCK_ID( rowid )
```

Description

It returns the GRID block ID.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT C1, ROWID_GRID_BLOCK_ID( ROWID ) FROM T1;
C1 ROWID_GRID_BLOCK_ID( ROWID )
-- ----------------------------
 1                           52
 2                           52
 3                           52
3 rows selected.
```

17.144 ROWID_GRID_BLOCK_SEQ

Syntax

```
ROWID_GRID_BLOCK_SEQ( rowid )
```

Description

It returns the GRID block sequence.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT C1, ROWID_GRID_BLOCK_SEQ( ROWID ) FROM T1;
C1 ROWID_GRID_BLOCK_SEQ( ROWID )
-- ------------------------------
 1                         747465
 2                         747466
 3                         747467
3 rows selected.
```

17.145 ROWID_MEMBER_ID

Syntax

```
ROWID_MEMBER_ID( rowid )
```

Description

It returns the member ID.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT C1, ROWID_MEMBER_ID( ROWID ) FROM T1;
C1 ROWID_MEMBER_ID( ROWID )
-- ------------------------
 1                        1
 2                        1
 3                        1
3 rows selected.
```

17.146 ROWID_OBJECT_ID

Syntax

```
ROWID_OBJECT_ID( rowid )
```

Description

It returns the object ID.

It is an invalid information in a cluster system.

Example

```
gSQL> SELECT ROWID_OBJECT_ID( t1.ROWID ) FROM t1;
ROWID_OBJECT_ID( T1.ROWID )
---------------------------
                      22012
                      22012
                      22012
                      22012
4 rows selected.
```

17.147 ROWID_PAGE_ID

Syntax

```
ROWID_PAGE_ID( rowid )
```

Description

It returns the page ID.

It is an invalid information in a cluster system.

Example

```
gSQL> SELECT ROWID_PAGE_ID( t1.ROWID ) FROM t1;
ROWID_PAGE_ID( T1.ROWID )
-------------------------
                     8227
                     8227
                     8227
                     8227
4 rows selected.
```

17.148 ROWID_ROW_NUMBER

Syntax

```
ROWID_ROW_NUMBER( rowid )
```

Description

It returns the row number.

It is an invalid information in a cluster system.

Example

```
gSQL> SELECT ROWID_ROW_NUMBER( t1.ROWID ) FROM t1;
ROWID_ROW_NUMBER( T1.ROWID )
----------------------------
                           0
                           1
                           2
                           3
4 rows selected.
```

17.149 ROWID_SHARD_ID

Syntax

```
ROWID_SHARD_ID( rowid )
```

Description

It returns the shard ID.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT C1, ROWID_SHARD_ID( ROWID ) FROM T1;
C1 ROWID_SHARD_ID( ROWID )
-- ------------------------
 1                       0
 2                       1
 3                       2
3 rows selected.
```

17.150 ROWID_TABLESPACE_ID

Syntax

```
ROWID_TABLESPACE_ID( rowid )
```

Description

It returns the tablespace ID.

It is an invalid information in a cluster system.

Example

```
gSQL> SELECT ROWID_TABLESPACE_ID( t1.ROWID ) FROM t1;
ROWID_TABLESPACE_ID( T1.ROWID )
------------------------------
                             2
                             2
                             2
                             2
4 rows selected.
```

17.151 ROWNUM

Syntax

```
ROWNUM
```

Description

It sequentially allocates a number starting from 1 to rows which satisfy the WHERE condition.

It allows using ROWNUM in WHERE clause for the compatibility with Oracle.

However, to restrict the number of the query results, it is recommended to use **offset limit clause** (the SQL standard) as follows.

- (Non standard) Describing the number of the results by using ROWNUM

```
gSQL> SELECT * FROM t1 WHERE ROWNUM <= 3;
C1
--
A
B
C
3 rows selected.
```

- (SQL standard) Describing the number of the results by using FETCH statement

```
gSQL> SELECT * FROM t1 FETCH 3;
C1
--
A
B
C
3 rows selected.
```

To restrict the range of the query results, it is recommended to use OFFSET, FETCH statement as follows.

- (Non standard) Describing the range of the number of the results by using ROWNUM

```
gSQL> SELECT c1
        FROM ( SELECT ROWNUM rn, c1
                 FROM t1 )
        WHERE rn BETWEEN 2 AND 3;
C1
--
B
C
2 rows selected.
```

- (SQL standard) Describing the range of the number of the results by using ROWNUM OFFSET, FETCH statement

```
gSQL> SELECT c1 FROM t1 OFFSET 1 FETCH 2;
C1
--
B
C
2 rows selected.
```

It is not recommended to use ROWNUM in WHERE clause for any other uses than the restriction of the n umber of the results.

The results for the same query may be different according to the execution method as follows when usin g the ambiguous condition (WHERE c1 < ROWNUM + 3).

- Creating the data

```
CREATE TABLE t1 ( c1 INTEGER );
CREATE INDEX t1_idx ON t1(c1);
INSERT INTO t1 VALUES (1);
INSERT INTO t1 VALUES (2);
INSERT INTO t1 VALUES (3);
INSERT INTO t1 VALUES (4);
INSERT INTO t1 VALUES (5);
COMMIT;
```

- In case of Oracle

```
SQL> SELECT ROWNUM, c1 FROM t1 WHERE c1 < ROWNUM + 3;
    ROWNUM       C1
---------- ----------
     1        1
```

```
     2        2
SQL> DROP INDEX t1_idx;
```

- The index has been deleted.

```
SQL> SELECT ROWNUM, c1 FROM t1 WHERE c1 < ROWNUM + 3;
    ROWNUM       C1
---------- ----------
     1        1
     2        2
     3        3
     4        4
     5        5
```

- In case of GOLDILOCKS

```
gSQL> SELECT ROWNUM, c1 FROM t1 WHERE c1 < ROWNUM + 3;
ROWNUM C1
------ --
     1  1
     2  2
     3  3
     4  4
     5  5
5 rows selected.
gSQL> DROP INDEX t1_idx;
Index dropped.
gSQL> SELECT ROWNUM, c1 FROM t1 WHERE c1 < ROWNUM + 3;
ROWNUM C1
------ --
     1  1
     2  2
     3  3
     4  4
     5  5
5 rows selected.
```

Example

```
gSQL> SELECT ROWNUM, c1 FROM t1;
ROWNUM C1
------ --
     1 A
     2 B
     3 C
     4 D
     5 E
5 rows selected.
```

17.152 RPAD

Syntax

```
RPAD( str, length, [, fill] )
```

Description

It adds fill string to the right side of str until the string's length becomes length, and it returns the result.

The str argument can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LON GVARYING, or a binary character type such as BINARY, BINARY VARYING, BINARY LONG VARYING.

The length argument can be a numeric type.

length means the number of characters, and its maximum range is the maximum PRECISION of the result type.
If fill is omitted, a white space is added.
If str is longer than length, it cuts the str as long as the length, then returns it.
If any of str, length, fill is NULL, the result is also NULL.
If length is 0 or a negative number, the result is NULL.

The following table describes the result types.

Table 17-20 Result type of RPAD

str type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT RPAD('AA', 5) AS RESULT1,
             RPAD('AA', 5, 'X') AS RESULT2,
             RPAD('AA', 1) AS RESULT3
```

```
      FROM DUAL;
RESULT1 RESULT2 RESULT3
------- ------- -------
AA      AAXXX   A
1 row selected.
```

17.153 RTRIM

Syntax

```
RTRIM( trim_source [, trim_character ] )
```

Description

It removes the matching characters by comparing from the right side of trim_character in trim_source unt il the matching character does not exist. Then it returns the result.

The data type of trim_character argument and trim_source argument can be a character type such as CH ARACTER, CHARACTER VARYING, CHARACTER LONG VARYING or a binary data type such as BINARY, BI NARY VARYING, BINARY LONG VARYING.

If any of trim_character, trim_source is NULL, the result is NULL.
If trim_character is omitted, a single blank space (' ') is specified by default.

The following table describes the result types.

Table 17-21 Result type of RTRIM

trim_source type, trim_character type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT RTRIM('      rtrim      ') AS RESULT1,
             RTRIM('______rtrim______','_') AS RESULT2
      FROM DUAL;
RESULT1     RESULT2
----------- -----------
      rtrim ______rtrim
```

```
1 row selected.
```

17.154 SESSION_ID

Syntax

```
SESSION_ID()
```

Description

It obtains the current session ID.

Example

```
gSQL> SELECT SESSION_ID() FROM dual;
SESSION_ID()
------------
           4
1 row selected.
```

17.155 SESSION_SERIAL

Syntax

```
SESSION_SERIAL()
```

Description

It obtains the serial number of current session.

Example

```
gSQL> SELECT SESSION_SERIAL() FROM dual;
SESSION_SERIAL()
----------------
              16
1 row selected.
```

17.156 SESSION_USER

Syntax

```
SESSION_USER[()]
```

Description

It returns the session user.

The user information is managed in three types as follows.

- Logon user: It is a user who performed login, and it is maintained until the connection is closed.
- Session user: It is as same as the first logon user, but it can be changed using the SET SESSION AUTH ORIZATION statement.
- Current user: It is generally as same as the session user, but it is temporarily changed internally in syst em to control access when using the PSM, view.
    - The session user and current user is similar to the difference between the unix system's real user and the effective user.

Example

```
% gsql sys gliese
gSQL>  SET SESSION AUTHORIZATION test;
Session set.
gSQL> SELECT LOGON_USER() AS result1, SESSION_USER() AS result2 FROM DUAL;
RESULT1 RESULT2
------- -------
SYS     TEST
1 row selected.
```

17.157 SESSIONTIMEZONE

Syntax

```
SESSIONTIMEZONE()
```

Description

SESSIONTIMEZONE returns the time zone of the current session.
The returned value is '[+|-]TZH:TZM' format character.
The returned type is varchar.

Example

Check the time zone of the current session.

```
gSQL> SELECT SESSIONTIMEZONE() FROM dual;
SESSIONTIMEZONE()
-----------------
+09:00
1 row selected.
```

When modifying the time zone of the current session, then it returns the modified time zone value.

```
gSQL> SET TIME ZONE '-05:00';
Session set.
gSQL> SELECT SESSIONTIMEZONE() FROM dual;
SESSIONTIMEZONE()
-----------------

```

17.158 SHARD_GROUP_ID

Syntax

```
SHARD_GROUP_ID( table_name, shard_key_value [, ... ] )
```

Description

It returns the group ID managing the shard which stores shard_key_value when the shard strategy is defi ned in the table_name.

The table_name (an input argument) should be described by an identifier. If an object corresponding to t he table_name is not a base table, or if the shard strategy is not defined, then an error occurs.

The shard_key_value (an input argument) should be listed in an order of shard key column in the shard st rategy defined in the table_name. If the number of shard_key_value and the number of shard key column is not same, then an error occurs.

The result type is NATIVE_BIGINT.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT T1.C1, SHARD_GROUP_ID( T1, T1.C1 ) FROM T1;
C1 SHARD_GROUP_ID( T1, T1.C1 )
-- --------------------------
A                           1
B                           2
C                           3
3 rows selected.
gSQL> SELECT SHARD_GROUP_ID( T1, 'B' ) FROM DUAL;
SHARD_GROUP_ID( T1, 'B' )
-------------------------
                        2
```

```
1 row selected.
```

17.159 SHARD_GROUP_NAME

Syntax

```
SHARD_GROUP_NAME( table_name, shard_key_value [, ... ] )
```

Description

It returns the group NAME managing the shard which stores shard_key_value when the shard strategy is defined in the table_name.

The table_name (an input argument) should be described by an identifier. If an object corresponding to t he table_name is not a base table, or if the shard strategy is not defined, then an error occurs.

The shard_key_value (an input argument) should be listed in an order of shard key column in the shard st rategy defined in the table_name. If the number of shard_key_value and the number of shard key column is not same, then an error occurs.

The result type is VARCHAR.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT T1.C1, SHARD_GROUP_NAME( T1, T1.C1 ) FROM T1;
C1 SHARD_GROUP_NAME( T1, T1.C1 )
-- ------------------------------
A  G1
B  G2
C  G3
3 rows selected.
gSQL> SELECT SHARD_GROUP_NAME( T1, 'B' ) FROM DUAL;
SHARD_GROUP_NAME( T1, 'B' )
---------------------------
G2
```

```
1 row selected.
```

17.160 SHARD_ID

Syntax

```
SHARD_ID( table_name, shard_key_value [, ... ] )
```

Description

It returns the ID for the shard which stores shard_key_value when the shard strategy is defined in the table_name.

The table_name (an input argument) should be described by an identifier. If an object corresponding to the table_name is not a base table, or if the shard strategy is not defined, then an error occurs.

The shard_key_value (an input argument) should be listed in an order of shard key column in the shard strategy defined in the table_name. If the number of shard_key_value and the number of shard key column is not same, then an error occurs.

The result type is NATIVE_BIGINT.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT T1.C1, SHARD_ID( T1, T1.C1 ) FROM T1;
C1 SHARD_ID( T1, T1.C1 )
-- --------------------
A                     0
B                     1
C                     2
3 rows selected.
gSQL> SELECT SHARD_ID( T1, 'B' ) FROM DUAL;
SHARD_ID( T1, 'B' )
-------------------
                  1
```

```
1 row selected.
```

17.161 SHARD_NAME

Syntax

```
SHARD_NAME( table_name, shard_key_value [, ... ] )
```

Description

It returns the NAME for the shard which stores shard_key_value when the shard strategy is defined in the table_name.

The table_name (an input argument) should be described by an identifier. If an object corresponding to t he table_name is not a base table, or if the shard strategy is not defined, then an error occurs.

The shard_key_value (an input argument) should be listed in an order of shard key column in the shard st rategy defined in the table_name. If the number of shard_key_value and the number of shard key column is not same, then an error occurs.

The result type is VARCHAR.

It is a valid information in a cluster system.

Example

```
gSQL> SELECT T1.C1, SHARD_NAME( T1, T1.C1 ) FROM T1;
C1 SHARD_NAME( T1, T1.C1 )
-- ----------------------
A  S1
B  S2
C  S3
3 rows selected.
gSQL> SELECT SHARD_NAME( T1, 'B' ) FROM DUAL;
SHARD_NAME( T1, 'B' )
---------------------
S2
```

```
1 row selected.
```

17.162 SHIFT_LEFT

Syntax

```
SHIFT_LEFT( num, cnt )
```

Description

It moves num to the left as many as cnt bits, and returns the movement values.

The data type of input num argument and cnt argument can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT, or the type which can be converted to NATIVE_BIGINT.
When converting to NATIVE_BIGINT type, the decimal point is truncated.

cnt is masked with 6 bit, and it is processed to a value in the range within 6 bit.

If either num or cnt is NULL, then NULL is returned.

The result type is NATIVE_BIGINT.

Example

```
gSQL> SELECT SHIFT_LEFT(1, 3) FROM DUAL;
SHIFT_LEFT(1, 3)
----------------
               8
1 row selected.
```

17.163 SHIFT_RIGHT

Syntax

```
SHIFT_RIGHT( num, cnt )
```

Description

It moves num to the right as many as cnt bits, and returns the movement values.

The data type of input num argument and cnt argument can be NATIVE_SMALLINT, NATIVE_INTEGER, NATIVE_BIGINT, or the type which can be converted to NATIVE_BIGINT.
When converting to NATIVE_BIGINT type, the decimal point is truncated.

cnt is masked with 6 bit, and it is processed to a value in the range within 6 bit.

If either num or cnt is NULL, then NULL is returned.

The result type is NATIVE_BIGINT.

Example

```
gSQL> SELECT SHIFT_RIGHT(8, 3) FROM DUAL;
SHIFT_RIGHT(8, 3)
-----------------
                1
1 row selected.
```

17.164 SIGN

Syntax

```
SIGN( num )
```

Description

It returns the sign of num.

The num argument can be a numeric data type.

The return value is as follows.

- If num < 0, -1 is returned.
- If num = 0, 0 is returned.
- If num > 0, 1 is returned.

If num is NULL, then NULL is returned.

Example

```
gSQL> SELECT SIGN(-10) AS RESULT1,
             SIGN(0) AS RESULT2,
             SIGN(10) AS RESULT3 FROM DUAL;
RESULT1 RESULT2 RESULT3
------- ------- -------
     -1       0       1
1 row selected.
```

17.165 SIN

Syntax

```
SIN( num )
```

Description

It returns the sine value of num.
If num is NULL, then NULL is returned.

Example

```
gSQL> SELECT SIN( 0 ) AS RESULT FROM DUAL;
RESULT
------
     0
1 row selected.
```

17.166 SPLIT_PART

Syntax

```
SPLIT_PART( string, delimiter, field )
```

Description

It returns a character string of the field by specifying a character as delimiter within a string.

The data type of string argument and delimiter argument can be a character data type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.

The field argument can be a numeric data type.

If any of string, delimiter, field is NULL, the result is also NULL.
The value of field should be a numeric value above 1, and if it is 0 or a negative number, an error is returned.

The following table describes the result types.

Table 17-22 Result type of SPLIT_PART

string type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR

Example

```
gSQL> SELECT SPLIT_PART( 'AB;CD;EF;GH', ';', 3  ) AS RESULT FROM DUAL;
RESULT
------
EF
1 row selected.
```

17.167 SQRT

Syntax

```
SQRT( num )
```

Description

It returns the square root of num.

The num argument can be a numeric type, and it should not be a negative number, but above 0.
If the num argument is NULL, then NULL is returned.

Example

```
gSQL> SELECT SQRT( 9 ) AS RESULT FROM DUAL;
RESULT
------
     3
1 row selected.
```

17.168 STATEMENT_DATE

Syntax

```
STATEMENT_DATE()
CURRENT_DATE [()]
```

Description

The current date(DATE type) value is obtained.

The differences among the functions to obtain the current date are as follows.

- TRANSACTION_DATE(): All date values in the transaction are same.
- STATEMENT_DATE(): All date values in an SQL statement are same.
- CLOCK_DATE(): Whenever the function is called, the current date value is obtained.

Example

```
gSQL> SELECT STATEMENT_DATE() AS result FROM t1;
RESULT
----------
2013-12-12
2013-12-12
2013-12-12
3 rows selected.
```

17.169 STATEMENT_LOCALTIME

Syntax

```
STATEMENT_LOCALTIME()
LOCALTIME [()]
```

Description

The current TIME WITHOUT TIME ZONE type value based on the session time is obtained.

LOCALTIME is an SQL standard function.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_LOCALTIME(): All time values in the transaction are same.
- TATEMENT_LOCALTIME(): All time values in an SQL statement are same.
- CLOCK_LOCALTIME(): Whenever the function is called, the current time value is obtained.

Example

All rows have the same time value.

```
gSQL> SELECT STATEMENT_LOCALTIME() AS result FROM t1;
RESULT
---------------
16:18:50.775870
16:18:50.775870
16:18:50.775870
3 rows selected.
```

17.170 STATEMENT_LOCALTIMESTAMP

Syntax

```
STATEMENT_LOCALTIMESTAMP()
LOCALTIMESTAMP [()]
```

Description

The current TIMESTAMP WITHOUT TIME ZONE type value based on the session time is obtained.

LOCALTIMESTAMP is an SQL standard function.

The differences among the functions to obtain the current timestamp are as follows.

- TRANSACTION_LOCALTIMESTAMP(): All timestamp values in the transaction are same.
- STATEMENT_LOCALTIMESTAMP(): All timestamp values in an SQL statement are same.
- CLOCK_LOCALTIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT STATEMENT_LOCALTIMESTAMP() FROM t1;
STATEMENT_LOCALTIMESTAMP()
--------------------------
2013-12-12 16:23:39.782187
2013-12-12 16:23:39.782187
2013-12-12 16:23:39.782187
3 rows selected.
```

17.171 STATEMENT_TIME

Syntax

```
STATEMENT_TIME()
CURRENT_TIME [()]
```

Description

The current TIME WITH TIME ZONE type value is obtained.

CURRENT_TIME is an SQL standard function.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_TIME(): All time values in the transaction are same.
- STATEMENT_TIME(): All time values in an SQL statement are same.
- CLOCK_TIME(): Whenever the function is called, the current time value is obtained.

Example

All rows have the same time value.

```
gSQL> SELECT STATEMENT_TIME() AS result FROM t1;
RESULT
----------------------
16:28:19.268513 +09:00
16:28:19.268513 +09:00
16:28:19.268513 +09:00
3 rows selected.
```

17.172 STATEMENT_TIMESTAMP

Syntax

```
STATEMENT_TIMESTAMP()
CURRENT_TIMESTAMP [()]
```

Description

The current TIMESTAMP WITH TIME ZONE type value is obtained.

CURRENT_TIMESTAMP is an SQL standard function.

The differences among the functions to obtain the current timestamp are as follows.

- TRANSACTION_TIMESTAMP(): All timestamp values in the transaction are same.
- STATEMENT_TIMESTAMP(): All timestamp values in an SQL statement are same.
- CLOCK_TIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All rows have the same value.

```
gSQL> SELECT STATEMENT_TIMESTAMP() AS result FROM t1;
RESULT
-------------------------------
2013-12-12 16:36:11.032957 +09:00
2013-12-12 16:36:11.032957 +09:00
2013-12-12 16:36:11.032957 +09:00
3 rows selected.
```

17.173 STATEMENT_VIEW_SCN

Syntax

```
STATEMENT_VIEW_SCN()
```

Description

It obtains VIEW SCN of the current STATEMENT.

Example

```
gSQL> SELECT STATEMENT_VIEW_SCN() FROM dual;
STATEMENT_VIEW_SCN()
--------------------
17697.658.17880
1 row selected.
```

17.174 STATEMENT_VIEW_SCN_DCN

Syntax

```
STATEMENT_VIEW_SCN_DCN()
```

Description

It obtains the Domain Change Number (DCN) value of the current STATEMENT's VIEW SCN.

Example

```
gSQL> SELECT STATEMENT_VIEW_SCN_DCN() FROM dual;
STATEMENT_VIEW_SCN_DCN()
------------------------
                     658
1 row selected.
```

17.175 STATEMENT_VIEW_SCN_GCN

Syntax

```
STATEMENT_VIEW_SCN_GCN()
```

Description

It obtains the Global Change Number (GCN) value of the current STATEMENT's VIEW SCN.

Example

```
gSQL> SELECT STATEMENT_VIEW_SCN_GCN() FROM dual;
STATEMENT_VIEW_SCN_GCN()
------------------------
                   17697
1 row selected.
```

17.176 STATEMENT_VIEW_SCN_LCN

Syntax

```
STATEMENT_VIEW_SCN_LCN()
```

Description

It obtains the Local Change Number (LCN) value of the current STATEMENT's VIEW SCN.

Example

```
gSQL> SELECT STATEMENT_VIEW_SCN_LCN() FROM dual;
STATEMENT_VIEW_SCN_LCN()
------------------------
                   17880
1 row selected.
```

17.177 STDDEV

Syntax

```
STDDEV( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregation function, and it obtains the standard deviation of an expr set.

If ALL is specified, this function is performed for all values. If DISTINCT is specified, this function is perfor med for the values of which the duplicates were deleted from. If it is not specified, it is processed as if AL L is apecified.

If the number of expr sets except for NULL after deleting the duplicates by using DISTINCT is one, then it r eturns 0 like as **VARIANCE**.

The following table describes the arguments and result types.

Table 17-23 Argument and result type of STDDEV

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

GOLDILOCKS gets the standard deviation as follows.

- If the number of expr sets are 1, then it returns 0.
- If the number of expr sets are bigger than 1, It returns the value of **STDDEV_SAMP(expr)**.

The standard deviation is a positive square root of a variance, and it is obtained calculating the s quare root of the variance. In other words, the STDDEV function is as same as the square root o f **VARIANCE** function.

```
STDDEV( [ ALL ] expr )
 = SQRT( VARIANCE( [ ALL ] expr ) )

STDDEV( DISTINCT expr )
 = SQRT( VARIANCE( DISTINCT expr ) )
```

Example

```
gSQL> SELECT STDDEV(c1) FROM t1;
      STDDEV(C1)
----------------
11.4978258814438
1 row selected.
gSQL> SELECT STDDEV(ALL c1) FROM t1;
  STDDEV(ALL C1)
----------------
11.4978258814438
1 row selected.
gSQL> SELECT STDDEV(DISTINCT c1) FROM t1;
STDDEV(DISTINCT C1)
-------------------
   13.2759180473518
1 row selected.
```

17.178 STDDEV() OVER

Syntax

```
STDDEV ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function STDDEV calculates the standard deviation of expr.
If the number of expr except for NULL is one, then it returns 0 as a result.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , STDDEV( min_price ) OVER ( ORDER BY min_price ) AS "STDDEV"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE           STDDEV
--------- ----------------
       73                0
      247 123.036579926459
      731 340.953564775811
     null 340.953564775811
     null 340.953564775811
5 rows selected.
```

17.179 STDDEV_POP

Syntax

```
STDDEV_POP( expr )
```

Description

It is an aggregation function, and it obtains the population standard deviation of an expr set.
If the number of expr sets except for NULL is one, then it returns 0.

The following table describes the arguments and result types.

Table 17-24 Argument and result type of STDDEV_POP

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

The population standard deviation is a positive square root of a population variance, and it is ob tained by calculating the square root of the population variance. In other words, the STDDEV_P OP function is as same as the square root of **VAR_POP** function.

STDDEV_POP(expr)
= SQRT(VAR_POP(expr))

Example

```
gSQL> SELECT STDDEV_POP(c1) FROM t1;
 STDDEV_POP(C1)
---------------
10.283968105746
1 row selected.
```

17.180 STDDEV_POP() OVER

Syntax

```
STDDEV_POP ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function STDDEV_POP calculates the population standard deviation of expr.
If the number of expr except for NULL is one, then it returns 0 as a result.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , STDDEV_POP( min_price ) OVER ( ORDER BY min_price ) AS "STDDEV_POP"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE      STDDEV_POP
--------- ---------------
       73               0
      247              87
      731 278.38741989457
     null 278.38741989457
     null 278.38741989457
5 rows selected.
```

17.181 STDDEV_SAMP

Syntax

```
STDDEV_SAMP( expr )
```

Description

It is an aggregation function, and it obtains the sample standard deviation of an expr set. If the number o f expr sets except for NULL is one, then it returns NULL.

The following table describes the arguments and result types.

Table 17-25 Argument and result type of STDDEV_SAMP

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

The sample standard deviation is a positive square root of a sample variance, and it is obtained by calculating the square root of the sample variance. In other words, the STDDEV_SAMP functi on is as same as the square root of **VAR_SAMP** function.

STDDEV_SAMP(expr)
= SQRT(VAR_SAMP(expr))

Example

```
gSQL> SELECT STDDEV_SAMP(c1) FROM t1;
 STDDEV_SAMP(C1)
----------------
11.4978258814438
1 row selected.
```

17.182 STDDEV_SAMP() OVER

Syntax

```
STDDEV_SAMP ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function STDDEV_SAMP calculates the sample standard deviation of expr.
If the number of expr except for NULL is one, then it returns NULL as a result.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , STDDEV_SAMP( min_price ) OVER ( ORDER BY min_price ) AS "STDDEV_SAMP"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE      STDDEV_SAMP
--------- ----------------
       73             null
      247 123.036579926459
      731 340.953564775811
     null 340.953564775811
     null 340.953564775811
5 rows selected.
```

17.183 STRING_AGG() OVER

Syntax

```
STRING_AGG( str [, delimiter] ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function STRING_AGG connects str according to the function's execution range defined in OVE R clause.

If str is NULL, then it is excluded.

A delimiter is str connection delimiter, and if it is omitted the default value is NULL.

str can be a character string or a binary string.
If str is a character string, then the result type is varchar.
If str is a binary string, then the result type is varbinary.

Example

```
gSQL>
SELECT regionkey,
       name,
       STRING_AGG( name ) OVER ( PARTITION BY regionkey
                                 ORDER BY nationkey
                                 ROWS BETWEEN UNBOUNDED PRECEDING
                                          AND CURRENT ROW )
       AS "STRING_AGG( name ) OVER",
       STRING_AGG( name, ', ' ) OVER ( PARTITION BY regionkey
                                       ORDER BY nationkey
                                       ROWS BETWEEN UNBOUNDED PRECEDING
                                                AND CURRENT ROW )
       AS "STRING_AGG( name, ', ' ) OVER"
  FROM nation;
```

```
REGIONKEY NAME    STRING_AGG( name ) OVER STRING_AGG( name, ', ' ) OVER

15 rows selected.
```

17.184 SUBSTR

Syntax

```
SUBSTR( str FROM start_position [ FOR string_length ] )
SUBSTR( str, start_position [ , string_length ] )
```

Description

It is an alias of **SUBSTRING**.

Example

- Multi byte character set (e.g. UTF8): 1 byte character

```
gSQL> SELECT
      SUBSTR( 'DATABASE MANAGEMENT SYSTEM', 10, 10 ) AS RESULT
      FROM DUAL;
RESULT
----------
MANAGEMENT
1 row selected.
```

- Multi byte character set (e.g. UTF8): 2 bytes or 3 bytes character

```
gSQL> SELECT SUBSTR( '“αβ≠AB”', 2, 5 ) AS RESULT FROM DUAL;
RESULT
------
αβ≠AB
1 row selected.
```

17.185 SUBSTRB

Syntax

```
SUBSTRB( str, start_position [ , string_length ] )
```

Description

It extracts characters which are within string_length range from start_position, and returns the result for s tr.

This function is as same as **SUBSTRING** function, except that start_position and string_length of the SUBS TR function are calculated in byte units.

Example

- Multi byte character set (e.g. UTF8): 1 byte character

```
gSQL> SELECT
      SUBSTRB( 'DATABASE MANAGEMENT SYSTEM', 10, 10 ) AS RESULT
      FROM DUAL;
RESULT
----------
MANAGEMENT
1 row selected.
```

- Multi byte character set (e.g. UTF8): 2 bytes or 3 bytes character

```
gSQL> SELECT SUBSTRB( '“αβ≠AB”', 4, 11 ) AS RESULT FROM DUAL;
RESULT
------
αβ≠AB
1 row selected.
```

17.186 SUBSTRING

Syntax

```
SUBSTRING( str FROM start_position [ FOR string_length ] )
SUBSTRING( str, start_position [ , string_length ] )
```

Description

It extracts characters which are within string_length range from start_position, and returns the result for s tr.

The str argument data type can be a character data type such as CHARACTER, CHARACTER VARYING, C HARACTER LONG VARYING, or a binary data type such as BINARY, BINARY VARYING, BINARY LONG VA RYING.

The start_position argument and string_length argument can be a numeric data type.

If any of str, start_position, string_length is NULL, the result is NULL.
The start_position and string_length start from 1, and they are calculated in character unit according to c haracter set (not in byte unit).

If start_position is 0, the start_position is assigned to 1.
If start_position is a positive number, it searches for the position forwards (towards right) from the begin ning of str.
If start_ position is a negative number, it searches for the position backwards (towards left) from the end of str.
If string_length is omitted, characters from the start_position to the last character of str, is returned.

If string_length is 0 or a negative number, the result is NULL.
If start_position > (str length), the result is NULL.
If (str length + start_position) < 0, the result is NULL.

It is an alias of **SUBSTR**.
For more information, refer to **SUBSTRB**.

The following table describes the result types.

Table 17-26 Result type of SUBSTRING

str type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

- Multi byte character set (e.g. UTF8): 1 byte character

```
gSQL> SELECT
      SUBSTRING( 'DATABASE MANAGEMENT SYSTEM' FROM 10 FOR 10 ) AS RESULT
      FROM DUAL;
RESULT
----------
MANAGEMENT
1 row selected.
```

- Multi byte character set (e.g. UTF8): 2 bytes or 3 bytes character

```
gSQL> SELECT SUBSTRING( '“αβ≠AB”' FROM 2 FOR 5 ) AS RESULT FROM DUAL;
RESULT
------
αβ≠AB
1 row selected.
```

17.187 SUM

Syntax

```
SUM( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregate function and the sum of expr value is obtained.

If ALL is explicitly specified, aggregation is executed for all values.
If DISTINCT is explicitly specified, aggregation is executed for the values which exclude duplicate values.
If ALL or DISTINCT is not explicitly specified, it is processed in the same way as when ALL is specified.

Example

```
gSQL> SELECT SUM(c1) FROM t1;
SUM(C1)
-------
      6
1 row selected.
```

17.188 SUM() OVER

Syntax

```
SUM ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function SUM calculates the sum of expr value.
NULL is excluded from the calculation.

Example

```
gSQL> SELECT min_price AS "MIN_PRICE"
             , SUM( min_price ) OVER ( ORDER BY min_price ) AS "SUM"
        FROM product_information
       WHERE supplier_id = 102050;
MIN_PRICE  SUM
--------- ----
       73   73
      247  320
      731 1051
     null 1051
     null 1051
5 rows selected.
```

17.189 SYSDATE

Syntax

```
SYSDATE
```

Description

It obtains the current DATE type value based on the OS time of the database server.

Example

```
gSQL> SELECT SYSDATE FROM t1;
SYSDATE
----------
2013-12-12
2013-12-12
2013-12-12
3 rows selected.
```

17.190 SYS_EXTRACT_UTC

Syntax

```
SYS_EXTRACT_UTC( datetime_with_timezone )
```

Description

It returns the UTC (Coordinated Universal Time—formerly Greenwich Mean Time) value.
If the timezone is not specified, it is calculated as session time zone.

The data type of an input argument can be time, time with time zone, timestamp, timestamp with time z one.
The result type is time or timestamp type.

Example

```
gSQL> SELECT
      SYS_EXTRACT_UTC(
          TO_TIMESTAMP_TZ( '2017-05-25 00:00:00.000000 +09:00',
                           'YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM' )
          ) AS RESULT
      FROM DUAL;
RESULT
--------------------------
2017-05-24 15:00:00.000000
1 row selected.
```

17.191 SYSTIME

Syntax

```
SYSTIME
```

Description

It obtains the current TIME WITH TIME ZONE type value based on the OS time of the database server.

Example

```
gSQL> SELECT SYSTIME FROM t1;
SYSTIME
----------------------
16:30:46.954941 +09:00
16:30:46.954941 +09:00
16:30:46.954941 +09:00
3 rows selected.
```

17.192 SYSTIMESTAMP

Syntax

```
SYSTIMESTAMP
```

Description

It obtains the current TIMESTAMP WITH TIME ZONE type value based on the OS time of the database ser ver.

Example

```
gSQL> SELECT SYSTIMESTAMP FROM t1;
SYSTIMESTAMP
---------------------------------
2013-12-12 16:37:34.432241 +09:00
2013-12-12 16:37:34.432241 +09:00
2013-12-12 16:37:34.432241 +09:00
3 rows selected.
```

17.193 TAN

Syntax

```
TAN( num )
```

Description

It returns the tangent value of num in radians unit.
If num is NULL, then NULL is returned.

Example

```
gSQL> SELECT TAN( 1 ) AS RESULT FROM DUAL;
         RESULT
---------------
1.5574077246549
1 row selected.
```

17.194 TO_BASE64

Syntax

```
TO_BASE64( str )
```

Description

It converts str by using base64 encoding, and returns the converted character.
str argument can be a character type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING, a type which can be converted to a character type, or a binary character type such as BINARY, BINARY VARYING, BINARY LONG VARYING.
The result type is a character such as CHARACTER VARYING or CHARACTER LONG VARYING.

If str is NULL, the result value is also NULL.

Base64 encoding represents 8 bit binary data in 64 characters consisting of ascii areas.
64 characters consist of A~Z, a~z, 0~9, +, /.

6 bit is represented as a character, and three characters (24 bits) are represented with 4 characters as a unit.
If the encoded characters can not fill 4 characters, then others are filled with '='.
If encoded characters are over 76, then a newline is added and they are divided into multiple lines.

Use FROM_BASE64() function to decode the base64 encoded character.
The newline, carriage return, tab, space are ignored when decoding base64.

For more information, refer to **FROM_BASE64**.

Example

```
gSQL> SELECT TO_BASE64( 'abc' ), TO_BASE64( 'abcd' ) FROM DUAL;
TO_BASE64( 'abc' ) TO_BASE64( 'abcd' )
------------------ -------------------
YWJj               YWJjZA==
1 row selected.
```

17.195 TO_CHAR(datetime)

Syntax

```
TO_CHAR( datetime [, fmt ] )
```

Description

It converts datetime to a string in the specified fmt format, and returns the result.

The datetime argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIME, TIME WITH TIME ZONE, INTERVAL.
The fmt argument data type can be a character data type such as CHARACTER, CHARACTER VARYING.
If any argument is NULL, then NULL is returned.

If fmt is omitted, it follows the default format.
- DATE: Refer to **NLS_DATE_FORMAT**.
- TIMESTAMP: Refer to **NLS_TIMESTAMP_FORMAT**.
- TIMESTAMP WITH TIME ZONE: Refer to **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**.
- TIME: Refer to **NLS_TIME_FORMAT**.
- TIME WITH TIME ZONE: Refer to **NLS_TIME_WITH_TIME_ZONE_FORMAT**.

If the data type of the datetime argument is INTERVAL, it is converted to a string then returned regardless of fmt.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**.

The result type is CHARACTER VARYING.

Example

The following is an example of when fmt is omitted, and NLS_DATE_FORMAT = 'YYYY-MM-DD'.

```
gSQL> SELECT
      TO_CHAR( TO_DATE( '2012-03-15','YYYY-MM-DD' ) ) AS RESULT
      FROM DUAL;
```

```
RESULT
----------
2012-03-15
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_CHAR( TO_DATE('2012-03-15','YYYY-MM-DD'), 'DD-MON-YY' ) AS RESULT
      FROM DUAL;
RESULT
---------
15-MAR-12
1 row selected.
```

17.196 TO_CHAR(number)

Syntax

```
TO_CHAR( number [, fmt ] )
```

Description

It converts the number to a string in the specified fmt format, and returns the result.

The number argument can be a numeric data type.
The fmt argument data type can be a character data type such as CHARACTER, CHARACTER VARYING.
If fmt is omitted, all significant digits are converted to the string and returned.
For more information about the string which can be specified in fmt, refer to **Number Format String**.
If any input argument is NULL, then NULL is returned.

The result type is CHARACTER VARYING.

Example

```
gSQL> SELECT TO_CHAR( 12500000 ) AS RESULT FROM DUAL;
RESULT
--------
12500000
1 row selected.
gSQL> SELECT TO_CHAR( 12500000, 'S999,999,999' ) AS RESULT FROM DUAL;
RESULT
------------
 +12,500,000
1 row selected.
```

17.197 TO_DATE

Syntax

```
TO_DATE( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to DATE type, and returns the result.

The str argument and fmt argument data type can be a character data type such as CHARACTER, CHARA CTER VARYING, CHARACTER LONG VARYING.
If fmt is omitted, the default format is NLS_DATE_FORMAT, and in this case str should be the default for mat string.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**.
For more information, refer to **NLS_DATE_FORMAT**.
If either str or fmt is NULL, then NULL is returned.

The result type is DATE.

Example

The following is an example of when fmt is omitted, and NLS_DATE_FORMAT = 'YYYY-MM-DD'.

```
gSQL> SELECT TO_DATE( '2009-07-29' ) AS RESULT FROM DUAL;
RESULT
----------
2009-07-29
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT TO_DATE( '29-JUL-09', 'DD-MON-YY' ) AS RESULT FROM DUAL;
RESULT
----------
```

```
2009-07-29
1 row selected.
```

17.198 TO_NATIVE_BIGINT

Syntax

```
TO_NATIVE_BIGINT( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to NATIVE_BIGINT type, and returns the result.

The str argument and fmt argument data type can be a character data type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NATIVE_BIGINT.

Example

```
gSQL> SELECT TO_NATIVE_BIGINT( '123.45' ) AS RESULT1,
             TO_NATIVE_BIGINT( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
    123     123
1 row selected.
```

17.199 TO_NATIVE_DOUBLE

Syntax

```
TO_NATIVE_DOUBLE( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to NATIVE_DOUBLE type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NATIVE_DOUBLE.

Example

```
gSQL> SELECT TO_NATIVE_DOUBLE( '123.45' ) AS RESULT1,
             TO_NATIVE_DOUBLE( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
 123.45  123.45
1 row selected.
```

17.200 TO_NATIVE_INTEGER

Syntax

```
TO_NATIVE_INTEGER( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to NATIVE_INTEGER type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NATIVE_INTEGER.

Example

```
gSQL> SELECT TO_NATIVE_INTEGER( '123.45' ) AS RESULT1,
             TO_NATIVE_INTEGER( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
    123     123
1 row selected.
```

17.201 TO_NATIVE_REAL

Syntax

```
TO_NATIVE_REAL( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to NATIVE_REAL type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NATIVE_REAL.

Example

```
gSQL> SELECT TO_NATIVE_REAL( '123.45' ) AS RESULT1,
             TO_NATIVE_REAL( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
 123.45  123.45
```

17.202 TO_NATIVE_SMALLINT

Syntax

```
TO_NATIVE_SMALLINT( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to NATIVE_SMALLINT type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NATIVE_SMALLINT.

Example

```
gSQL> SELECT TO_NATIVE_SMALLINT( '123.45' ) AS RESULT1,
             TO_NATIVE_SMALLINT( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
    123     123
1 row selected.
```

17.203 TO_NUMBER

Syntax

```
TO_NUMBER( str [, fmt] )
```

Description

It converts the str string in the specified fmt format to NUMBER type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.

If any of str, fmt is NULL, the result is also NULL.
For more information about the string which can be specified in fmt, refer to **Number Format String**.

The result type is NUMBER.

Example

```
gSQL> SELECT TO_NUMBER( '123.45' ) AS RESULT1,
             TO_NUMBER( '+123.45', 'S999.99' ) AS RESULT2
        FROM DUAL;
RESULT1 RESULT2
------- -------
 123.45  123.45
1 row selected.
```

17.204 TO_TIME

Syntax

```
TO_TIME( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to TIME type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.
If fmt is omitted, the default format is NLS_TIME_FORMAT, and in this case str should be the default for mat string.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**.
For more information, refer to **NLS_TIME_FORMAT**.
If either str or fmt is NULL, then NULL is returned.

The result type is TIME.

Example

The following is an example of when fmt is omitted, and NLS_TIME_FORMAT = 'HH24:MI:SS.FF6'.

```
gSQL> SELECT TO_TIME( '11:22:33.999999' ) AS RESULT FROM DUAL;
RESULT
---------------
11:22:33.999999
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_TIME( '112233.999999/P.M.', 'HH12MISS.FF6/P.M.' ) AS RESULT
      FROM DUAL;
```

```
RESULT
---------------
23:22:33.999999
1 row selected.
```

17.205 TO_TIME_TZ

Syntax

```
TO_TIME_TZ( str [, fmt ] )
```

Description

It is an alias of **TO_TIME_WITH_TIME_ZONE**.
For more information, refer to **NLS_TIME_WITH_TIME_ZONE_FORMAT**.

Example

The following is an example of when fmt is omitted, and NLS_TIME_WITH_TIME_ZONE_FORMAT = 'HH24:MI:SS.FF6 TZH:TZM'.

```
gSQL> SELECT TO_TIME_TZ( '11:22:33.999999 +09:00' ) AS RESULT FROM DUAL;
RESULT
----------------------
11:22:33.999999 +09:00
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT TO_TIME_TZ( '11:22:33.999999 +09:00 PM',
                         'HH12:MI:SS.FF6 TZH:TZM PM' ) AS RESULT
      FROM DUAL;
RESULT
----------------------
23:22:33.999999 +09:00
1 row selected.
```

17.206 TO_TIME_WITH_TIME_ZONE

Syntax

```
TO_TIME_WITH_TIME_ZONE( str [, fmt ] )
TO_TIME_TZ( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to TIME WITH TIME ZONE type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.
If fmt is omitted, the default format is NLS_TIME_WITH_TIME_ZONE_FORMAT, and in this case str should be the default format string.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**
For more information, refer to **NLS_TIME_WITH_TIME_ZONE_FORMAT**.
If either str or fmt is NULL, then NULL is returned.

It is an alias of **TO_TIME_TZ**.

The result type is TIME WITH TIME ZONE.

Example

The following is an example of when fmt is omitted, and NLS_TIME_WITH_TIME_ZONE_FORMAT = 'HH24:MI:SS.FF6 TZH:TZM'.

```
gSQL> SELECT
      TO_TIME_WITH_TIME_ZONE( '11:22:33.999999 +09:00' ) AS RESULT
      FROM DUAL;
RESULT
----------------------
11:22:33.999999 +09:00
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_TIME_WITH_TIME_ZONE( '11:22:33.999999 +09:00 PM',
                              'HH12:MI:SS.FF6 TZH:TZM PM' )
      AS RESULT
      FROM DUAL;
RESULT
----------------------
23:22:33.999999 +09:00
1 row selected.
```

17.207 TO_TIMESTAMP

Syntax

```
TO_TIMESTAMP( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to TIMESTAMP type, and returns the result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.
If fmt is omitted, the default format is NLS_TIMESTAMP_FORMAT, and in this case str should be the defa ult format string.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**.
For more information, refer to **NLS_TIMESTAMP_FORMAT**.
If either str or fmt is NULL, then NULL is returned.

The result type is TIMESTAMP.

Example

The following is an example of when fmt is omitted, and NLS_TIMESTAMP_FORMAT = 'YYYY-MM-DD H H24:MI:SS.FF6'.

```
gSQL> SELECT
      TO_TIMESTAMP( '2009-07-29 11:22:33.999999' ) AS RESULT
      FROM DUAL;
RESULT
--------------------------
2009-07-29 11:22:33.999999
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_TIMESTAMP( '090729 112233999999 PM', 'YYMMDD HH12MISSFF6 PM' )
      AS RESULT
      FROM DUAL;
RESULT
--------------------------
2009-07-29 23:22:33.999999
1 row selected.
```

17.208 TO_TIMESTAMP_TZ

Syntax

```
TO_TIMESTAMP_TZ( str [, fmt ] )
```

Description

It is an alias of **TO_TIMESTAMP_WITH_TIME_ZONE**.
For more information, refer to **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**.

Example

The following is an example of when fmt is omitted, and NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT = 'YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM'.

```
gSQL> SELECT
      TO_TIMESTAMP_TZ( '2009-07-29 11:22:33.999999 +09:00' ) AS RESULT
      FROM DUAL;
RESULT
--------------------------------
2009-07-29 11:22:33.999999 +09:00
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_TIMESTAMP_TZ( '29-JUL-09 11:22:33.999999 +09:00',
                       'DD-MON-RR HH12:MI:SS.FF6 TZH:TZM' ) AS RESULT
      FROM DUAL;
RESULT
--------------------------------
2009-07-29 11:22:33.999999 +09:00
1 row selected.
```

17.209 TO_TIMESTAMP_WITH_TIME_ZONE

Syntax

```
TO_TIMESTAMP_WITH_TIME_ZONE( str [, fmt ] )
TO_TIMESTAMP_TZ( str [, fmt ] )
```

Description

It converts the str string in the specified fmt format to TIMESTAMP WITH TIME ZONE type, and returns th e result.

The data type of str argument and fmt argument can be a character data type such as CHARACTER, CHA RACTER VARYING, CHARACTER LONG VARYING.
If fmt is omitted, the default format is NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT, and in this case str should be the default format string.

For more information about the string which can be specified in fmt, refer to **Datetime Format String**.
For more information, refer to **NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT**.
If either str or fmt is NULL, then NULL is returned.

It is an alias of **TO_TIMESTAMP_TZ**.

The result type is TIMESTAMP WITH TIME ZONE .

Example

The following is an example of when fmt is omitted, and NLS_TIMESTAMP_WITH_TIME_ZONE_FORMAT = 'YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM'.

```
gSQL> SELECT
      TO_TIMESTAMP_WITH_TIME_ZONE( '2009-07-29 11:22:33.999999 +09:00' )
      AS RESULT
      FROM DUAL;
RESULT
-------------------------------
```

```
2009-07-29 11:22:33.999999 +09:00
1 row selected.
```

The following is an example of when fmt is specified.

```
gSQL> SELECT
      TO_TIMESTAMP_WITH_TIME_ZONE( '29-JUL-09 11:22:33.999999 +09:00',
                                   'DD-MON-RR HH12:MI:SS.FF6 TZH:TZM' )
      AS RESULT
      FROM DUAL;
RESULT
--------------------------------
2009-07-29 11:22:33.999999 +09:00
1 row selected.
```

17.210 TRANSACTION_DATE

Syntax

```
TRANSACTION_DATE()
```

Description

It obtains the current date (DATE type) value based on the session time.

The differences among the functions to obtain the current date are as follows.

- TRANSACTION_DATE(): All date values in the transaction are same.
- STATEMENT_DATE(): All date values in an SQL statement are same.
- CLOCK_DATE(): Whenever the function is called, the current date value is obtained.

Example

All date values are always same within a single transaction.

```
gSQL> SELECT TRANSACTION_DATE() FROM dual;
TRANSACTION_DATE()
------------------
2013-12-12
1 row selected.
gSQL> SELECT TRANSACTION_DATE() FROM dual;
TRANSACTION_DATE()
------------------
2013-12-12
1 row selected.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT TRANSACTION_DATE() FROM dual;
TRANSACTION_DATE()
------------------
2013-12-13
1 row selected.
```

17.211 TRANSACTION_LOCALTIME

Syntax

```
TRANSACTION_LOCALTIME()
```

Description

It obtains the current TIME WITHOUT TIME ZONE type value based on the session time.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_LOCALTIME(): All time values in the transaction are same.
- STATEMENT_LOCALTIME(): All time values in an SQL statement are same.
- CLOCK_LOCALTIME(): Whenever the function is called, the current time value is obtained.

Example

All time values are always same within a single transaction.

```
gSQL> SELECT TRANSACTION_LOCALTIME() FROM dual;
TRANSACTION_LOCALTIME()
-----------------------
16:43:24.391834
1 row selected.
gSQL> SELECT TRANSACTION_LOCALTIME() FROM dual;
TRANSACTION_LOCALTIME()
-----------------------
16:43:24.391834
1 row selected.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT TRANSACTION_LOCALTIME() FROM dual;
TRANSACTION_LOCALTIME()
-----------------------
16:43:32.651833
1 row selected.
```

17.212 TRANSACTION_LOCALTIMESTAMP

Syntax

```
TRANSACTION_LOCALTIMESTAMP()
```

Description

It obtains the current TIMESTAMP WITHOUT TIME ZONE type value based on the session time.

The differences among the functions to obtain the current timestamp are as follows.

- TRANSACTION_LOCALTIMESTAMP(): All timestamp values in the transaction are same.
- STATEMENT_LOCALTIMESTAMP(): All timestamp values in an SQL statement are same.
- CLOCK_LOCALTIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All timestamp values are always same within a single transaction.

```
gSQL> SELECT TRANSACTION_LOCALTIMESTAMP() FROM dual;
TRANSACTION_LOCALTIMESTAMP()
----------------------------
2013-12-12 16:43:32.651833
1 row selected.
gSQL> SELECT TRANSACTION_LOCALTIMESTAMP() FROM dual;
TRANSACTION_LOCALTIMESTAMP()
----------------------------
2013-12-12 16:43:32.651833
1 row selected.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT TRANSACTION_LOCALTIMESTAMP() FROM dual;
TRANSACTION_LOCALTIMESTAMP()
----------------------------
2013-12-12 16:46:07.831834
1 row selected.
```

17.213 TRANSACTION_TIME

Syntax

```
TRANSACTION_TIME()
```

Description

It obtains the current TIME WITH TIME ZONE type value based on the session time.

The differences among the functions to obtain the current time are as follows.

- TRANSACTION_TIME(): All time values in the transaction are same.
- STATEMENT_TIME(): All time values in an SQL statement are same.
- CLOCK_TIME(): Whenever the function is called, the current time value is obtained.

Example

All time values are always same within a single transaction.

```
gSQL> SELECT TRANSACTION_TIME() FROM dual;
TRANSACTION_TIME()
----------------------
16:46:07.831834 +09:00
1 row selected.
gSQL> SELECT TRANSACTION_TIME() FROM dual;
TRANSACTION_TIME()
----------------------
16:46:07.831834 +09:00
1 row selected.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT TRANSACTION_TIME() FROM dual;
TRANSACTION_TIME()
----------------------
16:48:00.691827 +09:00
1 row selected.
```

17.214 TRANSACTION_TIMESTAMP

Syntax

```
TRANSACTION_TIMESTAMP()
```

Description

It obtains the current TIMESTAMP WITH TIME ZONE type value based on the session time.

The differences among the functions to obtain the current timestamp are as follows.

- TRANSACTION_TIMESTAMP(): All timestamp values in the transaction are same.
- STATEMENT_TIMESTAMP(): All timestamp values in an SQL statement are same.
- CLOCK_TIMESTAMP(): Whenever the function is called, the current timestamp value is obtained.

Example

All timestamp values are always same within a single transaction.

```
gSQL> SELECT TRANSACTION_TIMESTAMP() FROM dual;
TRANSACTION_TIMESTAMP()
-------------------------------
2013-12-12 16:48:00.691827 +09:00
1 row selected.
gSQL> SELECT TRANSACTION_TIMESTAMP() FROM dual;
TRANSACTION_TIMESTAMP()
-------------------------------
2013-12-12 16:48:00.691827 +09:00
1 row selected.
gSQL> COMMIT;
Commit complete.
gSQL>  SELECT TRANSACTION_TIMESTAMP() FROM dual;
TRANSACTION_TIMESTAMP()
-------------------------------
2013-12-12 16:49:26.291827 +09:00
1 row selected.
```

17.215 TRANSLATE

Syntax

```
TRANSLATE( string, from, to )
```

Description

It replaces characters. It replaces characters of string which corresponds to the the character of *from* with the character of *to* at the same position as the character of *from*.

The data type of the string argument, the from argument, and the to argument can be a data type such a s CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.

If any of *string, from, to* is NULL, the result is also NULL.

- When the character of string which are as same as those of *from* exists,
  - If the length of *from* is as same as that of *to*, then it is replaced with the character of *to* at the sa me position as the character of *from*.
  - If the length of *from* is longer than that of *to*, then characters of *from* at the position after that o f *to* length are deleted from the string.
  - If the character of *from* is duplicate, then it is replaced with the character of *to* at the same positi on as the first duplicate character of *from*.
- When the character of string which is as same as those of *from* does not exist, then the string is not r eplaced.

The following table describes the result types.

Table 17-27 Result type of TRANSLATE

string type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR

Example

- When the character of string which are as same as those of *from* exists, then it is replaced with the c haracter of *to* at the same position as the character of *from*.
  - A → Z, C → Y, E → X, G → W

```
gSQL> SELECT TRANSLATE('ABCDEFG', 'ACEG', 'ZYXW') AS RESULT
FROM DUAL;
RESULT
-------
ZBYDXFW
1 row selected.
```

- If the length of *from* string is longer than that of *to* string, then characters of *from* at the position aft er that of *to* string length are deleted *from* the string, and replaced.
  - A → Z, C → Y, deleting E, deleting G

```
gSQL> SELECT TRANSLATE('ABCDEFG', 'ACEG', 'ZY') AS RESULT
      FROM DUAL;
RESULT
------
ZBYDF
1 row selected.
```

17.216 TRIM

Syntax

```
TRIM([ [ LEADING ¦ TRAILING ¦ BOTH ]  [trim_character] FROM ] trim_source)
```

Description

It removes the matching characters by comparing trim_character in trim_source from the LEADING, TRAILING, BOTH direction until the matching character does not exist. Then it returns the result.

The trim_character argument and trim_source argument can be a character data type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING or a binary character data type such as BINARY, BINARY VARYING, BINARY LONG VARYING.

If any of trim_character, trim_source is NULL, the result is NULL.

- [LEADING | TRAILING | BOTH]
  - LEADING: Removes trim_character from the beginning of trim_source.
  - TRAILING: Removes trim_character from the back of trim_source.
  - BOTH: Removes trim_character from the both direction (the beginning, the back) of trim_source.
- trim_character should be a single character.
- If trim_character is omitted, single blank space (' ') is specified by default.
- When FROM is specified
  - [LEADING | TRAILING | BOTH], trim_character or [LEADING | TRAILING | BOTH] trim_character should be specified.
    - e.g. TRIM(LEADING FROM ' abc') , TRIM('x' FROM 'xabc') , TRIM(LEADING 'x' FROM 'xabc')
  - If [LEADING | TRAILING | BOTH] is omitted, BOTH is specified by default.
- When FROM is omitted.
  - It is TRIM(trim_source), it is executed in the same way as TRIM(BOTH ' ' FROM trim_source).

The following table describes the result types.

Table 17-28 Result type of TRIM

trim_character, trim_source type	Result type
CHAR or VARCHAR	VARCHAR
LONG VARCHAR	LONG VARCHAR

trim_character, trim_source type	Result type
BINARY or VARBINARY	VARBINARY
LONG VARBINARY	LONG VARBINARY

Example

```
gSQL> SELECT TRIM( LEADING '_' FROM '___TRIM FUNCTION___' ) AS RESULT
      FROM DUAL;
RESULT
----------------
TRIM FUNCTION___
1 row selected.
gSQL> SELECT TRIM( TRAILING '_' FROM '___TRIM FUNCTION___' ) AS RESULT
      FROM DUAL;
RESULT
----------------
___TRIM FUNCTION
1 row selected.
gSQL> SELECT TRIM( BOTH '_' FROM '___TRIM FUNCTION___' ) AS RESULT
      FROM DUAL;
RESULT
-------------
TRIM FUNCTION
1 row selected.
```

17.217 TRUNC(number)

Syntax

```
TRUNC( num [ , scale ] )
```

Description

It truncates the num based on scale, then returns the result.

The num argument and scale argument can be a numeric type.
If either the num argument or the scale argument is NULL, then NULL is returned.

If scale is omitted, the scale becomes 0, and it is executed as same as TRUNC(num, 0).
If scale is a positive number, it is truncated based on the number of right digit of the decimal point.
If scale is a negative number, it is truncated off based on the number of left digit of the decimal point.

Example

```
gSQL> SELECT TRUNC( 142.4282, 2 ) AS RESULT FROM DUAL;
RESULT
------
142.42
1 row selected.
gSQL> SELECT TRUNC( 142.4282, -2 ) AS RESULT FROM DUAL;
RESULT
------
   100
1 row selected.
```

17.218 TRUNC(date)

Syntax

```
TRUNC( date [ , fmt ] )
```

Description

It truncates the date in a specified fmt unit, and returns the result.

The date argument data type can be DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE.
The fmt argument data type can be a character data type such as CHARACTER, CHARACTER VARYING.
If either date argument or fmt argument is NULL, then NULL is returned.

The result type is always DATE regardless of the input date type.

If fmt is omitted, the default is *DAY*, and the available format string is described in the following table.

Table 17-29 Available format string in fmt

Format string	Description
CC, SCC	Century
YYYY, YEAR, SYYYY, SYEAR, YYY, YY, Y	Year
IYYY, IYY, IY, I	The year embracing the calendar week defined by ISO 8601 standards
Q	Quarter
MONTH, MON, MM, RM	Month
WW	The week whose first week starts from January 1st of the year
IW	The week containing the first thursday of the year designated as the calendar week by ISO 8601 standards (1 ~ 52 week or 1 ~ 53 weeks) becomes the first week.
W	The week whose first week starts from the first day of the month
DDD, DD, J	Day
DAY, DY, D	Day of week
HH, HH12, HH24	Hour
MI	Minute

Example

```
gSQL> SELECT
      TRUNC( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'CC' ) AS RESULT
      FROM DUAL;
RESULT
----------
2001-01-01
1 row selected.
gSQL> SELECT
      TRUNC( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'YYYY' ) AS RESULT
      FROM DUAL;
RESULT
----------
2051-01-01
1 row selected.
gSQL> SELECT
      TRUNC( TO_DATE( '2051-07-16', 'YYYY-MM-DD' ), 'MONTH' ) AS RESULT
      FROM DUAL;
RESULT
----------
2051-07-01
1 row selected.
gSQL> SELECT
      TRUNC( TO_TIMESTAMP( '2001-05-05 11:22:33.999999',
             'YYYY-MM-DD HH24:MI:SS.FF6' ) ) AS RESULT
      FROM DUAL;
RESULT
----------
2001-05-05
1 row selected.
```

17.219 UPPER

Syntax

```
UPPER( str )
```

Description

It returns the uppercase characters of str.

The str argument can be a character data type such as CHARACTER, CHARACTER VARYING, CHARACTER LONG VARYING.
If str is NULL, the result is NULL.

The return type is as same as the str argument type.

Example

```
gSQL> SELECT UPPER( 'spring' ) AS RESULT FROM DUAL;
RESULT
------
SPRING
1 row selected.
```

17.220 UNHEX

Syntax

```
UNHEX( str )
```

Description

str argument is a hexadecimal character and this function represents it as each byte and returns it as a bin ary string.

The input argument can be a character type such as CHARACTER VARYING, CHARACTER LONG VARYIN G. The result type is a binary character type such as BINARY VARYING or BINARY LONG VARYING.

If str is NULL, then the result value is also NULL.
If str includes a character which does not belong to the hexadecimal range, then it returns an error.

For more information, refer to **HEX**.

Example

```
gSQL> SELECT UNHEX( HEX( 'abc' ) ) FROM DUAL;
UNHEX( HEX( 'abc' ) )
---------------------
616263
1 row selected.
```

17.221 UNHEX_TO_CHARSTR

Syntax

```
UNHEX_TO_CHARSTR( str )
```

Description

str argument is a hexadecimal character and this function represents it as each byte and returns it as a ch aracter string.

The input argument can be a character type such as CHARACTER VARYING, CHARACTER LONG VARYIN G. The result type is a character type such as CHARACTER VARYING, CHARACTER LONG VARYING.

If str is NULL, then the result value is also NULL.
If str includes a character which does not belong to the hexadecimal range, then it returns an error.

For more information, refer to **HEX**, **UNHEX**.

Example

```
gSQL> SELECT UNHEX_TO_CHARSTR( '616263' ) FROM DUAL;
UNHEX_TO_CHARSTR( '616263' )
----------------------------
abc
1 row selected.
gSQL> SELECT UNHEX_TO_CHARSTR( HEX( 'abc' ) ) FROM DUAL;
UNHEX_TO_CHARSTR( HEX( 'abc' ) )
--------------------------------
abc
1 row selected.
```

17.222 USER_ID

Syntax

```
USER_ID ()
```

Description

It obtains the current user's number ID.

In cluster system, the value may vary depending on the connected server.
It is recommended to use **CURRENT_USER** function obtaining the current username.

Example

```
% gsql test test
gSQL> SELECT USER_ID() FROM dual;
USER_ID()
---------
        6
1 row selected.
```

17.223 UUID

Syntax

```
UUID()
```

Description

It creates the universal unique identifier, then returns it.
The return type is VARBINARY type, and it internally consists of 16 bytes.

Example

```
gSQL> SELECT HEX( UUID() ) FROM DUAL;
HEX( UUID() )
--------------------------------
E6F0A5C2387511E8B95259E479C2FD50
1 row selected.
```

17.224 VAR_POP

Syntax

```
VAR_POP( expr )
```

Description

It is an aggregation function, and it obtains the population variance of an expr set. If the number of expr sets except for NULL is one, then it returns 0.

The following table describes the arguments and result types.

Table 17-30 Argument and result type of VAR_POP

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

The population variance is a variance of the population (entire) group, and it is the average of t he square value of deviation. In other words, it is calculated by extracting the population averag e (the entire average) from each value of the data, and squaring each value, then adding them t ogether and dividing them by the number of datas in the population group.
This value is used to figure out how far each value is from the average value.

For more information, refer to **STDDEV_POP**.

Example

```
gSQL> SELECT VAR_POP(c1) FROM t1;
VAR_POP(C1)
-----------
     105.76
1 row selected.
```

17.225 VAR_POP() OVER

Syntax

```
VAR_POP ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function VAR_POP calculates the population variance of expr.
If the number of expr except for NULL is one, then it returns 0 as a result.

Example

```
gSQL> SELECT product_id, min_price
             , VAR_POP( min_price ) OVER ( ORDER BY product_id ) AS "VAR_POP"
        FROM product_information
       WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE          VAR_POP
---------- --------- ----------------
      1769      null             null
      1770        73                0
      2378       247             7569
      2382       731 77499.5555555556
      3355      null 77499.5555555556
5 rows selected.
```

17.226 VAR_SAMP

Syntax

```
VAR_SAMP( expr )
```

Description

It is an aggregation function, and it obtains the sample variance of an expr set. If the number of expr sets except for NULL is one, then it returns NULL.

The following table describes the arguments and result types.

Table 17-31 Argument and result type of VAR_SAMP

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

Unlike the population variance dealing with the population (entire) group, the sample variance deals with the average and deviation of extracted samples. In other words, it is calculated by ext racting the sample average from each value of the data, and squaring each value, then adding t hem together and dividing them by the number of datas in the population group minus 1.
This value is used to figure out the variance of the population group.

For more information, refer to **STDDEV_SAMP**.

Example

```
gSQL> SELECT VAR_SAMP(c1) FROM t1;
VAR_SAMP(C1)
------------
       132.2
1 row selected.
```

17.227 VAR_SAMP() OVER

Syntax

```
VAR_SAMP ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function VAR_SAMP calculates the sample variance of expr.
If the number of expr except for NULL is one, then it returns NULL as a result.

Example

```
gSQL> SELECT product_id, min_price
             , VAR_SAMP( min_price ) OVER ( ORDER BY product_id ) AS "VAR_SAMP"
        FROM product_information
       WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE         VAR_SAMP
---------- --------- ----------------
      1769      null             null
      1770        73             null
      2378       247            15138
      2382       731 116249.333333333
      3355      null 116249.333333333
5 rows selected.
```

17.228 VARIANCE

Syntax

```
VARIANCE( [ ALL ¦ DISTINCT ] expr )
```

Description

It is an aggregation function, and it obtains the variance of an expr set.

If ALL is specified, this function is performed for all values. If DISTINCT is specified, this function is perfor med for the values of which the duplicates were deleted from. If it is not specified, it is processed as if AL L is apecified.

If the number of expr sets except for NULL after deleting the duplicates by using DISTINCT is one, then it r eturns 0.

The following table describes the arguments and result types.

Table 17-32 Argument and result type of VARIANCE

expr	Result type
NATIVE_INTEGER family • NATIVE_SMALLINT • NATIVE_INTEGER • NATIVE_BIGINT	NATIVE_DOUBLE
NUMBER	NUMBER
NATIVE_DOUBLE family • NATIVE_REAL • NATIVE_DOUBLE	NATIVE_DOUBLE

GOLDILOCKS gets the variance as follows.

- If the number of expr sets are 1, then it returns 0.
- If the number of expr sets are bigger than 1, It returns the value of **STDDEV_SAMP (expr)**.

For more information, refer to **STDDEV**.

Example

```
gSQL> SELECT VARIANCE(c1) FROM t1;
VARIANCE(C1)
------------
       132.2
1 row selected.
gSQL> SELECT VARIANCE(ALL c1) FROM t1;
VARIANCE(ALL C1)
----------------
           132.2
1 row selected.
gSQL> SELECT VARIANCE(DISTINCT c1) FROM t1;
VARIANCE(DISTINCT C1)
---------------------
               176.25
1 row selected.
```

17.229 VARIANCE() OVER

Syntax

```
VARIANCE ( expr ) OVER < window name or specification >
```

For more information about < window name or specification >, refer to **window clause**.

Description

Window function VARIANCE calculates the variance of expr.
If the number of expr except for NULL is one, then it returns 0 as a result.

Example

```
gSQL> SELECT product_id, min_price
             , VARIANCE( min_price ) OVER ( ORDER BY product_id ) AS "VARIANCE"
        FROM product_information
       WHERE supplier_id = 102050;
PRODUCT_ID MIN_PRICE         VARIANCE
---------- --------- ----------------
      1769      null             null
      1770        73                0
      2378       247            15138
      2382       731 116249.333333333
      3355      null 116249.333333333
5 rows selected.
```

17.230 VERSION

Syntax

```
VERSION()
```

Description

It obtains the product's version string.

Example

```
gSQL> SELECT VERSION() FROM dual;
VERSION()
-------------------------------------
Release Name.X.X.X revision(XXXXX)
1 row selected.
```

17.231 WIDTH_BUCKET

Syntax

```
WIDTH_BUCKET( num, min, max, cnt )
```

Description

It creates a section of the same width as cnt within a range between specified min and max, and it return s the section location in which the num is located.

The data type of num argument, min argument, max argument and cnt argument can be a numeric data type.

min, max means the range for the section. If the min value is equal to the max value, an error is returned. cnt means the number of sections. The cnt value should be a positive number. If the cnt value is 0 or a ne gative number, an error is returned.
The section's location is numbered from one.

If any of num, min, max, cnt is NULL, the result is also NULL.

Example

```
gSQL> SELECT WIDTH_BUCKET( 5, 1, 20, 5 ) AS RESULT FROM DUAL;
RESULT
------
     2
1 row selected.
```

18.

SQL References (A~B)

18.1 ALTER AUDIT POLICY

Function

It adds an auditing target to an audit policy object, or drops an auditing target from an audit policy objec t.

Syntax

```
<alter audit policy statement> ::=
    ALTER AUDIT POLICY policy_name
    { <add_audit_option> ¦ <drop_audit_option> }
    ;
<add_audit_option> ::=
    ADD { <privilege_audit_clause> ¦  <action_audit_clause> ¦ <privilege_audit_clause>
<action_audit_clause> }
<drop_audit_option> ::=
    DROP { <privilege_audit_clause> ¦  <action_audit_clause> ¦ <privilege_audit_clause>
<action_audit_clause> }
<privilege_audit_clause> ::=
    PRIVILEGES <database_privilege> [, ...]
<action_audit_clause> ::=
    ACTIONS { <object_action_audit> ¦ <system_action_audit> } [, ...]
<object_action_audit> ::=
      ALL ON [schema_name.]object_name
    ¦ <object_action> ON [schema_name.]object_name
<system_action_audit> ::=
      ALL
    ¦ <system_action>
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <alter audit policy statement>.

Syntax Rules and Parameters

policy_name

It is the name of an audit policy object to be altered.

〈add_audit_option〉

It adds an auditing target to an audit policy.

〈drop_audit_option〉

It drops an auditing target from an audit policy.

〈privilege_audit_clause〉

For more information, refer to **CREATE AUDIT POLICY**.

〈action_audit_clause〉

For more information, refer to **CREATE AUDIT POLICY**.

Description

It can alter an audit policy which is already activated, and it does not effect the existing session but it effe cts only the newly created session.

When dropping ALL option as follows, not all actions are dropped, but only the corresponding ALL option is dropped.

```
CREATE AUDIT POLICY p1
       ACTIONS ALL ON u1.t1,
               SELECT ON u1.t1;
ALTER AUDIT POLICY p1 DROP
      ACTIONS ALL ON u1.t1;
```

Examples

The following is an example of adding a new audit option to an audit policy.

```
ALTER AUDIT POLICY policy_dml
      ADD ACTIONS SELECT ON u1.t1;
```

The following is an example of dropping an audit option from an audit policy.

```
ALTER AUDIT POLICY policy_dml
      DROP ACTIONS SELECT ON u1.t1;
```

Compatibility

The SQL standard does not have the audit policy.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**
- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**
- Enquiring audit trail: **AUDIT_TRAIL**
- Dropping audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

18.2 ALTER CLUSTER GROUP name ADD MEMBER

Function

It adds a cluster member to a cluster group.

Syntax

```
<alter cluster group add member statement> ::=
    ALTER CLUSTER GROUP group_name ADD
        <cluster member definition> [, ...]
    ;
<cluster member definition> ::=
    CLUSTER MEMBER member_name <connection attribute> [<member position>]
<connection attribute> ::=
    HOST 'address' PORT port_no
<member position> ::=
    POSITION DEFAULT
  ¦ POSITION MAX
  ¦ POSITION number
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter cluster group add member statement>.

Syntax Rules and Parameters

group_name

It is the cluster group name.

〈cluster member definition〉

It defines a cluster member to be included in a cluster group.
A cluster group may include maximum 32 cluster members.

member_name

It is the name of a cluster member.
The cluster member name should be as same as the member name which was defined when the databas e of that cluster member was created.
There should not be the same cluster group, nor the same cluster member.
The length of the name should be shorter than 128 bytes.

The start-up phase for the cluster member should be GLOBAL OPEN.

〈connection attribute〉

It defines the connection information for the communication between the cluster members.
〈connection attribute〉 should be as same as the HOST and PORT which were defined when the database of that cluster member was created.
The combination of HOST and PORT should be unique in the cluster system.

- HOST 'address' uses the host name or IPv4 address. If the host name is used, then it uses the first IPv 4 address of the system.
- PORT port_no should be in the range between 1024 ~ 49151.

〈member position〉

It assigns the position number of the cluster member.

- POSITION DEFAULT
  - The system automatically assigns the position number.
- POSITION MAX
  - It assigns the new member position number even when an empty position number exists.
  - It assigns the value bigger than the biggest member position.
- POSITION number
  - It assigns the position number corresponding to the number
  - The position number should be unique in the cluster system.
  - The position number should be an empty position number, and it should be same or smaller than the biggest position number.
- If it is omitted, the default value is POSITION DEFAULT.

The member_position information of the cluster member can be retrieved through DBA_CLUSTER view.

```
SELECT member_name, member_id, member_position FROM dba_cluster;
```

If the following position numbers are being used,

- G1N1: 0
- G1N2: 1
- G2N2: 3
- G3N2: 5

The following values are assigned according to each option.

- POSITION DEFAULT
  - It assigns 2 which is an empty value.
- POSITION MAX
  - It assigns 6 which is a value of a new position number.
- POSITION 3
  - It is duplicated, so it is an error.
- POSITION 4
  - It assigns 4 which is a position number.

Description

<alter cluster group add member statement> statement does not rebalance shards in the tables.
The following statement should be performed to rebalance shards on the added cluster member.

- **ALTER DATABASE REBALANCE**
- **ALTER TABLE name REBALANCE**

Examples

The following is an example of adding two cluster members to a cluster group.

```
gSQL>
ALTER CLUSTER GROUP g1 ADD
    CLUSTER MEMBER g1n3 HOST '192.168.0.13' PORT 10130,
    CLUSTER MEMBER g1n4 HOST '192.168.0.14' PORT 10140
;
```

```
Cluster Group altered.
```

The following is an example of designating the empty member position as a cluster member position.

```
ALTER CLUSTER GROUP g2 ADD
    CLUSTER MEMBER g2n1 HOST '192.168.0.21' PORT 10210 POSITION 4
;
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- CREATE CLUSTER GROUP
- DROP CLUSTER GROUP
- ALTER DATABASE REBALANCE
- ALTER TABLE name REBALANCE

18.3 ALTER CLUSTER GROUP name OFFLINE MEMBER

Function

It sets a cluster member of the cluster group to offline.

Syntax

```
<alter cluster group offline member statement> ::=
    ALTER CLUSTER GROUP group_name OFFLINE CLUSTER MEMBER member_name
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter cluster group offline member statement>.

Syntax Rules and Parameters

group_name

It is the cluster group name.

member_name

It is the name of a cluster member.
The cluster member should be included in the cluster group of group_name.
The cluster member should be inactive.

Description

It sets the inactive cluster member to offline.

<alter cluster group offline member statement> statement does not rebalance shards in the tables.

Examples

If trying to set the cluster member which is not inactive to offline, then the following error occurs.

```
gSQL>
ALTER CLUSTER GROUP g1 OFFLINE CLUSTER MEMBER g1n2;
ERR-42000(16417): active member 'G1N2' cannot be offlined
```

The following is an example of setting a specific cluster member to offline.

```
gSQL>
ALTER CLUSTER GROUP g1 OFFLINE
    CLUSTER MEMBER g1n3
;
Cluster Group altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- CREATE CLUSTER GROUP
- DROP CLUSTER GROUP
- ALTER DATABASE REBALANCE
- ALTER TABLE name REBALANCE

18.4 ALTER CLUSTER LOCATION

Function

It alters a cluster location information.

Syntax

```
<alter cluster location statement> ::=
    ALTER CLUSTER LOCATION member_name
    <cluster connection attribute>
    ;
<cluster connection attribute> ::
       HOST 'address' PORT port_no
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter cluster location statement>.

Syntax Rules and Parameters

member_name

It is the name of a cluster member.
The same cluster member name should exist in the registered cluster location information.
The length of the name should be shorter than 128 bytes.

<cluster connection attribute>

It defines the connection information for the communication between the cluster members.
The combination of HOST and PORT should be unique in the cluster system.

- HOST 'address' uses the host name or IPv4 address. If the host name is used, then it uses the first IPv 4 address of the system.
- PORT port_no should be in the range between 1024 ~ 49151.

Description

If the connection information of the cluster location is altered, the cluster member does not need to be dr opped or recreated, but the connection information can be altered by using **ALTER CLUSTER LOCATION**.

Examples

```
gSQL>
ALTER CLUSTER LOCATION g1n2
    HOST '192.168.0.12' PORT 10120
;
Location altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- **CREATE CLUSTER LOCATION**
- **DROP CLUSTER LOCATION**

18.5 ALTER DATABASE ADD LOGFILE

Function

It adds log file groups or log file members to the database.

Syntax

```
<alter database add logfile statement> ::=
      <add logfile member statement>
    ¦ <add logfile group statement>
    ;
<add logfile member statement> ::=
    ALTER DATABASE ADD LOGFILE MEMBER <add logfile clause> [, ...] TO
        <group clause>
<add logfile group statement> ::=
    ALTER DATABASE ADD LOGFILE <group clause> ( 'logfile_name' [, ...] )
        <size clause> [ REUSE ]
<group clause> ::=
    GROUP integer
<add logfile clause> ::=
    'logfile_name' [ REUSE ]
<size clause> ::=
    integer [ M ¦ G ]
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database add logfile statement>.

Syntax Rules and Parameters

〈alter database add logfile statement〉

The database should be in MOUNT phase.

〈add logfile member statement〉

The log member is added to an existing log file group.

- 〈add logfile clause〉
  - 'logfile_name' is the file name of logfile member to be added to the log file group.
  - If the file does not exist, a new file is created.
  - The length of the logfile_name should be shorter than 1024 bytes.
- 〈group clause〉
  - It specifies the identifier of the logfile group to be added to the database.
  - Integer should be an identifier of the existing logfile group.
  - If an identifier for the integer does not exist, an error occurs.

〈add logfile group statement〉

It adds a new log file group.

- It is added as the next group of the CURRENT log file group.
- 〈group clause〉
  - It specifies the identifier of the logfile group to be added to the database.
  - Integer should be an identifier of the unexisting logfile group.
  - If an identifier for the integer exists, an error occurs.
- 〈size clause〉
  - The file size can be specified minimum of 20 MB to maximum of 120 GB.
  - The file size should be bigger than the sum of redo log buffer size and pending log buffer size.
- When 'logfile_name' already exists, and the REUSE option is used, if the file size is as same as anothe r group member, then the existing log file is reused.

Description

It is recommended to back up the control file just in case for the file damage because the newly added lo g file groups and log members are stored in the control file.

Examples

The following is an example of adding two log file members to an existing log file group 3.

```
ALTER DATABASE ADD LOGFILE MEMBER 'logfile1.log', 'logfile2.log' TO GROUP 3;
```

The following is an example of adding a new log file group 4 to database. The size of log file group 4 is 1 00 M, and the log file name is 'logfile1.log'.

```
ALTER DATABASE ADD LOGFILE GROUP 4 ( 'logfile1.log' ) SIZE 100M;
```

When adding a log group, a single log file should be used, and multiple log files can be added t o an existing group as a member.

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- ALTER DATABASE ADD LOGFILE
- ALTER DATABASE DROP LOGFILE
- ALTER DATABASE RENAME LOGFILE

18.6 ALTER DATABASE ARCHIVELOG

Function

It alters an archive setting of the online log file in the database.

Syntax

```
<alter database archivelog statement> ::=
    ALTER DATABASE { ARCHIVELOG ¦ NOARCHIVELOG }
    ;
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database archivelog statement>.

Syntax Rules and Parameters

<alter database archivelog statement>

- The database should be in MOUNT phase.
- ARCHIVELOG
  - It archives the online log file.
- NOARCHIVELOG
  - It does not archive the online log file.

Description

For the database backup and the media recovery using the backup, the system should be operated in AR CHIVELOG mode.

Example

The following is an example of how to set up a database to archive mode.

```
ALTER DATABASE ARCHIVELOG;
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- **ALTER DATABASE BACKUP**
- **ALTER TABLESPACE name BACKUP**

18.7 ALTER DATABASE BACKUP

Function

The backup state is set to ACTIVE or INACTIVE to perform a full backup of the database. Then, the increm ental database backup and control file backup are performed.

Syntax

```
<alter database backup statement> ::=
      <database begin backup statement>
    ¦ <database end backup statement>
    ¦ <database incremental backup statement>
    ¦ <database controlfile backup statement>
    ;
<database begin backup statement> ::=
    ALTER DATABASE BEGIN BACKUP [ AT <domain name> ]
    ;
<database end backup statement> ::=
    ALTER DATABASE END BACKUP [ AT <domain name> ]
    ;
<database incremental backup statement> ::=
    ALTER DATABASE BACKUP INCREMENTAL
        <incremental backup option> [ AT <domain name> ]    ;
<incremental backup option> ::=
      LEVEL integer [ CUMULATIVE ¦ DIFFERENTIAL ]
<database controlfile backup statement> ::=
    ALTER DATABASE BACKUP CONTROLFILE TO 'target_name'
        [ AT <domain name> ]    ;
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database backup statement>.

Syntax Rules and Parameters

〈database begin backup clause〉

The database is set to the state which the full backup is available.

- All tablespaces in ONLINE state, which is created and used in the database, are set to the state of whi ch the full backup is available.
- The database should be OPEN state and operated in ARCHIVELOG mode.
- After starting BEGIN BACKUP, the following operations which require writing to the data file can not be performed.
  - SHUTDOWN NORMAL
  - OFFLINE / DROP TABLESPACE
  - ADD / DROP DATAFILE
- It may require media recovery on restart when a full backup is ACTIVE state and the instance is abnor mally terminated.

〈database end backup clause〉

The database is set to the state which the full backup is not available.

- All tablespaces in ONLINE state, which is created and used in the database, are set to the state which the full backup is not available.
- The database should be in OPEN phase and operated in ARCHIVELOG mode.

〈database incremental backup statement〉

- An incremental backup is performed for the database.
- The database should be in OPEN phase and operated in ARCHIVELOG mode.

〈incremental backup option〉

- 'integer' can be specified from 0 to 4.
- LEVEL 0 can not specify CUMULATIVE or DIFFERENTIAL.
- CUMULATIVE | DIFFERENTIAL
  - CUMULATIVE
    - If 'integer' is n, it backs up all pages which are altered after the most recent backups of LEVE L 0 ~ LEVEL n-1.
  - DIFFERENTIAL
    - If 'integer' is n, it backs up all pages which are altered after the most recent backups of LEVE L 0 ~ LEVEL n.

- If it is omitted, DIFFERENTIAL is specified by default.

〈database controlfile backup statement〉

- The control file is backed up.
  - The length of 'target_name' should be shorter than 1024 bytes.
  - If 'target_name' already exists, the operation fails.
- The database should be in OPEN phase and operated in ARCHIVELOG mode.

The maximum length of the 'target_name' managed by GOLDILOCKS is 1024 bytes. However, the maximum lengths of the file name varies depending on the OS, so the actual length of 'target_name' which is available to be created can be shorter than 1024 bytes.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

It backs up data files and control files in the database. A full backup of the database begins with BEGIN BACKUP, and copies the datafiles using OS file copy, then ends with END BACKUP. The incremental backup file is created in the path set by the BACKUP_DIR 1 property using a single statement.

Examples

The following is an example to set the entire backup state to ACTIVE.

```
ALTER SYSTEM BEGIN BACkUP;
```

The following is an example to set the entire backup state to INACTIVE.

```
ALTER SYSTEM END BACkUP;
```

The following is an example to create the incremental backup of LEVEL 1 by using DIFFERENTIAL.

```
ALTER DATABASE BACKUP INCREMENTAL LEVEL 1 DIFFERENTIAL;
```

The following is an example to create the 'controlfile.bak' backup file for the control file. If the absolute p ath is not included, a backup file is created in the path set by the LOG_DIR property.

```
ALTER DATABASE BACKUP CONTROLFILE TO 'controlfile.bak';
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- **ALTER TABLESPACE name BACKUP**
- **ALTER DATABASE RECOVER**

18.8 ALTER DATABASE CLEAR AUDIT TRAIL

Function

It purges audit records which are accumulated when applying an audit policy.

Syntax

```
<clear audit trail statement> ::=
    ALTER DATABASE CLEAR AUDIT TRAIL
;
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <clear audit trail statement>.

Description

If an audit policy is activated, an audit trails is getting longer as time goes by.
Tables configuring an audit trail are stored in MEM_AUX_TBS tablespace, and a user should be cautious not to let the audit trail keep increasing.

Storing Audit Trail

A user should purge an audit trail after storing it according to the following procedure to store an audit tr ail when it is necessary.

- When performing it for the first time

```
CREATE TABLE backup_audit_trail AS SELECT * FROM AUDIT_TRAIL;
COMMIT;
```

- When repeatedly performing it

```
INSERT INTO backup_audit_trail SELECT * FROM AUDIT_TRAIL;
COMMIT;
```

- When purging an audit trail

```
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Examples

Purge an audit trail by using the following statement.

```
ALTER DATABASE CLEAR AUDIT TRAIL;
```

Compatibility

The SQL standard does not have the audit policy.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**
- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**
- Enquiring audit trail: **AUDIT_TRAIL**
- Dropping audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

18.9 ALTER DATABASE CLEAR PASSWORD HISTORY

Function

It deletes the user's password change history which is accumulated due by applying the profile.

Syntax

```
<clear password history statement> ::=
    ALTER DATABASE CLEAR PASSWORD HISTORY
    ;
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <clear password history statement>.

Description

When a profile is applied to a user, the user's password change history is accumulated according to the PASSWORD_REUSE_MAX, PASSWORD_REUSE_TIME policy.

Table 18-1 Managing the change history

PASSWORD_REUSE_MAX	PASSWORD_REUSE_TIME	Managing the change history
value	value	It manages only the change history within the value range, and the change history out of the value range is automatically deleted.
value	UNLIMITED	It accumulates all change history and it does not delete any change history because all change history should be checked.
UNLIMITED	value	It accumulates all change history and it does not delete any change history because all change history should be checked.
UNLIMITED	UNLIMITED	It does not manage the change history because the change history is not checked.

〈Clear password history statement〉 deletes the accumulated user's password change history.

Examples

The following is an example of executing 〈clear password history statement〉 statement.

```
gSQL> ALTER DATABASE CLEAR PASSWORD HISTORY;
Database altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- CREATE PROFILE
- CREATE USER

18.10 ALTER DATABASE DATAFILE AUTOEXTEND

Function

It alters the property to automatically extend disk tablespace data file. If the property is ON, then the size to be extended and the maximum size of the data file also can be altered.

Syntax

```
<alter database datafile autoextend statement> ::=
    ALTER DATABASE DATAFILE datafile_name <autoextend clause>
        [ AT <domain name> ]
    ;
<autoextend clause>
    AUTOEXTEND { ON [ <next size clause> ] [ <max size clause> ] ¦ OFF }
<next size clause>
    NEXT <size clause>
<max size clause>
    MAXSIZE { <size clause> ¦ UNLIMITED }
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database datafile autoextend sta tement>

The datafile automatic expand property can alter the property of disk tablespace only.

datafile_name

It specifies the name of the data file to be altered.

<autoextend clause>

It sets the automatic expand property to ON or OFF. If it is set to ON, then it can specify the automatic ex panded size and the maximum size of the data file.

〈next size clause〉

It specifies the size to be extended when the data file in use does not have available space.

〈max size clause〉

It specifies the maximum expanded size of the data file.

Description

Refer to the syntax rules of each statement.

Examples

The following is an example of altering the automatic expand property of the datafile, the automatic exp anded size, and datafile size.

```
gSQL> ALTER DATABASE DATAFILE 'DISK_TBS.dbf' AUTOEXTEND OFF;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'DISK_TBS.dbf' AUTOEXTEND ON;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'DISK_TBS.dbf' AUTOEXTEND ON NEXT 20M;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'DISK_TBS.dbf' AUTOEXTEND ON MAXSIZE 1G;
Database altered.
gSQL> ALTER DATABASE DATAFILE 'DISK_TBS.dbf' AUTOEXTEND ON 20M MAXSIZE 1G;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the datafile.

For More Information

Refer to **CREATE DISK DATA TABLESPACE**.

18.11 ALTER DATABASE DELETE BACKUP

Function

It deletes the backup file and the backup information of incremental backup. It can delete all incremental backup of the database or no longer usable obsolete backup.

Syntax

```
<alter database delete backup statement> ::=
    ALTER DATABASE DELETE <delete backup list option>
        BACKUP LIST [ <including backup file option> ]
    ;
<delete backup list option> ::=
      OBSOLETE
    | ALL
<including backup file option> ::=
    INCLUDING BACKUP FILES
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database delete backup statement>.

Syntax Rules and Parameters

<alter database delete backup statement>

The database should be in MOUNT or OPEN phase.

〈delete backup list option〉

It selects the backups to be deleted among the existing incremental backups.

- OBSOLETE: It selects backups of database or tablespaces to be deleted, which was backed up before the most recent database LEVEL 0 backup.
- ALL: It selects all incremental backups to be deleted.

〈including backup file option〉

- If it is omitted, it deletes only the backup information from the control file.
- It also deletes not only backup information but also the backup files.

Description

Deletion of the OBSOLETE incremental backup deletes the incremental backup of which is before the most recent LEVEL 0 database backup. When non-LEVEL 0 incremental backup is performed, it is not deleted even if it includes the previously performed incremental backup. It is because it can be used when performing the incomplete recovery by using the incremental backups.

Be cautious of deleting the backup file together when an incremental backup is deleted. It cannot be recovered even by using the control file which has incremental backup information.

Example

The following is an example to delete the backup information and backup files of all existing incremental backups.

```
ALTER DATABASE DELETE ALL BACKUP LIST INCLUING BACKUP FILES;
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- **ALTER TABLESPACE name BACKUP**
- **ALTER DATABASE RECOVER**

18.12 ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS

Function

It drops the entire inactive cluster member.

Syntax

```
<alter database drop inactive members statement> ::=
    ALTER DATABASE DROP [ FORCE ¦ NO FORCE ] INACTIVE CLUSTER MEMBERS
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter database drop inactive cluster members statement>.

Syntax Rules and Parameters

[FORCE | NO FORCE]

- FORCE
  - It drops an inactive cluster member even when there is a possibility of data loss.
- NO FORCE
  - It can not drop an inactive cluster member if there is a possibility of data loss.
- The default value is NO FORCE.

Description

It drops the entire inactive cluster member.

The inactive state of a cluster member means that it is not connected to the cluster system, and it occurs i n the following cases.

- An error occurs on a cluster member in an operating cluster system.
- Trying to start-up the cluster system without driving the cluster member.

However, if the table shard is lost while dropping the cluster member, then an inactive cluster member ca n not be dropped.

Also, if there is a possibility of data loss when dropping the cluster member, then an inactive cluster mem ber can not be dropped. The data is not lost when it is guaranteed that the data in replica of the table or the shard which belongs the inactive cluster member to be dropped is not latest comparing to that in the members of that cluster group. Therefore, an inactive cluster member can be dropped when at least one online member exists in the same cluster group in case for the sharded table, and in the entire cluster in c ase for the cloned table.

However, if an online cluster member does not exist in the cluster group and the service is not available d ue to an inactive cluster member, then the inactive cluster member can be dropped by using FORCE optio n despite of the possibility of the data loss.

It is recommended to use <alter database drop inactive members statement> when an inactive cluster me mber can not be included in the cluster system any more.

Examples

The following is an example of executing <alter database drop inactive members statement>.

```
gSQL> ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER SYSTEM JOIN DATABASE**.

18.13 ALTER DATABASE DROP LOGFILE

Function

It drops a log file group or a member which exists in the database.

Syntax

```
<alter database drop logfile statement> ::=
      <drop logfile group statement>
    | <drop logfile member statement>
    ;
<drop logfile group statement> ::=
    ALTER DATABASE DROP LOGFILE <group clause>
<group clause> ::=
    GROUP integer
<drop logfile member statement> ::=
    ALTER DATABASE DROP LOGFILE MEMBER <logfile_list>
<logfile_list> ::=
      'logfile_name'
    | <logfile_list> , 'logfile_name'
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database drop logfile statement>.

Syntax Rules and Parameters

<alter database drop logfile statement>

The database should be in MOUNT phase.
An error occurs when the log file to be deleted is in CURRENT or ACTIVE stage.
At least four log file groups should be remained after dropping.

〈drop logfile group statement〉

It drops the existing log file group.

- 〈group clause〉
  - It specifies the log file group to be dropped.
  - An integer should be an identifier of the existing log file.
  - An error occurs if the integer does not exist.

〈drop logfile member statement〉

It drops the existing log file members.

- 〈logfile_list〉
  - It is the list of the log file members to be dropped.
  - 'logfile_name' should be an existing name.
  - An error occurs if 'logfile_name' does not exist.

Description

For more information, refer to the rules for each syntax.

Examples

The following is an example of dropping the existing log file GROUP 3.

```
ALTER DATABASE DROP LOGFILE GROUP 3;
```

The following is an example of dropping logfile1.log and logfile2.log from the existing logfile GROUP 3.

```
ALTER DATABASE DROP LOGFILE MEMBER 'logfile1.log', 'logfile2.log';
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the respective syntax rules, and the followings.

- ALTER DATABASE ADD LOGFILE
- ALTER DATABASE RENAME LOGFILE

18.14 ALTER DATABASE DROP OFFLINE SEGMENTS

Function

It drops segments of offline shards for all tables.

Syntax

```
〈alter database drop offline segments statement〉 ::=
    ALTER DATABASE DROP OFFLINE SEGMENTS
    ;
```

Invocation and Access Rules

It can be performed in the cluster system.

ALTER DATABASE ON DATABASE privilege is required to perform 〈alter database drop offline segments statement〉.

Description

It drops segments of offline shards for all tables and it can be performed even when an inactive cluster member exists.

The inactive state of the cluster member means that it is not connected to the cluster system, and it occurs in the following situations.

- When that cluster member fails in the operating cluster system
- When it tries to start-up the cluster system without running that cluster member

〈alter database drop offline segments statement〉 performs **〈alter table drop offline segments statement〉** per each table, and it is equivalent to the sum of following queries.

```
ALTER TABLE t1 DROP OFFLINE SEGMENTS;
COMMIT;
ALTER TABLE t2 DROP OFFLINE SEGMENTS;
COMMIT;
ALTER TABLE t3 DROP OFFLINE SEGMENTS;
COMMIT;
...
ALTER TABLE tn DROP OFFLINE SEGMENTS;
COMMIT;
```

<alter database drop offline segments statement> is not terminated even when an error occurs in a specif ic table, but proceeds in the next table, and succeeds with the following warning.

```
gSQL> ALTER DATABASE DROP OFFLINE SEGMENTS;
ERR-42000(16553): of the total '5' tables, '1' tables failed to drop offline segments
Database altered.
```

The error message above means that one of the five tables failed.

If <alter database drop offline segments statement> is performed again after taking an appropriate action for the error, then it is operated only for the failed table.

For more information about the error, refer to the system trace log (system.trc) of the member which exe cuted the statement.

Example

The following is an example of performing <alter database drop offline segments statement> statement.

```
gSQL> ALTER DATABASE DROP OFFLINE SEGMENTS;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER TABLE name DROP OFFLINE SEGMENTS**.

18.15 ALTER DATABASE MOVE SHARD

Function

It rebalances shard of all tables in a specific cluster group to another cluster group.

Syntax

```
<alter database move shard statement> ::=
    ALTER DATABASE MOVE SHARD FROM CLUSTER GROUP src_cluster_group
        TO CLUSTER GROUP dest_cluster_group
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

ALTER DATABASE ON DATABASE privilege is required to perform <alter database move shard statement>.

Syntax Rules and Parameters

src_cluster_group

It is a cluster group to which the table shard is moved.

dest_cluster_group

It is a target cluster group to which the table shard is moved.

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL
  - It does not rebalance tables in parallel.
- PARALLEL [integer]
  - It rebalances tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

When adding a cluster member and a cluster group using the following statements, the table shard is not rebalanced.

- CREATE CLUSTER GROUP
- ALTER CLUSTER GROUP name ADD MEMBER

Perform <alter database rebalance statement> to rebalance the shard of the entire table which was not rebalanced when adding a cluster group and a cluster member.

<alter database move shard statement> is performed as the following concepts for tables which did not rebalance the shard.

```
ALTER TABLE t1 MOVE SHARD FROM CLUSTER GROUP src_group TO CLUSTER GROUP dest_group;
COMMIT;
ALTER TABLE t2 MOVE SHARD FROM CLUSTER GROUP src_group TO CLUSTER GROUP dest_group;
COMMIT;
ALTER TABLE t3 MOVE SHARD FROM CLUSTER GROUP src_group TO CLUSTER GROUP dest_group;
COMMIT;
...
...
ALTER TABLE t_n MOVE SHARD FROM CLUSTER GROUP src_group TO CLUSTER GROUP dest_group;
COMMIT;
```

It is performed as above for all tables except for a CLONED table and a CLUSTER WIDE table. The <alter database move shard statement> is proceeded even when the rebalancing the shard of a specific table fails. It does not rollback the table which succeeded in rebalancing the shard.

Therefore, when performing <alter database move shard statement> again after appropriately processed an error, then it rebalances only the shard for the table requiring the rebalancing. In this case, the table which succeeded in rebalancing the shard is not included in a target of the rebalancing.

Examples

The following is an example of performing <alter database move shard statement>.

```
gSQL> ALTER DATABASE MOVE SHARD FROM CLUSTER GROUP G1 TO CLUSTER GROUP G2;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER TABLE name MOVE SHARD
- CREATE CLUSTER GROUP
- ALTER CLUSTER GROUP name ADD MEMBER

18.16 ALTER DATABASE OFFLINE INACTIVE CLUSTER MEMBERS

Function

It sets the entire inactive cluster member to offline. In other words, it sets the shard map for the cluster member to offline.

Syntax

```
<alter database offline inactive cluster members statement> ::=
    ALTER DATABASE OFFLINE INACTIVE CLUSTER MEMBERS
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter database offline inactive cluster members statement>.

Syntax Rules and Parameters

It sets the entire inactive cluster member to offline.
The inactive state of a cluster member means that it is not connected to the cluster system, and it occurs in the following cases.

- An error occurs on a cluster member in an operating cluster system.
- Trying to start-up the cluster system without driving the cluster member.

Description

It is recommended to use <alter database offline inactive members statement> when an inactive cluster member can not be included in the cluster system any more.

If an inactive cluster member can participate in a cluster system, then perform **ALTER SYSTEM JOIN DATABASE** to include it in a cluster system.

The cluster member which is set to offline can be shifted to online again by using the following statements after the join.

- **ALTER DATABASE REBALANCE**
- **ALTER TABLE name REBALANCE**

Examples

```
gSQL> ALTER DATABASE OFFLINE INACTIVE CLUSTER MEMBERS;
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- **ALTER SYSTEM JOIN DATABASE**
- **ALTER DATABASE REBALANCE**
- **ALTER TABLE name REBALANCE**

18.17 ALTER DATABASE REBALANCE

Function

It rebalances shard of all tables.

Syntax

```
<alter database rebalance statement> ::=
    ALTER DATABASE REBALANCE
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

ALTER DATABASE ON DATABASE privilege is required to perform <alter database rebalance statement>.

Syntax Rules and Parameters

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.

- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL
  - It does not rebalance tables in parallel.
- PARALLEL [integer]
  - It rebalances tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

When adding a cluster member and a cluster group using the following statements, the table shard is not rebalanced.

- CREATE CLUSTER GROUP
- ALTER CLUSTER GROUP name ADD MEMBER

Perform 〈alter database rebalance statement〉 to rebalance the shard of the entire table which was not re balanced when adding a cluster group and a cluster member.

〈alter database rebalance statement〉 is performed as the following concepts for tables which did not reb alance the shard.

```
ALTER TABLE t1 REBALANCE;
COMMIT;
ALTER TABLE t2 REBALANCE;
COMMIT;
ALTER TABLE t3 REBALANCE;
COMMIT;
...
...
ALTER TABLE t_n REBALANCE;
COMMIT;
```

The <alter database rebalance statement> is proceeded even when the rebalancing the shard of a specific table fails. It does not rollback the table which succeeded in rebalancing the shard.

Therefore, when performing <alter database rebalance statement> again after appropriately processed an error, then it rebalances only the shard for the table requiring the rebalancing. In this case, the table whic h succeeded in rebalancing the shard is not included in a target of the rebalancing.

Examples

The following is an example of performing <alter database rebalance statement>.

```
gSQL> ALTER DATABASE REBALANCE;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER TABLE name REBALANCE**.

18.18 ALTER DATABASE REBALANCE EXCLUDE CLUSTER GROUP

Function

It rebalances shard of all tables excluding shards of a specific cluster group.

Syntax

```
<alter database rebalance exclude cluster group statement> ::=
    ALTER DATABASE REBALANCE EXCLUDE CLUSTER GROUP cluster_group_name
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

ALTER DATABASE ON DATABASE privilege is required to perform <alter database rebalance exclude cluster group statement>.

Syntax Rules and Parameters

cluster_group_name

It is a name of the cluster group excluding a shard of the table.
If the specified cluster group is the only cluster group, then the statement can not be performed.

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL
  - It does not rebalance tables in parallel.
- PARALLEL [integer]
  - It rebalances tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

To drop a cluster group by using **DROP CLUSTER GROUP**, there should not be a shard in the cluster grou p.

Perform <alter database rebalance exclude cluster group statement> to exclude a shard from the cluster g roup. <alter database rebalance exclude cluster group statement> is performed as the following concepts for tables which include a shard in the cluster group.

```
ALTER TABLE t1 REBALANCE EXCLUDE CLUSTER GROUP g3;
COMMIT;
ALTER TABLE t2 REBALANCE EXCLUDE CLUSTER GROUP g3;
COMMIT;
ALTER TABLE t3 REBALANCE EXCLUDE CLUSTER GROUP g3;
COMMIT;
...
...
ALTER TABLE t_n REBALANCE EXCLUDE CLUSTER GROUP g3;
COMMIT;
```

If the <alter database rebalance exclude cluster group statement> fails due to the lack of storage space, it does not rollback the table which succeed in excluding a shard.

Therefore, when performing <alter database rebalance exclude cluster group statement> again after appr opriately processed an error, then it excludes and rebalances only the shard for the table requiring the reb alancing. In this case, the table which succeeded in excluding the shard is not included in a target of the r ebalancing.

Examples

The following is an example of performing <alter database rebalance exclude cluster group statement>.

```
gSQL> ALTER DATABASE REBALANCE EXCLUDE CLUSTER GROUP g3;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- DROP CLUSTER GROUP
- ALTER TABLE name REBALANCE EXCLUDE CLUSTER GROUP cluster_group_list

18.19 ALTER DATABASE RECOVER

Function

It recovers the entire data file or part of the data files in the database by using the online and archive log files.

Syntax

```
<alter database recover statement> ::=
      <complete database recover statement>
    ¦ <datafile recover statement>
    ¦ <complete tablespace recover statement>
    ¦ <incomplete database recover statement>
    ;
<complete database recover statement> ::=
    ALTER DATABASE RECOVER
<datafile recover statement> ::=
    ALTER DATABASE RECOVER DATAFILE <datafile recovery clause>
<datafile recovery clause> ::=
    <datafile recovery object> [, ...]
<datafile recovery object> ::=
    'datafile_name' [<recovery using backup option>] [recovery corruption option>]
<recovery using backup option> ::=
    USING BACKUP 'backup_datafile_name'
<recovery corruption option> ::=
    CORRUPTION
<complete tablespace recover statement> ::=
    ALTER DATABASE RECOVER TABLESPACE tablespace_name
<incomplete database recover statement> ::=
      <batch incomplete recovery statement>
    ¦ <interactive incomplete recovery statement>
    ;
<batch incomplete recovery statement> ::=
    ALTER DATABASE RECOVER <until clause> [<using backup controlfile option>]

<until clause> ::=
```

```
      UNTIL CHANGE integer
<using backup controlfile option> ::=
    USING BACKUP CONTROLFILE
<interactive incomplete recovery statement> ::=
    ALTER DATABASE <incomplete recovery option> [<using backup controlfile option>]
<incomplete recovery option> ::=
      BEGIN INCOMPLETE RECOVERY
    ¦ END INCOMPLETE RECOVERY
    ¦ RECOVER 'logfile name'
    ¦ RECOVER AUTOMATICALLY
    ¦ RECOVER SUGGESTION
    ;
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database recover statement>.

Syntax Rules and Parameters

<complete database recover statement>

The data files of the database are recovered up to date by using the online and archive log files.

- The recovery is performed for all tablespaces in the ONLINE state.
- The database should be in MOUNT phase and in ARCHIVELOG mode.
- If the required archived log file does not exist, it fails.

<datafile recover statement>

It recovers the backuped datafile, the datafile of the tablespace which requires the recovery by using the archive logfile due to an error during the backup, or the datafile of the tablespace which was set to offline by an immediate option, to the latest status.

- Datafile can be recovered on MOUNT phase or OPEN phase.
- The datafile of the tablespace which is in OFFLINE state can be recovered on OPEN phase, and datafile which is either in ONLINE/OFFLINE state can be recovered in MOUNT phase.
- If the required archive logfile does not exist, then the recovery fails.
- <datafile recovery clause>
    - It specifies one or more datafile object list which is a target of the recovery.

- 〈datafile recovery object〉
  - It sets the name of datafile which is a target of the recovery, and the recovery option.
- 〈recovery using backup option〉
  - It sets the name of backup datafile of the datafile which is a target of the recovery.
- 〈recovery corruption option〉
  - It determines whether to recover only the pages corrupted from the datafile which is a target of t he recovery.

〈complete tablespace recover statement〉

The data files of the tablespace is recovered up to date.

- Tablespace recovery should be performed when the database is in MOUNT or OPEN phase.
- The recovery in the OPEN phase can only be performed when the tablespaces is in the OFFLINE stage, and the recovery in MOUNT phase can be performed when the tablespace is either in ONLINE/ OFFLI NE stage.
- If the required archive log file does not exist, it fails.
- The following is the case which requires the tablespace recovery operation.
  - The tablespace became OFFLINE by IMMEDIATE.
  - The backed up data file is used.
  - A failure occurred during the entire backup.

〈incomplete database recover statement〉

〈batch incomplete database recover statement〉

The datafiles in the database are recovered in a batch up to a specific point of time by using the online an d archive logfile.

- The recovery is performed for all tablespaces in the ONLINE stage.
- The database should be in MOUNT phase and in ARCHIVELOG mode.
- It fails if using the data file containing data which is after the time of the incomplete recovery.
- The database should be OPEN by using RESETLOGS after completion of incomplete recovery.
- 〈until clause〉
  - A specific point of time for incomplete recovery
  - UNTIL CHANGE: The point of time is specified for incomplete recovery in log units
- 〈using backup controlfile〉
  - Deprecated

〈interactive incomplete database recover statement〉

The data files in the database are interactively recovered with a user up to a specific point of time by usin g online and archive log file.

- The recovery is performed for all tablespaces in the ONLINE stage.
- The database should be in MOUNT phase and in ARCHIVELOG mode.
- It fails if using the data file containing data which is after the time of the incomplete recovery.
- The database should be OPEN by using RESETLOGS after completion of incomplete recovery.
- 〈incomplete recovery option〉
  - It is an option to perform an interactive incomplete recovery in log units.
  - BEGIN INCOMPLETE RECOVERY: It starts an incomplete recovery.
  - END INCOMPLETE RECOVERY: It ends an incomplete recovery.
  - RECOVER 'logfile name': A user directly specifies the log file performing the recovery.
  - RECOVER AUTOMATICALLY: All recoverable archive log files are recovered.
  - RECOVER SUGGESTION: It recovers archive log files which are required for the recovery and reco mmended by the system.
- 〈using backup controlfile〉
  - Deprecated.

Description

Incomplete recovery of the database is not easy to find a recovery completion point at a time. Therefore, t he desired recovery point is found by performing it several times.
However, it becomes a new database if the database is started up with RESETLOGS option after an inco mplete recovery. Therefore, the incomplete recovery should be performed several times after creating a c opy of the archived log files and online redo log files.

Examples

The following is an example of a complete recovery for entire database.

```
ALTER DATABASE RECOVER;
```

The following is an example of a datafile recovery.

```
ALTER DATABASE RECOVER DATAFILE 'test.dbf';
```

The following is an example of a tablespace recovery.

```
ALTER DATABASE RECOVER TABLESPACE test_tbs;
```

The following is an example of incomplete recovery for the entire database until LSN is 11123.

```
ALTER DATABASE RECOVER UNTIL CHANGE 11123;
```

The following is an example of interactive incomplete recovery until the recoverable archive log files.

```
ALTER DATABASE BEGIN INCOMPLETE RECOVERY;
ALTER DATABASE RECOVER AUTOMATICALLY;
ALTER DATABASE END INCOMPLETE RECOVERY;
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- **ALTER DATABASE BACKUP**
- **ALTER TABLESPACE name BACKUP**
- **ALTER SYSTEM {MOUNT | OPEN} DATABASE**

18.20 ALTER DATABASE REGISTER

Function

It registers unrecoverable segments in the database.

Syntax

```
<alter database register statement> ::=
    ALTER DATABASE REGISTER IRRECOVERALBE SEGMENT
        <segment physical identifier list>
    ;
<segment physical identifier list> ::=
      integer
    | <segment physical identifier list> , integer
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database register statement>.

Syntax Rules and Parameters

<alter database register statement>

It registers the unrecoverable segments in the database. The statement can be used on the assumption th at the segment is not used any more, when the database is not recoverable and the backup does not exis t.

- The database should be in MOUNT phase.
- The registered segment identifier list is initialized at restart.
- If a server restart is successful, the registered segment becomes 'UNUSABLE' state, and that segment s should be deleted.

〈segment physical identifier list〉

The list of unrecoverable segment identifier
- Integer: 8 bytes integer segment identifier

Description

When a server restarts after abnormal termination, the database performs the recovery process. During t
his process, it executes pages again by using the REDO log to recover pages which was not reflected in th
e disk in the previous service stage.

If an unexpected failure occurs during execution of the REDO operation, that statement can be used to ig
nore the failure and to execute the recovery.

Example

The following is an example of giving up the recovery of the segment whose identifier is 402867932364
8.

```
ALTER DATABASE REGISTER IRRECOVERABLE SEGMENT 4028679323648;
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- ALTER TABLESPACE name BACKUP
- ALTER DATABASE RECOVER

18.21 ALTER DATABASE RENAME GLOBAL TRANSACTION LOGFILE

Function

It renames the global transaction logfile in the database.

Syntax

```
<alter database rename global transaction logfile statement> ::=
    ALTER DATABASE RENAME GLOBAL TRANSACTION LOGFILE <source_clause>
       TO <target_clause>
    ;
<source_clause> ::= <logfile_list>
<target_clause> ::= <logfile_list>
<logfile_list> ::=
      'logfile_name'
    | <logfile_list>, 'logfile_name'
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required for performing <alter database rename global transaction logfile statement>.

Syntax Rules and Parameters

<alter database rename global transaction logfile statement>

- The database should be in MOUNT phase.
- source_clause
  - The list of the global transaction log file to be modified in the database.
- target_clause
  - The list of the global transaction log file to be modified in the database.

- An error occurs if the file does not exist.
- The length of the name including the path should be shorter than 1024 bytes.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of modifying the global transaction logfile.

```
ALTER DATABASE RENAME GLOBAL TRANSACTION LOGFILE
 'org_commit_0.log', 'org_commit_1.log' TO 'new_commit_0.log', 'new_commit_1.log';
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to **ALTER DATABASE RENAME LOGFILE**.

18.22 ALTER DATABASE RENAME LOGFILE

Function

It renames the logfile in the database.

Syntax

```
<alter database rename logfile statement> ::=
    ALTER DATABASE RENAME LOGFILE <logfile_list> TO <logfile_list>
    ;
<logfile_list> ::=
      'logfile_name'
    | <logfile_list> , 'logfile_name'
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required for performing <alter database rename logfile statement>.

Syntax Rules and Parameters

<alter database rename logfile statement>

- The database should be in MOUNT phase.
- FROM <logfile_list>
  - The name list of the logfiles to modify in the database.
- TO <logfile_list>
  - The name list of the logfiles to be modified in the database.
  - <logfile_list> should be an existing file.
  - An error occurs if the file does not exist.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of modifying the existing 'logfile.log' logfile to 'newlogfile.log'.

```
ALTER DATABASE RENAME LOGFILE 'logfile.log' TO 'newlogfile.log';
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- ALTER DATABASE ADD LOGFILE
- ALTER DATABASE DROP LOGFILE

18.23 ALTER DATABASE RESET LOCAL CLUSTER MEMBER

Function

It resets the local cluster member except for the tablespace object to the time of creating the database.

Syntax

```
<alter database reset local cluster member statement> ::=
    ALTER DATABASE RESET LOCAL CLUSTER MEMBER
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

The start-up phase should be LOCAL OPEN.

ADMINISTRATION ON DATABASE privilege is required to perform <alter database reset local cluster member statement>.

Description

It resets the local cluster member except for the tablespace object to the time of creating the database. It drops all objects created by a user except for the tablespace object.

<alter database reset local cluster member statement> statement resets an inactive cluster member, and makes the new cluster member to participate in a cluster system.
An inactive cluster member which is disconnected from the cluster system is processed as follows.

- If it can join in a cluster system again, then use JOIN statement to make it join.
  - **ALTER SYSTEM JOIN DATABASE**
- If it can not join in a cluster system again, then use DROP statement to exclude it.

- ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS

In this case, the device corresponding to the cluster member which is excluded from a cluster system can be used again by using the following two methods.

- Method 1: Recreate the database of the local cluster member.
- Method 2: Reset the local cluster member by using <alter database reset local cluster member statement>.

The method 2 reduces the cost of recreating the tablespace comparing to the method 1.

Examples

The following is an example of a reset by using <alter database reset local cluster member statement> after driving the local cluster member, which is excluded from the cluster system, up to LOCAL OPEN phase.

```
gSQL> \startup nomount
Startup success
gSQL> ALTER SYSTEM MOUNT DATABASE;
System altered.
gSQL> ALTER SYSTEM OPEN LOCAL DATABASE;
System altered.
gSQL> ALTER DATABASE RESET LOCAL CLUSTER MEMBER;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER SYSTEM JOIN DATABASE
- ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS

18.24 ALTER DATABASE RESTORE

Function

It restores the data files in the database or tablespace by using the incremental backup.

Syntax

```
<alter database restore statement> ::=
      <database restore statement>
    ¦ <tablespace restore statement>
    ¦ <controlfile restore statement>
    ;
<database restore statement> ::=
    ALTER DATABASE RESTORE [ <until clause> ]
<until clause> ::=
    UNTIL CHANGE integer
<tablespace restore statement> ::=
    ALTER DATABASE RESTORE TABLESPACE tablespace_name
<controlfile restore statement> ::=
    ALTER DATABASE RESTORE CONTROLFILE FROM 'file_name'
```

Invocation and Access Rules

ALTER DATABASE ON DATABASE privilege is required to perform <alter database restore statement>.

Syntax Rules and Parameters

<database restore statement>

It restores the data files in the database by using the incremental backup.
The database should be in MOUNT phase.

〈tablespace restore statement〉

It restores the data files in the tablespace by using the incremental backup.

- The database should be in MOUNT or OPEN phase.
- The recovery in OPEN state can be performed only for the tablespaces in OFFLINE state. The recovery in MOUNT phase can be performed for the tablespace is either in ONLINE state or OFFLINE state.

〈controlfile restore statement〉

The control file is recovered using 'file_name'.

- The database should be in NOMOUNT phase.
- The absolute path is recommended for 'file_name' but if relative path is described, then <GOLDILOCKS_HOME>/wal/'file_name' is used.

Description

The data recovery using full backup uses OS copy command to directly copy the backup file to the data file path. The data recovery using incremental restores only the deleted data files or old data files.

Examples

The following is an example of recovering the database by using the incremental backup.

```
ALTER DATABASE RESTORE;
```

The following is an example of recovering the tablespace by using the incremental backup.

```
ALTER DATABASE RESTORE TABLESPACE test_tbs;
```

The following is an example of recovering the database by using only the incremental backup whose LSN is smaller than 11123.

```
ALTER DATABASE RESTORE UNTIL CHANGE 11123;
```

The following is an example of recovering the control file by using controlfile.bak.

```
ALTER DATABASE RESTORE CONTROLFILE FROM 'controlfile.bak'
```

Compatibility

The SQL standard does not define ALTER DATABASE statement.

For More Information

Refer to the followings.

- ALTER DATABASE BACKUP
- ALTER TABLESPACE name BACKUP
- ALTER DATABASE RECOVER

18.25 ALTER DATABASE SYNCHRONIZE

Function

It remotely synchronizes shards and sequences in all tables.

Syntax

```
<alter database synchronize statement> ::=
    ALTER DATABASE SYNCHRONIZE
       [ <synchronize target> ]
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<synchronize target> ::=
    TABLE
  ¦ SEQUENCE
  ¦ TABLE AND SEQUENCE
  ¦ SEQUENCE AND TABLE
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in the cluster system.

ALTER DATABASE ON DATABASE privilege is required to perform <alter database synchronize statement>

.

Syntax Rules and Parameters

〈synchronize target〉

It specifies the synchronization target object.

- TABLE
  - It synchronizes the table object.
- SEQUENCE
  - It synchronizes the sequence object.
- TABLE AND SEQUENCE or SEQUENCE AND TABLE
  - It synchronizes the table and the sequence object.
- If it is omitted, the default value is TABLE AND SEQUENCE.

[ONLINE | OFFLINE]

It determines whether to allow DML when performing the synchronization.

- ONLINE
  - It allows INSERT, UPDATE, DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- If it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then synchronizes it with the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

If 〈synchronize target〉 specifies only SEQUENCE, then it is ignored.

〈parallel clause〉

It specifies the number of threads to use when synchronizing the table.

- NOPARALLEL

    - It does not synchronize tables in parallel.
- PARALLEL [integer]
    - It synchronize tables in parallel.
    - The minimum value of an integer is 0 and the maximum value is 64.
    - If the integer is omitted, then it is 0.
    - If the integer is 0, then the system determines the optimal value.

If <synchronize target> specifies only SEQUENCE, then it is ignored.

Description

It synchronizes all existing offline shards and sequences, then switch them to online. Unlike **ALTER DATA BASE REBALANCE**, it can be performed even when an inactive cluster member exists.

The inactive state of the cluster member means that it is not connected to the cluster system, and it occur s in the following situations.

- When that cluster member fails in the operating cluster system
- When it tries to start-up the cluster system without running that cluster member

<alter database synchronize statement> performs **<alter table synchronize statement>** per each table, and it is equivalent to the sum of following queries.

```
ALTER TABLE t1 SYNCHRONIZE;
COMMIT;
ALTER TABLE t2 SYNCHRONIZE;
COMMIT;
ALTER TABLE t3 SYNCHRONIZE;
COMMIT;
...
ALTER TABLE tn SYNCHRONIZE;
COMMIT;
```

<alter database synchronize statement> is not terminated even when an error occurs while synchronizing a specific table, but proceeds to synchronize the next table, and succeeds with the following warning.

```
gSQL> ALTER DATABASE SYNCHRONIZE;
ERR-42000(16555): of the total '5' tables, '1' tables failed to synchronize
Database altered.
```

The error message above means that one of the five tables failed.

If <alter database synchronize statement> is performed again after taking an appropriate action for the error, then it is operated only for the failed table.

For more information about the error, refer to the system trace log (system.trc) of the member which executed the statement.

Example

The following is an example of performing <alter database synchronize statement> statement.

```
gSQL> ALTER DATABASE SYNCHRONIZE;
Database altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER DATABASE REBALANCE
- ALTER TABLE name REBALANCE

18.26 ALTER INDEX

Function

It alters the index definition.

Syntax

```
〈alter index statement〉 ::=
      〈alter index physical attribute statement〉
    ¦ 〈rename index statement〉
    ¦ 〈aging index statement〉
    ¦ 〈rebuild index statement〉
    ¦ 〈index coalesce statement〉
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform 〈alter index statement〉.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

Syntax Rules and Parameters

〈alter index physical attribute statement〉

It alters physical attributes of the index.
For more information, refer to **ALTER INDEX name STORAGE**.

〈rename index statement〉

It alters the index name.
For more information, refer to **ALTER INDEX name RENAME TO**.

〈aging index statement〉

It deletes the empty page of the index.
For more information, refer to **ALTER INDEX name AGING**.

〈rebuild index statement〉

It rebuilds the index.
For more information, refer to **ALTER INDEX name REBUILD**.

〈index coalesce statement〉

It drops the index fragmentation.
For more information, refer to **ALTER INDEX name COALESCE**.

Description

Refer to the descriptions of each detailed statement.

Examples

Refer to the examples of each detailed statement.

Compatibility

The SQL standard does not define the concepts of the index.

18.27 ALTER INDEX name AGING

Function

It deletes an empty page of the index.

Syntax

```
<aging index statement> ::=
    ALTER INDEX index_name AGING
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <aging index statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs.
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

Syntax Rules and Parameters

index_name

It is the name of the target index.

Description

This syntax returns pages whose all keys are deleted among index pages to a segment. Aging is processe d in two steps which are logical deletion and physical deletion. A logical deletion is disconnection of inde

x page, and it is performed when SCN of when deleting the last key of a page is smaller than the agable SCN of the system. Then the physical deletion is performed when the SCN of the logical deletion is smaller then the agable SCN of the system.

> ⚠ If the agable SCN of the system does not increase, then the empty page may not be deleted even though the index AGING statement succeeded.

Examples

The following is an example of aging the index.

```
gSQL> select index_name, empty_blocks from user_indexes where index_name = 'T1X';
INDEX_NAME EMPTY_BLOCKS
---------- ------------
T1X                   2
1 row selected.
gSQL> alter index t1x aging;
Index altered.
gSQL> select index_name, empty_blocks from user_indexes where index_name = 'T1X';
INDEX_NAME EMPTY_BLOCKS
---------- ------------
T1X                   0
1 row selected.
```

Compatibility

The SQL standard does not define the concepts of the index.

For More Information

Refer to the followings.

- CREATE INDEX
- ALTER INDEX
- DROP INDEX

18.28 ALTER INDEX name COALESCE

Function

It coalesces adjacent leaf pages of the index so that it decreases the index space in use.

Syntax

```
<index coalesce statement> ::=
    ALTER INDEX index_name COALESCE
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <index coalesce statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs.
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

At least one of the following privileges for a tablespace in which the index is to be created is required.

- CREATE OBJECT ON TABLESPACE for that tablespace
- USAGE TABLESPACE ON DATABASE

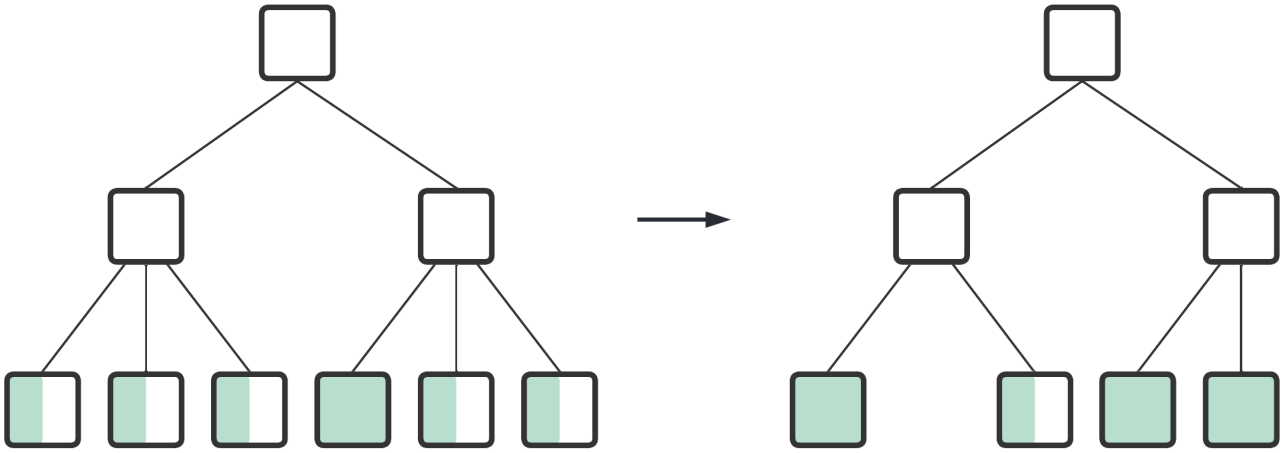
Syntax Rules and Parameters

index_name

It is the name of the target index.
The schema name can be specified, and the user's default schema name is used when it is omitted.

Description

Figure 1 Index coalesce



- It sequentially scans leaf pages and coalesces them when it is allowed to do so, then returns the delet ed pages to the segment.
- It can solve the fragmentation problem of leaf pages which occurred due to UPDATE/ DELETE.
- It drops keys related to invalid shards and frees the constraints about the shard sequence.
- It is operated only when the adjacent leaf pages are allowed to coalesce, so if the fragmentation level is low, then it may not be effective.
- If the fragmentation level of the index is high, then the processing time may take longer than INDEX REBUILD.

Table 18-2 Comparing to INDEX REBUILD

	INDEX REBUILD	INDEX COALESCE
Altering index attributes	Possible	Impossible
Moving tablespace	Possible	Impossible
Locking table	Required	Not required
Additional space for execution	Required	Not required
Decreasing tree height	Possible	Impossible

Examples

```
gsql> ALTER INDEX T1X COALESCE;
Index altered.
```

Compatibility

The SQL standard does not define the concepts of the index.

For More Information

Refer to the followings.

- ALTER INDEX
- ALTER INDEX name REBUILD

18.29 ALTER INDEX name REBUILD

Function

It rebuilds an index.

Syntax

```
<rebuild index statement> ::=
    ALTER INDEX index_name REBUILD
        [ ONLINE ¦ OFFLINE ]
        [ <index attributes> [...] ]
        [ TABLESPACE tablespace_name ]
    ;
<index attributes> ::=
      <physical attribute clause>
    ¦ STORAGE ( <segment attr clause> [...] )
    ¦ <parallel clause>
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
<parallel clause> ::=
      NOPARALLEL
    ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <rebuild index statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs.
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

At least one of the following privileges for a tablespace in which the index is to be created is required.

- CREATE OBJECT ON TABLESPACE for that tablespace
- USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

index_name

It is the name of the target index.
The schema name can be specified, and the user's default schema name is used when it is omitted.

[ONLINE | OFFLINE]

It determines whether to allow DML on the table when rebuilding the index.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

<physical attribute clause>

It defines the physical attribute information of an index.

- PCTFREE integer
  - Definition
    - It is the reserved space for adjusting the page split frequency caused by the key inserted in th e page.

- It can use the value from 0 to 99.
- If it is omitted, the default value is the value set in the existing index.

- INITRANS integer
  - Definition
    - It specifies the initial number of transactions which can simultaneously access the page.
    - If the number of users who access the index is small, INITRANS is set to low, and if the numb er of users who simultaneously access the index is big, INITRANS is set to high.
    - If necessary, it is automatically increased to the specified MAXTRANS.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is the value set in the existing index.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transactions which can simultaneously access the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is the value set in the existing index.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the ind ex.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
    - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

- NEXT integer
  - Definition
    - It specifies the physical space size to be allocated when adding the space to the table.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
    - NEXT operates as follows, depending on the remaining space size of the index available curr ently. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS si ze)

    - If the remaining space size is 0, then it can not extend the space.
    - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the

space as big as the remaining space.
- If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

- MINSIZE integer
  - Definition
    - It is the minimum space size of the index.
    - The value should be equal to or smaller MAXSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
  - If it is omitted, the default value is the value set in the existing index.

- MAXSIZE integer
  - Definition
    - It is the maximum space size of the index.
    - The value should be equal to or bigger than MINSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

〈size clause〉

It specifies the file size in bytes. (If the unit is omitted, the default value is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

NOPARALLEL | PARALLEL [integer]

It specifies the number of threads to be used when rebuilding an index.

- NOPARALLEL
  - It does not rebuild an index in parallel.
- PARALLEL [integer]
  - It rebuilds an index in parallel.
  - If an integer is omitted or set as 0, then it follows INDEX_BUILD_PARALLEL_FACTOR property.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer or the property value is 0, then the system determines the optimal value.

- If it is omitted, the default value is NOPARALLEL.

TABLESPACE tablespace_name

It specifies the name of the tablespace in which the index is to be rebuilt.

- When it specifies tablespace_name
  - if tablespace_name is data tablespace, then it is rebuilt as a LOGGING index.
  - if tablespace_name is temporary tablespace or nologging tablespace, then it is rebuilt as a NOLOGGING index.
- When TABLESPACE clause is omitted, then it is set to the tablespace of the existing index.

Description

- Dropping the index fragmentation
  - The fragmentation may occur on the index page, when DML is frequently performed in the index. If the tree becomes too big comparing to the valid data, then the index volume becomes larger and the performance is degraded. In this case, rebuilding the index can solve the index fragmentation issue so that the index volume is reduced and the index performance is recovered.
- Altering the tablespace in the index
  - The tablespace in the previously created index can be altered.
  - However, LOGGING should be set properly according to whether the tablespace is TEMPORARY or not.
- Altering LOGGING setting in the index
  - The data tablespace should be set in TABLESPACE option to switch to the LOGGING index.
  - The temporary tablespace or the nologging tablespace should be set in TABLESPACE option to switch to the NOLOGGING index.
- Dropping keys related to invalid shards
  - When shards are changed, the keys related to the previous shards may remain in the index. If they are not dropped but stacked, then *shard sequence exceed* error may occur. This error occurs when shards are frequently changed, and the solution is rebuilding the index.

Examples

The following is an example of altering the index logging setting and the tablespace.

```
gsql> SELECT INDEX_NAME, TABLESPACE_NAME FROM INDEXES AS IDX, TABLESPACES AS TBS WHERE
IDX.TABLESPACE_ID = TBS.TABLESPACE_ID AND IDX.INDEX_NAME = 'T1X';
INDEX_NAME TABLESPACE_NAME
```

```
---------- ---------------
T1X        MEM_TEMP_TBS
1 row selected.
gsql> ALTER INDEX T1X REBUILD TABLESPACE MEM_DATA_TBS;
SELECT INDEX_NAME, TABLESPACE_NAME FROM INDEXES AS IDX, TABLESPACES AS TBS WHERE
IDX.TABLESPACE_ID = TBS.TABLESPACE_ID AND IDX.INDEX_NAME = 'T1X';
INDEX_NAME TABLESPACE_NAME
---------- ---------------
T1X        MEM_DATA_TBS
1 row selected.
```

Compatibility

The SQL standard does not cover the concepts of the index.

For More Information

Refer to the followings.

- CREATE INDEX
- ALTER INDEX
- DROP INDEX

18.30 ALTER INDEX name RENAME TO

Function

It alters the index name.

Syntax

```
<rename index statement> ::=
    ALTER INDEX index_name
        RENAME TO new_index_name
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <rename index statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs.
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

Syntax Rules and Parameters

index_name

It is the name of the target index.
The schema name can not be described and it has the same schema name as same as that of the existing index.

new_index_name

It is the name of the new index, and it should be a unique index name within the schema.

Description

Refer to the syntax rules of each statement.

Examples

The following is an example of altering the index name.

```
gSQL> ALTER INDEX t1_idx1 RENAME TO idx_t1_id;
Index altered.
```

Compatibility

The SQL standard does not define the concepts of the index.

For More Information

Refer to the followings.

- CREATE INDEX
- ALTER INDEX
- DROP INDEX

18.31 ALTER INDEX name STORAGE

Function

It alters the physical attributes of the index.

Syntax

```
<alter index physical attribute statement> ::=
    ALTER INDEX index_name
    ¦ <physical attribute clause>
    ¦ [ STORAGE ( <segment attr clause> [...] ) ]
    ;
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
```

Invocation and Access Rules

One of the following privilege is required to perform <alter index physical attribute statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs.
- (ALTER INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- ALTER ANY INDEX ON DATABASE

Syntax Rules and Parameters

index_name

It is the target index name.

〈physical attribute clause〉

It defines the physical attribute information of the index.

- PCTFREE integer
  - Definition
    - The reserved space to adjust the frequency of page splits caused by inserting the key in the p age.
    - It is applied only when the index bottom-up build.
  - It can use of the value from 0 to 99.
  - If it is omitted, the value set in DEFAULT_INDEX_PCTFREE property is used by default.

- INITRANS integer
  - Definition
    - The initial number of transactions simultaneously accessing the page.
    - If the number of users accessing the index is small, then INITRANS is set low. If the number o f users simultaneously accessing the index is big, then INITRANS is set high.
    - If necessary, it is automatically increased to the specified MAXTRANS.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 4.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transaction simultaneously accessing the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 8.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the ind ex.

        - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
        - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
        - It is applied only when the index bottom-up build.
    - The minimum value is 1, and the maximum value depends on the system environment.
    - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the table belongs.

- NEXT integer
    - Definition
        - It specifies the physical space size to be allocated when adding the space to the table.
        - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
        - NEXT operates as follows depending on the remaining space size of the currently available in dex. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS siz e)

      - If the remaining space size is 0, then it can not extend the space.

      - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the space as big as the remaining space.

      - If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the index belongs.

- MINSIZE integer
    - Definition
        - It is the minimum space size of the index.
        - The value should be equal to or smaller MAXSIZE.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
    - If it is omitted, the default value is the size of two EXTENT.

- MAXSIZE integer
    - Definition
        - It is the maximum space size of the index.
        - The value should be equal to or bigger than MINSIZE.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
    - If it is omitted, the default value is 32 terabytes (35,184,372,088,832).
    - Even though the value is set to over 32 terabytes, it is adjusted and set to 32 terabytes.
    - If the newly allocated space is smaller than the already allocated space, then an error occurs.

〈size clause〉

It specifies the file size in byte. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

Description

Refer to the syntax rules of each statement.

Examples

The following is an example of altering the physical attributes of the index.

```
gSQL> ALTER INDEX idx_t1_id PCTFREE 10 INITRANS 4 MAXTRANS 8;
Index altered.
```

Compatibility

The SQL standard does not define the concepts of the index.

For More Information

Refer to the followings.

- CREATE INDEX
- ALTER INDEX
- DROP INDEX

18.32 ALTER PROFILE

Function

It alters the password management method.

Syntax

```
<alter profile statement> ::=
    ALTER PROFILE profile_name LIMIT
    { <password_parameters>, ...}
    ;
<password parameters> ::=
      FAILED_LOGIN_ATTEMPTS { integer ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_LOCK_TIME  { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_LIFE_TIME  { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_GRACE_TIME { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_REUSE_MAX  { integer ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_REUSE_TIME { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_VERIFY_FUNCTION { <verify_policy> ¦ NULL ¦ DEFAULT }
<verify_policy> ::=
      KISA_VERIFY_FUNCTION
    ¦ ORA12C_VERIFY_FUNCTION
    ¦ ORA12C_STRONG_VERIFY_FUNCTION
    ¦ VERIFY_FUNCTION_11G
    ¦ VERIFY_FUNCTION
<password_parameter_number_interval> ::=
   integer
 ¦ integer / integer
```

Invocation and Access Rules

ALTER PROFILE ON DATABASE privilege is required to perform <alter profile statement>.

Syntax Rules and Parameters

profile_name

It is a profile name to be altered.

FAILED_LOGIN_ATTEMPTS

It sets the number of consecutive login attempts allowed to fail.
For more information, refer to **CREATE PROFILE**.

PASSWORD_LOCK_TIME

It sets an account lockout duration (day) after the consecutive login failures.
For more information, refer to **CREATE PROFILE**.

PASSWORD_LIFE_TIME

It sets the password lifetime (day).
For more information, refer to **CREATE PROFILE**.

PASSWORD_GRACE_TIME

It sets a password expiration grace period when log in after PASSWORD_LIFE_TIME.
For more information, refer to **CREATE PROFILE**.

PASSWORD_REUSE_MAX

It specifies the number of the recent passwords which can not be reused when a user wants to reuse the old password.
For more information, refer to **CREATE PROFILE**.

PASSWORD_REUSE_TIME

It specifies the duration which the password can not be reused when a user wants to reuse the old passw ord.
For more information, refer to **CREATE PROFILE**.

PASSWORD_VERIFY_FUNCTION

It set the password complexity verification method.
For more information, refer to **CREATE PROFILE**.

Examples

The following is an example of changing the profile to control the account lockout.

```
gSQL> ALTER PROFILE prof1 LIMIT
        FAILED_LOGIN_ATTEMPTS 3
        PASSWORD_LOCK_TIME 3;
Profile altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of changing the profile to control the password lifetime.

```
gSQL> ALTER PROFILE prof1 LIMIT
        PASSWORD_LIFE_TIME 90
        PASSWORD_GRACE_TIME 7;
Profile altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of changing the profile to control the password reusability.

```
gSQL> ALTER PROFILE prof1 LIMIT
        PASSWORD_REUSE_MAX  DEFAULT
        PASSWORD_REUSE_TIME DEFAULT;
Profile altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of changing the profile to control the password complexity verification.

```
gSQL> ALTER PROFILE prof1 LIMIT
        PASSWORD_VERIFY_FUNCTION KISA_VERIFY_FUNCTION;
Profile altered.
gSQL> COMMIT;
```

```
Commit complete.
```

Compatibility

The SQL standard does not define the concepts of the profile.

For More Information

Refer to **DROP PROFILE**.

18.33 ALTER SEQUENCE

Function

It alters the sequence.

Syntax

```
<alter sequence generator statement> ::=
    ALTER SEQUENCE sequence_name <alter sequence generator options>
    ;
<alter sequence generator options> ::=
    <alter sequence generator option> [, ...]
<alter sequence generator option> ::=
      <alter sequence generator restart option>
    | <basic sequence generator option>
<alter sequence generator restart option> ::=
    RESTART [ WITH integer ]
<basic sequence generator option> ::=
      <sequence generator increment by option>
    | <sequence generator maxvalue option>
    | <sequence generator minvalue option>
    | <sequence generator cycle option>
    | <sequence generator cache option>
<sequence generator increment by option> ::=
    INCREMENT BY integer
<sequence generator maxvalue option> ::=
      MAXVALUE integer
    | (NO MAXVALUE | NOMAXVALUE)
<sequence generator minvalue option> ::=
      MINVALUE integer
    | (NO MINVALUE | NOMINVALUE)
<sequence generator cycle option> ::=
      CYCLE
    | (NO CYCLE | NOCYCLE)
<sequence generator cache option> ::=
      CACHE integer
```

```
    ¦ (NO CACHE ¦ NOCACHE)
```

Invocation and Access Rules

One of the following privilege is required to perform <alter sequence generator statement>.

- The owner of that sequence
- (ALTER SEQUENCE or CONTROL SCHEMA) ON SCHEMA for the schema to which the sequence belo ngs
- ALTER ANY SEQUENCE ON DATABASE

Syntax Rules and Parameters

sequence_name

It is the sequence name to be altered.
It can define schema to which the sequence belongs such as schema_name.sequence_name and if schem a_name is omitted, the default schema name of the user performing the statement is used.

<alter sequence generator restart option>

It sets NEXT VALUE of the sequence.
However, it does not change the value of START WITH which is defined in **CREATE SEQUENCE** statement.

- RESTART
  - If the value is not specified, the value of START WITH defined in <sequence generator definition> is set as the next value of the sequence.
- RESTART WITH integer
  - It sets an integer value as the next value of the sequence.
  - The integer value should be between MINVALUE and MAXVALUE.

If <alter sequence generator restart option> clause is not specified, it changes the sequence attributes bas ed on the current sequence value.

<sequence generator increment by option>

It changes the interval of the sequence number.
The constraints and characteristics are as follows.

- A positive or negative value can be used, but 0 can not be used.
- The absolute value of the interval should be smaller than the difference between MINVALUE and MA XVALUE.
- If it is a positive value, it an ascending sequence. If it is a negative value, it is a descending sequence.

〈sequence generator maxvalue option〉

It changes the maximum value which the sequence can generate.
However, the MAXVALUE should not be smaller than the current sequence value.

- MAXVALUE integer
  - The maximum value is in the range between the minimum (-9,223,372,036,854,775,808) and t he maximum (+9,223,372,036,854,775,807) of 64 bit integer.
  - It should be equal to or bigger than the value of START WITH, and bigger than the value of MINV ALUE.
- NO MAXVALUE | NOMAXVALUE
  - It changes the maximum value as follows.
    - If it is an ascending sequence, it is the maximum value (+9,223,372,036,854,775,807) of the 64 bit integer.
    - If it is a descending sequence, the value is -1.
    - NO MAXVALUE (SQL standard) and NOMAXVALUE are the reserved words with the same m eaning, and either of them can be used.

〈sequence generator minvalue option〉

It changes the minimum value which the sequence can generate.
However, the MINVALUE should not be bigger than the current sequence value.

- MINVALUE integer
  - The minimum value is in the range between the minimum (-9,223,372,036,854,775,808) and th e maximum (+9,223,372,036,854,775,807) of 64bit integer.
  - It should be equal to or smaller than the value of START WITH, and smaller than the value of MA XVALUE.
- NO MINVALUE | NOMINVALUE
  - It changes the minimum value as follows.
    - If it is an ascending sequence, the value is 1.
    - If it is a descending sequence, it is the minimum value (—9,223,372,036,854,775,808) of th e 64bit integer.
  - NO MINVALUE (SQL standard) and NOMINVALUE are the reserved words with the same meanin

g, and either of them can be used.

〈sequence generator cycle option〉

It changes whether to continue generating a value when the sequence value becomes the maximum or minimum value.

- CYCLE
  - If an ascending sequence becomes the maximum value, it generates the value again from the minimum value.
  - If a descending sequence becomes the minimum value, it generates the value again from the maximum value.
- NO CYCLE | NOCYCLE
  - It can not generate the value sequence when it becomes the maximum value or the minimum value.
  - NO CYCLE (SQL standard) and NOCYCLE are the reserved words with the same meaning, and either of them can be used.

〈sequence generator cache option〉

For quick access of a sequence, it defines the number of sequence values to be pre-loaded on the memory.
When restarting the database, the sequence value loaded on the memory is lost, and it starts from the value after loading.

- CACHE integer
  - The CACHE value should be equal to or bigger than 2.
  - If CYCLE exists, the CACHE value should not be bigger than the length of CYCLE.
    - The length of CYCLE: CEIL(MAXVALUE - MINVALUE) / ABS(INCREMENT)
- NO CACHE | NOCACHE
  - It does not pre-load the sequence value in memory.

Description

It can not change START WITH which is one of the sequence attributes defined in **CREATE SEQUENCE** statement. To change START WITH attribute, it should be re-created by performing **CREATE SEQUENCE** statement after performing **DROP SEQUENCE** statement.

Examples

The following is an example of restating the sequence value by using RESTART option, then assigning a n ew ID.

```
gSQL> SELECT id, name FROM t1 ORDER BY 1;
 ID NAME
--- ------
 10 leekmo
 42 mkkim
 51 jhkim
172 ehpark
4 rows selected.
gSQL> ALTER SEQUENCE seq1 RESTART;
Sequence altered.
gSQL> UPDATE t1 SET id = seq1.NEXTVAL;
4 rows updated.
gSQL> SELECT id, name FROM t1 ORDER BY 1;
ID NAME
-- ------
 1 leekmo
 2 mkkim
 3 jhkim
 4 ehpark
4 rows selected.
```

Compatibility

The SQL standard does not define CACHE/ NO CACHE statement.

Table 18-3 SQL standard compatibility

Feature ID	Description	Compatibility
T176	Sequence generator support	O
T177	Sequence generator support: simple restart option	O

For More Information

Refer to the followings.

- CREATE SEQUENCE
- DROP SEQUENCE

18.34 ALTER SESSION CLEANUP GLOBAL TEMPORARY SEGMENT POOL;

Function

It returns all segments which were caught to be reused in a session to tablespaces.

Syntax

```
<alter session cleanup global temporary segment pool statement> ::=
    ALTER SESSION CLEANUP GLOBAL TEMPORARY SEGMENT POOL
    ;
```

Description

It cleans up only the segments of a segment cache in the performed session.

Examples

The following is an example of cleaning up the segment cache of the session.

```
gSQL> ALTER SESSION CLEANUP GLOBAL TEMPORARY SEGMENT POOL;
Session altered.
```

Compatibility

The SQL standard does not define the concepts of the segment cache of a global temporary table and a global temporary index.

For More Information

Refer to **Global Temporary Table**.

18.35 ALTER SESSION SET property_name

Function

It sets the property value of the session.

Syntax

```
<alter session set statement> ::=
    ALTER SESSION SET <property name> { = <property value> | TO DEFAULT }
    ;
```

Syntax Rules and Parameters

<property name>

It is the property name to be set.
For more information, refer to **Server Property** in an administration manual.

<property value>

It is the property value to be set.

TO DEFAULT

It sets the session property value as a system property value.

Description

For more information about property, refer to **Server Property** in an administration manual.

Examples

The following is an example of an error when setting ERROR HINT property so the hint clause includes an error.

```
gSQL> ALTER SESSION SET HINT_ERROR = ON;
Session altered.
gSQL> SELECT /*+ INDEX( t1, invalid_index ) */ name FROM t1 WHERE id = 1;
ERR-42000(16058): not applicable hint :
SELECT /*+ INDEX( t1, invalid_index ) */ name FROM t1 WHERE id = 1
           *
ERROR at line 1:
```

The following is an example of setting the session property value as the system property value.

```
gSQL> ALTER SESSION SET HINT_ERROR TO DEFAULT;
Session altered.
```

Compatibility

The SQL standard does not define the concepts of the session property.

For More Information

Refer to **ALTER SESSION SET property_name**.

18.36 ALTER SYSTEM CHECKPOINT

Function

It performs CHECKPOINT.

Syntax

```
<alter system checkpoint statement> ::=
    ALTER SYSTEM CHECKPOINT
    [ AT <domain name> ]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system checkpoint statement>.

Syntax Rules and Parameters

<alter system checkpoint statement>

CHECKPOINT is an operation to ensure that all altered data by the committed transactions are written to disk.

- The database should be in OPEN phase.
- The database should be in TDS mode.
- When a full backup is in progress, the altered pages are not recorded in the data file, but only the RE DO logs and control files are written to the disk. If the server is abnormally terminated in this situatio n, a media recovery should be performed.

<domain name>

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

The checkpoint operation records all changes by the committed transactions to disk, so it enables a rapid recovery at system error.

Example

The following is an example of performing CHECKPOINT.

```
ALTER SYSTEM CHECKPOINT;
```

Compatibility

The SQL standard does not define the concepts of CHECKPOINT.

18.37 ALTER SYSTEM CLEANUP BUFFER_CACHE

Function

It clears all buffer pages which can be free from the buffer cache.

Syntax

```
<alter system cleanup buffer_cache statement> ::=
    ALTER SYSTEM CLEANUP BUFFER_CACHE
    [ AT <domain name> ]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system cleanup buffer_cache statement>.

Syntax Rules and Parameters

<alter system cleanup buffer_cache statement>

Syntax rules and parameters do not exist for <alter system cleanup buffer_cache statement>.

<domain name>

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

It flushes and frees all free buffer pages cached in the buffer.

It should be used to clear the buffer cache before the performance measuring.
If it is used on the operating server, then it could have fatal effect for the performance.

Example

The following is an example of performing CLEANUP BUFFER_CACHE.

```
ALTER SYSTEM CLEANUP BUFFER_CACHE;
```

Compatibility

The SQL standard does not define the concepts of CLEANUP BUFFER_CACHE.

18.38 ALTER SYSTEM CLEANUP PLAN

Function

It cleans up all SQL plans.

Syntax

```
<alter system cleanup plan statement> ::=
    ALTER SYSTEM CLEANUP PLAN
    [ AT <domain name> ]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system cleanup plan statement>.

Syntax Rules and Parameters

<alter system cleanup plan statement>

There is not any syntax rules or parameters for <alter system cleanup plan statement>.

<domain name>

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

It cleans up all of the cached SQL plan. However, the plan whose V$SQL CACHE.REF COUNT is bigger tha n 0 (the plan referenced by the prepared statement) is excluded from cleanup.

Examples

The following is an example of executing CLEANUP PLAN.

```
ALTER SYSTEM CLEANUP PLAN;
```

Compatibility

The SQL standard does not define the concepts of CLEANUP PLAN.

18.39 ALTER SYSTEM IRRECOVERABLE CLUSTER MEMBER

Function

It specifies an irrecoverable cluster member.

Syntax

```
<alter system irrecoverable cluster member statement> ::=
    ALTER SYSTEM IRRECOVERABLE CLUSTER MEMBER <domain name>
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system irrecoverable cluster member statement>.

Syntax Rules and Parameters

<alter system irrecoverable cluster member statement>

There is not any syntax rules or parameters for <alter system irrecoverable cluster member statement>.

<domain name>

It is a name of an irrecoverable member.
it is not allowed to specify all members in a group as an irrecoverable member.

Description

It is used to restart the system excluding the corresponding member if the cluster failed to restart due to an irrecoverable member. The corresponding member should be dropped by using **ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS** after the system succeeded to restart.

Examples

The following is an example of executing IRRECOVERABLE CLUSTER MEMBER.

```
gSQL> ALTER SYSTEM IRRECOVERABLE CLUSTER MEMBER g1n1;
```

Compatibility

The SQL standard does not define the concepts of IRRECOVERABLE CLUSTER MEMBER.

18.40 ALTER SYSTEM JOIN DATABASE

Function

It includes a specific inactive cluster member in a cluster system again.

Syntax

```
<alter system join database statement> ::=
    ALTER SYSTEM JOIN DATABASE
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <alter system join database statement>.

Description

The inactive state of a cluster member means that it is not connected to the cluster system, and it occurs in the following cases.

- An error occurs on a cluster member in an operating cluster system.
- Trying to start-up the cluster system without driving the cluster member included in the cluster system.

If a specific cluster member is inactive, then the member can be included in a cluster system again according to the following procedure.

- Start-up the unstarted cluster member to the local open phase.

```
$ gsql sys gliese --as sysdba --dsn=G3N2
gSQL> \startup
```

- Include it in a cluster system by using <alter system join database statement>.

```
$ gsql sys gliese --as sysdba --dsn=G3N2
gSQL> ALTER SYSTEM JOIN DATABASE;
```

Use <alter system join database statement> to make an inactive cluster member which is started up to the local open phase to participate in the cluster system without shutting it down.

To make the inactive cluster member to participate in the cluster system again, the database state of the cluster system and that of the inactive cluster member should be same.

The inactive cluster member can not participate in the cluster system again after the transaction altering t he database in the cluster system completed.

To operate the cluster system normally the inactive cluster members should be dropped according to the following procedure when multiple inactive cluster members exist.

1. JOIN inactive cluster members which can participate in the cluster system.

```
gSQL> ALTER SYSTEM JOIN DATABASE;
```

2. DROP inactive cluster members which can not participate in the cluster system.

```
gSQL> ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS;
```

All inactive cluster members which can participate in the cluster system should be included in the cluster s ystem before dropping because all inactive cluster members are dropped from the cluster system when p erforming <alter database drop inactive cluster member statement>.

Examples

```
gSQL> ALTER SYSTEM JOIN DATABASE;
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER DATABASE DROP INACTIVE CLUSTER MEMBERS**.

18.41 ALTER SYSTEM [KILL | DISCONNECT] SESSION

Function

It terminates a session.

Syntax

```
<alter system end session statement> ::=
      ALTER SYSTEM DISCONNECT SESSION [<member_position>,] <session_id>,
           <serial#> [<disconnect_option>] [AT <domain name>]
    ¦  ALTER SYSTEM KILL SESSION [<member_position>,]
           <session_id>, <serial#> [AT <domain name>]
    ;
<disconnect_option> ::=
      POST_TRANSACTION
    ¦ IMMEDIATE
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system end session statement>.

Syntax Rules and Parameters

<member_position>

It is a member position of a session which is a disconnect/kill target in a cluster environment.

<session_id>

It is the session ID.

〈serial#〉

It is the SERIAL NUMBER of the session.

〈disconnect_option〉

- POST_TRANSACTION: The session is terminated after completion of the transaction.
- IMMEDIATE: The session is immediately terminated without waiting for the completion of the transac tion.

If 〈disconnect_option〉 is not used, then it is operated in IMMEDIATE.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

DISCONNECT SESSION can specify the options such as POST TRANSACTION and IMMEDIATE.
POST TRANSACTION terminates the session after the currently running transaction is completed. IMMEDI ATE terminates the session after immediately cleaning up the currently running transaction.

KILL SESSION terminates the abnormal session which remains on the system without its process.

Example

```
gSQL> SELECT USER_NAME, SESSION_ID, SERIAL_NO, SESSION_STATUS, PROGRAM_NAME FROM V$SESSION
WHERE USER_NAME = 'TEST';
USER_NAME SESSION_ID SERIAL_NO SESSION_STATUS PROGRAM_NAME
--------- ---------- --------- -------------- ------------
TEST              62        49 CONNECTED      gsql
TEST              65       109 CONNECTED      gsqlnet
TEST              66       130 CONNECTED      gsql
3 rows selected.
gSQL> ALTER SYSTEM DISCONNECT SESSION 65, 109;
System altered.
```

Compatibility

The SQL standard does not define it.

18.42 ALTER SYSTEM {MOUNT | OPEN} DATABASE

Function

It mounts the database on system, or alters the database to the state which is available for the service.

Syntax

```
<alter system database statement> ::=
    ALTER SYSTEM <alter system database clause>
    ;
<alter system database clause> ::=
      MOUNT DATABASE
    | OPEN [ <database_scope> ] DATABASE [ <open_database_option> ]
<open_database_option> ::=
      NORESETLOGS
    | RESETLOGS
<database_scope> ::=
      LOCAL
    | GLOBAL
```

Invocation and Access Rules

ADMINISTRATION ON DATABASE privilege is required to perform <alter system database statement>.

Syntax Rules and Parameters

<alter system database clause>

- MOUNT DATATABASE
  - It mounts the database on the system.
- OPEN DATABASE

- It changes the database to the state which is available for the service.

〈open database option〉

- RESETLOGS / NORESETLOGS
  - It determines whether to keep the online redo logs after recovering the database.
  - NORESETLOGS maintains the existing redo log, but RESETLOGS initializes it.
  - RESETLOGS should be specified when the database is incompletely recovered.
  - If it is omitted, NORESETLOGS is specified by default.

〈database_scope〉

- LOCAL
  - It starts up the LOCAL server to the OPEN phase.
- GLOBAL
  - It starts up the GLOBAL server, the entire server, to the OPEN phase.
- If it is omitted in a cluster environment, it starts up the GLOBAL server.

Examples

The following is an example of initializing the online redo logs.

```
ALTER SYSTEM OPEN DATABASE RESETLOGS;
```

Compatibility

The SQL standard does not define the concepts of MOUNT or OPEN in the database.

For More Information

Refer to **ALTER DATABASE RECOVER**.

18.43 ALTER SYSTEM RECONNECT GLOBAL CONNECTION

Function

It determines whether to reconnect to the session which is connected in GLOBAL CONNECTION form.

Syntax

```
<alter system reconnect global connection statement> ::=
    ALTER SYSTEM RECONNECT GLOBAL CONNECTION
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system reconnect global connection statement>.

Description

Whether the GLOBAL CONNECTION client reconnects is determined by comparing SCN of a system object acquired from a server at the first connection and SCN of current server system object. This statement leads the client to reconnect by increasing SCN of the system object.

The client dose not necessarily reconnect immediately after this statement is performed. The client reconnects by comparing SCN when the client executes a command in a server, and it does not try to reconnect if connections to all members from a client are valid.

Examples

The following is an example of executing the statement.

```
gSQL> ALTER SYSTEM RECONNECT GLOBAL CONNECTION;
System altered.
```

Compatibility

The SQL standard does not define the concepts of GLOBAL CONNECTION.

18.44 ALTER SYSTEM RESET property_name

Function

It removes a property value from the property file.

Syntax

```
<alter system reset statement> ::=
    ALTER SYSTEM { RESET ¦ UNSET } <property name>
        [ SCOPE = { FILE ¦ SPFILE } ]
        [ AT <domain name>]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system reset statement>.

Syntax Rules and Parameters

{ RESET | UNSET }

RESET and UNSET are the reserved words with the same meaning, so either of them can be used.

<property name>

It is the property name to be removed.
For more information, refer to **Server Property** in an administration manual.

[SCOPE = { FILE | SPFILE }]

It removes the property from a property file, so only SCOPE=FILE/SPFILE can be used.

- SCOPE = FILE

- FILE and SPFILE are the reserved words with the same meaning, so either of them can be used.
- A property is removed from FILE, and is not applied to the current state.
- When restarting the database, the changes are applied.

If SCOPE clause is not specified, the default value is SCOPE = FILE.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

If a property is altered by using SCOPE=FILE/SPFILE, the updated property value is stored in the property fi le, and it is applied when restarting the database.

When executing RESET, the updated property value is removed from the property file and the default val ue is used when restarting the database.

Examples

The following is an example of altering the property by using SCOPE=FILE.

```
gSQL> ALTER SYSTEM SET PROCESS_MAX_COUNT=128 SCOPE=FILE;
System altered.
```

The following is an example of removing the property altered above.

```
gSQL> ALTER SYSTEM RESET PROCESS_MAX_COUNT SCOPE=FILE;
System altered.
gSQL> ALTER SYSTEM RESET PROCESS_MAX_COUNT SCOPE=SPFILE;
System altered.
gSQL> ALTER SYSTEM RESET PROCESS_MAX_COUNT;
System altered.
gSQL> ALTER SYSTEM UNSET PROCESS_MAX_COUNT;
System altered.
```

Compatibility

The SQL standard does not define the concepts of the system property.

For More Information

Refer to **ALTER SYSTEM SET property_name**.

18.45 ALTER SYSTEM SET property_name

Function

It sets the system property value.

Syntax

```
<alter system set statement> ::=
    ALTER SYSTEM SET <property name> { = <property value> ¦ TO DEFAULT }
        [ DEFERRED ]
        [ SCOPE = [ MEMORY ¦ { FILE ¦ SPFILE } ¦ BOTH ] ]
    [AT <domain name>]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system set statement>.

Syntax Rules and Parameters

<property name>

It is the property name to be set.
For more information, refer to **Server Property** in an administration manual.

<property value>

It is the property value to be set.

TO DEFAULT

It sets the system property value as the initial value of system driving.

[DEFERRED]

It defines the point of time to apply the altered property.

- DEFERRED
  - It does not effect the current SESSION, but it is applied to the newly generated SESSION.
  - It can be applied when ISSYS_MODIFIABL property value is IMMEDIATE/DEFERRED. It should be explicitly specified.
  - It is not applicable when the ISSYS_MODIFIABLE property value is FALSE.

If ISSYS_MODIFIABLE property value is IMMEDIATE, and DEFERRED is not explicitly specified, then it is im mediately applied to all sessions.

[SCOPE = [MEMORY | { FILE | SPFILE } | BOTH]]

It specifies the range which is affected by the property changes of the system.

- SCOPE = MEMORY
  - The changes are applied only to the current state, and the value is lost when restarting the datab ase.
- SCOPE = FILE
  - FILE and SPFILE are the reserved words with the same meaning, so either of them can be used.
  - The changes are stored in FILE, and not applied to the current state.
  - The changes are applied when restarting the database.
- SCOPE = BOTH
  - The changes are stored in FILE, and applied to the current state.

If SCOPE clause is omitted, the default value is SCOPE = MEMORY.
If ISSYS_MODIFIABLE property value is FALSE, it should be specified as SCOPE=FILE/SPFILE.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

For more information, refer to **Server Property** in an administration manual.

Examples

The following is an example of changing the property whose ISSYS_MODIFIABLE property is DEFERRED.

```
gSQL> ALTER SYSTEM SET SPIN_COUNT=1000;
ERR-22000(13019): Specified property cannot be modified.(SPIN_COUNT)
gSQL> ALTER SYSTEM SET SPIN_COUNT=1000 DEFERRED;
System altered.
```

The following is an example of changing the property whose ISSYS_MODIFIABLE property is FALSE.

```
gSQL> ALTER SYSTEM SET PROCESS_MAX_COUNT=128;
ERR-22000(13018): Specified property cannot be modified with this SCOPE
option.(PROCESS_MAX_COUNT)
gSQL> ALTER SYSTEM SET PROCESS_MAX_COUNT=128 SCOPE=FILE;
System altered.
```

The following is an example of changing the altered property to the default value of when the session wa s connected.

```
gSQL> ALTER SYSTEM SET TRANSACTION_COMMIT_WRITE_MODE=0;
System altered.
gSQL> ALTER SYSTEM SET TRANSACTION_COMMIT_WRITE_MODE TO DEFAULT;
System altered.
gSQL> ALTER SYSTEM SET TRANSACTION_COMMIT_WRITE_MODE TO DEFAULT DEFERRED;
System altered.
```

Compatibility

The SQL standard does not define the concepts of the system property.

For More Information

Refer to **ALTER SYSTEM RESET property_name**.

18.46 ALTER SYSTEM SWITCH LOGFILE

Function

It alters the log files in CURRENT state to ACTIVE state in database.

Syntax

```
<alter system switch logfile statement> ::=
    ALTER SYSTEM SWITCH LOGFILE
    [ AT <domain name> ]
    ;
```

Invocation and Access Rules

ALTER SYSTEM ON DATABASE privilege is required to perform <alter system switch logfile statement>.

Syntax Rules and Parameters

<alter system switch logfile statement>

The database should be in MOUNT or OPEN phase.

<domain name>

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

Basically, if the log file in CURRENT state is filled, the log switch automatically occurs. That statement is used to forcibly execute log switch in special circumstances.

Example

```
ALTER SYSTEM SWITCH LOGFILE;
```

Compatibility

The SQL standard does not define the concepts of the LOGFILE.

For More Information

Refer to **ALTER SYSTEM {MOUNT | OPEN} DATABASE**.

18.47 ALTER TABLE

Function

It alters the table definition.

Syntax

```
<alter table statement> ::=
      <alter table physical attribute statement>
    ¦ <rename table statement>
    ¦ <add column definition>
    ¦ <drop column definition>
    ¦ <alter column definition>
    ¦ <rename column statement>
    ¦ <add table constraint definition>
    ¦ <drop table constraint definition>
    ¦ <alter table constraint definition>
    ¦ <alter table drop offline segments statement>
    ¦ <rename table constraint statement>
    ¦ <add table supplemental log statement>
    ¦ <drop table supplemental log statement>
    ¦ <rebalance statement>
    ¦ <move shard statement>
    ¦ <merge shards statement>
    ¦ <split shard statement>
    ¦ <alter table synchronize statement>
    ¦ <rename shard statement>
    ¦ <read { only ¦ write } statement>
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <alter table statement>.

- (ALTER or CONTROL TABLE) ON TABLE for the table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

⟨alter table physical attribute statement⟩

It alters physical attributes of a table.
For more information, refer to **ALTER TABLE name STORAGE**.

⟨rename table statement⟩

It renames the table.
For more information, refer to **ALTER TABLE name RENAME TO**.

⟨add column definition⟩

It adds columns to the table.
For more information, refer to **ALTER TABLE name ADD COLUMN**.

⟨drop column definition⟩

It drops a column from the table.
For more information, refer to **ALTER TABLE name SET UNUSED COLUMN**.

⟨alter column definition⟩

It alters the column definition in the table.
For more information, refer to **ALTER TABLE name ALTER COLUMN**.

⟨rename column statement⟩

It renames the column in the table.
For more information, refer to **ALTER TABLE name RENAME COLUMN**.

〈add table constraint definition〉

It adds constraints to the table.
For more information, refer to **ALTER TABLE name ADD CONSTRAINT**.

〈drop table constraint definition〉

It drops the constraints of the table.
For more information, refer to **ALTER TABLE name DROP CONSTRAINT**.

〈alter table constraint definition〉

It alters the constraints of the table.
For more information, refer to **ALTER TABLE name ALTER CONSTRAINT**.

〈alter table drop offline segments statement〉

It drops offline shards in the table.
For more information, refer to **ALTER TABLE name DROP OFFLINE SEGMENTS**.

〈rename table constraint statement〉

It renames the constraints of the table.
For more information, refer to **ALTER TABLE name RENAME CONSTRAINT**.

〈add table supplemental log statement〉

It sets to add information to the redo log when the data is altered in the table.
For more information, refer to **ALTER TABLE name ADD SUPPLEMENTAL LOG**.

〈drop table supplemental log statement〉

It sets not to add information to the redo log when the data is altered in the table.
For more information, refer to **ALTER TABLE name DROP SUPPLEMENTAL LOG**.

〈rebalance statement〉

It restores the data file matching by rebalancing the shard of the table or by synchronizing the broken sha rd in a cluster environment.
For more information, refer to **ALTER TABLE name REBALANCE**.

〈alter table synchronize statement〉

It restores the data file matching by synchronizing the existing offline shards in cluster environment.
For more information, refer to **ALTER TABLE name SYNCHRONIZE**.

〈move shard statement〉

It rebalances a specific shard of a table on a specific cluster group in a cluster environment.
For more information, refer to **ALTER TABLE name MOVE SHARD** .

〈merge shards statement〉

It merges specific shards in a table in a cluster environment, then rebalances them.
For more information, refer to **ALTER TABLE name MERGE SHARDS**.

〈split shard statement〉

It rebalances a specific shard of a table on a specific cluster group by splitting the shard in a cluster enviro nment.
For more information, refer to **ALTER TABLE name SPLIT SHARD**.

〈rename shard statement〉

It renames a specific shard of a table in cluster environment.
For more information, refer to **ALTER TABLE name RENAME SHARD**.

〈read { only | write } statement〉

It sets READ (only | write } to a table.
For more information, refer to **ALTER TABLE name READ { ONLY | WRITE }**.

Description

For more information, refer to the description of each detailed statement.

Example

Refer to the examples of each detailed statement.

Compatibility

The SQL standard does not define the following statements.

- 〈alter table physical attribute statement〉
- 〈rename table statement〉
- 〈rename column statement〉
- 〈rename table constraint statement〉
- 〈add table supplemental log statement〉
- 〈drop table supplemental log statement〉
- 〈rebalance statement〉
- 〈move shard statement〉
- 〈split shard statement〉
- 〈rename shard statement〉
- 〈read { only | write } statement〉

18.48 ALTER TABLE name ADD COLUMN

Function

It adds a column to the table.

Syntax

```
<add column definition> ::=
      ALTER TABLE table_name ADD [ COLUMN ] <column definition>
    ¦ ALTER TABLE table_name ADD [ COLUMN ] ( <column definition> [, ...] )
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <add column definition>.

- At least one of the following privileges is required to alter the table.
  - (ALTER or CONTROL TABLE) ON TABLE for that table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - ALTER ANY TABLE ON DATABASE

- If the constraints are specified with the added columns, the conditions should be satisfied to generate the constraints as follows.
  - One of the following privileges is required for the schema in which constraints are to be generated.
    - (ADD CONSTRAINT or CONTROL SCHEMA) ON SCHEMA for the schema
    - ALTER ANY TABLE ON DATABASE
  - If the key constraint is to be generated, one of the following privileges is required for the tablespace in which an index is to be created.
    - CREATE OBJECT ON TABLESPACE for the tablespace
    - USAGE TABLESPACE ON DATABASE

- The table owner has the following privileges for the added columns.
  - Privileges on all added columns
    - SELECT(columns) ON TABLE WITH GRANT OPTION

        - INSERT(columns) ON TABLE WITH GRANT OPTION
        - UPDATE(columns) ON TABLE WITH GRANT OPTION
        - REFERENCES(columns) ON TABLE WITH GRANT OPTION
    - Privilege on the constraint generated together
        - The owner of that constraint
        - The index owner generated together with the constraint

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

ADD [COLUMN]

The reserved word COLUMN can be omitted.

〈column definition〉

It defines the column to be added. For more information, refer to **〈column definition〉** clause of **CREATE TABLE** statement.
There should not be columns with the same name in a table.

If DEFAULT clause is specified when defining the column, the default value of all rows are stored in the added column.
If 〈identity column specification〉 clause is specified when defining the column, each automatically generated value of all rows is stored in the added column.
If NOT NULL constraint is specified when defining the column, the table should be empty or it should be specified together with DEFAULT or 〈identity column specification〉 clause.

(〈column definition〉 [, ...])

It adds multiple columns.
It lists multiple 〈column definition〉 inside the parentheses.

Description

The added column is positioned at the end of the existing columns.
When specifying DEFAULT or <identity column specification> clause, the processing time is increased in p roportion to the number of the rows in the table.

Examples

The following is an example of adding a column.

```
gSQL> ALTER TABLE region ADD COLUMN r_new_comment VARCHAR(152);
Table altered.
```

The following is an example of adding multiple columns.

```
gSQL> ALTER TABLE partsupp ADD COLUMN (
   ps_retailprice NUMERIC(12,2),
   ps_acctbal NUMERIC(12,2), ps_mktsegment  CHAR(10) );
Table altered.
```

The following is an example of adding the identity column and the column including DEFAULT clause.

```
gSQL> ALTER TABLE region ADD COLUMN (
    r_regionkey INTEGER GENERATED BY DEFAULT AS IDENTITY PRIMARY KEY,
    r_comment   VARCHAR(152) DEFAULT 'N/A' );
Table altered.
gSQL> SELECT r_regionkey, r_name, r_comment FROM region;
R_REGIONKEY R_NAME                    R_COMMENT
----------- ------------------------- ---------
          1 AFRICA                    N/A
          2 AMERICA                   N/A
          3 ASIA                      N/A
          4 EUROPE                    N/A
          5 MIDDLE EAST               N/A
5 rows selected.
```

The following is an example of adding the column including the deferrable constraint.

```
gSQL> ALTER TABLE t1 ADD COLUMN ( id INTEGER CONSTRAINT t1_uk UNIQUE DEFERRABLE );
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define of adding multiple column definitions.

For More Information

Refer to the followings.

- ALTER TABLE
- ALTER TABLE name SET UNUSED COLUMN
- ALTER TABLE name ALTER COLUMN
- ALTER TABLE name RENAME COLUMN

18.49 ALTER TABLE name ADD CONSTRAINT

Function

It adds a table constraint.

Syntax

```
<add table constraint definition> ::=
    ALTER TABLE table_name
        ADD <table constraint definition>
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <add table constraint definition> clause.

- One of the following privileges is required on the table to create the constraint.
  - (ALTER or CONTROL TABLE) ON TABLE for that table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - ALTER ANY TABLE ON DATABASE

- One of the following privileges is required on the schema to create the constraint.
  - (ADD CONSTRAINT or CONTROL SCHEMA) ON SCHEMA for the schema
  - ALTER ANY TABLE ON DATABASE

- One of the following privileges is required for the tablespace in which the index is to be created to cr eate the key constraint
  - CREATE OBJECT ON TABLESPACE for the tablespace
  - USAGE TABLESPACE ON DATABASE

- The owner of the created constraint is determined as follow.
  - The owner of the schema to which the constraint belongs.
  - If the schema to which the constraint belongs is PUBLIC, then it is the user who executed the stat ement.

Constraints of PRIMARY KEY, UNIQUE in a cluster system should include all sharding keys.

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

〈table constraint definition〉

It defines the constraint to be added.
NOT NULL constraint can not be added by using ALTER TABLE .. ADD CONSTRAINT statement, and it can be defined by using **ALTER TABLE name ALTER COLUMN** statement as follows.

```
ALTER TABLE t1 ALTER COLUMN c1 SET NOT NULL;
```

For more information, refer to **〈table constraint definition〉** clause of **CREATE TABLE** statement.

Description

When adding the key constraints such as primary key, unique key, the index is automatically created for t hem.

Examples

The following is an example of adding the primary key constraint to the table.

```
gSQL> ALTER TABLE t1 ADD PRIMARY KEY ( id );
Table altered.
```

The following is an example of specifying the constraint name when adding a primary key constraint to th e table.

```
gSQL> ALTER TABLE t1 ADD CONSTRAINT t1_pk PRIMARY KEY ( id );
Table altered.
```

The following is an example of adding a DEFERRABLE constraint.

```
gSQL> ALTER TABLE t1 ADD CONSTRAINT t1_uk UNIQUE ( id ) DEFERRABLE INITIALLY DEFERRED;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

Table 18-4 SQL standard compatibility

Feature ID	Description	Compatibility
F381	Extended schema manipulation	O

For More Information

Refer to the followings.

- CREATE TABLE
- CREATE INDEX
- ALTER TABLE
- ALTER TABLE name DROP CONSTRAINT

18.50 ALTER TABLE name ADD GLOBAL SECONDARY INDEX

Function

It creates a global secondary index in a table.

Syntax

```
<alter table add global secondary index definition> ::=
    ALTER TABLE table_name
        ADD GLOBAL SECONDARY INDEX
        [ <index attributes> [...] ] [ TABLESPACE tablespace_name ]
    ;
<index attributes> ::=
      <physical attribute clause>
    ¦ STORAGE ( <segment attr clause> [...] )
    ¦ <parallel clause>
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
<parallel clause> ::=
      NOPARALLEL
    ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

〈alter table add global secondary index definition〉 can be defined in a cluster system, and a user should s atisfy the following conditions.

- At least one of the following privileges for a table in which the index is to be created is required.
  - (ALTER or CONTROL TABLE) ON TABLE for that table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs.
  - ALTER ANY TABLE ON DATABASE

- At least one of the following privileges for a tablespace in which the index is to be created is required.
  - CREATE OBJECT ON TABLESPACE for that tablespace
  - USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a table in which the index is to be created.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.

〈physical attribute clause〉

It defines the physical attribute information of the index.

- PCTFREE integer
  - Definition
    - The reserved space to adjust the frequency of page splits caused by inserting the key in the p age.
    - It is applied only when the index bottom-up build.
  - It can use of the value from 0 to 99.
  - If it is omitted, the value set in DEFAULT_INDEX_PCTFREE property is used by default.

- INITRANS integer
  - Definition
    - The initial number of transactions simultaneously accessing the page.
    - If the number of users accessing the index is small, then INITRANS is set low. If the number o f users simultaneously accessing the index is big, then INITRANS is set high.
    - If necessary, it is automatically increased to the specified MAXTRANS.

- It can use the value from 1 to 32.
- If it is omitted, the default value is 4.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transaction simultaneously accessing the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 8.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the ind ex.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
    - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the table belongs.

- NEXT integer
  - Definition
    - It specifies the physical space size to be allocated when adding the space to the index.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
    - NEXT operates as follows, depending on the remaining space size of the index available curr ently. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS si ze)

    - If the remaining space size is 0, then it can not extend the space.
    - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the space as big as the remaining space.
    - If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the index belongs.

- MINSIZE integer
  - Definition
    - It is the minimum space size of the index.
    - The value should be equal to or smaller MAXSIZE.

    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
    - If it is omitted, the default value is the size of two EXTENT.

- MAXSIZE integer
    - Definition
        - It is the maximum space size of the index.
        - The value should be equal to or bigger than MINSIZE.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is omitted, the default value is EXTENT size * 2147483647(The maximum positive integer of I NT32).

〈size clause〉

It specifies the file size in byte. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

NOPARALLEL | PARALLEL [integer]

It specifies the number of threads to be used when building an index.

- NOPARALLEL
    - It does not build an index in parallel.
- PARALLEL [integer]
    - It builds an index in parallel.
    - If an integer is omitted or set as 0, then it follows the property (INDEX_BUILD_PARALLEL_FACTO R).
    - The minimum value of an intege is 0 and the maximum value is 16.
    - If the property value is 0, then the system determines the optimal value.
- If it is omittted, the default value is PARALLEL.

TABLESPACE tablespace_name

It specifies the name of the tablespace in which the index is to be stored.

- If it specifies tablespace_name

    - tablespace_name should be a data tablespace to switch to the LOGGING index.
    - tablespace_name should be a temporary tablespace or a nologging tablespace to switch to the NOLOGGING index

- If it omits TABLESPACE clause, then it follows the settings of the existing index.

Description

A non-deterministic query requires the global secondary index. LOGGING index and NOLOGGING inde have the following trade-offs.

- LOGGING index
    - Advantage: It does not separately build an index because the index is automatically restored by using the log when starting up the system.
    - Disadvantage: A disk I/O occur because the changes on the index is recorded on the log when altering the row.
- NOLOGGING index
    - Advantage: A disk I/O does not occur for the changes on the index when altering the row.
    - Disadvantage: It automatically rebuilds the index when starting up the system because the log information of the index does not exist.

Examples

The following is an example of adding a global secondary index to the table T1.

```
gSQL> ALTER TABLE T1 ADD GLOBAL SECONDARY INDEX;
Table altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of creating a global secondary index as a logging index on the tablespace USER_DATA_TBS of table T1.

```
gSQL> ALTER TABLE T1 ADD GLOBAL SECONDARY INDEX LOGGING TABLESPACE USER_DATA_TBS;
Table altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of creating a global secondary index as a nologging index on the tablespace

USER_TEMP_TBS of table T1.

```
gSQL> ALTER TABLE T1 ADD GLOBAL SECONDARY INDEX NOLOGGING TABLESPACE USER_TEMP_TBS;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define the concepts of the global secondary index.

For More Information

Refer to the followings.

- ALTER TABLE name DROP GLOBAL SECONDARY INDEX
- ALTER TABLE name ALTER GLOBAL SECONDARY INDEX
- CREATE TABLE

18.51 ALTER TABLE name ADD SUPPLEMENTAL LOG

Function

If the primary key exists in the table when table data is altered, it sets to add the primary key value to redo log.

Syntax

```
<add table supplemental log statement> ::=
    ALTER TABLE table_name
        ADD SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <add table supplemental log statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

Even when the primary key does not exist in the table, the statement can be executed.

Description

It additionally records SUPPLEMENTAL LOG when executing UPDATE/DELETE on the corresponding TABLE. The recorded SUPPLEMENTAL LOG is used to analyze logs or tools such as CDC.

To record SUPPLEMENTAL LOG of every TABLE, set the property as *SUPPLEMENTAL_LOG_DATA_PRIMARY_KEY = YES*.

Example

The following is an example of setting to additionally add a primary key value to the redo log when changing the data in the table.

```
gSQL> ALTER TABLE t1 ADD SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS;
Table altered.
```

Compatibility

The SQL standard does not cover <add table supplemental log statement>.

For More Information

Refer to **ALTER TABLE name DROP SUPPLEMENTAL LOG**.

18.52 ALTER TABLE name ALTER COLUMN

Function

It alters the column definition.

Syntax

```
<alter column definition> ::=
    ALTER TABLE table_name
        ALTER [ COLUMN ] column_name <alter column action>
<alter column action> ::=
      <set column default clause>
    ¦ <drop column default clause>
    ¦ <set column not null clause>
    ¦ <drop column not null clause>
    ¦ <alter column data type clause>
    ¦ <alter identity column specification>
    ¦ <drop identity property clause>
    ;
<set column default clause> ::=
    SET DEFAULT <default option>
<drop column default clause> ::=
    DROP DEFAULT
<set column not null clause> ::=
    SET [ CONSTRAINT constraint_name ] NOT NULL [ <constraint characteristics> ]
<constraint characteristics> ::=
      [ NOT ] DEFERRABLE [ <constraint check time> ]
    ¦ <constraint check time> [ [ NOT ] DEFERRABLE ]
<constraint check time> ::=
      INITIALLY DEFERRED
    ¦ INITIALLY IMMEDIATE
<drop column not null clause> ::=
    DROP NOT NULL
<alter column data type clause> ::=
    SET DATA TYPE <data type>
<alter identity column specification> ::=
```

```
     <set identity column generation clause> [ <alter identity column option> ... ]
   ¦ <alter identity column option> ...
<set identity column generation clause> ::=
   SET GENERATED { ALWAYS ¦ BY DEFAULT }
<alter identity column option> ::=
     <alter sequence generator restart option>
   ¦ [ SET ] <basic sequence generator option>
<alter sequence generator restart option> ::=
    RESTART [ WITH integer ]
<basic sequence generator option> ::=
      <sequence generator increment by option>
    ¦ <sequence generator maxvalue option>
    ¦ <sequence generator minvalue option>
    ¦ <sequence generator cycle option>
    ¦ <sequence generator cache option>
<drop identity property clause> ::=
    DROP IDENTITY
```

Invocation and Access Rules

One of the following privileges is required to performing <alter column definition>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

ALTER [COLUMN]

The reserved word COLUMN can be omitted.

column_name

It is the column name to be altered.

〈set column default clause〉

It sets the default value of the column.
It should not be an identity column.

The default value set when using the DEFAULT clause is used in INSERT statement later.

The data type of DEFAULT expression should be compatible with the data type of the column.
If the data type is not compatible or the expression is not valid, an error occurs.

For more information, refer to **〈default clause〉** of **CREATE TABLE** statement.

〈drop column default clause〉

It drops the default value of the column.
It should not be an identity column.
If the default value is dropped, NULL is set when using DEFAULT clause in INSERT statement.

〈set column not null clause〉

- SET [CONSTRAINT constraint_name] NOT NULL [〈constraint characteristics〉]
  - It sets NOT NULL constraint on the column.
  - NULL is not allowed as the column value.
  - NULL should not exist in the column.

- If [CONSTRAINT constraint_name] is omitted, the constraint name is automatically given.
- If 〈constraint characteristics〉 is omitted, it has NOT DEFERRABLE INITIALLY IMMEDIATE property.
- The Identity column can not have DEFERRABLE property.

For more information about the DEFERRABLE constraint, refer to **SET CONSTRAINTS**.

〈drop column not null clause〉

- DROP NOT NULL
  - It drops NOT NULL constraint from the column.

〈alter column data type clause〉

- SET DATA TYPE 〈data type〉
  - It changes the data type of the column.

SET DATA TYPE is a DDL statement which is automatically committed.

The type conversion can be executed among the same family, and it should satisfy the following conditio ns.

Table 18-5 Conversion of character string type

from ₩ to	CHAR(n)	VARHCAR(n)	LONG VARCHAR
CHAR(m)	X	X	X
VARCHAR(m)	X	n >= m	X

from ₩ to	ROWID
ROWID	O

〈alter identity column specification〉

It alters the identity property of the column.
The column should be an identity column.

- SET GENERATED [ALWAYS | BY DEFAULT]
  - It changes the method of generating the identity column.
  - For more information, refer to **〈identity column specification〉** of **CREATE TABLE** statement.
- 〈alter sequence generator restart option〉
  - It changes NEXT VALUE of the identity column.
  - For more information, refer to **〈alter sequence generator restart option〉** clause of **ALTER SEQUENCE** statement.
- 〈basic sequence generator option〉
  - It changes the property of the identity column.
  - In SQL standard, it is defined to be described in the form of SET 〈basic sequence generator option〉, but it can be omitted.
  - For more information, refer to **ALTER SEQUENCE** statement.

〈drop identity property clause〉

It drops the identity property of the column.
The column should be the identity column.

Description

SET NOT NULL clause requires the time for checking null in proportion to the number of table rows.

The following columns do not allow NULL values. In other words, even if DROP NOT NULL clause is perfor med, NULL is not allowed in the following cases.

- A column which includes NOT NULL constraint
- A column which is included in primary key constraint
- An identity column

The change of the default value using SET DEFAULT clause and the change of the identity property using <alter identity column specification> clause, is applied to INSERT or UPDATE statement which is performe d later.

Examples

The following is an example of setting DEFAULT property to the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_comment SET DEFAULT 'N/A';
Table altered.
```

The following is an example of dropping DEFAULT property from the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_comment DROP DEFAULT;
Table altered.
```

The following is an example of setting NOT NULL constraint to the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_regionkey SET NOT NULL;
Table altered.
```

The following is an example of dropping the NOT NULL constraint from the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_regionkey DROP NOT NULL;
Table altered.
```

The following is an example of extending the data type size of the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_comment SET DATA TYPE VARCHAR(512);
Table altered.
```

The following is an example of restarting the next value of the identity column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_regionkey RESTART;
Table altered.
```

The following is an example of dropping the identity property from the column.

```
gSQL> ALTER TABLE region ALTER COLUMN r_regionkey DROP IDENTITY;
Table altered.
```

Refer to the followings.

- **ALTER TABLE**
- **ALTER TABLE name ADD COLUMN**
- **ALTER TABLE name SET UNUSED COLUMN**
- **ALTER TABLE name RENAME COLUMN**

18.53 ALTER TABLE name ALTER CONSTRAINT

Function

It alters the characteristics of the table constraint.

Syntax

```
<alter table constraint definition> ::=
    ALTER TABLE table_name
        ALTER <constraint object> <constraint characteristics>
    ;
<constraint object> ::=
      CONSTRAINT constraint_name
    ¦ PRIMARY KEY
    ¦ UNIQUE ( column_name [, ...] )
<constraint characteristics> ::=
      [ NOT ] DEFERRABLE [ <constraint check time> ]
    ¦ <constraint check time> [ [ NOT ] DEFERRABLE ]
<constraint check time> ::=
      INITIALLY DEFERRED
    ¦ INITIALLY IMMEDIATE
```

Invocation and Access Rules

One of the following privileges is required to perform <alter table constraint definition>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Cluster does not support the deferrable constraints.

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

〈constraint object〉

The constraint to be altered is specified as follows.

- CONSTRAINT constraint_name
  - The constraint name to be altered.
- PRIMARY KEY
  - PRIMARY KEY constraint of the table
- UNIQUE(column [,...])
  - UNIQUE constraint which satisfies the column list.

DEFERRABLE | NOT DEFERRABLE

It alters whether the constraint state is deferrable.

- DEFERRABLE
  - The constraint is altered to be deferrable.
- NOT DEFERRABLE
  - The constraint is altered not to be deferrable.

For more information about the deferrable constraints, refer to **SET CONSTRAINTS**.

INITIALLY IMMEDIATE | INITIALLY DEFERRED

It alters an initial value of the check point for the constraint.

- INITIALLY IMMEDIATE
  - It checks the constraints at the time of DML.
- INITIALLY DEFERRED
  - It checks the constraints at the time of COMMIT.

The constraints defined as NOT DEFERRABLE can not be altered to INITIALLY DEFERRED.

Description

For more information about the deferrable constraints, refer to **SET CONSTRAINTS**.

Example

The following is an example that the constraint t1_uk is set as deferrable and its checking time is set as D EFERRED.

```
gSQL> ALTER TABLE t1 ALTER CONSTRAINT t1_uk DEFERRABLE INITIALLY DEFERRED;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define the following clauses.

- ALTER PRIMARY KEY clause
- ALTER UNIQUE(column [,...]) clause

Table 18-18 SQL standard compatibility

Feature ID	Description	Compatibility
F492	Optional table constraint enforcement	X

18.54 ALTER TABLE name ALTER GLOBAL SECONDARY INDEX

Function

It alters the physical attributes of the global secondary index in the table.

Syntax

```
<alter table alter global secondary index storage statement> ::=
    ALTER TABLE table_name ALTER GLOBAL SECONDARY INDEX
      <physical attribute clause>
    ¦ [ STORAGE ( <segment attr clause> [...] ) ]
    ;
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
```

Invocation and Access Rules

One of the following privileges is required to perform <alter table alter global secondary index storage statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a table in which the index is to be created.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.

〈physical attribute clause〉

It defines the physical attribute information of the index.

- PCTFREE integer
  - Definition
    - The reserved space to adjust the frequency of page splits caused by inserting the key in the page.
    - It is applied only when the index bottom-up build.
  - It can use of the value from 0 to 99.
  - If it is omitted, the value set in DEFAULT_INDEX_PCTFREE property is used by default.

- INITRANS integer
  - Definition
    - The initial number of transactions simultaneously accessing the page.
    - If the number of users accessing the index is small, then INITRANS is set low. If the number of users simultaneously accessing the index is big, then INITRANS is set high.
    - If necessary, it is automatically increased to the specified MAXTRANS.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 4.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transaction simultaneously accessing the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 8.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition

        - It specifies the size of physical storage space which is initially allocated when creating the ind ex.
        - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
        - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
    - The minimum value is 1, and the maximum value depends on the system environment.
    - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the table belongs.

- NEXT integer
    - Definition
        - It specifies the physical space size to be allocated when adding the space to the table.
        - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
        - NEXT operates as follows, depending on the remaining space size of the index available curr ently. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS si ze)

      - If the remaining space size is 0, then it can not extend the space.

      - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the space as big as the remaining space.

      - If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the index belongs.

- MINSIZE integer
    - Definition
        - It is the minimum space size of the index.
        - The value should be equal to or smaller MAXSIZE.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment.
    - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
    - If it is omitted, the default value is the size of two EXTENT.

- MAXSIZE integer
    - Definition
        - It is the maximum space size of the index.
        - The value should be equal to or bigger than MINSIZE.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
    - The minimum value is 1 and the maximum value depends on the system environment
    - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
    - If it is omitted, the default value is 32 terabytes (35,184,372,088,832).
    - Even though the value is set to over 32 terabytes, it is adjusted and set to 32 terabytes.
    - If the newly allocated space is smaller than the already allocated space, then an error occurs.

〈size clause〉

It specifies the file size in byte. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

Description

A global secondary index is required to enquire a non-deterministic query.

Examples

It alters the maximum available size to be used by a global secondary index in the table T1 to 100 MBytes.

```
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX STORAGE( MAXSIZE 100M );
Table altered.
gSQL> COMMIT;
Commit complete.
```

It alters the INITRANS value and the MAXTRANS value to 2 and 4 each which are to be used by a global s econdary index in the table T1

```
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX INITRANS 2 MAXTRANS 4;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define the concepts of the global secondary index.

For More Information

Refer to the followings.

- **ALTER TABLE name ADD GLOBAL SECONDARY INDEX**
- **ALTER TABLE name DROP GLOBAL SECONDARY INDEX**

18.55 ALTER TABLE name ALTER GLOBAL SECONDARY INDEX COALESCE

Function

It drops the fragmentation of the global secondary index.

Syntax

```
<global secondary index coalesce statement> ::=
    ALTER TABLE table_name ALTER GLOBAL SECONDARY INDEX COALESCE
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <global secondary index coalesce.

- At least one of the following privileges for a table in which the index is to be rebuilt is required.
  - (ALTER or CONTROL TABLE) ON TABLE for that table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs.
  - ALTER ANY TABLE ON DATABASE

- At least one of the following privileges for a tablespace in which the index is to be created is required.
  - CREATE OBJECT ON TABLESPACE for that tablespace
  - USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of the target table.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

Description

- It sequentially scans leaf pages and coalesces them when it is allowed to do so, then returns the delet ed pages to the segment.
- It can solve the fragmentation problem of leaf pages which occurred due to UPDATE/ DELETE.
- It is operated only when the adjacent leaf pages are allowed to coalesce, so if the fragmentation level is low, then it may not be effective.
- If the fragmentation level of the index is high, then the processing time may take longer than INDEX REBUILD.

Table 18-19 Comparing to INDEX REBUILD

	INDEX REBUILD	INDEX COALESCE
Altering index attributes	Possible	Impossible
Moving tablespace	Possible	Impossible
Locking table	Required	Not required
Additional space for execution	Required	Not required
Decreasing tree height	Possible	Impossible

Examples

It drops the fragmentation of the global secondary index in table T1.

```
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX COALESCE;
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the global secondary index.

For More Information

Refer to **ALTER TABLE name ALTER GLOBAL SECONDARY INDEX REBUILD**.

18.56 ALTER TABLE name ALTER GLOBAL SECONDARY INDEX REBUILD

Function

It rebuilds a global secondary index

Syntax

```
<global secondary index rebuild statement> ::=
    ALTER TABLE table_name ALTER GLOBAL SECONDARY INDEX REBUILD
        [ ONLINE ¦ OFFLINE ]
        [ <index attributes> [...] ]
        [ TABLESPACE tablespace_name ]
    ;
<index attributes> ::=
      <physical attribute clause>
    ¦ STORAGE ( <segment attr clause> [...] )
    ¦ <parallel clause>
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
<parallel clause> ::=
      NOPARALLEL
    ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <global secondary index rebuild statement>.

- One of the following privileges is required for the table on which the index is to be rebuilt.
  - (ALTER or CONTROL TABLE) ON TABLE for the table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - ALTER ANY TABLE ON DATABASE

- One of the following privileges is required for the tablespace on which the index is to be rebuilt.
  - CREATE OBJECT ON TABLESPACE for the tablespace
  - USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name on which the index is to be rebuilt.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

[ONLINE | OFFLINE]

It determines whether to allow DML on the table when rebuilding the index.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

<physical attribute clause>

It defines the physical attribute information of an index.

- PCTFREE integer
  - Definition
    - It is the reserved space for adjusting the page split frequency caused by the key inserted in th e page.

- It can use the value from 0 to 99.
- If it is omitted, the default value is the value set in the existing index.

- INITRANS integer
  - Definition
    - It specifies the initial number of transactions which can simultaneously access the page.
    - If the number of users who access the index is small, INITRANS is set to low, and if the numb er of users who simultaneously access the index is big, INITRANS is set to high.
    - If necessary, it is automatically increased to the specified MAXTRANS.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is the value set in the existing index.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transactions which can simultaneously access the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is the value set in the existing index.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the ind ex.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
    - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

- NEXT integer
  - Definition
    - It specifies the physical space size to be allocated when adding the space to the table.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
    - NEXT operates as follows, depending on the remaining space size of the index available curr ently. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS si ze)

    - If the remaining space size is 0, then it can not extend the space.
    - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the

space as big as the remaining space.
- If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

- MINSIZE integer
  - Definition
    - It is the minimum space size of the index.
    - The value should be equal to or smaller MAXSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
  - If it is omitted, the default value is the value set in the existing index.

- MAXSIZE integer
  - Definition
    - It is the maximum space size of the index.
    - The value should be equal to or bigger than MINSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is the value set in the existing index.

〈size clause〉

It specifies the file size in bytes. (If the unit is omitted, the default value is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

NOPARALLEL | PARALLEL [integer]

It specifies the number of threads to be used when rebuilding an index.

- NOPARALLEL
  - It does not rebuild an index in parallel.
- PARALLEL [integer]
  - It rebuilds an index in parallel.
  - If an integer is omitted or set as 0, then it follows INDEX_BUILD_PARALLEL_FACTOR property.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer or the property value is 0, then the system determines the optimal value.

- If it is omitted, the default value is NOPARALLEL.

TABLESPACE tablespace_name

It specifies the name of the tablespace in which the index is to be rebuilt.

- When it specifies tablespace_name
  - if tablespace_name is data tablespace, then it is rebuilt as a LOGGING index.
  - if tablespace_name is temporary tablespace or nologging tablespace, then it is rebuilt as a NOLOGGING index.
- When TABLESPACE clause is omitted, then it is set to the tablespace of the existing index.

Description

- Dropping the index fragmentation
  - The fragmentation may occur on the index page, when update DML is frequently performed in the index. If the tree becomes too big comparing to the valid data, then the index volume becomes larger and the performance is degraded. In this case, rebuilding the index can solve the index fragmentation issue so that the index volume is reduced and the index performance is recovered.
- Altering the tablespace in the index
  - The tablespace in the previously created index can be altered.
  - However, LOGGING should be set properly according to whether the tablespace is TEMPORARY or not.
- Altering LOGGING setting in the index
  - The LOGGING setting in the previously created index can be altered by using TABLESPACE option.
  - The data tablespace should be set in TABLESPACE option to switch to the LOGGING index.
  - The temporary tablespace or the nologging tablespace should be set in TABLESPACE option to switch to the NOLOGGING index.

Examples

Rebuild the global secondary index in the table T1.

```
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX REBUILD;
```

Alter the tablespace and logging settings of the global secondary index in the table T1.

```
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX REBUILD TABLESPACE MEM_DATA_TBS;
gSQL> ALTER TABLE T1 ALTER GLOBAL SECONDARY INDEX REBUILD TABLESPACE MEM_TEMP_TBS;
```

Compatibility

The SQL standard does not cover the concepts of the global secondary index.

For More Information

Refer to the followings.

- ALTER TABLE name ADD GLOBAL SECONDARY INDEX
- ALTER TABLE name DROP GLOBAL SECONDARY INDEX
- ALTER INDEX name REBUILD

18.57 ALTER TABLE name DROP CONSTRAINT

Function

It drops a table constraint.

Syntax

```
<drop table constraint definition> ::=
    ALTER TABLE table_name
        DROP <constraint object>
        [ <drop behavior> ]
    ;
<constraint object> ::=
      CONSTRAINT constraint_name
    ¦ PRIMARY KEY
    ¦ UNIQUE ( column_name [, ...] )
<drop behavior> ::=
      RESTRICT
    ¦ CASCADE
    ¦ CASCADE CONSTRAINTS
```

Invocation and Access Rules

One of the following privileges is required to perform <drop table constraint definition>.

- The owner of that constraint
- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

CONSTRAINT constraint_name

It is the constraint name to be dropped.

PRIMARY KEY

It is the primary key constraint for the table.

UNIQUE(column_name [, ...])

It is the unique constraint for the columns.

〈drop behavior〉

When it is omitted, the default value is RESTRICT.
Currently, RESTRICT/CASCADE is operated in the same way.

Description

〈drop column not null clause〉 of **ALTER TABLE name ALTER COLUMN** is used to drop NOT NULL constrai nt without using the constraint name.

Examples

The following is an example of dropping a primary key constraint from the table.

```
gSQL> ALTER TABLE t1 DROP PRIMARY KEY;
Table altered.
```

The following is an example of dropping the table constraint by specifying the constraint name.

```
gSQL> ALTER TABLE t1 DROP CONSTRAINT t1_pk;
Table altered.
```

Compatibility

The SQL standard does not define the following clauses.

- DROP PRIMARY KEY
- DROP UNIQUE (column_name [, ...])
- CASCADE CONSTRAINTS

Table 18-20 SQL standard compatibility

Feature ID	Description	Compatibility
F381	Extended schema manipulation	O

For More Information

Refer to the followings.

- **ALTER TABLE**
- **ALTER TABLE name ADD CONSTRAINT**
- **DROP INDEX**

18.58 ALTER TABLE name DROP GLOBAL SECONDARY INDEX

Function

It drops a global secondary index from the table.

Syntax

```
<alter table drop global secondary index definition> ::=
    ALTER TABLE table_name
        DROP GLOBAL SECONDARY INDEX
    ;
```

Invocation and Access Rules

<alter table drop global secondary index definition> statement can be defined in a cluster system, and the user should satisfy the following conditions.

- The following privilege for the table from which the index is to be dropped is required
  - (ALTER or CONTROL TABLE) ON TABLE for that table
  - (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a table from which the index is to be dropped.

Description

A global secondary index is required to enquire a non-deterministic query.

Examples

It drops a global secondary index from the table T1.

```
gSQL> ALTER TABLE T1 DROP GLOBAL SECONDARY INDEX;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define the concepts of the global secondary index.

For More Information

Refer to the followings.

- ALTER TABLE name ADD GLOBAL SECONDARY INDEX
- ALTER TABLE name ALTER GLOBAL SECONDARY INDEX

18.59 ALTER TABLE name DROP OFFLINE SEGMENTS

Function

It drops segments of offline shards.

Syntax

```
<alter table drop offline segments statement> ::=
    ALTER TABLE table_name
        DROP OFFLINE SEGMENTS
;
```

Invocation and Access Rules

It can be performed in the cluster system.

One of the following privilege is required to perform <alter table drop offline segments statement>.

- (ALTER or CONTROL TABLE) ON TABLE for the table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

Description

It drops segments of offline shards.

<alter table drop offline segments statement> can be performed even when an inactive cluster member exists.

If it can not satisfy the following conditions, then it fails.

- At least one member of the cluster system should have the online replica of the cloned table to drop the segments of the cloned table.
- At least one member per group should have the online replica of the sharded table to drop the segments of the sharded table.

For example, if all replicas in cluster group G3 of the sharded table t1 are offline, then the following error occurs.

```
gSQL> ALTER TABLE t1 DROP OFFLINE SEGMENTS;
ERR-42000(16361): sharded table "PUBLIC"."T1" must be accessible to at least one member of
group 'G3'
```

Use **<alter database drop offline segments statement>** to perform it for all tables.

Example

The following is an example of performing <alter table drop offline segments statement> for the table T1.

```
gSQL> ALTER TABLE t1 DROP OFFLINE SEGMENTS;
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER DATABASE DROP OFFLINE SEGMENTS**.

18.60 ALTER TABLE name DROP SUPPLEMENTAL LOG

Function

It sets not to leave the primary key information on the redo log when changing the data in the table.

Syntax

```
<add table supplemental log statement> ::=
    ALTER TABLE table_name
        DROP SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <drop table supplemental log statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.
It should have been set by using **ALTER TABLE name ADD SUPPLEMENTAL LOG** statement.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of setting not to leave the primary key information on the redo log when cha nging the data in the table.

```
gSQL> ALTER TABLE t1 DROP SUPPLEMENTAL LOG DATA ( PRIMARY KEY ) COLUMNS;
Table altered.
```

Compatibility

The SQL standard does not cover <drop table supplemental log statement>.

18.61 ALTER TABLE name MERGE SHARDS

Function

It merges specific shards in a table in a cluster environment, and rebalances them.

Syntax

```
<alter table merge shards statement> ::=
    ALTER TABLE table_name MERGE SHARDS <source shard list>
       INTO dest_shard_name [ <dest shard placement> ]
    ;
<source shard list> ::=
    source_shard_name [, ...]
  | start_shard_name TO end_shard_name
<dest shard placement> ::=
    AT CLUSTER GROUP dest_group_name
```

Invocation and Access Rules

It can be performed in the cluster system.

One of the following privilege is required to perform <alter table merge shards statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a table.
It can define a schema to which the table belongs such as schema_name.table_name. If schema_name is

omitted, the default schema name of the user performing the statement is used.
The statement can be performed only when the table is a cluster-specific, and a list shard or a range shar d.

〈source shard list〉

It is the list of original shards to be merged.
The shard specified by a list should exist in the table.

source_shard_name

It is the name of an original shard to be merged.
If the shard does not exist in the table, then the statement can not be performed.

start_shard_name

It is the name of the first shard in the range of merging.
It is used only in a range shard.

end_shard_name

It is the name of the last shard in the range of merging.
It is used only in a range shard.

dest_shard_name

It is the name of a target shard.

〈dest shard placement〉

It is the name of a cluster group in which the target shard is to be placed.
If the corresponding clause is omitted, *dest_shard_name* should be included in 〈source shard list〉.

Description

It merges specific shards in a specific table, then places them in an arbitrary cluster group.

- It can not be performed in a standalone database.

- It can not be performed in a hash sharded table nor in a cloned table.
- It can not be performed in a table created as cluster wide.
- DML can not be performed for source shards while merging is in progress.
- If it is a range shard, the beginning and ending original shards to be merged can be defined.
- Original shards to be merged can be listed in a range shard or a list shard.
  In this case, shards listed in a range shard should be the neighboring shard.

The following is an error which occurred when merging shards which are not neighboring in a range shar ded table in a way of listing.

```
CREATE TABLE t1( i1 INTEGER )
    SHARDING BY RANGE (i1)
    SHARD shard1 VALUES LESS THAN ( 200 )      AT CLUSTER GROUP G1,
    SHARD shard2 VALUES LESS THAN ( 400 )      AT CLUSTER GROUP G2,
    SHARD shard3 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP G3
;
Table created.
ALTER TABLE t1 MERGE SHARDS shard1, shard3 INTO shard4 AT CLUSTER GROUP G2;
ERR-42000(16488): shards being merged are not adjacent :
ALTER TABLE t1 MERGE SHARDS shard1, shard3 INTO shard4 AT CLUSTER GROUP G2
                                    *
ERROR at line 1:
```

Examples

The following is an example of merging shards in a way of listing.

```
gSQL> ALTER TABLE t1 MERGE SHARDS shard1, shard2, shard3 INTO shard4 AT CLUSTER GROUP G2;
Table altered
```

The following is an example of merging shards in a way of ranging.

```
gSQL> ALTER TABLE t1 MERGE SHARDS shard1 TO shard3 INTO shard4 AT CLUSTER GROUP G2;
Table altered
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER TABLE name MOVE SHARD
- ALTER TABLE name SPLIT SHARD

18.62 ALTER TABLE name MOVE SHARD

Function

It rebalances a specific shard of a table, or the entire shard in a specific cluster group to a specific cluster group.

Syntax

```
<alter table move shard statement> ::=
    ALTER TABLE table_name MOVE SHARD
        { shard_name_list ¦ FROM CLUSTER GROUP src_cluster_group }
        TO CLUSTER GROUP dest_cluster_group
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

One of the following privileges is required to perform <alter table move shard statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.
The statement can be performed only when that table is a cluster group specific table.

shard_name_list

It is the shard name list to be rebalanced.
If the shard does not exist in that table, then the statement can not be performed.

src_cluster_group

It is the name of a specific cluster group to be rebalanced.

dest_cluster_group

It is the name of a target cluster group on which the shard of the table is to be rebalanced.
If the cluster group specified by the shard of that table already exists then the statement can not be perfo rmed.

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.

- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL
  - It does not rebalance tables in parallel.
- PARALLEL [integer]
  - It rebalances tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

It rebalances a specific shard of the table from a specific cluster group to another cluster group.

To drop a specific cluster group, rebalance the shard of the table then perform the **DROP CLUSTER GROU P** statement.

To move shards of all tables from a specific cluster group to another cluster group, then perform the ALT ER DATABASE MOVE SHARD FROM CLUSTER GROUP TO CLUSTER GROUP statement.

If it is a CLONED table or a CLUSTER WIDE table, then an error occurs and it fails.

Examples

The following is an example of executing the 〈alter table move shard statement〉 statement.

```
gSQL> ALTER TABLE t1 MOVE SHARD shard1, shard2 TO CLUSTER GROUP g3;
Table altered.
gSQL> ALTER TABLE t1 MOVE SHARD FROM CLUSTER GROUP g1 TO CLUSTER GROUP g3;
Table altered.
```

The following is an example of which a CLONED table and a CLUSTER WIDE table fails to move shard.

```
gSQL> CREATE TABLE T1 ( C1 INTEGER ) SHARDING BY RANGE (C1)
         AT CLUSTER WIDE
         SHARD s1 VALUES LESS THAN (10),
         SHARD s2 VALUES LESS THAN (MAXVALUE);
Table created.
gSQL> ALTER TABLE T1 MOVE SHARD s1 TO CLUSTER GROUP g2;
ERR-42000(16440): cannot execute on cluster wide sharded tables
gSQL> CREATE TABLE T2 ( C1 INTEGER ) CLONED AT CLUSTER GROUP g1, g2;
Table created.
gSQL> ALTER TABLE T2 MOVE SHARD FROM CLUSTER GROUP g1 TO CLUSTER GROUP g3;
ERR-42000(16437): cannot execute on cloned tables
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **ALTER DATABASE MOVE SHARD**.

18.63 ALTER TABLE name READ { ONLY | WRITE }

Function

It sets READ { ONLY | WRITE } in a table.

Syntax

```
<alter table read { only ¦ write } statement> :==
     ALTER TABLE table_name
         READ { ONLY ¦ WRITE }
     ;
```

Invocation and Access Rules

One of the following privileges is required to perform <alter table read { only | write } statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.

Description

It sets table property to READ { ONLY | WRITE }.

If it is set to READ ONLY, neither SELECT .. FOR UPDATE statement, nor DML/ DDL statement which updates table data can be used. However, DDL statement which does not update the table data is allowed.

Disallowed SQL statements when it is set to READ ONLY

- INSERT, UPDATE, DELETE
- TRUNCATE
- SELECT .. FOR UPDATE
- ALTER TABLE RENAME/DROP COLUMN
- ALTER TABLE SET COLUMN UNUSED

Allowed SQL statements when it is set to READ ONLY

- SELECT
- CREATE/ALTER/DROP INDEX
- ALTER TABLE ADD/ALTER COLUMN
- ALTER TABLE ADD/ALTER/RENAME/DROP CONSTRAINT
- ALTER TABLE for physical property changes
- ALTER TABLE DROP UNUSED COLUMNS
- ALTER TABLE RENAME TO
- DROP TABLE
- ALTER TABLE ADD/DROP SUPPLEMENTAL LOG
- LOCK TABLE

Examples

The following is an example of executing <alter table read { only | write } statement>.

```
gSQL> ALTER TABLE t1 READ ONLY;
Table altered.
gSQL> ALTER TABLE t1 READ WRITE;
Table altered.
```

Compatibility

The SQL standard does not define <alter table read { only | write } statement>.

For More Information

Refer to **ALTER TABLE**.

18.64 ALTER TABLE name REBALANCE

Function

It rebalances the shard in a table.

Syntax

```
<alter table rebalance statement> ::=
    ALTER TABLE table_name REBALANCE
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

One of the following privileges is required to perform <alter table rebalance statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL
  - It does not rebalance tables in parallel.
- PARALLEL [integer]
  - It rebalances tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

It does not rebalance shards in a table when adding a cluster member or a cluster group by using the foll owing statements.

- CREATE CLUSTER GROUP
- ALTER CLUSTER GROUP name ADD MEMBER

To rebalance the shards of a table in the added cluster group and the cluster member, perform the <alter table rebalance statement> statement. The operation succeeds without a separate rebalancing if the shar d of the table is already rebalanced.

To rebalance shards in all tables, perform the **ALTER DATABASE REBALANCE** statement.

Examples

The following is an example of executing the <alter table rebalance statement> statement.

```
gSQL> ALTER TABLE t1 REBALANCE;
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

18.65 ALTER TABLE name REBALANCE EXCLUDE CLUSTER GROUP cluster_group_list

Function

It rebalances the shard of the table not to include a shard in a specific cluster group.

Syntax

```
<alter table rebalance exclude cluster group statement> ::=
    ALTER TABLE table_name REBALANCE
        EXCLUDE CLUSTER GROUP cluster_group_list
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in a cluster system.

One of the following privileges is required to perform <alter table rebalance exclude cluster group statem ent>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.
The statement can be performed only when that table is a cluster-wide table.

cluster_group_list

It is a list of the cluster group which does not include a shard of a table.
If the cluster group to be excluded from the rebalancing is the entire group, the statement can not be per formed.

[ONLINE | OFFLINE]

It determines whether to allow DML when rebalancing table shard.

- ONLINE
  - It allows INSERT, UPDATE, and DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- When it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then rebalances them in the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when rebalancing the table.

- NOPARALLEL

    - It does not rebalance tables in parallel.
- PARALLEL [integer]
    - It rebalances tables in parallel.
    - The minimum value of an integer is 0 and the maximum value is 64.
    - If the integer is omitted, then it is 0.
    - If the integer is 0, then the system determines the optimal value.

Description

It excludes a specific cluster group and rebalances the shard of the table.
If the shard of the table does not exist in that cluster group, the operation succeeds without a separate re balancing.
It rebalances the shard based on the cluster group in which the shard of the table is located.

To drop a specific cluster group, rebalance the shard of the table and perform **DROP CLUSTER GROUP** st atement.
To rebalance the shard excluding a cluster group from all tables, perform the **ALTER DATABASE REBALA NCE EXCLUDE CLUSTER GROUP** statement.

Examples

The following is an example of executing the <alter table rebalance exclude cluster group statement> stat ement.

```
gSQL> ALTER TABLE t1 REBALANCE EXCLUDE CLUSTER GROUP g3;
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

18.66 ALTER TABLE name RENAME COLUMN

Function

It renames the table column.

Syntax

```
<rename column statement> ::=
    ALTER TABLE table_name
        RENAME COLUMN old_column_name TO new_column_name
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <rename column statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

old_column_name

It is the old column name to be altered.

new_column_name

It is the new column name to be altered.
The same column name should not exist in a table.

Description

Even when the column name is altered it does not require the object change such as index, constraint wh ich is generated based on the previous column.

Example

The following is an example of exchanging the names of two columns, col_1 and col_2.

```
gSQL> ALTER TABLE t1 RENAME COLUMN col_1 TO col_temp;
Table altered.
gSQL> ALTER TABLE t1 RENAME COLUMN col_2 TO col_1;
Table altered.
gSQL> ALTER TABLE t1 RENAME COLUMN col_temp TO col_2;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define <rename column statement>.

For More Information

Refer to the followings.

- ALTER TABLE
- ALTER TABLE name ADD COLUMN
- ALTER TABLE name SET UNUSED COLUMN
- ALTER TABLE name ALTER COLUMN

18.67 ALTER TABLE name RENAME CONSTRAINT

Function

It renames the table constraints.

Syntax

```
<rename table constraint statement> ::=
    ALTER TABLE table_name
        RENAME <constraint object> TO new_constraint_name
    ;
<constraint object> ::=
      CONSTRAINT constraint_name
    ¦ PRIMARY KEY
    ¦ UNIQUE ( column_name [, ...] )
```

Invocation and Access Rules

One of the following privileges is required to perform <rename table constraint statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

〈constraint object〉

The existing name of the constraint to be altered is specified as follows.

- CONSTRAINT constraint_name
  - The constraint name to be altered
- PRIMARY KEY
  - PRIMARY KEY constraint of the table
- UNIQUE(column [,...])
  - UNIQUE constraint which satisfies the column list

new_column_name

It is the new name of a constraint to be altered.

Description

The index name which was automatically created with a key constraint such as primary key, unique key is not altered. Use **ALTER INDEX name RENAME TO** statement to rename the index.

Examples

The following is an example of renaming the primary key constraint of the table.

```
gSQL> ALTER TABLE t1 RENAME PRIMARY KEY TO pk_t1;
Table altered.
```

The following is an example of renaming the table constraint by specifying the constraint name.

```
gSQL> ALTER TABLE t1 RENAME CONSTRAINT pk_t1 TO t1_pk;
Table altered.
```

Compatibility

The SQL standard does not define the 〈rename table constraint statement〉 statement.

For More Information

Refer to the followings.

- ALTER TABLE
- ALTER TABLE name ADD CONSTRAINT
- ALTER TABLE name DROP CONSTRAINT
- ALTER TABLE name ALTER CONSTRAINT

18.68 ALTER TABLE name RENAME SHARD

Function

It renames a specific shard of a table in cluster environment.

Syntax

```
<alter table rename shard statement> ::=
    ALTER TABLE table_name
        RENAME SHARD shard_name TO new_shard_name
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.

One of the following privileges is required to perform <alter table rename shard statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.

shard_name

It is the existing name of a shard to be altered.
If the shard does not exist in that table, then the statement can not be performed.

new_shard_name

It is the new name of a shard to be altered.
The same shard name should not exist in the table.

Description

It alters the name of a specific shard of a hash, a range, or a list table. This statement can not be perform ed for a cloned table.

Examples

The following is an example of executing <alter table rename shard statement> statement.

```
gSQL> ALTER TABLE t_range RENAME SHARD r_01 TO r_new_01;
Table altered.
gSQL> ALTER TABLE t_list RENAME SHARD l_01 TO l_new_01;
Table altered.
gSQL> ALTER TABLE t_hash RENAME SHARD shard_000000 TO h_new_00;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER TABLE
- ALTER TABLE name MOVE SHARD
- ALTER TABLE name SPLIT SHARD
- ALTER TABLE name REBALANCE

18.69 ALTER TABLE name RENAME TO

Function

It renames the table.

Syntax

```
<rename table statement> ::=
    ALTER TABLE table_name
        RENAME TO new_table_name
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <rename table statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the existing name of the table.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

new_table_name

It is a new name of the table.
The same table name should not exist in the schema.

Description

Even when the table is renamed, the object referring to the table such as index, constraint does not need to be renamed.

Example

The following is an example of exchanging the name of the two tables t1, t2.

```
gSQL> ALTER TABLE t1 RENAME TO t_temp;
Table altered.
gSQL> ALTER TABLE t2 RENAME TO t1;
Table altered.
gSQL> ALTER TABLE t_temp RENAME TO t2;
Table altered.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not define <rename table statement>.

For More Information

Refer to **ALTER TABLE**.

18.70 ALTER TABLE name SET UNUSED COLUMN

Function

It drops a table column.

Syntax

```
<drop column definition> ::=
    ALTER TABLE table_name <drop column clause>
    ;
<drop column clause> ::=
      SET UNUSED [ COLUMN ] <column_name_list> [ <drop behavior> ]
<column name list> ::=
      column_name
    ¦ ( column_name [, ...] )
<drop behavior> ::=
      RESTRICT
    ¦ CASCADE
    ¦ CASCADE CONSTRAINTS
```

Invocation and Access Rules

One of the following privileges is required to perform <drop column definition>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

SET UNUSED [COLUMN]

It sets the column not to be used.

column_name_list

One or more column names to be dropped.

- e.g. ALTER TABLE t1 SET UNUSED COLUMN c1
- e.g. ALTER TABLE t1 SET UNUSED COLUMN (c1, c2)

column_name

It is the column name to be dropped.
It also drops the constraints and indexes which use the column.

drop behavior

When it is omitted, the default value is RESTRICT.
Currently, RESTRICT/CASCADE is operated in the same way.

Description

SET UNUSED COLUMN does not delete the data physically, so it ensures consistent performance regardle ss of the number of the rows.

Example

The following is an example of setting the column not to be used.

```
gSQL> ALTER TABLE t1 SET UNUSED COLUMN ( addr );
Table altered.
```

Compatibility

The SQL standard does not define the following clauses.

- SET UNUSED
- CASCADE CONSTRAINTS
- Listing multiple columns

Table 18-21 SQL standard compatibility

Feature ID	Description	Compatibility
F033	ALTER TABLE statement: DROP COLUMN clause	X

For More Information

Refer to the followings.

- **ALTER TABLE**
- **ALTER TABLE name ADD COLUMN**
- **ALTER TABLE name ALTER COLUMN**
- **ALTER TABLE name RENAME COLUMN**

18.71 ALTER TABLE name SPLIT SHARD

Function

It rebalances a specific shard of a table by splitting it in a cluster environment.

Syntax

```
<alter table split shard statement> ::=
    ALTER TABLE table_name SPLIT SHARD source_shard_name
        INTO ( <split shard placement> [, ...] )
    ;
<split shard placement> ::=
    <split shard bound def> AT CLUSTER GROUP dest_group_name
<split shard bound def> ::=
    <split list shard def>
  ¦ <split range shard def>
<split list shard def> :=
    SHARD dest_shard_name VALUES IN ( <split list value clause> )
<split list value clause> :=
    <split list value> [, ...]
<split list value> :=
    constant
  ¦ NULL
<split range shard def> :=
    SHARD dest_shard_name VALUES LESS THAN ( <split range value clause> )
<split range value clause> :=
    <split range value> [, ...]
<split range value> :=
    constant
```

Invocation and Access Rules

It can be performed in a cluster system.

One of the following privileges is required to perform 〈alter table split shard statement〉.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define a schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.
The statement can be performed only when that table is a cluster group specific table, and when the shar d is a list shard or a range shard.

source_shard_name

It is the name of an original shard to be splitted.
If the shard does not exist in that table, the statement can not be performed.

〈split shard placement〉

It defines the target shard to which the original shard is rebalanced by splitting.

〈split shard bound def〉

It defines the bound of a target shard to be splitted.

It can be defined as one of two following bound defs.

- 〈split list shard def〉
- 〈split range shard def〉

〈split list shard def〉

It defines a split shard bound for a list shard.

- dest_shard_name
  - It is the name of a target shard.

- <split list value clause>
  - <split list value> should be an integer.
  - <split list value> can not be NULL.
  - <split list value> can not be DEFAULT.
  - S1 : (1, 11, 21, 31, NULL) SPLIT SHARD S1 INTO (<split list value clause> ..)
    - (O) SHARD S11 VALUES IN (1)
    - (O) SHARD S11 VALUES IN (1, NULL)
    - (O) SHARD S11 VALUES IN (1, 11, 21, 31)
    - (X) SHARD S11 VALUES IN (2)
    - (X) SHARD S11 VALUES IN (DEFAULT)
    - (X) SHARD S11 VALUES IN (1, 11, 21, 31, NULL)

<split range shard def>

It defines a split shard bound for a range shard.

- <split range value clause>
  - <split list value> should be an integer.
  - <split list value> can not be NULL.
  - <split list value> can not be MAXVALUE.
  - S1 : (100, 100), S2 : (50, 50) SPLIT SHARD S1 INTO (<split range value clause> ..)
    - (O) SHARD S11 VALUES IN (50, 100)
    - (O) SHARD S11 VALUES IN (100, 50)
    - (O) SHARD S11 VALUES IN (60, 60)
    - (X) SHARD S11 VALUES IN (50, NULL)
    - (X) SHARD S11 VALUES IN (50, 50)
    - (X) SHARD S11 VALUES IN (100, 100)
    - (X) SHARD S11 VALUES IN (100, 110)
    - (X) SHARD S11 VALUES IN (MAXVALUE, 100)

dest_group_name

It is the name of a cluster group in which the splitted shard is to be rebalanced.

Description

It splits a specific shard of a specific table and rebalances it to a random cluster group.
This is used to distribute records and loads by splitting the shards when records corresponding to a specifi c shard is too much or when a specific group member is overloaded.

Examples

The following is an example of executing the <alter table split shard statement> statement.

```
gSQL> ALTER TABLE t1 SPLIT SHARD shard1 INTO ( SHARD shard11 VALUES IN ( 11 ) AT CLUSTER GROUP
G2 );
Table altered.
gSQL> ALTER TABLE t1 SPLIT SHARD shard1 INTO ( SHARD shard11 VALUES LESS THAN ( 11 ) AT
CLUSTER GROUP G2 );
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- **ALTER TABLE name REBALANCE**
- **ALTER TABLE name REBALANCE EXCLUDE CLUSTER GROUP cluster_group_list**
- **ALTER TABLE name MOVE SHARD**
- **ALTER TABLE name MERGE SHARDS**

18.72 ALTER TABLE name STORAGE

Function

It alters physical attributes of a table.

Syntax

```
<alter table physical attribute statement> ::=
    ALTER TABLE table_name
      [ <physical attribute clause> ]
    ¦ [ STORAGE ( <segment attr clause> [...] ) ]
    ;
<physical attribute clause> ::=
      PCTFREE integer
    ¦ PCTUSED integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
    NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
```

Invocation and Access Rules

One of the following privileges is required to perform <alter table physical attribute statement>.

- (ALTER or CONTROL TABLE) ON TABLE for that table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name to be altered.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

〈physical attribute clause〉

It alters the physical attribute of a page which configures the table.
It is not applied to the already allocated page, but is applied to the newly allocated page.
For more information, refer to **〈table physical attribute clause〉** of **CREATE TABLE**.

〈segment attr clause〉

It alters the physical attribute of the extent configuring the segment. It is not applied to the already allocated extent but is applied to the newly allocated extent.

- MAXSIZE integer
  - It alters the space size of the segment which can be allocated.
  - If the newly allocated space is smaller than the already allocated space, then an error occurs.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of changing the physical attribute of the table.

```
gSQL> ALTER TABLE t1 PCTFREE 10 PCTUSED 40 STORAGE ( NEXT 10M  MAXSIZE  100M );
Table altered.
```

Compatibility

The SQL standard does not define the physical attribute of a table.

For More Information

Refer to **ALTER TABLE**.

18.73 ALTER TABLE name SYNCHRONIZE

Function

It remotely synchronizes shards of the existing table.

Syntax

```
<alter table synchronize statement> ::=
    ALTER TABLE table_name SYNCHRONIZE
       [ ONLINE ¦ OFFLINE ]
       [ <shard divisor> ]
       [ <parallel clause> ]
    ;
<shard divisor> ::=
    SHARD DIVISOR integer
<parallel clause> ::=
    NOPARALLEL
  ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

It can be performed in the cluster system.

One of the following privilege is required to perform <alter table synchronize statement>.

- (ALTER or CONTROL TABLE) ON TABLE for the table
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the table name.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

[ONLINE | OFFLINE]

It determines whether to allow DML when synchronizing the table shard.

- ONLINE
  - It allows INSERT, UPDATE, DELETE.
- OFFLINE
  - It does not allow INSERT, UPDATE, DELETE.
- If it is omitted, the default value is ONLINE.

〈shard divisor〉

It specifies the number of shard's partitions.

- It divides the shard as many as the number of partitions, then synchronizes it with the remote server.
- The minimum value of an integer is 0 and the maximum value is 1000.
- If it is omitted, then it follows REBALANCE_SHARD_DIVISOR property.
- If the integer is smaller than the parallel integer, then it is revised to the same value as the parallel int eger.

〈parallel clause〉

It specifies the number of threads to use when synchronizing the table.

- NOPARALLEL
  - It does not synchronize tables in parallel.
- PARALLEL [integer]
  - It synchronize tables in parallel.
  - The minimum value of an integer is 0 and the maximum value is 64.
  - If the integer is omitted, then it is 0.
  - If the integer is 0, then the system determines the optimal value.

Description

The table synchronization synchronizes the existing offline shards to restore the data file matching. Unlike **〈alter table rebalance statement〉**, it can be performed even when an inactive cluster member exists.

If it can not satisfy the following conditions, then it fails.

- At least one member of the cluster system should have the online replica of the cloned table to synch ronize shards of the cloned table.
- At least one member per group should have the online replica of the sharded table to synchronize sh ards of the sharded table.

For example, if all replicas in cluster group G3 of the sharded table t1 are offline, then the following error occurs.

```
gSQL> ALTER TABLE t1 SYNCHRONIZE;
ERR-42000(16546): sharded table "PUBLIC"."T1" must have at least one online replica of group
'G3'
```

Perform **〈alter database synchronize statement〉** to synchronize shards in all tables.

Example

The following is an example of performing〈alter table synchronize statement〉 for the table T1.

```
gSQL> ALTER TABLE t1 SYNCHRONIZE;
Table altered.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- ALTER TABLE

- ALTER TABLE name REBALANCE
- ALTER DATABASE SYNCHRONIZE

18.74 ALTER TABLESPACE

Function

It alters the tablespace definition.

Syntax

```
<alter tablespace statement> ::=
      <rename tablespace statement>
    ¦ <backup tablespace statement>
    ¦ <on/offline tablespace statement>
    ¦ <add file statement>
    ¦ <drop file statement>
    ¦ <rename datafile statement>
    ;
```

Invocation and Access Rules

ALTER TABLESPACE privilege is required to perform <alter tablespace statement>.

Syntax Rules and Parameters

<rename tablespace statement>

It renames the tablespace.
For more information, refer to **ALTER TABLESPACE name RENAME TO** statement.

<backup tablespace statement>

It backs up the tablespace.
For more information, refer to **ALTER TABLESPACE name BACKUP** statement.

〈on-offline tablespace statement〉

It changes all files in the tablespace to the online state or offline state.
For more information, refer to **ALTER TABLESPACE name [ONLINE|OFFLINE]** statement.

〈add file statement〉

It adds a file to the tablespace.
For more information, refer to **ALTER TABLESPACE name ADD [DATAFILE|MEMORY]** statement.

〈drop file statement〉

It drops a file from the tablespace.
For more information, refer to **ALTER TABLESPACE name DROP [DATAFILE|MEMORY]** statement.

〈rename datafile statement〉

It renames the datafile in the data tablespace.
For more information, refer to **ALTER TABLESPACE name RENAME DATAFILE** statement.

Description

Unlike other Data Definition Language (DDL), ALTER TABLESPACE statement is not allowed to ROLLBAC K, and its transaction is automatically committed after executing the statement.

Example

Refer to the examples of each detailed statement.

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- CREATE TABLESPACE
- DROP TABLESPACE

18.75 ALTER TABLESPACE name ADD [DATAFILE| MEMORY]

Function

It extends the space of the tablespace.

Syntax

```
<add space statement> ::=
    ALTER TABLESPACE tablespace_name ADD <space specification>
        [AT <domain name>]
    ;
<space specification> ::=
      MEMORY <memory clause> [, ...]
    ¦ DATAFILE <add datafile clause> [, ...]
<size clause> ::=
    integer [ K ¦ M ¦ G ¦ T ]
<memory clause>
     'memory_name' { SIZE <size clause> }
<add datafile clause> ::=
     'filename'
        { SIZE <size clause> ¦ REUSE ¦ SIZE <size clause> REUSE }
        [ <autoextend clause> ]
<autoextend clause>
    AUTOEXTEND { ON [ <next size clause> ] [ <max size clause> ] ¦ OFF }
<next size clause>
    NEXT <size clause>
<max size clause>
    MAXSIZE { <size clause> ¦ UNLIMITED }
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege is required to perform <add space statement>.

Syntax Rules and Parameters

tablespace_name

It is the tablespace name to be altered.

<file specification>

The following syntax should be used according to the tablespace type.

- Memory data tablespace
  - DATAFILE <add datafile clause>
- Memory temporary tablespace
  - MEMORY <memory clause>

<add datafile clause>

It defines the memory datafile to be added.

- 'filename'
  - It is the file name to store and manage the data.
  - It is the space to store the checkpoint image for the memory data.
  - The filename can be either the new file or existing file.
  - The length of filename should be shorter than 1024 bytes.

- SIZE <size clause>
  - For the new file, the initial size is specified by using SIZE clause.
  - An error occurs if the file exists.
  - The file size can be specified from 1M to 30G.

- REUSE
  - If the file exists, it uses REUSE clause.
  - If the file does not exist, a new file is created.
  - The size of newly created file
    - For the data tablespace, it is determined by MEMORY_DATA_TABLESPACE_SIZE property.

        - For the temporary table space, it is determined by MEMORY_TEMP_TABLESPACE_SIZE property.

- SIZE 〈size clause〉 REUSE
    - If both of SIZE clause and REUSE clause are specified, it is operated as follows based on the presence of the filename.
        - For the new filename, the initial file size is specified by using SIZE clause.
        - For the existing filename, it is adjusted to the SIZE clause value by using the existing file.

〈memory clause〉

- 〈size clause〉
    - It defines the memory to be added.

For more information, refer to **〈memory clause〉** of **CREATE MEMORY TEMPORARY TABLESPACE** statement.

〈autoextend clause〉

It sets the automatic extending property when adding the data file of the disk tablespace. Set the automatic extending property to *ON* or *OFF*. If it is set to *ON*, then it can define the size of the automatic extending and the maximum size of the data file.

〈next size clause〉

It defines the space size to be extended when there is not any space available in the current data file in use.

〈max size clause〉

It defines the maximum size of the data file which can be extended.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of adding datafile to the tablespace.

```
gSQL> ALTER TABLESPACE space1 ADD DATAFILE 'test_file_a2.dbf' SIZE 10M REUSE;
Tablespace altered.
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- CREATE MEMORY DATA TABLESPACE
- CREATE MEMORY TEMPORARY TABLESPACE
- ALTER TABLESPACE

18.76 ALTER TABLESPACE name BACKUP

Function

It switches the tablespace to backup enabled state and backup disabled state to perform backup.

Syntax

```
<backup tablespace statement> ::=
      <tablespace begin backup statement>
    ¦ <tablespace end backup statement>
    ¦ <tablespace incremental backup statement>
    ;
<tablespace begin backup statement> ::=
    ALTER TABLESPACE tablespace_name BEGIN BACKUP [AT <domain_name>]
    ;
<tablespace end backup statement> ::=
    ALTER TABLESPACE tablespace_name END BACKUP [AT <domain_name>]
    ;
<tablesapce incremental backup statement> ::=
    ALTER TABLESPACE tablespace_name
        BACKUP INCREMENTAL <incremental backup option> [AT <domain_name>]    ;
<incremental backup option> ::=
      LEVEL integer [ CUMULATIVE ¦ DIFFERENTIAL ]
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege is required to perform <backup space statement>.

Syntax Rules and Parameters

〈tablespace begin backup statement〉

It sets the tablespace to the backup enabled state.

- The tablespace being used is set to the backup enabled state.
- The backup state of the tablespace such as OFFLINE/ temporary can not be switched.

tablespace_name

It is the tablespace name whose backup state is to be switched.

〈tablespace end backup statement〉

It sets the tablespace to the backup disabled state.

〈tablesapce incremental backup statement〉

It performs the incremental backup of the tablespace.
The database is in OPEN phase and it should be operated in ARCHIVELOG mode.

〈incremental backup option〉

- An 'Integer' can be specified from 0 to 4.
- 'LEVEL 0' can not specify CUMULATIVE or DIFFERENTIAL.
- CUMULATIVE | DIFFERENTIAL
  - CUMULATIVE
    - If 'integer' is n, it backs up all pages which are altered after the most recent backups of LEVE L 0 ~ LEVEL n-1.
  - DIFFERENTIAL
    - If 'integer' is n, it backs up all pages which are altered after the most recent backups of LEVE L 0 ~ LEVEL n.
  - If it is omitted, DIFFERENTIAL is specified by default.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

It backs up the datafiles which are created in the tablespace. A full backup of the tablespace begins with BEGIN BACKUP, and copies the datafiles by OS file copy and ends with END BACKUP. The incremental ba ckup file is created in the path set by BACKUP_DIR 1 property using a single statement.

Examples

The following is an example of setting the full backup state to 'ACTIVE' for the tablespace DICTIONARY_ TBS.

```
ALTER TABLESPACE DICTIONARY_TBS BEGIN BACKUP;
```

The following is an example of setting the full backup state to 'INACTIVE' for the tablespace DICTIONARY _TBS.

```
ALTER TABLESPACE DICTIONARY_TBS END BACKUP;
```

The following is an example of generating the LEVEL 0 incremental backup of the tablespace DICTIONAR Y_TBS.

```
ALTER TABLESPACE DICTIONARY_TBS BACKUP INCREMENTAL LEVEL 0;
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- ALTER TABLESPACE
- ALTER TABLESPACE name [ONLINE|OFFLINE]

18.77 ALTER TABLESPACE name DROP [DATAFILE|MEMORY]

Function

It reduces the space of the tablespace.

Syntax

```
<drop space statement> ::=
    ALTER TABLESPACE tablespace_name DROP <file specification>
    [ AT <domain name> ]
    ;
<file specification> ::=
      DATAFILE 'filename'
    | MEMORY 'memory_name'
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege is required to perform <drop space statement>.

Syntax Rules and Parameters

tablespace_name

It is the tablespace name to be altered.

<file specification>

The following syntax should be used according to the tablespace type.

- Memory data tablespace
  - DATAFILE 'filename'

- Memory temporary tablespace
  - MEMORY 'memory_name'

The file of OFFLINE tablespace can not be dropped.
The first file of the tablespace can not be dropped.
The data file which has been used once can not be dropped.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

For more information, refer to the rules for each syntax.

Example

The following is an example of dropping the file from the tablespace.

```
gSQL> ALTER TABLESPACE space1 DROP DATAFILE 'test_file_f2.dbf';
Tablespace altered.
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- **ALTER TABLESPACE**
- **ALTER TABLESPACE name ADD [DATAFILE|MEMORY]**
- **ALTER TABLESPACE name RENAME DATAFILE**

18.78 ALTER TABLESPACE name [ONLINE|OFFLINE]

Function

It alters the tablespace status.

Syntax

```
<on/off tablespace statement> ::=
    ALTER TABLESPACE tablespace_name { ONLINE ¦ OFFLINE [ NORMAL ¦ IMMEIDATE ] }
    [ AT <domain name> ]
    ;
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege is required to perform <on/off tablespace statement>.

Syntax Rules and Parameters

ONLINE

It alters the tablespace status in OFFLINE state to ONLINE state.

OFFLINE NORMAL

It alters the tablespace status in ONLINE state to OFFLINE state.

The media recovery is not required in ONLINE state because the tablespace which was altered to OFFLINE state is in consistent state.

OFFLINE NORMAL is not allowed in MOUNT phase.
(However, if the previous instance is terminated by \SHUTDOWN NORMAL, OFFLINE NORMAL i s allowed.)

OFFLINE IMMEDIATE

It alters the tablespace status in ONLINE state to OFFLINE state.

The media recovery is required in ONLINE state because the tablespace which was altered to OFFLINE stat e is in inconsistent state.

The SYSTEM tablespace can not be altered to OFFLINE state.
OFFLINE IMMEDIATE requires the media recovery, so it can be performed only in ARCHIVELOG mode.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

For more information, refer to the rules for each syntax.

Examples

The following is an example of setting the tablespace to OFFLINE.

```
gSQL> ALTER TABLESPACE space1 OFFLINE;
Tablespace altered.
```

The following is an example of that OFFLINE NORMAL for the tablespace fails in MOUNT phase.

```
gSQL> ALTER TABLESPACE space1 OFFLINE;
ERR-42000(16290): OFFLINE NORMAL is only allowed if the database is in OPEN phase :
```

```
ALTER TABLESPACE space1 OFFLINE
                 *
ERROR at line 1:
gSQL> ALTER TABLESPACE space1 OFFLINE NORMAL;
ERR-42000(16290): OFFLINE NORMAL is only allowed if the database is in OPEN phase :
ALTER TABLESPACE space1 OFFLINE NORMAL
                 *
ERROR at line 1:
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- ALTER TABLESPACE
- ALTER TABLESPACE name BACKUP

18.79 ALTER TABLESPACE name RENAME DATAFILE

Function

It renames the datafiles which configures the tablespace.

Syntax

```
<rename datafile statement> ::=
    ALTER TABLESPACE tablespace_name RENAME DATAFILE <filename_list> TO <filename_list>
    ;
    <filename_list> ::=
        'filename' [, ...]
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege is required to perform <rename datafile statement>.

ONLINE tablespace file can not be altered when it is in TDS mode and the database is in OPEN phase. (Except for the temporary memory tablespace.)
The file should exist even after the alteration.

Syntax Rules and Parameters

tablespace_name

It is the tablespace name to be altered.

'filename'

The memory temporary tablespace is 'memory_name' and the other kinds of tablespace is 'filename'.

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

Description

The tablespace status determines whether the operation can be performed.

- OFFLINE: It can be performed in MOUNT or OPEN phase.
- ONLINE: It can be performed only in MOUNT phase.

Example

The following is an example of renaming 'test.dbf' to 'test1.dbf'.

```
gSQL> ALTER TABLESPACE TEST_TBS RENAME DATAFILE 'test.dbf' TO 'test1.dbf';
Tablespace altered.
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- ALTER TABLESPACE
- ALTER TABLESPACE name ADD [DATAFILE|MEMORY]
- ALTER TABLESPACE name DROP [DATAFILE|MEMORY]

18.80 ALTER TABLESPACE name RENAME TO

Function

It renames the tablespace.

Syntax

```
<rename tablespace statement> ::=
    ALTER TABLESPACE tablespace_name RENAME TO <new_tablespace_name>
    ;
```

Invocation and Access Rules

ALTER TABLESPACE ON DATABASE privilege required to perform <rename space statement>.

Syntax Rules and Parameters

tablespace_name

It is a name of the old tablespace.

- The built-in tablespace can not be renamed.
- The OFFLINE tablespace can not be renamed.

new_tablespace_name

It is a name of the new tablespace.

Description

Even when the tablespace is renamed, the table or index which was already created in the existing tables pace does not need to be renamed.

Example

The following is an example of renaming the tablespace.

```
gSQL> ALTER TABLESPACE space1 RENAME TO space2;
Tablespace altered.
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to **ALTER TABLESPACE**.

18.81 ALTER USER

Function

It alters the user definition of the database.

Syntax

```
<alter user statement> ::=
      ALTER USER user_identifier <alter user action>
    ¦ ALTER USER PUBLIC <alter schema path>
    ;
<alter user action> ::=
      <alter password>
    ¦ <alter profile>
    ¦ <password expire>
    ¦ <account lock>
    ¦ <alter default tablespace>
    ¦ <alter temporary tablespace>
    ¦ <alter schema path>
<alter password> ::=
    IDENTIFIED BY new_password [ REPLACE old_password ]
<alter profile> ::=
    PROFILE { profile_name ¦ DEFAULT ¦ NULL }
<password expire> ::=
    PASSWORD EXPIRE
<account lock> ::=
    ACCOUNT { LOCK ¦ UNLOCK }
<alter default tablespace> ::=
    DEFAULT TABLESPACE tablespace_name
<alter temporary tablespace> ::=
    TEMPORARY TABLESPACE tablespace_name
<alter schema path> ::=
    SCHEMA PATH ( { schema_name ¦ CURRENT PATH } [, ...] )
```

Invocation and Access Rules

ALTER USER ON DATABASE privilege is required to perform <alter user statement>.
However, <alter password> can be performed without any privilege, when the user and the user identifier are identical.

Syntax Rules and Parameters

user_identifier

It is the username to be altered.

<alter password>

It alters the user's password.

- IDENTIFIED BY new_password
  - The new password is encrypted and stored.
  - The length of the password should be shorter than 128 byte.
  - The password is case sensitive.

- REPLACE old_password
  - It can be omitted when ALTER USER ON DATABASE privilege is given.
  - It can not be omitted when ALTER USER ON DATABASE privilege is not given.
    - The user and the user identifier should be identical.

<alter profile>

It alters the profile for the password management policy.

- PROFILE profile_name
  - It allocates profile_name which is created by a user.
- PROFILE DEFAULT
  - It allocates "DEFAULT" which is the default profile.
- PROFILE NULL
  - It does not allocate the profile.

〈password expire〉

It expires the user's password.

〈account lock〉

- ACCOUNT LOCK
  - It locks the user account.
- ACCOUNT UNLOCK
  - It unlocks the user account.

〈alter default tablespace〉

It alters the user's default tablespace.
The tablespace_name should be a data tablespace.

〈alter temporary tablespace〉

It alters the user's temporary tablespace.
The tablespace_name should be a temporary tablespace.

〈alter index tablespace〉

It alters an index tablespace of the user.

- It specifies INDEX TABLESPACE tablespace_name.
  - If the data tablespace is specified, then it becomes a LOGGING index.
  - If the temporary tablespace is specified, then it becomes a NOLOGGING index.
- INDEX TABLESPACE NULL
  - It does not specify an index tablespace.

〈alter schema path〉

It alters the user's schema access path.
If the schema is not specified in user's SQL statement, the schema access path is determined in the schem a order for the naming resolution of the object.

If the schema name is as same as another schema which is previously listed, it is not applied.

The following is an example of objects existing in a schema when performing *ALTER USER u1 SCHEMA PATH (u1, s2, public);* statement.

Schema name	u1	s2	public
-	t1	-	t1
-	-	t2	-
-	-	-	t3

The object name whose schema name is not specified when the user u1 executes the schema is interpreted by the SCHEMA PATH as follows.

- CREATE statement
  - CREATE TABLE t1 (c1 INTEGER);
    - Error: CREATE TABLE u1.t1 (c1 INTEGER);
  - CREATE TABLE t2 (c1 INTEGER);
    - Execution: CREATE TABLE u1.t2 (c1 INTEGER);

- SELECT statement
  - SELECT * FROM t1;
    - Execution: SELECT * FROM u1.t1;
  - SELECT * FROM t2;
    - Execution: SELECT * FROM s2.t2;
  - SELECT * FROM t3;
    - Execution: SELECT * FROM public.t3;

CURRENT PATH

It is the current user's schema path.

A new schema path can be added using CURRENT PATH maintaining the existing schema path as follows.

- The u1's current schema path
  - (u1, public)
- The statement execution
  - ALTER USER u1 SCHEMA PATH (s1, CURRENT PATH, s2);
- The u1's schema path is altered as follows.
  - (s1, u1, public, s2)

ALTER USER PUBLIC <alter schema path>

It alters the schema path of PUBLIC account.
The schema path of PUBLIC account is included in every user's the schema path.

The initial schema path which is allocated to PUBLIC account is as follows.

- DICTIONARY_SCHEMA
- INFORMATION_SCHEMA
- DEFINITION_SCHEMA
- PERFORMANCE_VIEW_SCHEMA
- FIXED_TABLE_SCHEMA

Description

For more information, refer to the rules for each syntax.

Examples

The following is an example of altering the user's password.

```
gSQL> ALTER USER u1 IDENTIFIED BY new_password;
User altered.
```

The following is an example of allocating the profile to the user.

```
gSQL> ALTER USER u1 PROFILE prof1;
User altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of dropping the user's profile.

```
gSQL> ALTER USER u1 PROFILE NULL;
User altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of expiring the user's password.

```
gSQL> ALTER USER u1 PASSWORD EXPIRE;
User altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of unlocking the user's account.

```
gSQL> ALTER USER u1 ACCOUNT UNLOCK;
User altered.
gSQL> COMMIT;
Commit complete.
```

The following is an example of altering the user's DEFAULT TABLESPACE.

```
gSQL> ALTER USER u1 DEFAULT TABLESPACE mem_data_tbs;
User altered.
```

The following is an example of altering the user's TEMPORARY TABLESPACE.

```
gSQL> ALTER USER u1 TEMPORARY TABLESPACE mem_temp_tbs;
User altered.
```

The following is an example of altering the user's INDEX TABLESPACE.

```
gSQL> ALTER USER u1 INDEX TABLESPACE mem_temp_tbs;
User altered.
```

The following is an example of altering the user's schema path.

```
gSQL> ALTER USER u1 SCHEMA PATH ( s1, CURRENT PATH );
User altered.
```

Compatibility

SQL standard covers the concepts of a user, but it does not define the SQL statements associated with cre ating, altering, dropping a user.

For More Information

Refer to the followings.

- CREATE USER
- DROP USER

18.82 ALTER VIEW

Function

It alters the view definition.

Syntax

```
<alter view statement> ::=
    ALTER VIEW view_name <alter view action>
    ;
<alter view action> ::=
    COMPILE
```

Invocation and Access Rules

One of the following privileges is required to perform <alter view statement>.

- (ALTER or CONTROL TABLE) ON TABLE for the view
- (ALTER TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the view belongs
- ALTER ANY TABLE ON DATABASE

Syntax Rules and Parameters

view_name

It is the view name to be altered.
It can define the schema to which the view belongs, such as schema_name.view_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

COMPILE

It compiles the view again.
COMMENT which is given to the view column is initialized.

Description

When the table or the view which is referenced by the view is altered or dropped, then it affects that vie w.

This information can be retrieved from INFORMATION_SCHEMA.VIEWS.

- IS_COMPILED column
  - TRUE: The view was successfully created.
  - FALSE: The view was created with FORCE option when an error exists.

- IS_AFFECTED column
  - TRUE: The table and the view which was referenced by the view was altered.
  - FALSE: After creation and compilation of a view, the table and the view which was referenced by the view was not altered.

Example

The following is an example of compiling the view which is affected by the table change referenced by th at view.

```
gSQL> SELECT TABLE_NAME, IS_AFFECTED
        FROM INFORMATION_SCHEMA.VIEWS
       WHERE TABLE_SCHEMA = 'PUBLIC'
         AND TABLE_NAME = 'V1';
TABLE_NAME IS_AFFECTED
---------- -----------
V1         TRUE
1 row selected.
gSQL> ALTER VIEW v1 COMPILE;
View altered.
COMMIT;
Commit complete.
gSQL> SELECT TABLE_NAME, IS_AFFECTED
```

```
        FROM INFORMATION_SCHEMA.VIEWS
       WHERE TABLE_SCHEMA = 'PUBLIC'
         AND TABLE_NAME = 'V1';
TABLE_NAME IS_AFFECTED
---------- -----------
V1         FALSE
1 row selected.
```

Compatibility

The SQL standard does not define <alter view statement>.

For More Information

Refer to the followings.

- CREATE VIEW
- DROP VIEW

18.83 ANALYZE SYSTEM

Function

It controls the statistics information of the system.

Syntax

```
<analyze system statement> ::=
    ANALYZE SYSTEM [ <analyze action> ]
    ;
<analyze action> ::=
      COMPUTE STATISTICS
    ¦ DELETE STATISTICS
```

Invocation and Access Rules

ANALYZE ANY ON DATABASE privilege is required to perform <analyze system statement>.

Syntax Rules and Parameters

<analyze action>

When it is omitted, the default value is COMPUTE STATISTICS.

COMPUTE STATISTICS

It builds the following statistics information related to the system.

- CPU_OPS (Operations Per Second)
  - It is the number of operations of which the CPU can process per second.
- NETWORK_IOPS (I/O operations Per Second)
  - It is valid for the cluster.

    - It is the number of the network I/O which can be processed per second.

- BUFFER_MISS_PERCENT
    - It is the probability of the disk buffer miss

DELETE STATISTICS

It deletes the statistics information of the system.

Description

The built statistics information of the system is used to calculate the cost of optimization for the query pr ocess.

Examples

The following is an example of building the statistics information of the system by using the <analyze syst em statement> statement.

```
gSQL> ANALYZE SYSTEM COMPUTE STATISTICS;
analyzed.
```

The following is an example of retrieving the built statistics information of the system.

```
gSQL>
SELECT * FROM DBA_STAT_SYSTEM;
 CPU_OPS NETWORK_IOPS NETWORK_BUFSIZE BUFFER_MISS_PERCENT LAST_ANALYZED
-------- ------------ ---------------- -------------------- ----------------------------
53000412         2914            65536                   99  2017-03-30 16:49:42.200000
1 row selected.
```

Compatibility

The SQL standard does not define the concepts of the statistics information.

For More Information

Refer to **ANALYZE TABLE**.

18.84 ANALYZE TABLE

Function

It controls the statistics information of the table.

Syntax

```
<analyze table statement> ::=
    ANALYZE TABLE table_name
    [ <parallel clause> ]
    [ <analyze action> ]
    ;
<parallel clause> ::=
      NOPARALLEL
    | PARALLEL [thread_count]
<analyze action> ::=
      COMPUTE STATISTICS [ <for_clause> ]
    | ESTIMATE STATISTICS <sample_clause> [ <for_clause> ]
    | DELETE STATISTICS
<sample_clause>
      SAMPLE row_count ROWS
    | SAMPLE percentage PERCENT
<for_clause>
      FOR ALL COLUMNS
    | FOR ALL INDEXED COLUMNS
    | FOR COLUMNS column_name [, ...]
    | FOR ALL INDEXES
    | FOR INDEXES index_name [, ...]
```

Invocation and Access Rules

ANALYZE ANY ON DATABASE privilege is required to perform <analyze table statement>.

Syntax Rules and Parameters

table_name

It is the table name.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

〈parallel clause〉

It specifies the number of threads to be used in a analyzing process.
If it is not specified, the default value is PARALLEL.

- NOPARALLEL
  - It does not analyze in parallel.

- PARALLEL [thread_count]
  - It analyzes in parallel.
  - The minimum value of the thread_count is 0, and the maximum value is 64.
  - If the thread_count value is 0 or it is omitted, then it is determined by the number of CPUs in the system.

〈analyze action〉

When it is omitted, the default value is COMPUTE STATISTICS.

COMPUTE STATISTICS

It builds the following statistics information related to the table through the all inspection.

- The table statistics information
  - Row count
  - The number of pages
- The statistics information of each column
  - The number of different values
  - The number of NULL values
  - The average length of the value
  - The minimum value
  - The maximum value
- The statistics information of an index

- The number of different keys
- The number of pages
- The number of leaf pages
- The tree level
- The clustering factor of the index

The statistics information which is built according to the data type of the column is as follows.

Table 18-22 Statistics information built according to the data type

Data type	NUM_DISTINCT	NUM_NULLS	AVG_LENGTH	MIN/MAX
BOOLEAN	O	O	O	X
NATIVE_SMALLINT	O	O	O	O
NATIVE_INTEGER	O	O	O	O
NATIVE_BIGINT	O	O	O	O
NATIVE_REAL	O	O	O	O
NATIVE_DOUBLE	O	O	O	O
NUMBER	O	O	O	O
NUMERIC	O	O	O	O
FLOAT	O	O	O	O
CHAR(n)	O	O	O	It is built when it is 6 4 bytes or smaller.
VARCHAR(n)	O	O	O	It is built when it is 6 4 bytes or smaller.
LONG VARCHAR	X	X	X	X
BINARY	O	O	O	X
VARBINARY	O	O	O	X
LONG VARBINARY	X	X	X	X
DATE	O	O	O	O
TIME	O	O	O	O
TIMESTAMP	O	O	O	O
INTERVAL	O	O	O	O
ROWID	O	O	O	X

ESTIMATE STATISTICS 〈sample_clause〉

It builds the statistics information of the column and the index by using as many samples as the specified 〈sample_clause〉.

- SAMPLE row_count ROWS
  - It uses as many samples as the specied number of rows.
  - row_count is a positive integer bigger than 0.

- SAMPLE percentage PERCENT
  - It uses as many samples as the specied ratio.
  - The percentage is a positive intege in the range between 1 and 99.

If the number of the sampling rows are smaller than the value of **MIN_SAMPLE_ROW_COUNT** property, t hen it follows the property value.

〈for_clause〉

If it is omitted, it builds the statistics information of all possible columns and indexes.

FOR ALL COLUMNS

It builds the statistics information of all possible columns.
It does not build the statistics information of an index.

FOR ALL INDEXED COLUMNS

It builds the statistics information of all columns included in an index.
It does not build the statistics information of other columns.
It does not build the statistics information of an index.

FOR COLUMNS column_name [, ...]

It builds the statistics information of the listed columns.
It does not build the statistics information of unlisted columns.
It does not build the statistics information of an index.

FOR ALL INDEXES

It builds the statistics information of all indexes.
It does not build the statistics information of columns.

FOR INDEXES index_name [, ...]

It builds the statistics information of the listed indexes.
It does not build the statistics information of unlisted indexes.
It does not build the statistics information of a column.

DELETE STATISTICS

It deletes the statistics information of the table.

Description

The statistics information of the table affects the query optimization, so it is very important information.

The time to build the statistics information is increased in proportion to the data volumes in a table. There fore, when the data volume is big, then it is recommended to build the statistics information by using the sampling or to build only the statistics of major information which affects the query.

- The following is an example of building the statistics information by using the sampling.

```
ANALYZE TABLE lineitem ESTIMATE STATISTICS SAMPLE 10 PERCENT;
```

- The following is an example of building the statistics information only of major columns and the inde x.

```
ANALYZE TABLE lineitem COMPUTE STATISTICS FOR ALL INDEXED COLUMNS;
ANALYZE TABLE lineitem COMPUTE STATISTICS FOR ALL INDEXES;
```

Examples

The following is an example of building the statistics information through the all inspection.

```
gSQL> ANALYZE TABLE orders;
Table analyzed.
```

The following is an example of retrieving the built statistics information of the table.

```
gSQL>
SELECT
       TABLE_NAME
     , NUM_ROWS
  FROM
       DICTIONARY_SCHEMA.USER_TABLES
 WHERE
       TABLE_SCHEMA = 'PUBLIC'
   AND TABLE_NAME   = 'ORDERS'
```

```
;
TABLE_NAME NUM_ROWS
---------- --------
ORDERS      1500000
1 row selected.
gSQL>
SELECT
       TABLE_NAME
     , COLUMN_NAME
     , NUM_DISTINCT
     , NUM_NULLS
     , LOW_VALUE
     , HIGH_VALUE
  FROM
       DICTIONARY_SCHEMA.USER_TAB_COLUMNS
 WHERE
       TABLE_SCHEMA = 'PUBLIC'
   AND TABLE_NAME   = 'ORDERS'
;
TABLE_NAME COLUMN_NAME     NUM_DISTINCT NUM_NULLS LOW_VALUE           HIGH_VALUE
---------- --------------- ------------ --------- ------------------- -------------------
ORDERS     O_ORDERKEY           1500000         0 1                   6000000
ORDERS     O_CUSTKEY              99996         0 1                   149999
ORDERS     O_ORDERSTATUS              3         0 F                   P
ORDERS     O_TOTALPRICE         1464556         0 857.71              555285.16
ORDERS     O_ORDERDATE             2406         0 1992-01-01 00:00:00 1998-08-02 00:00:00
ORDERS     O_ORDERPRIORITY            5         0 1-URGENT            5-LOW
ORDERS     O_CLERK                 1000         0 Clerk#000000001     Clerk#000001000
ORDERS     O_SHIPPRIORITY             1         0 0                   0
ORDERS     O_COMMENT            1482071         0 null                null
9 rows selected.
gSQL>
SELECT
       TABLE_NAME
     , INDEX_NAME
     , DISTINCT_KEYS
  FROM
       DICTIONARY_SCHEMA.USER_INDEXES
 WHERE
       TABLE_SCHEMA = 'PUBLIC'
   AND TABLE_NAME   = 'ORDERS'
```

```
;
TABLE_NAME INDEX_NAME        DISTINCT_KEYS
---------- ----------------- -------------
ORDERS     ORDERS_PK_INDEX         1500000
ORDERS     ORDERS_CUSTKEY_FK         99996
2 rows selected.
```

Compatibility

The SQL standard does not define the concepts of the statistics information.

For More Information

Refer to **ANALYZE SYSTEM**.

18.85 AUDIT POLICY

Function

It activates the audit policy.

Syntax

```
<audit policy statement> ::=
    AUDIT POLICY policy_name
    [ <specified_user_option> ]
    [ <specified_success_option> ]
    ;
<specified_user_option> ::=
      BY user_name [, ...]
    ¦ EXCEPT user_name [, ...]
<specified_success_option> ::=
      WHENEVER SUCCESSFUL
    ¦ WHENEVER NOT SUCCESSFUL
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <audit policy statement>.

Syntax Rules and Parameters

policy_name

It is the name of the audit policy object to be activated.
The activated audit policy does not effect on the existing session, and it effects only on the newly created session.

〈specified_user_option〉

It specifies the user to be audited.
If omitted, all users are audited.

BY clause and EXCEPT clause can not be used together for the same audit policy.

- BY user_list: If the user to be audited is specified, then use BY clause.
- EXCEPT user_list: If other users excluding a specific user is to be audited, use EXCEPT clause.

〈specified_success_option〉

- WHENEVER SUCCESSFUL
  - If an action succeeds, then the audit record is created.
- WHENEVER NOT SUCCESSFUL
  - If an action fails, then the audit record is created.
- If omitted, both when an action succeeds and fails, the audit record is created.

Description

Activating the audit policy does not affect the existing session, but it starts to audit the newly created ses sion.

Retrieving Audit Record

The audit record is created when it corresponds to the audit policy, and it can be retrieved through DICTI ONARY_SCHEMA.AUDIT_TRAIL view as follows.

```
SELECT logon_user
     , event_timestamp
     , action_name
     , object_name
     , sql_text
  FROM audit_trail
 WHERE policy_name = 'P1'
;
```

SELECT privilege should be given to an ordinary user to retrieve AUDIT_TRAIL.

```
GRANT SELECT ON DICTIONARY_SCHEMA.AUDTI_TRAIL TO user_name;
```

Retrieving Audit Policy Information

The information about the audit policy object can be retrieved through DICTIONARY_SCHEMA.AUDIT_POLICY_OPTIONS view.

```
SELECT policy_name
     , audit_option
     , object_schema
     , object_name
  FROM audit_policy_options
;
```

The information about whether the audit policy object is activated can be retrieved through DICTIONARY_SCHEMA.AUDIT_POLICY_ENABLED view.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
;
```

Cautions When Using BY and EXCEPT Clauses

Activate the users group if multiple AUDIT POLICY BY clauses are used for the same audit policy.
In other words, the following two examples have the same meaning.

- Example 1: It activates the p1 audit policy for u1 and u2.

```
AUDIT POLICY p1 BY u1;
AUDIT POLICY p1 BY u2;
```

- Example 2: It activates the p1 audit policy for u1 and u2.

```
AUDIT POLICY p1 BY u1, u2;
```

If multiple AUDIT POLICY EXCEPT clauses are used for the same audit policy, only the last AUDIT POLICY clause is valid.

In other words, the following two examples have different meanings.

- Example 1: Only the last clause is valid, and activates the p1 audit policy excluding u2.

```
AUDIT POLICY p1 EXCEPT u1;
AUDIT POLICY p1 EXCEPT u2;
```

- Example 2: It activates the p1 audit policy excluding u1 and u2.

```
AUDIT POLICY p1 EXCEPT u1, u2;
```

BY and EXCEPT can not be used together for the same policy.

- If the audit policy is activated with BY clause, then only BY clause can be used afterwards.

```
AUDIT POLICY p1 BY u1;
```

    - Error

```
AUDIT POLICY p1 EXCEPT u2;
```

- If the audit policy is activated with EXCEPT clause, then only EXCEPT clause can be used afterwards.

```
AUDIT POLICY p1 EXCEPT u1;
```

    - Error: It corresponds to *by all users*.

```
AUDIT POLICY p1;
```

If a user wants to convert the audit policy activated with BY to EXCEPT or to convert the audit policy activ ated with EXCEPT to BY, the activated audit policy should be deactivated first, then it can be converted.

Deactivate the audit policy with NOAUDIT POLICY statement as follows.

- AUDIT POLICY p1 BY u1, u2;
    - NOAUDIT POLICY p1 BY u1, u2;
- AUDIT POLICY p1;
    - NOAUDIT POLICY p1;
- AUDIT POLICY p1 EXCEPT u1, u2;
    - NOAUDIT POLICY p1;
    - NOAUDIT POLICY statement does not have an EXCEPT option.

WHENEVER clause which is used together with BY clause is accumulated.

The following two examples have the same meaning.

- Example 1: It creates the audit record regardless of success/ failure.

```
AUDIT POLICY p1 BY u1 WHENEVER SUCCESSFUL;
AUDIT POLICY p1 BY u1 WHENEVER NOT SUCCESSFUL;
```

- Example 2: It creates the audit record regardless of success/ failure.

```
AUDIT POLICY p1 BY u1;
```

If WHENEVER clauses are used together with EXCEPT clause, only the last WHENEVER clause is valid.

The following two examples have different meanings.

- Example 1: It creates the audit record when it fails.

```
AUDIT POLICY p1 EXCEPT u1 WHENEVER SUCCESSFUL;
AUDIT POLICY p1 EXCEPT u1 WHENEVER NOT SUCCESSFUL;
```

- Example 2: It creates the audit record regardless of success/ failure.

```
AUDIT POLICY p1 EXCEPT u1;
```

Examples

The following is an example of activating the audit policy for all users.

```
AUDIT POLICY table_pol;
```

The information about activation can be viewed through the following query.

```
SELECT policy_name
     , enabled_opt
     , user_name
  FROM audit_policy_enabled
 WHERE policy_name = 'TABLE_POL';
POLICY_NAME  ENABLED_OPT  USER_NAME
-----------  -----------  ---------
TABLE_POL    BY           ALL USERS
```

The following is an example of activating the audit policy by defining specific users.

```
AUDIT POLICY dml_pol BY u1, u2;
```

The following is an example of activating the audit policy by excluding a specific user.

```
AUDIT POLICY read_seq_pol EXCEPT sys;
```

The following is an example of auditing the failure of SQL statement by a specific user.

```
AUDIT POLICY delete_pol BY u1 WHENEVER NOT SUCCESSFUL;
```

Compatibility

The SQL standard does not have the audit policy.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**
- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**
- Viewing audit trail: **AUDIT_TRAIL**
- Clearing audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

19.

SQL References (C~G)

19.1 CLOSE cursor_name

Function

It closes a cursor.

Syntax

```
<close statement> ::=
    CLOSE cursor_name
    ;
```

Syntax Rules and Parameters

cursor_name

The cursor should be open.
The cursor should be declared with **DECLARE cursor_name** statement in the session.

Description

The cursor is an object which exists in the session and it does not affect the cursor in a different session.

Example

The following is an example of DECLARE, OPEN, FETCH, and CLOSE the cursor by using gsql (interactive SQL tool).

```
gSQL> DECLARE cur1 CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
```

```
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
no rows fetched.
gSQL> CLOSE cur1;
Cursor closed.
```

Compatibility

Table 19-1 SQL standard compatibility

Feature ID	Description	Compatibility
B031	Basic dynamic SQL	O

For More Information

Refer to the followings.

- **DECLARE cursor_name**
- **OPEN cursor_name**
- **FETCH cursor_name**

19.2 COMMENT ON name IS

Function

It stores the comments about the object in the dictionary.

Syntax

```
<comment statement> ::=
    COMMENT ON <comment object> IS 'comment string'
    ;
<comment object> ::=
      CLUSTER GROUP group_name
    ¦ CLUSTER MEMBER member_name
    ¦ DATABASE
    ¦ PROFILE profile_name
    ¦ AUTHORIZATION user_name
    ¦ TABLESPACE tablespace_name
    ¦ SCHEMA schema_name
    ¦ TABLE [schema_name].table_name
    ¦ COLUMN [schema_name].table_name.column_name
    ¦ INDEX [schema_name].index_name
    ¦ SEQUENCE [schema_name].sequence_name
    ¦ CONSTRAINT [schema_name].constraint_name
    ¦ PROCEDURE [schema_name].procedure_name
```

Invocation and Access Rules

The altering privileges on each object are required to perform <comment statement> as follows.

- CLUSTER GROUP
  - ALTER SYSTEM ON DATABASE
- CLUSTER MEMBER
  - ALTER SYSTEM ON DATABASE
- DATABASE

    - ALTER DATABASE ON DATABASE
- PROFILE
    - ALTER PROFILE ON DATABASE
- AUDIT POLICY
    - AUDIT SYSTEM ON DATABASE
- AUTHORIZATION (user)
    - ALTER USER ON DATABASE
- AUTHORIZATION (role)
    - ALTER ROLE ON DATABASE
- TABLESPACE
    - ALTER TABLESPACE ON DATABASE
- SCHEMA: One of the following privileges is required.
    - The owner of the schema
    - CONTROL SCHEMA ON SCHEMA for the schema
    - ALTER SCHEMA ON DATABASE
- TABLE: One of the following privileges is required.
    - The owner of the table
    - CONTROL TABLE ON TABLE for the table
    - CONTROL SCHEMA ON SCHEMA for the schema to which the table belongs
    - ALTER ANY TABLE ON DATABASE
- COLUMN: One of the following privileges is required.
    - The owner of the table to which the column belongs
    - CONTROL TABLE ON TABLE for the table to which the column belongs
    - CONTROL SCHEMA ON SCHEMA for the schema of the table to which the column belongs
    - ALTER ANY TABLE ON DATABASE
- INDEX: One of the following privileges is required.
    - The owner of the index
    - CONTROL SCHEMA ON SCHEMA for the schema to which the index belongs
    - ALTER ANY INDEX ON DATABASE
- SEQUENCE
    - The owner of the sequence
    - CONTROL SCHEMA ON SCHEMA for the schema to which the sequence belongs
    - ALTER ANY SEQUENCE ON DATABASE
- CONSTRAINT
    - The owner of that constraint
    - CONTROL SCHEMA ON SCHEMA for the schema to which the constraint belongs
    - ALTER ANY TABLE ON DATABASE
- PROCEDURE
    - The owner of the stored procedure/function
    - CONTROL SCHEMA ON SCHEMA for the schema to which the stored procedure/function belong
      s

- ALTER ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

〈comment object〉

It is an object in which the comments are to be stored. The comments for the following database objects are stored.

- Cluster object
  - CLUSTER GROUP
  - CLUSTER MEMBER
- Non-schema object
  - DATABASE
  - PROFILE
  - AUDIT POLICY
  - AUTHORIZATION (User or role)
  - TABLESPACE
  - SCHEMA
- Schema object
  - TABLE or VIEW
  - COLUMN
  - INDEX
  - SEQUENCE
  - CONSTRAINT
  - PROCEDURE or FUNCTION

If schema_name for the schema object is not specified, the schema name is determined by **Schema Path** of the user performing the statement.

```
COMMENT ON TABLE test_table IS 'test comment';
→ COMMENT ON TABLE user_default_schema.test_table IS 'test comment';
```

'comment string'

It describes the comments to be stored.
Use the empty string ('') to delete the comments as follows.

```
COMMENT ON TABLE test_table IS '';
```

The length of the comment string can not exceed 1024 bytes.

Description

The information can be retrieved from the COMMENTS column of the following dictionary view per each object type.

- Cluster objects
  - CLUSTER GROUP & CLUSTER MEMBER
    - DICTIONARY_SCHEMA.DBA_CLUSTER_COMMENTS view
- Non-schema objects
  - DATABASE
    - DICTIONARY_SCHEMA.ALL_NONSCHEMA_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_NONSCHEMA_COMMENTS view
  - PROFILE
    - DICTIONARY_SCHEMA.DBA_NONSCHEMA_COMMENTS view
  - AUDIT POLICY
    - DICTIONARY_SCHEMA.AUDIT_POLICIES view
  - USER
    - DICTIONARY_SCHEMA.ALL_NONSCHEMA_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_NONSCHEMA_COMMENTS view
  - TABLESPACE
    - DICTIONARY_SCHEMA.ALL_NONSCHEMA_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_NONSCHEMA_COMMENTS view
  - SCHEMA
    - DICTIONARY_SCHEMA.ALL_NONSCHEMA_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_NONSCHEMA_COMMENTS view
- SQL schema objects
  - TABLE
    - DICTIONARY_SCHEMA.USER_TAB_COMMENTS view
    - DICTIONARY_SCHEMA.ALL_TAB_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_TAB_COMMENTS view
  - VIEW
    - DICTIONARY_SCHEMA.USER_TAB_COMMENTS view
    - DICTIONARY_SCHEMA.ALL_TAB_COMMENTS view
    - DICTIONARY_SCHEMA.DBA_TAB_COMMENTS view
  - COLUMN
    - DICTIONARY_SCHEMA.USER_COL_COMMENTS view

        - DICTIONARY_SCHEMA.ALL_COL_COMMENTS view
        - DICTIONARY_SCHEMA.DBA_COL_COMMENTS view
    - INDEX
        - DICTIONARY_SCHEMA.USER_INDEXES view
        - DICTIONARY_SCHEMA.ALL_INDEXES view
        - DICTIONARY_SCHEMA.DBA_INDEXES view
    - SEQUENCE
        - DICTIONARY_SCHEMA.USER_SEQUENCES view
        - DICTIONARY_SCHEMA.ALL_SEQUENCES view
        - DICTIONARY_SCHEMA.DBA_SEQUENCES view
    - CONSTRAINT
        - DICTIONARY_SCHEMA.USER_CONSTRAINTS view
        - DICTIONARY_SCHEMA.ALL_CONSTRAINTS view
        - DICTIONARY_SCHEMA.DBA_CONSTRAINTS view
    - PROCEDURE & FUNCTION
        - DICTIONARY_SCHEMA.USER_PROCEDURES view
        - DICTIONARY_SCHEMA.ALL_PROCEDURES view
        - DICTIONARY_SCHEMA.DBA_PROCEDURES view

For more information about the detailed description of each view, refer to **DICTIONARY_SCHEMA**.

Examples

The following is an example of creating the comment on the table.

```
gSQL> COMMENT ON TABLE t1 IS 'test comment on table t1';
Comment created.
```

The following is an example of creating the comment on the column.

```
gSQL> COMMENT ON COLUMN t1.id IS 'test comment on column t1.id';
Comment created.
```

The following is an example of creating the comment on the schema.

```
gSQL> COMMENT ON SCHEMA s1 IS 'test comment on schema s1';
Comment created.
```

Compatibility

〈comment statement〉 does not exist in SQL standard.

19.3 COMMIT

Function

It terminates the current transaction and makes all changes permanent.

Syntax

```
<commit statement> ::=
    COMMIT [ WORK ]
       [ [ <commit comment clause> ] [ <commit write clause> ] ¦
         [ <commit force clause> ] [ <commit comment clause> ] ]
    ;
<commit comment clause> ::=
      COMMENT 'comment_string'
<commit write clause> ::=
      WRITE [ WAIT ¦ NOWAIT ]
<commit force clause> ::=
    FORCE 'xid_string'
```

Syntax Rules and Parameters

WORK

It is the reserved word which does not affect the operation.

〈commit comment clause〉

- COMMENT 'comment_string'
  - It specifies the comment to the transaction when committing the transaction.

〈commit write clause〉

It determines whether to wait until the redo logs generated by the commit operation are written on the r edo log file.

- WAIT
  - It waits until the redo logs generated by the commit operation are written to the redo log file, and then the operation is terminated.
- NOWAIT
  - The operation is terminated when the redo logs generated by the commit operation are written to the redo log buffer.
- If it is not specified, it follows the property.

〈commit force clause〉

It is used to manually commit a distributed transaction.

- FORCE 'xid_string'
  - It commits the distributed transaction 'xid_string'.
  - 'xid_string' consists of *'format_id.transaction_id.branch_id'*.

Description

COMMIT statement completes the following statements which were executed in a transaction.

- Data Manipulation Language (DML) statement
  - It is the statement which changes data, such as INSERT, UPDATE, DELETE.
- Data Definition Language (DDL) statement
  - It is the statement which changes the structure and definition of the objects, such as CREATE, DROP, ALTER, TRUNCATE, GRANT, REVOKE.

Exceptionally, the following DDL statements which manage the OS resources or change the DATA TYPE are automatically committed.

- **CREATE TABLESPACE**
- **DROP TABLESPACE**
- **ALTER TABLESPACE**
- ALTER TABLE .. ALTER COLUMN .. SET DATA TYPE: **〈alter column data type clause〉**

When performing COMMIT, the cursor opened by WITHOUT HOLD option is automatically closed. For more information about cursors, refer to the following cursor related statements.

- **DECLARE cursor_name**
- **OPEN cursor_name**

If the transaction violates the DEFERRED constraint, the COMMIT statement fails and the transaction is rol

led back. For more information about DEFERRED constraint, refer to **SET CONSTRAINTS**.

Example

The following is an example of performing COMMIT after executing INSERT statement.

```
gSQL> INSERT INTO t1 VALUES ( 1, 'anonymous' );
1 row created.
gSQL> COMMIT WORK COMMENT 'INSERT T1';
Commit complete.
```

Compatibility

Table 19-2 SQL standard compatibility

Feature ID	Description	Compatibility
T261	Chained transactions	X

For More Information

Refer to the followings.

- **ROLLBACK**
- **SAVEPOINT savepoint_specifier**

19.4 CREATE AUDIT POLICY

Function

It creates an audit policy object.
AUDIT POLICY should be performed to activate the created audit policy object.

Syntax

```
<audit policy definition> ::=
    CREATE AUDIT POLICY policy_name
    { <privilege_audit_clause> ¦  <action_audit_clause> ¦ <privilege_audit_clause>
<action_audit_clause> }
    ;
<privilege_audit_clause> ::=
    PRIVILEGES <database_privilege> [, ...]
<action_audit_clause> ::=
    ACTIONS { <object_action_audit> ¦ <system_action_audit> } [, ...]
<object_action_audit> ::=
      ALL ON [schema_name.]object_name
    ¦ <object_action> ON [schema_name.]object_name
<system_action_audit> ::=
      ALL
    ¦ DDL
    ¦ <system_action>
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <audit policy definition>.

Syntax Rules and Parameters

policy_name

It is the name of the audit policy to be created.

〈privilege_audit_clause〉

The privilege audit is auditing when the SQL statement is successfully performed by using the database pr ivilege.
It can audit a specific user performing SQL statement by using the database privilege, and it does not rec ord the privilege audit for SYS user who is the owner of the database.

The following is an example of granting SELECT ANY TABLE privilege to user u1 and activating the audit policy.

```
CREATE AUDIT POLICY p1
       PRIVILEGES SELECT ANY TABLE;
AUDIT POLICY p1;
```

If the user u1 performs the following SQL statement, the privilege audit differently operates.

- SELECT * FROM u1.t1;
  - It does not create the audit record by performing SQL statement with the privilege as an owner o f table u1.t1.
- SELECT * FROM u2.t1;
  - It creates the audit record by performing SQL statement with SELECT ANY TABLE privilege.

〈database_privilege〉 which can be described in the privilege audit can be viewed with the following quer y.

```
SELECT PRIVILEGE_NAME FROM V$AUDITABLE_DB_PRIVILEGES;
```

〈action_audit_clause〉

It audits an action for a specific object and an action for the entire database.

〈object_action_audit〉

ALL ON object_name

It means all actions which can list objects corresponding to object_name.

The following table describes audit actions of which each object type can audit.

Table 19-3 Audit action per object type

Object type	Action
Table	ALTER, COMMENT, DELETE, GRANT, INDEX, INSERT, LOCK, RENAME, SELECT, UPDATE
View	ALTER, COMMENT, GRANT, SELECT
Sequence	ALTER, COMMENT, GRANT, SELECT
Stored Function/Procedure	ALTER, COMMENT, EXECUTE, GRANT

〈object_action〉 ON object_name

Each separate action per a specific object should be listed by specifying ON clause as follows.

```
CREATE AUDIT POLICY p1
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
;
```

Caution of EXECUTE action

Auditing the success or the failure of stored function or stored procedure is determined only based on whether it is executable at the time of execution.

- WHENEVER NOT SUCCESSFUL creates the audit record when neither the stored function nor procedure is executable.
- WHENEVER SUCCESSFUL creates the audit record even though an error occurs while executing SQL statement within the stored function or the procedure
- If an auditing for the failure of SQL statement within the stored function or the procedure is required, then the audit target should include the corresponding SQL statement.

〈system_action_audit〉

It audits the system action which occurs in the database regardless of a specific object.

- 〈system_action〉

The valid system action can be retrieved by using the following query.

```
SELECT ACTION_NAME FROM V$AUDITABLE_SYSTEM_ACTIONS;
```

- ALL

It means all system actions.

- DDL

It means all Data Definition Language (DDL).

Description

An audit policy object is an object which defines auditing targets.
Perform AUDIT POLICY statement to activate an audit policy.

Though it is possbile to define and activate multiple audit policies, but it is recommended to maintain cert ain numbers of audit policies.
It is also recommended to bind multiple small pieces of policies into a small number of groups.

The information about an option of the created audit policy object can be retrieved through AUDIT_POLI CY_OPTIONS view as follows.

```
SELECT audit_option
     , audit_option_type
     , object_schema
     , object_name
  FROM audit_policy_options
 WHERE policy_name = 'P1'
;
AUDIT_OPTION AUDIT_OPTION_TYPE OBJECT_SCHEMA  OBJECT_NAME
------------ ----------------- -------------- ------------
DELETE         OBJECT ACTION     U1           T1
INSERT         OBJECT ACTION     U1           T1
UPDATE         OBJECT ACTION     U1           T1
```

Creating Audit Record

If an action corresponding to multiple audit policies occurs, then one or more audit records are created.

If similar audit options are listed as follows, then one audit record is created.

- Defining an audit policy

```
CREATE AUDIT POLICY p1
       PRIVILEGES SELECT ANY TABLE
       ACTIONS SELECT;
AUDIT POLICY p1;
```

- Performing an audit action

```
SELECT * FROM other_user.t1;
```

If two different audit options are listed as follows, then two audit records are created.

- Defining an audit policy

```
CREATE AUDIT POLICY p1
       ACTIONS SELECT ON u1.t1
             , SELECT ON u2.t2;
AUDIT POLICY p1;
```

- Performing an audit action

```
SELECT COUNT(*) FROM u1.t1 A, u2.t2 B WHERE A.id = B.id;
```

If multiple audit policies are activated for the same action as follows, then two audit records are created.

- Defining an audit policy

```
CREATE AUDIT POLICY p1
       PRIVILEGES SELECT ANY TABLE;
AUDIT POLICY p1;
CREATE AUDIT POLICY p2
       ACTIONS SELECT;
AUDIT POLICY p2;
```

- Performing an audit action

```
SELECT * FROM other.t1;
```

Examples

The following is an example of defining an audit policy which audits an privilege.

```
CREATE AUDIT POLICY policy_table
       PRIVILEGES CREATE ANY TABLE
                , DROP ANY TABLE
;
```

The following is an example of defining an audit policy which audits an action for an object.

```
CREATE AUDIT POLICY policy_dml
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
             , ALL    ON u1.t2
;
```

The following is an example of defining an audit policy which audits the system action.

```
CREATE AUDIT POLICY policy_drop
       ACTIONS DROP TABLE, TRUNCATE TABLE
;
```

The following is an example of defining an audit policy which combines all examples above.

```
CREATE AUDIT POLICY policy_group
       PRIVILEGES CREATE ANY TABLE
                , DROP ANY TABLE
       ACTIONS INSERT ON u1.t1
             , DELETE ON u1.t1
             , UPDATE ON u1.t1
             , ALL    ON u1.t2
             , DROP TABLE
             , TRUNCATE TABLE
;
```

Compatibility

The audit policy does not exist in SQL standard.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**

- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**

- Retrieving audit trail: **AUDIT_TRAIL**

- Clearing audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

19.5 CREATE CLUSTER GROUP

Function

It creates a cluster group which is to participate in a cluster system.

Syntax

```
<cluster group definition> ::=
    CREATE CLUSTER GROUP group_name
        <cluster member definition> [, ...]
    ;
<cluster member definition> ::=
    CLUSTER MEMBER member_name <connection attribute> [<member position>]
<connection attribute> ::=
    HOST 'address' PORT port_no
<member position> ::=
    POSITION DEFAULT
  ¦ POSITION MAX
  ¦ POSITION number
```

Invocation and Access Rules

It can be performed in a cluster system.
ADMINISTRATION ON DATABASE privilege is required to perform <cluster group definition>.

Syntax Rules and Parameters

group_name

It is the name of a cluster group.
An identical cluster group name or a cluster member name should not exist.
The name length should be shorter than 128 bytes.

〈cluster member definition〉

It defines a cluster member to be included in a cluster group.
A cluster group can include maximum 32 cluster members.
A cluster group which is created first in a cluster system can define only one cluster member, and should i nclude itself as a cluster member.

member_name

It is the name of a cluster member.
The name of a cluster member should be same as the name of the member which was defines when crea ting the database of that member.
An identical cluster group name or a cluster member name should not exist.
The name length should be shorter than 128 bytes.

The start-up phase of the cluster member should be the GLOBAL OPEN phase.

〈connection attribute〉

It defines the connection information for the communication between the cluster members.
〈connection attribute〉 should be as same as the HOST and PORT which were defined when the database of that cluster member was created.
The combination of HOST and PORT should be unique in the cluster system.

- HOST 'address' uses the host name or IPv4 address. If the host name is used, then it uses the first IPv 4 address of the system.
- PORT port_no should be in the range between 1024 ~ 49151.

〈member position〉

It assigns the position number of the cluster member.

- POSITION DEFAULT
  - The system automatically assigns the position number.
- POSITION MAX
  - It assigns the new member position number even when an empty position number exists.
  - It assigns the value bigger than the biggest member position.
- POSITION number
  - It assigns the position number corresponding to the number
  - The position number should be unique in the cluster system.
  - The position number should be an empty position number, and it should be same or smaller than

the biggest position number.
- If it is omitted, the default value is POSITION DEFAULT.

The member_position information of the cluster member can be retrieved through DBA_CLUSTER view.

```
SELECT member_name, member_id, member_position FROM dba_cluster;
```

If the following position numbers are being used,

- G1N1: 0
- G1N2: 1
- G2N2: 3
- G3N2: 5

The following values are assigned according to each option.

- POSITION DEFAULT
  - It assigns 2 which is an empty value.
- POSITION MAX
  - It assigns 6 which is a value of a new position number.
- POSITION 3
  - It is duplicated, so it is an error.
- POSITION 4
  - It assigns 4 which is a position number.

Description

<cluster group definition> statement does not rebalance the shard of tables.

Perform the following statements to rebalance the shard to an added cluster group.

- **ALTER DATABASE REBALANCE**
- **ALTER TABLE name REBALANCE**

Examples

The following is an example of creating a cluster group which consists of two cluster members.

```
gSQL>
CREATE CLUSTER GROUP g1
    CLUSTER MEMBER g1n1 HOST '192.168.0.11' PORT 10110
;
Cluster Group created.
gSQL>
ALTER CLUSTER GROUP g1
    ADD CLUSTER MEMBER g1n2 HOST '192.168.0.12' PORT 10120
;
Cluster Group altered.
gSQL>
CREATE CLUSTER GROUP g2
    CLUSTER MEMBER g2n1 HOST '192.168.0.21' PORT 10210,
    CLUSTER MEMBER g2n2 HOST '192.168.0.22' PORT 10220
;
Cluster Group created.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- **DROP CLUSTER GROUP**
- **ALTER CLUSTER GROUP name ADD MEMBER**

19.6 CREATE CLUSTER LOCATION

Function

It creates the connection information of a cluster member.

Syntax

```
<cluster location definition> ::=
    CREATE CLUSTER LOCATION member_name
    <cluster connection attribute>
    ;
<cluster connection attribute> ::
       HOST 'address' PORT port_no
```

Invocation and Access Rules

It can be performed in a cluster system.

ADMINISTRATION ON DATABASE privilege is required to perform <cluster location definition>.

Syntax Rules and Parameters

member_name

It is the name of a cluster member.
The same cluster member name should not exist in the registered cluster location information.
The length of the name should be shorter than 128 bytes.

<cluster connection attribute>

It defines the connection information for the communication between the cluster members.
The combination of HOST and PORT should be unique in the cluster system.

- HOST 'address' uses the host name or IPv4 address. If the host name is used, then it uses the first IPv 4 address of the system.
- PORT port_no should be in the range between 1024 ~ 49151.

Description

Generally, the information of the cluster location is automatically created by using the connection inform ation provided when creating the cluster group or adding the cluster member. The created information is deleted together when deleting the cluster member and the cluster group.

If the information of the cluster location is modified, then the connection information can be modified by using **ALTER CLUSTER LOCATION** without deleting or recreating the cluster member.

Examples

```
gSQL>
CREATE CLUSTER LOCATION g1n2
    HOST '192.168.0.12' PORT 10120,
;
Created
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **DROP CLUSTER LOCATION** .

19.7 CREATE DISK DATA TABLESPACE

Function

It defines the disk data tablespace.

Syntax

```
<disk data tablespace statement> ::=
    CREATE DISK [ DATA ] TABLESPACE tablespace_name
        DATAFILE <disk datafile clause> [, ...]
        [ <data tablespace management clause> [, ...] ]
<disk datafile clause> ::=
     'filename'
        [ SIZE <size clause> ¦ REUSE ¦ SIZE <size clause> REUSE ]
        [ <autoextend clause> ]
        [ AT <domain_name> ]
<autoextend clause>
    AUTOEXTEND { ON [ <next size clause> ] [ <max size clause> ] ¦ OFF }
<next size clause>
    NEXT <size clause>
<max size clause>
    MAXSIZE { <size clause> ¦ UNLIMITED }
<size clause> ::=
    integer [ K ¦ M ¦ G ¦ T ]
<data tablespace management clause> ::=
      { ONLINE ¦ OFFLINE }
    ¦ EXTSIZE <size clause>
```

Invocation and Access Rules

CREATE TABLESPACE ON DATABASE privilege is required to perform <disk data tablespace definition>.

The user who performed the statement has CREATE OBJECT ON TABLESPACE privilege for the created ta
blespace.

The following privileges are required to create an object on the created tablespace.

- CREATE OBJECT ON TABLESPACE for the tablespace
- USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

tablespace_name

It is the name of the tablespace to be created.
The length of the tablespace name should be shorter than 128 bytes.

〈disk datafile clause〉

- 'filename'
  - It is the name of the file which stores and manages the data.
  - It is the space to store tables and index pages which were created in the disk tablespace.
  - filename is either a new file or an existing file.
  - filename length should be shorter than 1024 bytes.

- SIZE 〈size clause〉
  - If it is a new file, then it specifies the initial size by using SIZE clause.
  - If a file exists, then an error occurs.
  - The file size can be in the range between 1 M ~ maximum 30 G.

- REUSE
  - If it is an existing file, then it uses REUSE clause.
  - If a file does not exist, then it creates a new file.
  - The size of the newly created files is determined by USER_DATA_TABLESPACE_SIZE property.

- SIZE 〈size clause〉 REUSE
  - If both SIZE clause and REUSE clause are specified, then it is operated according to the existence of filename as follows.
    - If it is a new filename, then it specifies the initial file size by using SIZE clause.
    - If it is an existing filename, then it adjust the size to the value in SIZE clause.

〈autoextend clause〉

It sets the automatic expand property to ON or OFF. If it is set to ON, then it can specify the automatic ex panded size and the maximum size of the data file.

〈next size clause〉

It specifies the size to be extended when the data file in use does not have available space.

〈max size clause〉

It specifies the maximum expanded size of the data file.

〈size clause〉

It specifies the file size in byte. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

〈domain_name〉

It is the name of member or the group to performs the statement.
If it is omitted, then it is performed for all groups.

ONLINE | OFFLINE

It determines whether to ONLINE/ OFFLINE the tablespace.

- If it is set to ONLINE, then the tablespace is available as soon as it is created.
- If it is set to OFFLINE, then it is not available, It is available only after it is switched to ONLINE.

EXTSIZE 〈size clause〉

It specifies the extent size of the tablespace.

- The extent size is specified in byte, and one of the six (64 K, 128 K, 256 K, 512 K, 1 M, 2 M) is selecte d.
- If the extent size is set specified between 64 K ~ 128 K, then it is set to 128 K, and if it is specifies big ger than 2 M, then it is set to 2 M.

Description

The data tablespace is an object which provides a physical storage to store SQL schema objects such as a table, and index (LOGGING).

Examples

The following is an example of creating the disk data tablespace.

```
gSQL> CREATE DISK TABLESPACE space1 DATAFILE 'test_file_1.dbf' SIZE 10M REUSE;
Tablespace created.
```

The following is an example of creating the tablespace which consists of multiple data files.

```
gSQL> CREATE DISK TABLESPACE space1
             DATAFILE 'test_file_3_1.dbf' SIZE 10M REUSE,
                      'test_file_3_2.dbf' SIZE 10M REUSE;
Tablespace created.
```

Compatibility

The SQL standard does not define the concepts of the tablespace.

For More Information

Refer to the followings.

- DROP TABLESPACE
- ALTER TABLESPACE
- ALTER DATABASE DATAFILE AUTOEXTEND

19.8 CREATE GLOBAL TEMPORARY TABLE

Function

It creates a new global temporary table.

Syntax

```
<global temporary table definition> ::=
    CREATE GLOBAL TEMPORARY TABLE table_name
        ( <table element> [, ...] )
        [ <table commit action clause> ]
        [ TABLESPACE tablespace_name ]
    ;
<global temporary table definition: AS query expression> ::=
    CREATE GLOBAL TEMPORARY TABLE table_name
        [ TABLESPACE tablespace_name ]
        AS <query expression> [ WITH [ NO ] DATA ]
    ;
<table commit action clause> ::=
    ON COMMIT { PRESERVE ¦ DELETE } ROWS
```

The definition of <table element> is as same as that of <table_definition>.
For more information, refer to **CREATE TABLE**.

Invocation and Access Rules

A user should satisfy the following conditions to perform <global temporary table definition> statement.

- Table creation privilege
  - Refer to the access privilege in **CREATE TABLE**.
- SELECT access privilege
  - Refer to the access privilege in **SELECT**.

Syntax Rules and Parameters

table_name

It is the table name to be created.
For more information, refer to **table_name**.

other syntax

For more information about other syntaxes, refer to the syntax in **CREATE TABLE** and in **CREATE TABLE AS SELECT** statement.

Description

GLOBAL TEMPORARY TABLE is used to store the data which is maintained while a transaction or a session is performed.
It is used for the purpose as same as that of the variable of which a developer temporarily stores the mid-data of the operation when developing an application.

The global temporary table has the following features.

- The definition of the global temporary table can be viewed in every session.
- The physical segment is not allocated when defining the global temporary table, but the segment subordinated to that session is allocated when it is inserted for the first time.
- The data of the global temporary table can be viewed in a session or a transaction which was inserted.
- The tablespace to store the data of the global temporary table is determined as follows.

Whether to specify tablespace	The tablespace in which the table is created
It specifies the tablespace.	It is created in the specified tablespace.
It does not specify the tablespace.	It is created in the default temporary tablespace of the current session user.

- The index for the global temporary table is subordinate to the same session of the corresponding table, and the time duration is as same as that of the table.
- It can define the view for the global temporary table.
- It can not specify <table sharding strategy> statement which describe the cluster-related features of the table for the global temporary table, nor <table global secondary index clause> statement.
- It can not specify <table attribute clause> which describes the physical attributes of the table for the global temporary table, nor <index attribute clause> which describes the physical attributes of the inde

x.

- <index attribute clause> which describes the physical attributes of the index can not be specified for t he index which is created based on the global temporary table.
- If a transaction is terminated by <table commit action clause>, it can determine how to process the re maining data.

Table commit action	Description
ON COMMIT PRESERVE ROWS	It maintains the data remained in a table even after COMMIT or ROLLBACK.
ON COMMIT DELETE ROWS (defa ult)	It deletes all data remained in a table at the time of COMMIT or ROLLBACK (TR UNCATE).

- It supports most of DDLs for an ordinary table. (Including ALTER and TRUNCATE)
  - It does not support CLUSTER-related statement (SHARD and global secondary index-related state ment).
  - DDL for the global temporary table which is currently used in its own session or in another sessio n causes an error.
  - DDL is available after removing all segments which is used as TRUNCATE TABLE or COMMIT in all sessions in use.
- It supports all DMLs and select statements for an ordinary table.
- All alteration for the global temporary table (DML) do not leave the redo log.
- All alteration for the global temporary table (DML) leaves the undo log, the location of the undo log i s determined according to TEMP_UNDO_ENABLED property.

TEMP_UNDO_ENABLED value	Description
TRUE	The undo log is recorded in the default temporary tablespace of the database sy stem.
FALSE	The undo log is recorded in the undo tablespace of the database system.

- TRUNCATE command for the global temporary table truncates only the segment of the correspondin g session.
- If the session is terminated, all segments are TRUNCATEd and then returned.

Examples

The following is an example of performing CREATE GLOBAL TEMPORARY TABLE statement.

```
gSQL> CREATE  GLOBAL TEMPORARY TABLE SESSION_TABLE1(
        COL1    CHAR(10)
       ,COL2    VARCHAR2(20)
       ,COL3    NUMBER(10)
```

```
)   ON  COMMIT  DELETE ROWS;
Table created.
```

The following is an example of performing CREATE GLOBAL TEMPORARY TABLE ... AS SELECT statemen t.

```
gSQL> CREATE  GLOBAL TEMPORARY TABLE SESSION_TABLE2
    ON  COMMIT  PRESERVE ROWS
    AS  SELECT  *
          FROM  EMPLOYEES;
Table created.
```

Compatibility

CREATE GLOBAL TEMPORARY TABLE and CREATE GLOBAL TEMPORARY TABLE AS SELECT statement fo llows the definition of SQL standard <table definition>. However, the following is an extension of SQL sta ndard.

- SQL standard require parentheses outside SELECT clause, but it is optional in GOLDILOCKS.
- SQL standard require WITH [NO] DATA clause, but it is optional in GOLDILOCKS.
- The concepts of tablespace in GOLDILOCKS is an extended concept, and it is not supported in SQL st andard.

Table 19-4 SQL standard compatibility

Feature ID	Description	Compatibility
T171	LIKE clause in table definition	X
T172	AS subquery clause in table definition	O
F531	Temporary tables	X
S051	Create table of type	X
S043	Enhanced reference types	X
S081	Subtables	X
T173	Extended LIKE clause in table definition	X
T180	System-versioned tables	X
F692	Extended collation support	X
T174	Identity columns	O
T175	Generated columns	X
S071	SQL paths in function and type name resolution	X
F321	User authorization	O
T322	Extended roles	X
F762	CURRENT_CATALOG	O

Feature ID	Description	Compatibility
F763	CURRENT_SCHEMA	O

For More Information

Refer to the followings.

- CREATE TABLE
- CREATE TABLE AS SELECT

19.9 CREATE IMMUTABLE TABLE

Function

It creates a new immutable table.

Syntax

```
<immutable table definition> ::=
    CREATE IMMUTABLE TABLE table_name
        ( <table element> [, ...] )
        [ <table sharding strategy> ]
        [ <table attribute clause> [...] ]
        [ TABLESPACE tablespace_name ]
        [ <table global secondary index clause> ]
    ;
<immutable table definition: AS query expression> ::=
    CREATE IMMUTABLE TABLE table_name
        [ ( column_name [, ...] ) ]
        [ <table sharding strategy> ]
        [ <table attribute clause> [, ...] ]
        [ TABLESPACE tablespace_name ]
        [ <table global secondary index clause> ]
        AS <query expression> [ WITH [ NO ] DATA ]
    ;
```

The definition for <table element>, <table sharding strategy>, <table attribute clause> and <table global secondary index clause> are as same as that of <table_definition>. For more information, refer to **CREATE TABLE**.

Invocation and Access Rules

The user should satisfy the following conditions to perform <immutable table definition>.

- The privilege to create the table
  - Refer to the access rules for **CREATE TABLE** statement.
- The privilege for SELECT to access
  - Refer to the access rules for **SELECT** statement.

Syntax Rules and Parameters

table_name

It is the table name to be created and it should be unique in the schema.
It can define the schema to which the table belongs, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.
The length of the table name should be shorter than 128 byte.

Other Syntax

For other syntaxes, refer to the syntaxes for **CREATE TABLE** and **CREATE TABLE AS SELECT**.

Description

An immutable table is used when it is required to prevent the record stored in the table from being altered or deleted and to prevent the table from being dropped.

An immutable table can be dropped when a user, a schema, a tablespace and a cluster group are dropped.

The following SQL statements are not allowed for an immutable table.

- UPDATE
- DELETE
- ALTER TABLE RENAME/DROP COLUMN
- ALTER TABLE SET UNUSED COLUMN
- ALTER TABLE DROP UNUSED COLUMNS
- ALTER TABLE RENAME TO
- TRUNCATE TABLE
- DROP TABLE

The following SQL statements are allowed for an immutable table.

- INSERT
- SELECT
- SELECT .. FOR UPDATE
- CREATE/ALTER/DROP INDEX
- ALTER TABLE ADD/ALTER COLUMN
- ALTER TABLE ADD/ALTER/RENAME/DROP CONSTRAINT
- ALTER TABLE for physical property changes
- ALTER TABLE ADD/DROP SUPPLEMENTAL LOG
- LOCK TABLE
- ALTER TABLE .. ADD/ALTER/DROP GLOBAL SECONDARY INDEX
- ALTER DATABASE MOVE SHARD
- ALTER TABLE .. MOVE SHARD
- ALTER TABLE .. SPLIT SHARD
- ALTER TABLE .. MERGE SHARD
- DROP TABLESPACE
- DROP SCHEMA
- DROP USER
- DROP CLUSTER GROUP

Examples

The following is an example of executing CREATE IMMUTABLE TABLE statement.

```
gSQL> CREATE IMMUTABLE TABLE t1
(
    id INTEGER PRIMARY KEY,
    name VARCHAR(128),
    addr VARCHAR(128)
);
Table created.
```

The following is an example of executing CREATE IMMUTABLE TABLE ... AS SELECT statement.

```
gSQL> CREATE IMMUTABLE TABLE T2
       AS SELECT *
             FROM T1;
```

```
Table created.
```

Compatibility

The SQL standard does not cover CREATE IMMUTABLE TABLE and CREATE IMMUTABLE TABLE AS SELEC T statements.

For More Information

Refer to the followings.

- CREATE TABLE
- CREATE TABLE AS SELECT

19.10 CREATE INDEX

Function

It creates an index.

Syntax

```
<index definition> ::=
    CREATE [ UNIQUE ] INDEX index_name
        ON table_name ( <index column element> [, ...] )
        [ <index attributes> [...] ]
        [ TABLESPACE tablespace_name ]
    ;
<index column element> ::=
    column_name [ ASC ¦ DESC ] [ NULLS FIRST ¦ NULLS LAST ]
<index attributes> ::=
      <physical attribute clause>
    ¦ STORAGE ( <segment attr clause> [...] )
    ¦ <parallel clause>
<physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
<parallel clause> ::=
      NOPARALLEL
    ¦ PARALLEL [ integer ]
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <index definition>.

- One of the following privileges is required to create an index on the table.
  - (INDEX or CONTROL TABLE ON) TABLE for that table
  - CONTROL SCHEMA ON SCHEMA for the schema to which the table belongs
  - CREATE ANY INDEX ON DATABASE

- One of the following privileges is required for the schema on which the index is to be created.
  - (CREATE INDEX or CONTROL SCHEMA) ON SCHEMA for the schema
  - CREATE ANY INDEX ON DATABASE

- One of the following privileges is required for the tablespace on which the index is to be created.
  - CREATE OBJECT ON TABLESPACE for that tablespace
  - USAGE TABLESPACE ON DATABASE

- The owner of the index is determined as follow.
  - The owner of the schema to which the index belongs.
  - If the schema to which the index belongs is PUBLIC, then it is the user who executed the stateme nt.

Unique indexes in a cluster system should include all sharding keys.

Syntax Rules and Parameters

UNIQUE

It does not allow duplicate values for the columns of the index.

index_name

It is the index name to be created and it should be a unique name within the schema.
If the schema name is omitted, the index is created in the schema to which the referring table belongs.
The length of the index name should be shorter than 128 bytes.

table_name

It is the table name which creates the index.
The schema to which a table belongs, such as schema_name.table_name, can be defined. If schema_name is omitted, the default schema name of the user performing the statement is used.

column_name

It is the column name to be used as an index key.
One or more columns should be defined, and maximum 32 columns can be used as an index key.

The following constraints can occur depending on the implementation.

- If the column data type included in an index is LONG CHARACTER VARYING, LONG BINARY VARYING, an index can not be created.
- An index is created only when the sum of the column precisions is less than 1200 bytes.

ASC | DESC

It specifies the sort order of a column.

- ASC: It is sorted in ascending order.
- DESC: It is sorted in descending order.
- If not specified, the default value is ASC.

NULLS FIRST | NULLS LAST

It specifies the sort order of the NULL value.

- NULLS FIRST: It precedes the non-NULL values.
- NULLS LAST: It is behind the non-NULL values.
- If not specified, the default value is NULLS LAST.

〈physical attribute clause〉

It defines the physical attribute of the index.

- PCTFREE integer
  - Definition
    - It is the reserved space for adjusting the page split frequency caused by the key inserted in the page.
    - It applies only to the index bottom-up build.

- It can use the value from 0 to 99.
- If it is omitted, the default value is the value set in DEFAULT_INDEX_PCTFREE property.

- INITRANS integer
  - Definition
    - It specifies the initial number of transactions which can simultaneously access the page.
    - If the number of users who access the index is small, INITRANS is set to low, and if the numb er of users who simultaneously access the index is big, INITRANS is set to high.
    - If necessary, it is automatically increased to the specified MAXTRANS.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 4.

- MAXTRANS integer
  - Definition
    - It specifies the maximum number of transactions which can simultaneously access the page.
  - It can use the value from 1 to 32.
  - If it is omitted, the default value is 8.

〈segment attr clause〉

It specifies the information for the index storage space.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the ind ex.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' is actually operated as 8192 bytes.)
    - The size (aligned to the EXTENT size of TABLESPACE) should be equal to or bigger than MIN EXTENTS, or it should be equal to or less than MAXEXTENTS.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the table belongs.

- NEXT integer
  - Definition
    - It specifies the physical space size to be allocated when adding the space to the table.
    - This size is aligned to the EXTENT size of the TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'NEXT 100' is actually operated as 8192 bytes.)
    - NEXT operates as follows, depending on the remaining space size of the index available curr ently. (Obtained by subtracting the amount of currently used space from the MAXEXTENTS si ze)

    - If the remaining space size is 0, then it can not extend the space.
    - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the

space as big as the remaining space.
- If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is one EXTENT size of TABLESPACE to which the index belongs.

- MINSIZE integer
  - Definition
    - It is the minimum space size of the index.
    - The value should be equal to or smaller than MAXSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is smaller than the size of two EXTENT, it is specified to the size of two EXTENT.
  - If it is omitted, the default value is the size of two EXTENT.

- MAXSIZE integer
  - Definition
    - It is the maximum space size of the index.
    - The value should be equal to or bigger than MINSIZE.
  - This size is aligned to the EXTENT size of the TABLESPACE to which the index belongs.
  - The minimum value is 1 and the maximum value depends on the system environment.
  - If it is omitted, the default value is 32 terabytes (35,184,372,088,832).
  - Even though the value is set to over 32 terabytes, it is adjusted and set to 32 terabytes.

〈size clause〉

It specifies the file size in bytes. (If the unit is omitted, the default value is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

NOPARALLEL | PARALLEL [integer]

It specifies the number of threads to be used when building an index.

- NOPARALLEL
  - It does not build an index in parallel.
- PARALLEL [integer]
  - It builds an index in parallel.
  - If an integer is omitted or set as 0, then it follows INDEX_BUILD_PARALLEL_FACTOR property.
  - The minimum value of an integer is 0 and the maximum value is 16.

    - If the property value is 0, then the system determines the optimal value.
- If it is omitted, the default value is PARALLEL.

TABLESPACE tablespace_name

It specifies the name of the tablespace in which the index is to be stored.

- When it specifies tablespace_name
    - if tablespace_name is data tablespace, then a LOGGING index is created.
    - if tablespace_name is temporary tablespace or nologging tablespace, then a NOLOGGING index i s created.

- When it omits TABLESPACE clause
    - If INDEX TABLESPACE tablespace_name of USER is specified
        - The defined tablespace is used.
    - If INDEX TABLESPACE of USER is NULL
        - The index of the DISK table uses the user's default data tablespace.
        - The index of the MEMORY table uses the user's default temporary tablespace.

Description

LOGGING index and NOLOGGING index have the following trade-offs.

- LOGGING index
    - Advantage: It does not separately build an index because the index is automatically restored by u sing the log when starting up the system.
    - Disadvantage: A disk I/O occur because the changes on the index is recorded on the log when alt ering the row.
- NOLOGGING index
    - Advantage: A disk I/O does not occur for the changes on the index when altering the row.
    - Disadvantage: It automatically rebuilds the index when starting up the system because the log inf ormation of the index does not exist.

Examples

The following is an example of creating the unique index.

```
gSQL> CREATE UNIQUE INDEX idx_t1_id ON t1( id );
Index created.
```

The following is an example of creating an index for multiple columns.

```
gSQL> CREATE INDEX idx_t1_id_name ON t1( id, name );
Index created.
```

The following is an example of specifying the sort order of the index column.

```
gSQL> CREATE INDEX idx_t1_dept_id ON t1( dept_id DESC );
Index created.
```

The following is an example of specifying the sort order of NULL value of the index column.

```
gSQL> CREATE INDEX idx_t1_name ON t1( name NULLS FIRST );
Index created.
```

The following is an example of setting information about the space in which index is stored.

```
gSQL> CREATE INDEX idx_t1_id ON t1( id )
             STORAGE ( INITIAL 10M NEXT 1M MINSIZE 10M MAXSIZE 100M );
Index created.
```

The following is an example of creating the redo logging for the index.

```
gSQL> CREATE INDEX idx_t1_id ON t1( id );
Index created.
```

The following is an example of creating the index with parallel option.

```
gSQL> CREATE INDEX idx_t1_name ON t1( name ) PARALLEL;
Index created.
```

The following is an example of specifying the tablespace when creating an index.

```
gSQL> CREATE INDEX idx_t1_name ON t1( name ) TABLESPACE mem_temp_tbs;
Index created.
```

Compatibility

The SQL standard does not cover the concepts of the index.

For more information

Refer to **DROP INDEX**.

19.11 CREATE MEMORY DATA TABLESPACE

Function

It defines a memory data tablespace.

Syntax

```
<memory data tablespace statement> ::=
    CREATE [ MEMORY ] [ DATA ] TABLESPACE tablespace_name
        DATAFILE <memory datafile clause> [, ...]
        [ <data tablespace management clause> [, ...] ]
<memory datafile clause> ::=
     'filename'
        [ SIZE <size clause> ¦ REUSE ¦ SIZE <size clause> REUSE ]
        [ AT <domain_name> ]
<size clause> ::=
    integer [ K ¦ M ¦ G ¦ T ]
<data tablespace management clause> ::=
      { ONLINE ¦ OFFLINE }
    ¦ EXTSIZE <size clause>
```

Invocation and Access Rules

CREATE TABLESPACE ON DATABASE privilege is required to perform <memory data tablespace definition>
.

The user who performed the statement has CREATE OBJECT ON TABLESPACE privilege on the created ta
blespace.

One of the following privileges is required to create the objects on the created tablespace.

- CREATE OBJECT ON TABLESPACE for that tablespace
- USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

[MEMORY] [DATA]

It is a memory tablespace to store the permanent objects such as tables, indexes, etc.
The reserved words, MEMORY and DATA, can be omitted.

tablespace_name

It is the tablespace name to be created.
The length of the tablespace name should be shorter than 128 bytes.

〈memory datafile clause〉

- 'filename'
  - It is the file name to store and manage the data.
  - It is the space to store the checkpoint image for the memory data.
  - filename can be either a new file or an already existing file.
  - The length of the filename should be shorter than 1024 bytes.

- SIZE 〈size clause〉
  - The initial size is assigned for a new file by using the SIZE clause.
  - An error occurs if the file already exists.
  - The file size can be specified between minimum 1M and maximum 30G.

- REUSE
  - If the file already exists, REUSE clause is used.
  - If the file does not exist, a new file is created.
  - The newly created file size is
    - determined by USER_DATA_TABLESPACE_SIZE property in case of the data tablespace.
    - determined by USER_TEMP_TABLESPACE_SIZE property in case of the temporary tablespace.

- SIZE 〈size clause〉 REUSE
  - If both SIZE clause and REUSE clause are specified, it is operated as follows according to the pres ence of the filename.
    - For the new filename, the initial file size is assigned by using the SIZE clause.
    - For the existing filename, the size is adjusted to the value of SIZE clause by using the existing file.

〈size clause〉

It specifies the file size in bytes. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

ONLINE | OFFLINE

It sets ONLINE or OFFLINE of the tablespace.

- ONLINE is the state which a tablespace can be used as soon as it is created.
- OFFLINE is the state which a tablespace is unable to be used, it can be used after switching to ONLIN E state.

EXTSIZE 〈size clause〉

It specifies extent size of the tablespace.

- The extent size is specified in bytes, and one of the six (64 K, 128 K, 256 K, 512 K, 1 M, 2 M) is select ed.
- If the extent size is defined as a value between 64 K ~ 128 K, 128 K is set. If the extent size is defined as 2 M or bigger, 2 M is set.

Description

The data tablespace is an object which provides the physical space to store the SQL schema object such a s a table, an index (LOGGING).

Examples

The following is an example of creating a memory data tablespace.

```
gSQL> CREATE TABLESPACE space1 DATAFILE 'test_file_1.dbf' SIZE 10M REUSE;
Tablespace created.
```

The following is an example of creating a tablespace which consists of multiple data files.

```
gSQL> CREATE TABLESPACE space1
             DATAFILE 'test_file_3_1.dbf' SIZE 10M REUSE,
                      'test_file_3_2.dbf' SIZE 10M REUSE;
Tablespace created.
```

Compatibility

The SQL standard does not cover the concepts of the tablespace.

For More Information

Refer to the followings.

- DROP TABLESPACE
- ALTER TABLESPACE

19.12 CREATE MEMORY TEMPORARY TABLESPACE

Function

It defines a memory temporary tablespace.

Syntax

```
<memory temporary tablespace statement> ::=
    CREATE [ MEMORY ] TEMPORARY TABLESPACE tablespace_name
        MEMORY <memory clause> [, ...]
        <temporary tablespace management clause>
<memory clause>
     'memory_name' { SIZE <size clause> } [ AT <domain_name> ]
<temporary tablespace management clause> ::=
    EXTSIZE <size clause>
```

Invocation and Access Rules

CREATE TABLESPACE ON DATABASE privilege is required to perform <memory temporary tablespace definition>.

The user who performed the statement has CREATE OBJECT ON TABLESPACE privilege on the created tablespace.

One of the following privileges is required to create the objects on the created tablespace.

- CREATE OBJECT ON TABLESPACE for the tablespace.
- USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

[MEMORY] TEMPORARY

It is a memory temporary tablespace to store the no logging indexes or the temporary objects such as inte rmediate results which are generated during the query processing.
The reserved word, MEMORY, can be omitted.

tablespace_name

It is the tablespace name to be created.
The length of the tablespace name should be shorter than 128 bytes.

〈memory clause〉

- 'memory_name'
  - It is a memory name to store the temporary data.
  - memory_name should be guaranteed to be unique within the tablespace.
  - The length of the memory_name should be shorter than 1024 bytes.
- SIZE 〈size clause〉
  - It specifies the initial size.
  - It can be specified between minimum 1M and maximum 30G.

〈size clause〉

It specifies the size of shared memory space in bytes.(If it is omitted, the default unit is bytes.)
The image is not managed as a file in case of the temporary memory data.

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

〈domain name〉

It is a name of a member or a group for which the statement is performed.
If it is omitted, it is performed for all groups.

EXTSIZE <size clause>

It specifies extent size of the tablespace.

- The extent size is specified in bytes, and one of the six (64 K, 128 K, 256 K, 512 K, 1 M, 2 M) is select ed.
- If the extent size is defined as a value between 64 K ~ 128 K, 128 K is set. If the extent size is defined as 2 M or bigger, 2 M is set.

Description

The temporary tablespace is an object which provides the physical space to store the SQL schema object s uch as an index (NOLOGGING), and to store the intermediate results for sorting, hashing during the quer y processing.

Examples

The following is an example of creating a temporary tablespace.

```
gSQL> CREATE TEMPORARY TABLESPACE temp_space1 MEMORY 'test_memory_1' SIZE 10M;
Tablespace created.
```

The following is an example of creating a temporary tablespace which includes multiple memory spaces.

```
gSQL> CREATE TEMPORARY TABLESPACE temp_space1
              MEMORY 'test_memory_3_1' SIZE 10M,
                     'test_memory_3_2' SIZE 10M;
Tablespace created.
```

Compatibility

The SQL standard does not cover the concepts of the tablespace.

For More Information

Refer to the followings.

- DROP TABLESPACE
- ALTER TABLESPACE

19.13 CREATE PROFILE

Function

It is the statement which creates the profile, and it sets the password management method.
When a profile is allocated to a user, the user's password is managed in the way defined in the profile.

Syntax

```
<profile definition> ::=
    CREATE PROFILE profile_name LIMIT
    { <password_parameters>, ...}
    ;
<password parameters> ::=
      FAILED_LOGIN_ATTEMPTS { integer ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_LOCK_TIME  { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_LIFE_TIME  { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_GRACE_TIME { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_REUSE_MAX  { integer ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_REUSE_TIME { password_parameter_number_interval ¦ UNLIMITED ¦ DEFAULT }
    ¦ PASSWORD_VERIFY_FUNCTION { <verify_policy> ¦ NULL ¦ DEFAULT }
<verify_policy> ::=
      KISA_VERIFY_FUNCTION
    ¦ ORA12C_VERIFY_FUNCTION
    ¦ ORA12C_STRONG_VERIFY_FUNCTION
    ¦ VERIFY_FUNCTION_11G
    ¦ VERIFY_FUNCTION
<password_parameter_number_interval> ::=
   integer
 ¦ integer / integer
```

Invocation and Access Rules

CREATE PROFILE ON DATABASE privilege is required to perform <profile definition>.

Syntax Rules and Parameters

profile_name

It specifies the profile name to be created.

password_parameters

It sets the parameters for password management.

- The following parameters are to be set.
  - FAILED_LOGIN_ATTEMPTS
  - PASSWORD_LOCK_TIME
  - PASSWORD_LIFE_TIME
  - PASSWORD_GRACE_TIME
  - PASSWORD_REUSE_MAX
  - PASSWORD_REUSE_TIME
  - PASSWORD_VERIFY_FUNCTION

The omitted parameters follows the "DEFAULT" profile policy.

FAILED_LOGIN_ATTEMPTS

It sets the number of consecutive login attempts allowed to fail.
If the failed attempts exceed the specified number, the account is locked.

- FAILED_LOGIN_ATTEMPTS integer
  - The value range should be a positive integer bigger than 0.
- FAILED_LOGIN_ATTEMPTS UNLIMITED
  - Account lockout which is due to a login failure does not occur.
- FAILED_LOGIN_ATTEMPTS DEFAULT
  - It follows the "DEFAULT" profile policy.

PASSWORD_LOCK_TIME

It sets the period (days) which the account is locked after consecutive login failure.

- PASSWORD_LOCK_TIME constant_expression
  - It is the lock duration (day).
  - The default unit is a day.
  - Hours(n/24), minutes (n/1440), seconds (n/86400) can be specified for testing.

    - The value range is from one second (1/86400) to 100,000 days.
- PASSWORD_LOCK_TIME UNLIMITED
    - If an account lockout occurs, the lock is not release until performing ALTER USER user_name AC COUNT UNLOCK statement.
- PASSWORD_LOCK_TIME DEFAULT
    - It follows the "DEFAULT" profile policy.

PASSWORD_LIFE_TIME

It sets the life time of the password (day).

- PASSWORD_LIFE_TIME constant_expression
    - It is the life time of the password (day).
    - The default unit is a day.
    - Hours(n/24), minutes (n/1440), seconds (n/86400) can be specified for testing.
    - The value range is from one second (1/86400) to 100,000 days.
- PASSWORD_LIFE_TIME UNLIMITED
    - The password does not have the expiration date.
- PASSWORD_LIFE_TIME DEFAULT
    - It follows the "DEFAULT" profile policy.

PASSWORD_GRACE_TIME

It sets the grace period of password expiration when logging in after PASSWORD_LIFE_TIME.

- PASSWORD_GRACE_TIME constant_expression
    - The grace period for password expiration (day)
    - The default unit is a day.
    - Hours (n/24), minutes (n/1440), seconds (n/86400) can be specified for testing.
    - The value range is from one second (1/86400) to 100,000 days.
- PASSWORD_GRACE_TIME UNLIMITED
    - It continues to defer the password expiration.
- PASSWORD_GRACE_TIME DEFAULT
    - It follows the "DEFAULT" profile policy.

PASSWORD_GRACE_TIME starts at first login trial after the password life time. If the password is not alte red during the grace period, the password expires.

PASSWORD_REUSE_MAX

It sets the number of the recent passwords which can not be reused when the user wants to reuse the old password.

PASSWORD_REUSE_MAX should be used together with PASSWORD_REUSE_TIME.

- PASSWORD_REUSE_MAX integer
  - The value range should be a positive integer bigger than 0.
- PASSWORD_REUSE_MAX UNLIMITED
  - If PASSWORD_REUSE_TIME is UNLIMITED, all old passwords can be reused.
  - If PASSWORD_REUSE_TIME is not UNLIMITED, any old password can not be reused.
- PASSWORD_REUSE_MAX DEFAULT
  - It follows the "DEFAULT" profile policy.

PASSWORD_REUSE_TIME

It sets the duration which the password can not be reused when the user wants to reuse the old password.

PASSWORD_REUSE_TIME should be used together with PASSWORD_REUSE_MAX.

- PASSWORD_REUSE_TIME constant_expression
  - It is the duration which the password can not be reused. (day)
  - The default unit is a day.
  - Hours(n/24), minutes (n/1440), seconds (n/86400) can be specified for testing.
  - The value range is from one second (1/86400) to 100,000 days.
- PASSWORD_REUSE_TIME UNLIMITED
  - If PASSWORD_REUSE_MAX is UNLIMITED, all old passwords can be reused.
  - If PASSWORD_REUSE_MAX is not UNLIMITED, any old password can not be reused.
- PASSWORD_REUSE_TIME DEFAULT
  - It follows the "DEFAULT" profile policy.

PASSWORD_VERIFY_FUNCTION

It sets the password complexity verification methods.

- PASSWORD_VERIFY_FUNCTION null
  - The password complexity verification is not performed.
- PASSWORD_VERIFY_FUNCTION DEFAULT
  - It follows the "DEFAULT" profile policy.
- PASSWORD_VERIFY_FUNCTION <verify policy>
  - The password complexity verification methods can be specified as follows.

- KISA_VERIFY_FUNCTION
- ORA12C_VERIFY_FUNCTION
- ORA12C_STRONG_VERIFY_FUNCTION
- VERIFY_FUNCTION_11G
- VERIFY_FUNCTION

KISA_VERIFY_FUNCTION

It is the password verification method of KISA (Korea Internet & Security Agency).

- 8 or more letters
- One or more characters
- One or more numbers
- One or more special characters

ORA12C_VERIFY_FUNCTION

It is the password verification method of Oracle, ORA 12C VERIFY_FUNCTION.

- 8 or more letters
- 1 or more characters
- 1 or more numbers
- The database name should not be included.
- The username or the reversed username should not be included.
- *goldilocks* should not be included.
- *oracle* should not be included.
- The following simple passwords are not allowed.
  - welcome1, database1, account1, user1234, password1, oracle123, computer1, abcdefg1, change_on_intall
- At least 3 characters of the new password should be different from the old password.

ORA12C_STRONG_VERIFY_FUNCTION

It is the password verification method of Oracle, ORA12C_STRONG_VERIFY_FUNCTION.

- 9 or more letters
- 2 or more uppercases
- 2 or more lowercases
- 2 or more numbers
- 2 or more special characters
- At least 4 characters of the new password should be different from the old password.

VERIFY_FUNCTION_11G

It is the password verification method of Oracle, VERIFY_FUNCTION_11G.

- 8 or more letters
- 1 or more characters
- 1 or more numbers
- The username should not be included.
- At least 3 characters of the new password should be different from the old password.

VERIFY_FUNCTION

It is the password verification method of Oracle, VERIFY_FUNCTION.

- It should not be as same as the username.
- 4 or more letters
- 1 or more characters
- 1 or more numbers
- 1 or more special characters
- The following simple passwords are not allowed.
  - welcome, database, account, user, password, oracle, computer, abcd
- At least 3 characters of the new password should be different from the old password.

Description

Account Lockout

The followings are the parameters affecting the account lockout.

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

For example, when a user and a profile are created as follows

```
CREATE PROFILE prof LIMIT
    FAILED_LOGIN_ATTEMPTS 4
    PASSWORD_LOCK_TIME 30;
ALTER USER u1 PROFILE prof;
```

If the user u1 fails to log in more than four times, the account is locked for 30 days. Then the account loc kout is released after 30 days.

If PASSWORD_LOCK_TIME is UNLIMITED, the account lockout should be explicitly released by using ALTER USER statement.

```
ALTER USER user1 ACCOUNT UNLOCK;
```

Password Expiration

The followings are the parameters affecting the password expiration.

- PASSWORD_LIFE_TIME
- PASSWORD_GRACE_TIME

The password is expired in the following order.

1. The password is set.
   - The time of the password expiration is set to the time elapsed as much as PASSWORD_LIFE_TIME since when a password is altered.
   - The password expiration status is OPEN, and it allows a normal login.

2. When a user logs in after the password expiration
   - The login succeeds but the password expiration status becomes EXPIRED (GRACE) and the following warnings occur.
     - ERR-28000(16310): The password will expire in n days
     - ERR-28000(16311): The password will expire soon
     - The SQL standard does not cover the concepts of password expiration.
     - 28000 is the authentication warning or SQL standard status code of an error. 16310, 16311 are the GOLDILOCKS error code.
   - The time of the password expiration is reset to the time elapsed as much as PASSWORD_GRACE_TIME since when a user logged in.

3. When a user logs in after the grace time
   - The password expiration status becomes EXPIRED, the user can not log in, and the following error occurs.
     - ERR-28000(16312): The password has expired
     - The SQL standard does not cover the concepts of password expiration.
     - 28000 is the authentication warning or SQL standard status code of an error. 16312 is the GOLDILOCKS error code.
     - GOLDILOCKS internal error code of 16312 should be used to control password reentering using program.

Table 19-5 Password expiration status transition

Step	Point of time	login	Status
1	The password is changed.	Success	OPEN

Step	Point of time	login	Status
2	PASSWORD_LIFE_TIME is elapsed.	Success with warning	EXPIRED(GRACE)
3	PASSWORD_GRACE_TIME is elapsed.	Error	EXPIRED

The following is another example.

```
CREATE PROFILE prof LIMIT
   PASSWORD_LIFE_TIME 90
   PASSWORD_GRACE_TIME 3;
ALTER USER u1 PROFILE prof;
```

The example above describes that the user u1 succeeds in login after 90 days of password expiration. Ho wever, the user receives a warning that the password expires in three days.

If the password is not changed within three days, the password expires.
Once the password expires, it reminds that the new password should be entered when logging in, and th e account access is denied.

Password Reusability

The followings are the parameters affecting the password reusability.

- PASSWORD_REUSE_MAX
- PASSWORD_REUSE_TIME

The password reusability of the two parameters above are determined according to the following table.

Table 19-6 Conditions for the password reusability

PASSWORD_REUSE_MAX	PASSWORD_REUSE_TIME	Reusable condition
value	value	It can be reused when both conditions of PASSWORD_R EUSE_TIME and PASSWORD_REUSE_MAX are satisfied.
value	UNLIMITED	It can not be reused.
UNLIMITED	value	It can not be reused.
UNLIMITED	UNLIMITED	It can always be reused.

If a profile is created as follows,

```
CREATE PROFILE prof LIMIT
   PASSWORD_REUSE_MAX 5
   PASSWORD_REUSE_TIME 3;
```

the password can not be reused if it is the five recent passwords or the password changed within three d

ays.

The following is an example of the user u1's password change history. If the current password is P # _000 007 and the current date is 2015-08-08, the reusability of existing passwords is as follows.

Table 19-7 Examples of password reusability

Password	Password_date	Password reusability
P#_000001	2015-08-01	It can be reused.
P#_000002	2015-08-02	It can be reused.
P#_000003	2015-08-03	It violates REUSE_MAX.
P#_000004	2015-08-04	It violates REUSE_MAX.
P#_000005	2015-08-05	It violates REUSE_MAX, REUSE_TIME.
P#_000006	2015-08-06	It violates REUSE_MAX, REUSE_TIME.
P#_000007	2015-08-07	It violates REUSE_MAX, REUSE_TIME.

The password change history accumulated for checking the password reusability can be deleted by using the following statement.

```
ALTER DATABASE CLEAR PASSWORD HISTORY;
```

DEFAULT profile

When creating the database, the following "DEFAULT" profile is automatically created. The password par ameters of the "DEFAULT" profile are as follows.

Table 19-8 Configuration of DEFAULT profile

Parameter	Value
FAILED_LOGIN_ATTEMPTS	10
PASSWORD_LOCK_TIME	1
PASSWORD_LIFE_TIME	180
PASSWORD_GRACE_TIME	7
PASSWORD_REUSE_MAX	UNLIMITED
PASSWORD_REUSE_TIME	UNLIMITED
PASSWORD_VERIFY_FUNCTION	NULL

The default values of "DEFAULT" profile have the following characteristics.

- Account lockout
  - The account is locked for one day (PASSWORD_LOCK_TIME) after ten consecutive login failure (F AILED_LOGIN_ATTEMPTS).
- Password expiration
  - The password expires after the grace period of seven days (PASSWORD_GRACE_TIME) after 180

days (PASSWORD_LIFE_TIME) are exceeded.

- Password reusability
  - The old password can be reused.
- Password complexity verification
  - It is not performed.

DEFAULT profile can not be dropped but it can be altered as follows.

```
ALTER PROFILE DEFAULT LIMIT ...
```

Examples

The following is an example of creating the profile to control the account lockout. The account is locked f or three days after three consecutive login failures.

```
gSQL> CREATE PROFILE prof1 LIMIT
        FAILED_LOGIN_ATTEMPTS 3
        PASSWORD_LOCK_TIME 3;
Profile created.
gSQL> COMMIT;
Commit complete.
```

The following is an example of creating the profile to control the password expiration. The life time of th e password is 90 days, and the grace time of the password is seven days.

```
gSQL> CREATE PROFILE prof1 LIMIT
        PASSWORD_LIFE_TIME 90
        PASSWORD_GRACE_TIME 7;
Profile created.
gSQL> COMMIT;
Commit complete.
```

The following is an example of creating the profile to control whether the password is reusable. The follo wing example does not verify the old password when changing the password.

```
gSQL> CREATE PROFILE prof1 LIMIT
        PASSWORD_REUSE_MAX  DEFAULT
        PASSWORD_REUSE_TIME DEFAULT;
Profile created.
gSQL> COMMIT;
```

```
Commit complete.
```

The following is an example of creating the profile to control the password complexity check.

```
gSQL> CREATE PROFILE prof1 LIMIT
        PASSWORD_VERIFY_FUNCTION KISA_VERIFY_FUNCTION;
Profile created.
gSQL> COMMIT;
Commit complete.
```

The following is an example of creating the profile by setting all parameter.

```
gSQL> CREATE PROFILE prof1 LIMIT
        FAILED_LOGIN_ATTEMPTS 3
        PASSWORD_LOCK_TIME 3
        PASSWORD_LIFE_TIME 90
        PASSWORD_GRACE_TIME 7
        PASSWORD_REUSE_MAX  DEFAULT
        PASSWORD_REUSE_TIME DEFAULT
        PASSWORD_VERIFY_FUNCTION KISA_VERIFY_FUNCTION;
Profile created.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not cover the concepts of the profile.

For More Information

Refer to the followings.

- DROP PROFILE
- ALTER PROFILE
- CREATE USER
- ALTER USER
- ALTER DATABASE CLEAR PASSWORD HISTORY

19.14 CREATE SCHEMA

Function

It defines the schema.

Syntax

```
<schema definition> ::=
    CREATE SCHEMA <schema name clause>
        [ <schema element> [...] ]
    ;
<schema name clause> ::=
      schema_name
    ¦ AUTHORIZATION user_identifier
    ¦ schema_name AUTHORIZATION user_identifier
<schema element> ::=
      <table definition>
    ¦ <view definition>
    ¦ <index definition>
    ¦ <sequence generator definition>
    ¦ <grant privilege statement>
    ¦ <comment statement>
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <schema definition>.

- CREATE SCHEMA ON DATABASE privilege is required to create the schema.
- If <schema element> exists, the privilege to perform each <schema element> is required.
  For more information about the access privilege, refer to *invocation and access rules* in the following statements.
  - **CREATE TABLE**
  - **CREATE VIEW**
  - **CREATE INDEX**

    - **CREATE SEQUENCE**
    - **GRANT privileges TO**
    - **COMMENT ON name IS**

- The user who is user_identifier has the following privileges for the created schema.
    - The owner of the created schema, which is schema_name
    - The owner of the object which is created by <schema element> clause

- An appropriate privilege for the schema is required to create an object because a separate privilege o n the created schema is not granted.
  For more information about schema privilege types, refer to **<schema privilege>** of GRANT privileges TO statement.
  For more information about usage example, refer to **Examples** of CREATE USER statement.

Syntax Rules and Parameters

schema_name

It is the schema name to be created.
An identical schema name should not exist in the database.
The length of the schema name should be shorter than 128 bytes.

AUTHORIZATION user_identifier

If the schema name is omitted, a schema with the same name as the user_identifier is created.
If the AUTHORIZATION is not specified, the user_identifier of the user performing the statement is used.

schema_name AUTHORIZATION user_identifier

It specifies the schema name and schema owner to be created.
The owner can not be a role or PUBLIC.

<schema element>

It defines the objects to be created in the schema along with the schema creation.
The schema_element is executed in the listed order, and they are separated by a white space without a c omma (,).
The object can not be defined in a schema which has different name from the schema to be created.

- The <grant privilege statement> can be specified only for the following privileges.
  - <schema privilege>
  - <table privilege>
  - <sequence privilege>

- The <comment statement> can be specified only for the following objects.
  - SCHEMA schema_name
  - TABLE [schema_name].table_name
  - COLUMN [schema_name].table_name.column_name
  - INDEX [schema_name].index_name
  - SEQUENCE [schema_name].sequence_name
  - CONSTRAINT [schema_name].constraint_name

Description

A schema is an object which logically classifies SQL schema objects such as table, view, index, sequence a nd constraint.

In GOLDILOCKS, the relationship between the user and the schema is 1 : N. In other words, the schema o wned by a user may not exist, or the user may own multiple schemas.

The SQL standard does not explicitly define the relationship of the non-schema objects such as user, sche ma, database, but each DBMS defines the relationship between the non-schema objects as a different co ncept. Refer to the following note.

The relationship between user and schema in other DBMS

- Oracle
  - User : schema = 1 : 1

- DB2
  - User : schema = 1 : N

- Postgres
  - User : schema = 1 : N

- MySQL
  - Database : schema = 1 : 1
  - User is a subordinate object of a database (schema).

Examples

The following is an example of creating a schema.

```
gSQL> CREATE SCHEMA s1;
Schema created.
```

The following is an example of creating a schema and assigning the schema owner.

```
gSQL> CREATE SCHEMA s1 AUTHORIZATION test;
Schema created.
```

The following is an example of creating a schema together with the objects which belong to the schema.

```
gSQL> CREATE SCHEMA s1
              CREATE TABLE t1 ( id INTEGER, name VARCHAR(128) )
              CREATE INDEX idx_t1_id ON t1 ( id )
              COMMENT ON TABLE t1 IS 'comment on s1.t1'
;
Schema created.
```

Compatibility

Table 19-9 SQL standard compatibility

Feature ID	Description	Compatibility
S071	SQL paths in function and type name resolution	X
F461	Named character sets	X
F171	Multiple schemas per user	O
T332	Extended roles	X

For More Information

Refer to the followings.

- DROP SCHEMA
- CREATE USER
- CREATE TABLE
- CREATE VIEW
- CREATE INDEX
- CREATE SEQUENCE
- GRANT privileges TO
- COMMENT ON name IS

19.15 CREATE SEQUENCE

Function

It creates a sequence.

Syntax

```
<sequence generator definition> ::=
    CREATE SEQUENCE [schema_name.] sequence_name
        [ <sequence generator option> [, ...] ]
    ;
<sequence generator option> ::=
      <sequence generator start with option>
    ¦ <basic sequence generator option>
<sequence generator start with option> ::=
    START WITH integer
<basic sequence generator option> ::=
      <sequence generator increment by option>
    ¦ <sequence generator maxvalue option>
    ¦ <sequence generator minvalue option>
    ¦ <sequence generator cycle option>
    ¦ <sequence generator cache option>
<sequence generator increment by option> ::=
    INCREMENT BY integer
<sequence generator maxvalue option> ::=
      MAXVALUE integer
    ¦ (NO MAXVALUE ¦ NOMAXVALUE)
<sequence generator minvalue option> ::=
      MINVALUE integer
    ¦ (NO MINVALUE ¦ NOMINVALUE)
<sequence generator cycle option> ::=
      CYCLE
    ¦ (NO CYCLE ¦ NOCYCLE)
<sequence generator cache option> ::=
      CACHE integer
    ¦ (NO CACHE ¦ NOCACHE)
```

Invocation and Access Rules

The user should have one of the following privileges to perform 〈sequence generator definition〉 statement.

- (CREATE SEQUENCE or CONTROL SCHEMA) ON SCHEMA for the schema to which the sequence belongs
- CREATE ANY SEQUENCE ON DATABASE

The sequence owner is determined as follows.

- The owner of the schema to which the sequence belongs
- If the schema to which the sequence belongs is PUBLIC, then it is the user who executed the statement.

The sequence owner has USAGE ON SEQUENCE WITH GRANT OPTION privilege.

One of the following privileges is required to use the created sequence.

- USAGE ON SEQUENCE for the sequence
- (USAGE SEQUENCE or CONTROL SCHEMA) ON SCHEMA for the schema to which the sequence belongs
- USAGE ANY SEQUENCE ON DATABASE

Syntax Rules and Parameters

sequence_name

It is the sequence name to be created, and it should be a unique name within the schema.
The schema to which the sequence belongs, such as schema_name.sequence_name, can be defined. If schema_name is omitted, the default schema name of the user performing the statement is used.
The length of the sequence name should be shorter than 128 bytes.

〈sequence generator option〉

If any of 〈sequence generator option〉 is not used, the following two statements have the same meaning.

- CREATE SEQUENCE test_seq;
- CREATE SEQUENCE test_seq START WITH 1 INCREMENT BY 1 NO MINVALUE NO MAXVALUE NO CYCLE CACHE 20;

〈sequence generator start with option〉

It defines the first sequence number to be generated.
Depending on the ascending or the descending order, it has the following features.

- Ascending sequence (INCREMENT BY a positive number)
  - It is used when starting the sequence with bigger sequence value than the minimum value.
  - If START WITH clause is omitted, the default value is the minimum value (MINVALUE value).
- Descending sequence (INCREMENT BY a negative number)
  - It is used when starting the sequence with smaller sequence value than the maximum value.
  - If START WITH clause is omitted, the default value is the maximum value (MAXVALUE value).

〈sequence generator increment by option〉

It defines the interval of sequence numbers.
The constraints and features are as follows.

- A positive number or a negative number is allowed, but 0 is not allowed.
- The absolute value of the interval should be smaller than the difference between MINVALUE and MA XVALUE.
- The ascending sequence is generated if it is a positive number, and the descending sequence is gener ated if it is a negative number.
- If INCREMENT BY clause is omitted, the default is a positive number 1.

〈sequence generator maxvalue option〉

It defines the maximum value of which the sequence can generate.

- MAXVALUE integer
  - The maximum value range is between the minimum (-9,223,372,036,854,775,808) and the max imum (+9,223,372,036,854,775,807) of the 64 bit integer.
  - It should be equal to or bigger than START WITH value, and bigger than MINVALUE value.
- NO MAXVALUE | NOMAXVALUE
  - The maximum value is defined as follows.
    - If it is an ascending sequence, it is the maximum value (+9,223,372,036,854,775,807) of the 64 bit integer.
    - If it is a descending sequence, it is -1.
  - NO MAXVALUE(SQL standard) and NOMAXVALUE are the reserved words with the same meani ng, so either of them can be used.
- If MAXVALUE and NO MAXVALUE are not specified, the default value is NO MAXVALUE.

〈sequence generator minvalue option〉

It defines the minimum value of which the sequence can generate.

- MINVALUE integer
  - The minimum value range is between the minimum (-9,223,372,036,854,775,808) and the maximum (+9,223,372,036,854,775,807) of the 64 bit integer.
  - It should be equal to or smaller than START WITH value, and smaller than MAXVALUE.
- NO MINVALUE | NOMINVALUE
  - The minimum value is defined as follows.
    - If it is an ascending sequence, it is 1.
    - If it is a descending sequence, it is the minimum value (-9,223,372,036,854,775,808) of the 64 bit integer.
  - NO MINVALUE(SQL standard) and NOMINVALUE are the reserved words with the same meaning, so either of them can be used.
- If MINVALUE and NO MINVALUE are not specified, the default value is NO MINVALUE.

〈sequence generator cycle option〉

It specifies whether to continue generating a value when the sequence value becomes the maximum value or the minimum value.

- CYCLE
  - When the ascending sequence becomes the maximum value, it generates the value again from the minimum value.
  - When the descending sequence becomes the minimum value, it generates the value again from the maximum value.
- NO CYCLE | NOCYCLE
  - When the sequence value becomes the maximum value or the minimum value, it does not generate a sequence value.
  - NO CYCLE(SQL standard) and NOCYCLE are the reserved words with the same meaning, so either of them can be used.
- If CYCLE and NO CYCLE are not specified, the default value is NO CYCLE.

〈sequence generator cache option〉

For quick access of a sequence, it defines the number of the sequence values to be preloaded in memory. When restarting database, the sequence values loaded in memory are lost, and it starts from the value since being loaded.

- CACHE integer
  - CACHE value should be equal to or bigger than 2.

    - CACHE value should not be bigger than CYCLE length, if CYCLE exists.
        - CYCLE length: CEIL(MAXVALUE - MINVALUE) / ABS(INCREMENT)
- NO CACHE | NOCACHE
    - The sequence values are not preloaded in memory.
- If CACHE and NO CACHE are not specified, the default value is CACHE 20.

Description

The sequence values of the created sequence objects are used by using **NEXTVAL** and **CURRVAL** function s.

The sequence value does not have a transaction property. The sequence value maintains the most recent value, even when an error occurs in the SQL statement in which the sequence function is used or when e xplicit ROLLBACK is performed.

CURRVAL function returns NEXTVAL value from the most recent call by a session.
Therefore, using this feature, the sequence value obtained by NEXTVAL can still be usable in the other SQ L statements. However, when the session does not call NEXTVAL, using CURRVAL function generates an error.

Examples

The object seq1 without the defined sequence options is an ascending sequence of the same meanings a s the object seq2 in the following example.

```
gSQL> CREATE SEQUENCE seq1;
Sequence created.
gSQL> CREATE SEQUENCE seq2 START WITH 1 INCREMENT BY 1 NO MINVALUE NO MAXVALUE NO CYCLE CACHE
20;
Sequence created.
```

The following is an example of a sequence which generates an odd value.

```
gSQL> CREATE SEQUENCE seq1 START WITH 1 INCREMENT BY 2;
Sequence created.
```

The following is an example of generating sequence which repeatedly generates an even number starting from 0 to 1000.

```
gSQL> CREATE SEQUENCE seq1 START WITH 0 MINVALUE 0 MAXVALUE 1000 INCREMENT BY 2 CYCLE;
Sequence created.
```

The following is an example of generating a descending sequence starting from -1.

```
gSQL> CREATE SEQUENCE seq1 INCREMENT BY -1;
Sequence created.
```

Compatibility

The SQL standard does not define <sequence generator cache option> clause.

Table 19-10 SQL standard compatibility

Feature ID	Description	Compatibility
T176	Sequence generator support	O

For More Information

Refer to the followings.

- DROP SEQUENCE
- ALTER SEQUENCE
- NEXTVAL
- CURRVAL

19.16 CREATE SYNONYM

Function

It creates a synonym. A synonym is an alternative name for a table, view, sequence, or another synonym, and it can be used in the following statements.

- DML: SELECT, INSERT, UPDATE, DELETE, LOCK TABLE, CALL
- DDL: GRANT, REVOKE, COMMENT

Syntax

```
<table definition> ::=
    CREATE [OR REPLACE] [PUBLIC] SYNONYM [schema_name.]synonym_name
    FOR [schema_name.]object_name
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <synonym definition> statement.

- CREATE PUBLIC SYNONYM ON DATABASE privilege is required to create public synonym by explicitly specifying PUBLIC.

- The owner of public synonym is PUBLIC. The user who created the synonym does not have any privile ge.

- One of the following privileges is required to create the private synonym.
  - (CREATE SYNONYM or CONTROL SCHEMA) ON SCHEMA for that schema
  - CREATE ANY SYNONYM ON DATABASE

- The private synonym owner is determined as follows.
  - The owner of the schema to which the private synonym belongs
  - If the schema to which the private synonym belongs is PUBLIC, then it is the user who executed t he statement.

- If the user does not have privilege on the base object, the user is not allowed to execute the stateme

nt using its synonym even when the user created the synonym.

- Be cautious when allowing the privilege on the synonym because it means allowing privilege on the b ase object to which the synonym indicates.

Syntax Rules and Parameters

[OR REPLACE]

It replaces the existing synonym If the synonym already exists.

[PUBLIC]

It is specified when creating public synonym.
If it is omitted, private synonym is created.

synonym_name

It is the synonym name to be created, and it should be a unique name within the schema.
The schema to which the synonym belongs, such as schema_name.synonym_name, can be defined. If sch ema_name is omitted, default schema name of the user performing the statement is used.
The length of the synonym name should be shorter than 128 bytes.
Public synonym is a non-schema object. Therefore, a schema name can not be specified when creating p ublic synonym by explicitly specifying PUBLIC.

object_name

The schema to which the object belongs, such as schema_name.object_name, can be defined. If schema _name is omitted, default schema name of the user performing the statement is used.

The object types which can specify the object_name are as follows.

- Table
- View
- Sequence
- Another synonym

Existence of the target object, cycle check and privilege check are performed when executing the statem ent using the synonym.

Description

A synonym is an alternative name for a table, view, sequence, or another synonym.

If synonym is created, the applications does not need to be modified even when the base object is changed instead only the synonyms should be redefined. Therefore, it is convenient.
Also, the database security is improved by hiding the objects' real names and their schemas, and the usability is enhanced by changing the object's long name to a shorter name.

The synonym is literally an alternative name so creating the synonym does not mean that the synonym can be used to access the object. The proper privilege is required to access the object.

When executing the statement using the synonym, the object access procedure is as follows.

1. Find a table of the corresponding name.
2. If the table does not exist, find the private synonym of the corresponding name.
3. If the private synonym does not exist, find the public synonym of the corresponding name.

```
gSQL> CREATE PUBLIC SYNONYM syn1 FOR u1.t1;
Synonym created.
gSQL> CREATE PUBLIC SYNONYM syn2 FOR syn1;
Synonym created.
gSQL> SELECT * FROM syn2;
```

The example above is the object access procedure in SELECT statement.

1. It searched for the table syn2, but it does not exist.
2. It searched for the private synonym syn2, but it does not exist.
3. It searched for the public synonym syn2, and it exists.
    I. It searched for the table syn1, but it does not exist.
    II. It searched for the private synonym syn1, but it does not exist.
    III. It searched for the public synonym syn2, and it exists.
        i. It searched for the table u1.t1, and it exists.

Examples

The following is an example of creating a private synonym.

```
gSQL> CREATE SYNONYM MyEmp FOR branch.Employee;
Synonym created.
```

```
gSQL> SELECT * FROM MyEmp;
```

The following is an example of creating a public synonym.

```
gSQL> CREATE PUBLIC SYNONYM MainEmp FOR main.Employee;
Synonym created.
gSQL> SELECT * FROM MainEmp;
```

Compatibility

The SQL standard does not define the CREATE SYNONYM statement.

For More Information

Refer to **DROP SYNONYM**.

19.17 CREATE TABLE

Function

It defines a table.

Syntax

```
<table definition> ::=
    CREATE TABLE table_name
        ( <table element> [, ...] )
        [ <table sharding strategy> ]
        [ <table attribute clause> [...] ]
        [ TABLESPACE tablespace_name ]
        [ <table global secondary index clause> ]
    ;
<table element> ::=
      <column definition>
    ¦ <table constraint definition>
<column definition> ::=
    column_name <data type>
        [ <default clause> ¦ <identity column specification> ]
        [ <column constraint definition> ]
<data type> ::=
      <character string type>
    ¦ <binary string type>
    ¦ <numeric type>
    ¦ <boolean type>
    ¦ <datetime type>
    ¦ <interval type>
<character string type> ::=
      CHARACTER [ ( integer [ <character length units> ] ) ]
    ¦ CHAR [ ( integer [ <character length units> ] ) ]
    ¦ CHARACTER VARYING ( integer [ <character length units> ] )
    ¦ CHAR VARYING ( integer [ <character length units> ] )
    ¦ VARCHAR ( integer [ <character length units> ] )
    ¦ CHARACTER LONG VARYING
```

```
    ¦ LONG VARCHAR

<character length units> ::=
      CHARACTERS
    ¦ CHAR
    ¦ OCTETS
    ¦ BYTE
<binary string type> ::=
      BINARY [ ( length ) ]
    ¦ BINARY VARYING ( length )
    ¦ VARBINARY ( length )
    ¦ LONG BINARY VARYING
    ¦ LONG VARBINARY
<numeric type> ::=
      <exact numeric type>
    ¦ <approximate numeric type>
    ¦ <native numeric type>
<exact numeric type> ::=
      NUMERIC [ ( precision [, scale ] ) ]
    ¦ SMALLINT
    ¦ INTEGER
    ¦ INT
    ¦ BIGINT
<approximate numeric type> ::=
    ¦ FLOAT [ ( precision ) ]
    ¦ REAL
    ¦ DOUBLE PRECISION
<native numeric type> ::=
      NATIVE_SMALLINT
    ¦ NATIVE_INTEGER
    ¦ NATIVE_BIGINT
    ¦ NATIVE_REAL
    ¦ NATIVE_DOUBLE
<boolean type> ::=
    BOOLEAN
<datetime type> ::=
      DATE
    ¦ TIME [ ( time_precision ) ] [ WITH TIME ZONE ¦ WITHOUT TIME ZONE ]
    ¦ TIMESTAMP [ ( timestamp_precision ) ] [ WITH TIME ZONE ¦ WITHOUT TIME ZONE ]
<interval type> ::=
    INTERVAL <interval qualifier>
```

```
<interval qualifier> ::=
      <non-second primary datetime field> [ ( interval_leading_field_precision ) ]
          TO { <non-second primary datetime field> ¦ SECOND [ (
interval_fractional_seconds_precision ) ] }
    ¦ <non-second primary datetime field> [ ( interval_leading_field_precision ) ]
    ¦ SECOND [ ( interval_leading_field_precision [, interval_fractional_seconds_precision ] )
]
<non-second primary datetime field> ::=
      YEAR
    ¦ MONTH
    ¦ DAY
    ¦ HOUR
    ¦ MINUTE
<default clause> ::=
    DEFAULT <default option>
<default option> ::=
      constant
    ¦ NULL
    ¦ expression
<identity column specification> ::=
    GENERATED { ALWAYS ¦ BY DEFAULT } AS IDENTITY
    [ ( <common sequence generator option> [, ...] ) ]
<common sequence generator option> ::=
      START WITH integer_constant
    ¦ <basic sequence generator option>
<basic sequence generator option> ::=
      INCREMENT BY integer_constant
    ¦ { MAXVALUE integer_constant ¦ NO MAXVALUE }
    ¦ { MINVALUE integer_constant ¦ NO MINVALUE }
    ¦ { CYCLE ¦ NO CYCLE }
    ¦ { CACHE integer_constant ¦ NO CACHE }
<column constraint definition> ::=
    [ CONSTRAINT constraint_name ] <column constraint> [ <constraint characteristics> ]
<column constraint> ::=
      NOT NULL
    ¦ { UNIQUE ¦ PRIMARY KEY } [ <index name clause> [ <index attributes> ] [ TABLESPACE
index_tablespace_name ] ]
<index name clause> ::=
    INDEX index_name
<index attributes> ::=
      <index physical attribute clause>
```

```
    ¦ STORAGE ( <segment attr clause> [...] )
<table constraint definition> ::=
    [ CONSTRAINT constraint_name ] <table constraint> [ <constraint characteristics> ]
<table constraint> ::=
      <unique constraint definition> [ <index name clause> [ <index attributes> ] [ TABLESPACE
index_tablespace_name ] ]
<unique constraint definition> ::=
    { UNIQUE ¦ PRIMARY KEY } ( <key column element> [, ...] )
<key column element> ::=
    column_name [ ASC ¦ DESC ] [ NULLS FIRST ¦ NULLS LAST ]
<table sharding strategy> ::=
      <cloned strategy>
    ¦ <hash sharding strategy>
    ¦ <range sharding strategy>
    ¦ <list sharding strategy>
<cloned strategy> ::=
    CLONED [ <clone placement> ]
<clone placement> ::=
      AT CLUSTER WIDE
    ¦ AT CLUSTER GROUP group_list
<hash sharding strategy> ::=
    SHARDING BY [HASH] ( column_list )
    [ <hash shard count> ]
    [ <hash shard placement> ]
<hash shard count> ::=
    SHARD COUNT integer
<hash shard placement> ::=
      AT CLUSTER WIDE
    ¦ AT CLUSTER GROUP group_list
<range sharding strategy> ::=
    SHARDING BY RANGE ( column_list )
    { <cluster-wide range shard placement> ¦ <group-specific range shard placement> }
<cluster-wide range shard placement> ::=
    AT CLUSTER WIDE
    <range shard definition> [, ...]
<group-specific range shard placement> ::=
    <group-specific range shard definition> [, ...]
<group-specific range shard definition> ::=
    <range shard definition> AT CLUSTER GROUP group_name
<range shard definition> ::=
    SHARD range_name VALUES LESS THAN ( <range value clause> )
```

```
<range value clause> ::=
    <range value> [, ...]
<range value> ::=
      constant
    ¦ MAXVALUE
<list sharding strategy> ::=
    SHARDING BY LIST ( column_name )
    { <cluster-wide list shard placement> ¦ <group-specific list shard placement> }
<cluster-wide list shard placement> ::=
    AT CLUSTER WIDE
    <list shard definition> [, ...]
<group-specific list shard placement> ::=
    <group-specific list shard definition> [, ...]
<group-specific list shard definition> ::=
    <list shard definition> AT CLUSTER GROUP group_name
<list shard definition> ::=
      SHARD shard_name VALUES IN ( <list value clause> )
<list value clause> ::=
    <list value> [, ...]
<list value> ::=
      constant
    ¦ NULL
    ¦ DEFAULT
<table attribute clause> ::=
      [ <table physical attribute clause> ]
    ¦ [ STORAGE ( <segment attr clause> [...] ) ]
<table physical attribute clause> ::=
      PCTFREE integer
    ¦ PCTUSED integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<index physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
```

```
      integer [ K ¦ M ¦ G ¦ T ]
<constraint characteristics> ::=
      [ NOT ] DEFERRABLE [ <constraint check time> ]
    ¦ <constraint check time> [ [ NOT ] DEFERRABLE ]
<constraint check time> ::=
      INITIALLY DEFERRED
    ¦ INITIALLY IMMEDIATE
<table global secondary index clause> ::=
      WITH GLOBAL SECONDARY INDEX [ <index attributes> [...] ] [ TABLESPACE tablespace_name ]
    ¦  WITHOUT GLOBAL SECONDARY INDEX
```

Invocation and Access Rules

The differences between the stand-alone database and the cluster database are as follows.

- Stand-alone
  - It can not define <table sharding strategy>.
  - It can not define <table global secondary index clause>.
- Cluster
  - Constraints of PRIMARY KEY, UNIQUE should include all sharding keys.
  - It can not define the deferrable constraints.

The user should satisfy the following conditions to perform <table definition> statement.

- One of the following privileges is required for the schema in which a table is to be created.
  - (CREATE TABLE or CONTROL SCHEMA) ON SCHEMA for that schema
  - CREATE ANY TABLE ON DATABASE

- One of the following privileges is required for the tablespace in which a table is to be created.
  - CREATE OBJECT ON TABLESPACE for that tablespace
  - USAGE TABLESPACE ON DATABASE

- One of the following privileges is required for the schema in which the constraints are to be created when the constraints exists which were created together.
  - (ADD CONSTRAINT or CONTROL SCHEMA) ON SCHEMA for that schema
  - ALTER ANY TABLE ON DATABASE

- One of the following privileges is required for the tablespace in which the index is to be created whe n the key constraint is created together.
  - CREATE OBJECT ON TABLESPACE for that tablespace
  - USAGE TABLESPACE ON DATABASE

- The owner of the table is determined as follows.
  - The owner of the schema to which the table belongs
  - If the schema to which the table belongs is PUBLIC, then it is the user who executed the statement.

- The table owner has the following privileges for the created table.
  - The privilege for the table
    - SELECT ON TABLE WITH GRANT OPTION
    - INSERT ON TABLE WITH GRANT OPTION
    - UPDATE ON TABLE WITH GRANT OPTION
    - DELETE ON TABLE WITH GRANT OPTION
    - TRIGGER ON TABLE WITH GRANT OPTION
    - REFERENCES ON TABLE WITH GRANT OPTION
    - LOCK ON TABLE WITH GRANT OPTION
    - INDEX ON TABLE WITH GRANT OPTION
    - ALTER ON TABLE WITH GRANT OPTION
  - The privilege for all columns in the table.
    - SELECT(columns) ON TABLE WITH GRANT OPTION
    - INSERT(columns) ON TABLE WITH GRANT OPTION
    - UPDATE(columns) ON TABLE WITH GRANT OPTION
    - REFERENCES(columns) ON TABLE WITH GRANT OPTION
  - The privilege for the constraint which was generated together
    - The owner of that constraint
    - The owner of the index which was generated together with the constraint

〈table sharding strategy〉 statement can be used in a cluster system.

Syntax Rules and Parameters

table_name

It is the table name to be created and it should be a unique name within the schema.
The schema to which the table belongs, such as schema_name.table_name, can be defined. If schema_name is omitted, The default schema name of the user performing the statement is used.
The length of the table name should be shorter than 128 bytes.

〈column definition〉

It defines the columns which configure the table.
The table should include one or more column definitions.
It can specify the column data type, default value, automatically generated value, and constraints.

column_name

It is name of the column which configure a table and each column should have a unique name within the table.
The length of the column name should be shorter than 128 bytes.

〈data type〉

- 〈character string type〉
- 〈binary string type〉
- 〈numeric type〉
- 〈exact numeric type〉
- 〈approximate numeric type〉
- 〈boolean type〉
- 〈datetime type〉
- 〈interval type〉
- 〈interval qualifier〉
- 〈non-second primary datetime field〉

It defines the data type of the column.
When defining the column including automatically generated values(〈identity column specification〉), its data type should be one of SMALLINT, INTEGER or BIGINT.
For more information about data types, refer to **Data Type**.

〈character length units〉

It specifies the length unit of a single character for the character type.

- CHARACTERS/ CHAR assigns the maximum bytes of a single character as the length of a single chara cter. Therefore, the length of multi-bytes single character such as Hangul is 1.
- OCTETS/ BYTE assigns one byte for the length of a single character. Therefore, the length of multi-by tes single character such as Hangul is multi-bytes.
- If it is omitted, it follows CHAR_LENGTH UNITS property which is used when creating the database.

SQL standard define CHARACTERS as a default value.

The default value of the char length unit in other DBMS are as follows.

- Oracle, DB2: OCTETS
- MS-SQL, MySQL, PostgreSQL: CHARACTERS

[<default clause> | <identity column specification>]

It specifies the default value of a column.
<default clause> and <identity column specification> can not be used together.
When both of them are omitted, the default value is NULL.

<default clause>

The DEFAULT clause defines the default value to be used when DEFAULT is specified in INSERT, UPDATE statements or the corresponding column name is omitted.

- When DEFAULT clause is used
  - e.g. CREATE TABLE t1 (id INTEGER, name VARCHAR(32) DEFAULT 'anonymous');
  - When the column is omitted
    - INSERT INTO t1(id) VALUES (1);
    - INSERT INTO t1(id) SELECT id FROM other_table;
  - When the DEFAULT is specified
    - INSERT INTO t1 DEFAULT VALUES;
    - INSERT INTO t1 VALUES (2, DEFAULT);
    - UPDATE t1 SET name = DEFAULT;

The data type of DEFAULT expression should be compatible with the data type of the column.
If the data type is not compatible or the expression is not valid, an error occurs.

```
--# result: error
CREATE TABLE t1 ( c1 INTEGER DEFAULT 1 / 0 );
ERR-22012(12122): divisor is equal to zero
--# result: success
CREATE TABLE t1 ( c1 INTEGER DEFAULT 1 / 1 );
Table created.
```

DEFAULT expression can use any built-in functions but it can not use the followings.

- Logical operators (AND, OR, NOT), comparison operators (=,>, ...)
- Stored function

- Column name
- Subquery expression

〈identity column specification〉

It defines a column which has automatically generated values.

The table can have only one identity column.
The identity column becomes *not nullable* column even though NOT NULL constraint is not specified.

〈identity column specification〉 clause can not be specified together with DEFAULT clause.
〈identity column specification〉 clause, like as DEFAULT clause, specifies DEFAULT in INSERT, UPDATE stat ements or it defines the default value to be used when the column name is omitted.

The generation method is defined as follows.

- GENERATED BY DEFAULT AS IDENTITY
  A user defined value is applied if defined, but the value is automatically generated, like as DEFAULT cl ause, when the default value should be used.
  - CREATE TABLE t1 (id INTEGER GENERATED BY DEFAULT AS IDENTITY, name VARCHAR(32));
  - (O) INSERT INTO t1 VALUES (12345, 'GOLDILOCKS');
    - It inserts the user defined value (12345).
  - (O) INSERT INTO t1(name) VALUES ('GOLDILOCKS');
    - It inserts the automatically generated value in an id column.
  - (O) INSERT INTO t1(id, name) SELECT other_id, other_name FROM other_table;
    - It inserts the user defined value.
  - (O) INSERT INTO t1(name) SELECT other_name FROM other_table;
    - It inserts the automatically generated value in an id column.
  - (O) UPDATE t1 SET id = 10000 WHERE id = 12345;
    - It inserts the user defined value
  - (O) UPDATE t1 SET id = DEFAULT WHERE id = 12345;
    - It inserts the automatically generated value in an id column.

- GENERATED ALWAYS AS IDENTITY
  A user can not define the value and the default value should be generated like as DEFAULT clause.
  - CREATE TABLE t1 (id INTEGER GENERATED ALWAYS AS IDENTITY, name VARCHAR(32));
  - (X) INSERT INTO t1 VALUES (12345, 'GOLDILOCKS');
    - Error, a user can not define the value.
  - (O) INSERT INTO t1(name) VALUES ('GOLDILOCKS');
    - It inserts the automatically generated value in an id column.
  - (X) INSERT INTO t1(id, name) SELECT other_id, other_name FROM other_table;
    - Error, a user can not define the value.

- (O) INSERT INTO t1(name) SELECT other_name FROM other_table;
  - It inserts the automatically generated value in an id column.
- (X) UPDATE t1 SET id = 10000 WHERE id = 12345;
  - Error, a user can not define the value.
- (O) UPDATE t1 SET id = DEFAULT WHERE id = 12345;
  - It inserts the automatically generated value in an id column.

For more information about <common sequence generator option> and <basic sequence generator option>, which is an option to create an identity column, refer to **CREATE SEQUENCE**.

<column constraint definition>

It defines the following constraints for a column.

- NOT NULL constraints
- UNIQUE constraints
- PRIMARY KEY constraints

constraint_name

It is the constraint name and it can be omitted.

If the constraint_name is omitted, it is automatically set as follows.
If the automatically generated name is duplicated, the constraint_name should be explicitly specified.

- NOT NULL constraints
  - "table_name" + "_" + "NOT_NULL" + "_" + "column_name"
- UNIQUE constraints
  - "table_name" + "_" + "UNIQUE" + "_" + "column_name"
- PRIMARY KEY constraints
  - "table_name" + "_" + "PRIMARY_KEY"

The length of the constraint name should be shorter than 128 bytes.

NOT NULL Constraint

NULL is not allowed for the column value.

UNIQUE Constraint

The identical value is not allowed for the column value, but NULL is allowed.

PRIMARY KEY Constraint

NULL or the identical value is not allowed as the column value. A single PRIMARY KEY constraint can be defined on a single table.

〈index name clause〉

It defines the index name to be created when defining UNIQUE constraint and PRIMARY KEY constraint.

- INDEX index_name
  - It defines the index name for the constraint.
  - It can not be used together with a schema name and it is created in the same schema where the constraint is created.

When defining UNIQUE constraint and PRIMARY KEY constraint, if INDEX clause is omitted, an index whi ch satisfies the constraints is automatically created.
"constraint_name" + "INDEX" is added to the name of index which is automatically generated.

- 〈index attributes〉
  - It specifies the physical attributes of the index to be created.
  - For more information, refer to **CREATE INDEX**.
- TABLESPACE index_tablespace_name
  - It specifies the tablespace where the index is to be created.
  - For more information, refer to **CREATE INDEX**.

〈table constraint definition〉

〈unique constraint definition〉

- When defining a table, the constraints can be classified in two ways depending on the location in the statement.
  - When defining a column, column constraints can be specified by using 〈column constraint defini tion〉.
  - On the other hand, the table constraint definition clause, 〈table constraint definition〉, can be sp ecified separately from the column definition and the constraints on one or more columns can be specified.

The table constraint definition has the following syntactic difference compared to the column constraint definition.

- NOT NULL constraint
  - It can not be specified by using the table constraint definition.
- It should explicitly specify the column unlike the column constraint definition.
  - UNIQUE constraint <unique constraint definition>
    - UNIQUE (column_name [, ...])
  - PRIMARY KEY CONSTRAINT <unique constraint definition>
    - PRIMARY KEY (column_name [, ...])

key column element

It specifies the column to be a target of the key.

- column name
  - It is name of the column which creates the key.
- ASC | DESC
  - ASC: It is sorted in an ascending order.
  - DESC: It is sorted in a descending order.
  - If not specified, the default value is ASC.
- NULLS FIRST | NULLS LAST
  - NULLS FIRST: It is located before non-NULL values.
  - NULLS LAST: It is located after non-NULL values.
  - If not specified, the default value is NULLS LAST.

<table sharding strategy>

It defines the sharding strategy of a table.
It can be defined as one of the four following strategies.

- <cloned strategy>
- <hash sharding strategy>
- <range sharding strategy>
- <list sharding strategy>

If it is omitted, it is determined by **DEFAULT_SHARDING** property value.

- If DEFAULT_SHARDING value is 0
  - <cloned strategy>
- If DEFAULT_SHARDING value is 1
  - <hash sharding strategy>

〈cloned strategy〉

It clones all data in a table.

〈clone placement〉

It defines the placement strategy of a clone.

- AT CLUSTER WIDE
  - It places clones in all cluster members of all cluster groups in a cluster system.
  - A clone can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster group and a cluster member.
- AT CLUSTER GROUP group_list
  - It places clones in all cluster members of a specified cluster groups.
  - A clone can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster member in a specified cluster group.
  - Adding a cluster group does not affect the relocation of the clone.
- When it is omitted, the default value is AT CLUSTER WIDE.

〈hash sharding strategy〉

It shards the table data according to the hash value of the sharding key.

SHARDING BY [HASH] (column_list)

It defines a sharding key for a hash sharding.

- It can list maximum 32 columns.
- It can not use a duplicate column.
- It can not use a LONG VARCHAR type column or a LONG VARBINARY type column.

〈hash shard count〉

It defines the number of the hash shards to be sharded.
The number of shards can be defined from 1 to 512.
If it is omitted, the default value is 24.

〈hash shard placement〉

It defines the placement strategy of a hash shard.

- AT CLUSTER WIDE
  - It places shards in all cluster members of all cluster groups in a cluster system.
  - A shard can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster group and a cluster member.
- AT CLUSTER GROUP group_list
  - It places hash shards in all cluster members of a specified cluster groups.
  - The number of group_list should be equal to or smaller than the value of <hash shard count>.
  - Unlike a range shard and a list shard, the cluster group on which the specific hash shard is to be located can not be specified, but the system automatically determines a cluster group on which the shard is to be located.
  - A shard can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster member in a specified cluster group.
  - Adding a cluster group does not affect the relocation of the hash shard.
- When it is omitted, the default value is AT CLUSTER WIDE.

<range sharding strategy>

It shards the table data according to the range value of the sharding key.

SHARDING BY RANGE (column_list)

It defines a sharding key for the range sharding.

- It can list maximum 32 columns.
- It can not use a duplicate column.
- It can not use a LONG VARCHAR type column or a LONG VARBINARY type column.

<cluster-wide range shard placement>

It automatically places range shards in all cluster groups of a cluster system.
AT CLUSTER WIDE statement is described before describing <range shard definition>.
Shards can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster group and a cluster member.

- Create a range sharded table.
- Place six shards in the existing cluster groups (g1, g2, g3).

```
CREATE TABLE t1
(
   id   INTEGER,
   name VARCHAR(32)
)
```

```
SHARDING BY RANGE (id)
    AT CLUSTER WIDE
    SHARD s1 VALUES LESS THAN ( 200000 ),
    SHARD s2 VALUES LESS THAN ( 400000 ),
    SHARD s3 VALUES LESS THAN ( 500000 ),
    SHARD s4 VALUES LESS THAN ( 600000 ),
    SHARD s5 VALUES LESS THAN ( 800000 ),
    SHARD s6 VALUES LESS THAN ( MAXVALUE )
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Relocate the range shard.
- Place six shards in the cluster groups (g1, g2, g3, g4) including the added g4.

```
ALTER TABLE t1 REBALANCE;
```

〈group-specific range shard placement〉

It places range shards in a specified cluster group.
It describes AT CLUSTER GROUP group_name statement which places that shard together with 〈range shard definition〉.
Shards can be automatically relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster member to a specified cluster group.
Adding a cluster group does not affect the relocation of the range shard.

- Create a range sharded table.
- Place each range shard in a specified cluster group.

```
CREATE TABLE t1
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY RANGE (id)
    SHARD s1 VALUES LESS THAN ( 200000 )   AT CLUSTER GROUP g1,
    SHARD s2 VALUES LESS THAN ( 400000 )   AT CLUSTER GROUP g2,
```

```
    SHARD s3 VALUES LESS THAN ( 500000 )   AT CLUSTER GROUP g3,
    SHARD s4 VALUES LESS THAN ( 600000 )   AT CLUSTER GROUP g2,
    SHARD s5 VALUES LESS THAN ( 800000 )   AT CLUSTER GROUP g3,
    SHARD s6 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP g1
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Relocate a range shard.
- The shard is not placed in a newly created cluster group g4.

```
ALTER TABLE t1 REBALANCE;
```

<range shard definition>

SHARD range_name should be unique in a table.

It can define maximum 512 of <range shard definition>.

The listed <range shard definition> is sorted in an order of <range value clause>, and it should use each di
fferent <range value clause>.

The <range shard definition> whose all values are define as MAXVALUE is a MAX shard.
MAX shard should exist, and it should be a single one.

- It should include a MAX shard.

```
gSQL>
CREATE TABLE t1
(
   id INTEGER,
   name VARCHAR(32)
)
SHARDING BY RANGE (id)
   AT CLUSTER WIDE
   SHARD s1 VALUES LESS THAN ( 100000 ),
   SHARD s2 VALUES LESS THAN ( 200000 ),
   SHARD s3 VALUES LESS THAN ( MAXVALUE )
```

```
;
Table created.
```

- If it does not include a MAX shard, then an error occurs.

```
gSQL>
CREATE TABLE t1
(
   id INTEGER,
   name VARCHAR(32)
)
SHARDING BY RANGE (id)
   AT CLUSTER WIDE
   SHARD s1 VALUES LESS THAN ( 100000 ),
   SHARD s2 VALUES LESS THAN ( 200000 ),
   SHARD s3 VALUES LESS THAN ( 300000 )
;
ERR-42000(16377): MAX shard not defined :
   SHARD s3 VALUES LESS THAN ( 300000 )
   *
ERROR at line 10:
```

〈range value clause〉

〈range value〉 should be a constant or a MAXVALUE (a maximum value).
NULL can not be used as 〈range value〉.

- (O) SHARD s1 VALUES LESS THAN (1)
- (O) SHARD s2 VALUES LESS THAN (1 + 1)
- (O) SHARD s3 VALUES LESS THAN (MAXVALUE)
- (X) SHARD s4 VALUES LESS THAN (SYSDATE)
- (X) SHARD s5 VALUES LESS THAN (NULL)

MAXVALUE is always bigger than any other value, and it includes null.

If there are multiple sharding keys, only a MAXVALUE can be specified after the MAXVALUE.

- (O) SHARD s1 VALUES LESS THAN (100, MAXVALUE)
- (X) SHARD s2 VALUES LESS THAN (MAXVALUE, 100)
- (O) SHARD s3 VALUES LESS THAN (MAXVALUE, MAXVALUE)

If a sharding key is defined by using multiple columns, a MAX shard which is listed with MAXVALUE for it

s all values as like the SHARD s3 below should exist.

```
CREATE TABLE t1
(
   id INTEGER,
   name VARCHAR(32)
)
SHARDING BY RANGE (id, name)
   AT CLUSTER WIDE
   SHARD s1 VALUES LESS THAN ( 100000, MAXVALUE ),
   SHARD s2 VALUES LESS THAN ( 200000, 20000 ),
   SHARD s3 VALUES LESS THAN ( MAXVALUE, MAXVALUE )
;
```

〈list sharding strategy〉

It shards the table data according to the listed value of the sharding key.

SHARDING BY LIST (column_name)

It defines a sharding key for a list sharding.

- It can use only one column.
- It can not use a LONG VARCHAR type column or a LONG VARBINARY type column.

〈cluster-wide list shard placement〉

It automatically places list shards in all cluster groups of a cluster system.
AT CLUSTER WIDE statement is described before describing 〈range shard definition〉.
Shards can be relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster grou p and a cluster member.

- Create a list sharded table.
- Place five shards in the existing cluster groups (g1, g2, g3).

```
CREATE TABLE city
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY LIST (name)
```

```
    AT CLUSTER WIDE
    SHARD s1 VALUES IN ( 'SEOUL' ),
    SHARD s2 VALUES IN ( 'PUSAN', 'ULSAN', 'DAEGU' ),
    SHARD s3 VALUES IN ( 'DAEJEON', 'GWANGJU' ),
    SHARD s4 VALUES IN ( 'ANSAN', 'GOYANG' ),
    SHARD s5 VALUES IN ( DEFAULT )
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Relocate a list shard.
- Place five shards in the cluster groups (g1, g2, g3, g4) including the added g4.

```
ALTER TABLE t1 REBALANCE;
```

<group-specific list shard placement>

It places list shards in a specified cluster group.
It describes AT CLUSTER GROUP group_name statement which places that shard together with <list shard definition>.
Shards can be automatically relocated by using **ALTER TABLE name REBALANCE** statement when adding a cluster member to a specified cluster group.
Adding a cluster group does not affect the relocation of the list shard.

- Create a list sharded table.
- Place each list shard in a specified cluster group.

```
CREATE TABLE city
(
   id   INTEGER,
   name VARCHAR(32)
)
SHARDING BY LIST (name)
    SHARD s1 VALUES IN ( 'SEOUL' )                  AT CLUSTER GROUP g1,
    SHARD s2 VALUES IN ( 'PUSAN', 'ULSAN', 'DAEGU' ) AT CLUSTER GROUP g2,
    SHARD s3 VALUES IN ( 'DAEJEON', 'GWANGJU' )     AT CLUSTER GROUP g3,
    SHARD s4 VALUES IN ( 'ANSAN', 'GOYANG' )        AT CLUSTER GROUP g2,
```

```
    SHARD s5 VALUES IN ( DEFAULT )                  AT CLUSTER GROUP g1
;
```

- Add a cluster group.

```
CREATE CLUSTER GROUP g4
       CLUSTER MEMBER g4n1 HOST '192.168.0.41' PORT 10401
;
```

- Relocate a list shard.
- The shard is not placed in a newly added cluster group g4.

```
ALTER TABLE t1 REBALANCE;
```

〈list shard definition〉

LIST list_name should be unique in a table.

It can define maximum 512 of 〈list shard definition〉.
All 〈list value〉 of the listed 〈list shard definition〉 should be different each other.

DFFAULT are other values which is not the listed 〈list value〉.
DFFAULT can not be defined together with another value.
A shard including DEFAULT is a DEFAULT shard.

MAX shard should exist, and it should be a single one.

- It should include a DEFAULT shard.

```
gSQL>
CREATE TABLE t1
(
   category INTEGER,
   name     VARCHAR(32)
)
SHARDING BY LIST (category)
   AT CLUSTER WIDE
   SHARD s1 VALUES IN ( 1, 3, 5, 7 ),
   SHARD s2 VALUES IN ( 2, 4, 6, 8 ),
   SHARD s3 VALUES IN ( DEFAULT )
;
Table created.
```

- If it does not include a DEFAULT shard, then an error occurs.

```
gSQL>
CREATE TABLE t1
(
   category INTEGER,
   name     VARCHAR(32)
)
SHARDING BY LIST (category)
   AT CLUSTER WIDE
   SHARD s1 VALUES IN ( 1, 3, 5, 7 ),
   SHARD s2 VALUES IN ( 2, 4, 6, 8 ),
   SHARD s3 VALUES IN ( 9, 10 )
;
ERR-42000(16385): DEFAULT shard not defined :
   SHARD s3 VALUES IN ( 9, 10 )
   *
ERROR at line 10:
```

〈list value clause〉

〈list value〉 should be a constant.
NULL or DEFAULT can be used as 〈list value〉.

- (O) SHARD s1 VALUES IN (1, 1 + 1, 3, 4)
- (O) SHARD s2 VALUES IN (5, 6, 7, NULL)
- (O) SHARD s3 VALUES IN (DEFAULT)
- (X) SHARD s4 VALUES IN (DEFAULT, 8, 9, 10)
- (X) SHARD s5 VALUES IN (current_timestamp, systimestamp)
- (X) SHARD s6 VALUES IN (c1, c2)

〈table physical attribute clause〉

It defines the physical attribute information of the table.

- PCTFREE integer
  - Definition
    - The reserved space in case the row size is increased when altering or updating a row in a pag e.
    - The initial input is input in other space except for this reserved space.
    - If PCTFREE is not enough ROW MIGRATION occurs when altering or updating the data.

    - It can use of the value from 0 to 99.
    - If it is omitted, the default value is 10.

- PCTUSED integer
    - Definition
        - It is the minimum percentage which can be used for the row data and overhead before addi ng a new row to a page.
        - It can be input only on this page when the value got smaller than PCTUSED due to alteration or deletion of the existing data.
    - It can use of the value from 0 to 99.
    - If it is omitted, the default value is 40.

- INITRANS integer
    - Definition
        - It specifies the initial number of transactions which can simultaneously access the page.
        - If the number of users who access the index is small, INITRANS is set to low, and if the numb er of users who simultaneously access the index is big, INITRANS is set to high.
        - If necessary, it is automatically increased to the specified MAXTRANS.
    - It can use the value from 1 to 32.
    - If it is omitted, the default value is 4.

- MAXTRANS integer
    - Definition
        - It specifies the maximum number of transactions which can simultaneously access the page.
    - It can use the value from 1 to 32.
    - If it is omitted, the default value is 8.

〈index physical attribute clause〉

It defines the physical attributes of the index.

- PCTFREE integer
    - Definition
        - It is a reserved space for adjusting the frequency of page splits caused by the key insertion in the page.
        - It is applied only to the index bottom-up build.
    - It can use the value from 0 to 99.
    - If it is omitted, the value set in DEFAULT_INDEX_PCTFREE property is used.
- INITRANS integer
    - It is as same as INITRANS in 〈table physical attribute clause〉.
- MAXTRANS integer
    - It is as same as MAXTRANS in 〈table physical attribute clause〉.

〈segment attr clause〉

It describes the information about the space in which the table is stored.

- INITIAL integer
  - Definition
    - It specifies the size of physical storage space which is initially allocated when creating the tabl e.
    - The size is aligned to the EXTENT size of TABLESPACE to which the table belongs. (e.g. If the EXT size is 8192 bytes, 'INITIAL 100' actually operates as 8192 bytes.)
    - The size (aligned to the size of TABLESPACE EXTENT) should be equal to or bigger than the s ize of MINEXTENTS, and it should be equal to or smaller than the size of the MAXEXTENTS.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is a single EXTENT size of TABLESPACE where the table belongs.

- NEXT integer
  - Definition
    - It specifies the physical space size to be allocated when adding the space to the table.
    - The size is aligned to EXTENT size of TABLESPACE to which the table belongs. (e.g. If the EX T size is 8192 bytes, 'INITIAL 100' actually operates as 8192 bytes.)
    - NEXT is operated as follows according to the size of the remaining space of the currently avai lable table. (The size of subtracting the currently used space from the size of MAXEXTENTS.)

    - If the remaining space size is 0, then it can not extend the space.
    - If the remaining space size is bigger than 0, but smaller than NEXT, then it allocates the space as big as the remaining space.
    - If the remaining space size is bigger than NEXT, then it allocates the space as big as the NEXT.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is omitted, the default value is a single EXTENT size of TABLESPACE to which the table belon gs.

- MINSIZE integer
  - Definition
    - It is the minimum space size which the table should maintain.
    - It should be equal to or smaller than the value of MAXSIZE.
  - It is aligned to the EXTENT size of TABLESPACE to which the table belongs.
  - The minimum value is 1, and the maximum value depends on the system environment.
  - If it is smaller than the size of two EXTENTs, the size of two EXTENTs is allocated.
  - If it is omitted, the default value is the size of two EXTENTs.

- MAXSIZE integer
  - Definition
    - It is the maximum space size which can be allocated to a table.
    - It should be equal to or bigger than the value of MINSIZE.

- This size is aligned to the EXTENT size of TABLESPACE to which the table belongs.
- The minimum value is 1, and the maximum value depends on the system environment.
- If it is omitted, the default value is 32 terabytes (35,184,372,088,832).
- Even though the value is set to over 32 terabytes, it is adjusted and set to 32 terabytes.

〈size clause〉

It specifies the file size in bytes. (If it is omitted, the default unit is bytes.)

- K: Kilobytes
- M: Megabytes
- G: Gigabytes
- T: Terabytes

TABLESPACE tablespace_name

It specifies the tablespace name in which a table is to be stored.
If TABLESPACE clause is omitted, the default tablespace_name of the user performing the statement is us ed.

TABLESPACE index_tablespace_name

It specifies the tablespace name in which an index is to be stored.
If TABLESPACE clause is omitted, then it uses the index tablespace of the user.
If the index tablespace of the user is NULL, then the DISK table uses the user's data tablespace and the M EMORY table uses the user's default temporary tablespace.

〈constraint characteristics〉

It defines characteristics of the constraint.
When defining constraints, the following characteristics can be set.

- DEFERRABLE | NOT DEFERRABLE
- 〈constraint check time〉

If 〈constraint characteristics〉 is omitted, it is set to NOT DEFERRABLE INITIALLY IMMEDIATE.

DEFERRABLE | NOT DEFERRABLE

It sets whether the constraints checking is deferrable so that the constraints can be checked when executi ng COMMIT without checking when executing DML statements.

The checking time of the deferrable constraint is controlled by **SET CONSTRAINTS**.

- NOT DEFERRABLE
  - The checking point is not deferrable, and the constraints are checked when executing INSERT/DE LETE/UPDATE statements.
- DEFERRABLE
  - The checking point can be controlled by **SET CONSTRAINTS** statement.
  - SET CONSTRAINTS constraint_name IMMEDIATE
    - The constraint is checked when executing DML statement.
  - SET CONSTRAINTS constraint_name DEFERRED
    - The constraint is checked when executing COMMIT statement.
- If not specified, the default value is determined in accordance with the 〈constraint check time〉.
  - If INITIALLY IMMEDIATE is specified, the constraint check time is NOT DEFERRABLE.
  - If INITIALLY DEFERRED is specified, the constraint check time is DEFERRABLE.
  - If 〈constraint check time〉 is not specified, the constraint check time is NOT DEFERRABLE.

〈constraint check time〉

If the constraints are DEFERRABLE, it sets an initial value for the checking time.

- INITIALLY IMMEDIATE
  - The constraint is checked when executing the DML statements.
- INITIALLY DEFERRED
  - The constraint is checked when executing the COMMIT statements.
  - It can not be used together with NOT DEFERRABLE.
- If not specified, the default value is INITIALLY IMMEDIATE.

For more information about the deferrable constraints, refer to **SET CONSTRAINTS**.

〈table global secondary index clause〉

It defines a global secondary index of the table.

- WITH GLOBAL SECONDARY INDEX [〈index attributes〉 [...]] [TABLESPACE tablespace_name]
  - It creates a global secondary index when creating a table in a cluster system environment.
  - 〈index attribute〉
    - It sets an index attribute of a global secondary index.
  - TABLESPACE tablespace_name

        - It specifies a tablespace to create a global secondary index.
- WITHOUT GLOBAL SECONDARY INDEX
    - It does not create a global secondary index when creating a table in a cluster system environment.

Description

Constraint Characteristics

GOLDILOCKS automatically creates an index to check the uniqueness when generating key constraints.

The following columns do not allow NULL value.

- A column including NOT NULL constraint
- A column which is included in primary key constraints
- An identity column

Cluster Table

A table manages data using one of the following sharding strategies in a cluster environment.

- Cloned table
    - It duplicates all table data and place them in a cluster system.
- Hash sharded table
    - It divides the table data into several shards based on the hash value of a sharding key, then place s them in the cluster system.
- Range sharded table
    - It divides the table data into several shards based on the range value of a sharding key, then plac es them in the cluster system.
- List sharded table
    - It divides the table data into several shards based on the list value of a sharding key, then places t hem in the cluster system.

The sharding strategy is determined considering the followings when creating a table. Tables operated in a cluster system are specified as a code table and a fact table based on its features.

- Code table
    - It is a table such as a product list or a provider list whose data is relatively small and is not often al tered
    - This table is referenced often together with a fact table.
- Fact table
    - It is a table such as a transaction history or a call history whose data is relatively big and is often al tered.

- Its data is big so required to be sharded.

<cloned strategy> is appropriate for a code table, and an appropriate <table sharding strategy> should be determined according to the table access pattern in case of a fact table.

Examples

The following is an example of generating an ordinary table.

```
gSQL> CREATE TABLE region
(
    r_regionkey    INTEGER
  , r_name         CHAR(25)
  , r_comment      VARCHAR(152)
);
Table created.
```

The following is an example of specifying the constraints on the columns when creating a table.

```
gSQL> CREATE TABLE supplier
(
    s_suppkey      INTEGER PRIMARY KEY
  , s_name         CHAR(25) NOT NULL
  , s_address      VARCHAR(40)
  , s_nationkey    INTEGER
  , s_phone        CHAR(15)
  , s_acctbal      NUMERIC(12,2)
  , s_comment      VARCHAR(101)
);
Table created.
```

The following is an example of specifying the constraint which includes multiple columns when creating a table.

```
gSQL> CREATE TABLE partsupp
(
    ps_partkey     INTEGER
  , ps_suppkey     INTEGER
  , ps_availqty    INTEGER
  , ps_supplycost NUMERIC(12,2)
```

```
  , ps_comment    VARCHAR(199)
  , CONSTRAINT ps_unique_key UNIQUE(ps_partkey, ps_suppkey)
);
Table created.
```

The following is an example of specifying whether constraints are deferrable when creating a table.

```
gSQL> CREATE TABLE t1
(
    id     NUMBER        PRIMARY KEY
                         NOT DEFERRABLE INITIALLY IMMEDIATE
  , name   VARCHAR(128)  CONSTRAINT t1_nn NOT NULL
                         DEFERRABLE INITIALLY IMMEDIATE
  , addr   VARCHAR(1024)
  , CONSTRAINT t1_uk UNIQUE ( id, name )
                     DEFERRABLE INITIALLY DEFERRED
);
Table created.
gSQL> COMMIT;
Commit complete.
```

The following is an example of specifying a column including automatically generated values and the def ault value when creating a table.

```
CREATE TABLE customer
(
    c_custkey     INTEGER   GENERATED BY DEFAULT AS IDENTITY
  , c_name        VARCHAR(25)
  , c_address     VARCHAR(40) DEFAULT 'N/A'
  , c_nationkey   INTEGER
  , c_phone       CHAR(15)
  , c_acctbal     NUMERIC(12,2)
  , c_mktsegment  CHAR(10)
  , c_comment     VARCHAR(117)
);
Table created.
```

The following is an example of specifying the tablespace which is to be stored when creating a table.

```
gSQL> CREATE TABLE lineitem
(
    l_orderkey      INTEGER
```

```
  , l_partkey       INTEGER
  , l_suppkey       INTEGER
  , l_linenumber    INTEGER
  , l_quantity      NUMERIC(12,2)
  , l_extendedprice NUMERIC(12,2)
  , l_discount      NUMERIC(12,2)
  , l_tax           NUMERIC(12,2)
  , l_returnflag    CHAR(1)
  , l_linestatus    CHAR(1)
  , l_shipdate      DATE
  , l_commitdate    DATE
  , l_receiptdate   DATE
  , l_shipinstruct  CHAR(25)
  , l_shipmode      CHAR(10)
  , l_comment       VARCHAR(44)
  , PRIMARY KEY (l_orderkey, l_linenumber) INDEX lineitem_pk_idx TABLESPACE mem_temp_tbs
) TABLESPACE mem_data_tbs;
Table created.
```

The following is an example of defining a cluster-wide cloned table. The table data is copied and placed a ll over the cluster system.

```
gSQL>
CREATE TABLE region
(
    r_regionkey   INTEGER
  , r_name        CHAR(25)
  , r_comment     VARCHAR(152)
)
CLONED
AT CLUSTER WIDE
;
Table created.
```

The following is an example of defining a group-specific cloned table. The table data is copied and placed in a cluster group g1 and g2 specified by a user.

```
gSQL>
CREATE TABLE region
(
    r_regionkey   INTEGER
  , r_name        CHAR(25)
```

```
  , r_comment     VARCHAR(152)
)
CLONED
AT CLUSTER GROUP g1, g2
;
Table created.
```

The following is an example of defining a cluster-wide hash sharded table. The table data is divided into 2 4 shards based on the hash value of a ps_partkey column, and each shard is automatically placed all over the cluster system.

```
gSQL>
CREATE TABLE partsupp
(
    ps_partkey    INTEGER
  , ps_suppkey    INTEGER
  , ps_availqty   INTEGER
  , ps_supplycost NUMERIC(12,2)
  , ps_comment    VARCHAR(199)
)
SHARDING BY HASH ( ps_partkey )
SHARD COUNT 24
AT CLUSTER WIDE
;
Table created.
```

The following is an example of defining a group-specific hash sharded table. The table data is divided int o 24 shards based on the hash value of a ps_partkey column, and each shard is automatically placed in a specified cluster group g2 and g3.

```
gSQL>
CREATE TABLE partsupp
(
    ps_partkey    INTEGER
  , ps_suppkey    INTEGER
  , ps_availqty   INTEGER
  , ps_supplycost NUMERIC(12,2)
  , ps_comment    VARCHAR(199)
)
SHARDING BY HASH ( ps_partkey )
SHARD COUNT 24
AT CLUSTER GROUP g2, g3
```

```
;
Table created.
```

The following is an example of defining a cluster-wide range sharded table. The table data is divided into 24 shards based on the range value of D_ID column, and each shard is automatically placed all over the cl uster system.

```
gSQL>
CREATE TABLE DISTRICT (
    D_ID        INTEGER,
    D_W_ID      INTEGER,
    D_NAME      VARCHAR(10),
    D_STREET_1  VARCHAR(20),
    D_STREET_2  VARCHAR(20),
    D_CITY      VARCHAR(20),
    D_STATE     CHAR(2),
    D_ZIP       CHAR(9),
    D_TAX       NUMERIC(4,4),
    D_YTD       NUMERIC(15,2),
    D_NEXT_O_ID INTEGER,
    PRIMARY KEY (D_W_ID, D_ID) INDEX DISTRICT_PK_IDX
)
    SHARDING BY RANGE (D_ID)
    AT CLUSTER WIDE
    SHARD s1 VALUES LESS THAN ( 100 ),
    SHARD s2 VALUES LESS THAN ( 200 ),
    SHARD s3 VALUES LESS THAN ( 300 ),
    SHARD s4 VALUES LESS THAN ( 400 ),
    SHARD s5 VALUES LESS THAN ( 500 ),
    SHARD s6 VALUES LESS THAN ( 600 ),
    SHARD s7 VALUES LESS THAN ( 700 ),
    SHARD s8 VALUES LESS THAN ( MAXVALUE );
;
Table created.
```

The following is an example of defining a group-specific range sharded table. The table data is divided int o three range values based on the range value of a NO_D_ID column, and a shard s1 is placed in a cluster group g1, a shard s2 is placed in a cluster group g2, a shard s3 is placed in a cluster group g3.

```
gSQL>
CREATE TABLE NEW_ORDER
(
```

```
    NO_O_ID INTEGER,
    NO_D_ID INTEGER,
    NO_W_ID INTEGER,
    PRIMARY KEY(NO_W_ID, NO_D_ID, NO_O_ID) INDEX NEW_ORDER_PK_IDX
)
    SHARDING BY RANGE (NO_D_ID)
    SHARD s1 VALUES LESS THAN ( 5 )        AT CLUSTER GROUP g1,
    SHARD s2 VALUES LESS THAN ( 8 )        AT CLUSTER GROUP g2,
    SHARD s3 VALUES LESS THAN ( MAXVALUE ) AT CLUSTER GROUP g3
;
Table created.
```

The following is an example of defining a cluster-wide list sharded table. A list shard is divided into five b ased on a city column, and each shard is automatically placed all over the cluster system.

```
gSQL>
CREATE TABLE t1
(
    id   INTEGER
  , name VARCHAR(32)
  , city VARCHAR(128)
)
   SHARDING BY LIST (city)
      AT CLUSTER WIDE
      SHARD s1 VALUES IN ( 'seoul' ),
      SHARD s2 VALUES IN ( 'busan', 'ulsan' ),
      SHARD s3 VALUES IN ( 'suwon', 'ansan', 'osan' ),
      SHARD s4 VALUES IN ( 'goyang', 'paju', 'guri' ),
      SHARD s5 VALUES IN ( DEFAULT )
;
Table created.
```

The following is an example of defining a group-specific list sharded table. A list shard is divided into five based on a city column, and each shard is placed in a specified cluster group.

```
gSQL>
CREATE TABLE t1
(
    id   INTEGER
  , name VARCHAR(32)
  , city VARCHAR(128)
)
```

```
   SHARDING BY LIST (city)
      SHARD s1 VALUES IN ( 'seoul' )                 AT CLUSTER GROUP g1,
      SHARD s2 VALUES IN ( 'busan', 'ulsan' )        AT CLUSTER GROUP g2,
      SHARD s3 VALUES IN ( 'suwon', 'ansan', 'osan' ) AT CLUSTER GROUP g1,
      SHARD s4 VALUES IN ( 'goyang', 'paju', 'guri' ) AT CLUSTER GROUP g2,
      SHARD s5 VALUES IN ( DEFAULT )                 AT CLUSTER GROUP g3
;
Table created.
```

A table T1 is created without a global secondary index.

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I1 CHAR(32) )  WITHOUT GLOBAL SECONDARY INDEX;
Table created.
```

A global secondary index is created after creating a table T1.

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I1 CHAR(32) )  WITH GLOBAL SECONDARY INDEX;
Table created.
```

A global secondary index of table T1 is created in a tablespace USER_DATA_TBS as a logging index after creating a table T1.

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I1 CHAR(32) )
      WITH GLOBAL SECONDARY INDEX
      TABLESPACE USER_DATA_TBS;
Table created.
```

A global secondary index of table T1 is created in a tablespace USER_TEMP_TBS as a nologging index aft er creating a table T1.

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I1 CHAR(32) )
      WITH GLOBAL SECONDARY INDEX
      TABLESPACE USER_TEMP_TBS;
Table created.
```

Compatibility

The SQL standard does not define the following clauses.

- The physical concepts of TABLESPACE clause and <physical attribute clause> clause.
- The SQL standard does not allow an operation in DEFAULT clause.

Table 19-11 SQL standard compatibility

Feature ID	Description	Compatibility
T171	LIKE clause in table definition	X
F531	Temporary tables	X
S051	Create table of type	X
S043	Enhanced reference types	X
S081	Subtables	X

Refer to the followings.

- DROP TABLE
- ALTER TABLE
- CREATE TABLESPACE
- CREATE SCHEMA
- CREATE INDEX
- CREATE SEQUENCE
- SET CONSTRAINTS
- ALTER TABLE name ADD GLOBAL SECONDARY INDEX

19.18 CREATE TABLE AS SELECT

Function

It creates a new table from the query result.

Syntax

```
<table definition: AS query expression> ::=
    CREATE TABLE table_name
        [ ( column_name [, ...] ) ]
        [ <table sharding strategy> ]
        [ <table attribute clause> [, ...] ]
        [ TABLESPACE tablespace_name ]
        [ <table global secondary index clause> ]
        AS <query expression> [ WITH [ NO ] DATA ]
    ;
<table sharding strategy> ::=
      <cloned strategy>
    ¦ <hash sharding strategy>
    ¦ <range sharding strategy>
    ¦ <list sharding strategy>
<cloned strategy> ::=
    CLONED [ <clone placement> ]
<clone placement> ::=
      AT CLUSTER WIDE
    ¦ AT CLUSTER GROUP group_list
<hash sharding strategy> ::=
    SHARDING BY [HASH] ( column_list )
    [ <hash shard count> ]
    [ <hash shard placement> ]
<hash shard count> ::=
    SHARD COUNT integer
<hash shard placement> ::=
      AT CLUSTER WIDE
    ¦ AT CLUSTER GROUP group_list
<range sharding strategy> ::=
```

```
    SHARDING BY RANGE ( column_list )
    { <cluster-wide range shard placement> ¦ <group-specific range shard placement> }
<cluster-wide range shard placement> ::=
    AT CLUSTER WIDE
    <range shard definition> [, ...]
<group-specific range shard placement> ::=
    <group-specific range shard definition> [, ...]
<group-specific range shard definition> ::=
    <range shard definition> AT CLUSTER GROUP group_name
<range shard definition> ::=
    SHARD range_name VALUES LESS THAN ( <range value clause> )
<range value clause> ::=
    <range value> [, ...]
<range value> ::=
      constant
    ¦ MAXVALUE
<list sharding strategy> ::=
    SHARDING BY LIST ( column_name )
    { <cluster-wide list shard placement> ¦ <group-specific list shard placement> }
<cluster-wide list shard placement> ::=
    AT CLUSTER WIDE
    <list shard definition> [, ...]
<group-specific list shard placement> ::=
    <group-specific list shard definition> [, ...]
<group-specific list shard definition> ::=
    <list shard definition> AT CLUSTER GROUP group_name
<list shard definition> ::=
      SHARD shard_name VALUES IN ( <list value clause> )
<list value clause> ::=
    <list value> [, ...]
<list value> ::=
      constant
    ¦ NULL
    ¦ DEFAULT
<table attribute clause> ::=
      [ <table physical attribute clause> ]
    ¦ [ STORAGE ( <segment attr clause> [...] ) ]
<table physical attribute clause> ::=
      PCTFREE integer
    ¦ PCTUSED integer
    ¦ INITRANS integer
```

```
    ¦ MAXTRANS integer
<index physical attribute clause> ::=
      PCTFREE integer
    ¦ INITRANS integer
    ¦ MAXTRANS integer
<segment attr clause> ::=
      INITIAL <size_clause>
    ¦ NEXT <size_clause>
    ¦ MINSIZE <size_clause>
    ¦ MAXSIZE <size_clause>
<size clause> ::=
      integer [ K ¦ M ¦ G ¦ T ]
<table global secondary index clause> ::=
      WITH GLOBAL SECONDARY INDEX [ <index attributes> [...] ] [ TABLESPACE tablespace_name ]
    ¦  WITHOUT GLOBAL SECONDARY INDEX
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <table definition:AS query expression>statement.

- Table creation privilege
  - Refer to the access privilege in **CREATE TABLE**.
- SELECT access privilege
  - Refer to the access privilege in **SELECT**.

Syntax Rules and Parameters

table_name

It is the table name to be created.
For more information, refer to **table_name**.

column_name_list

It is the name of columns which configure the table, and it should be unique names within the table.
The number of columns should be as same as the number of result columns in SELECT clause.
If not specified, the column names of SELECT clause in <query expression> are used.

However, if there is a expression (function, operation, subquery, etc.) instead of a column in SELECT clau se, the alias or column name should be specified.

The length of the column name should be shorter than 128 bytes.

WITH [NO] DATA

If WITH DATA is specified, the result of SELECT clause is inserted to the table to be created.
If WITH NO DATA is specified, the result of SELECT clause is not inserted to the table to be created.
If not specified, it is operated as same as when WITH DATA is specified.

Other Syntax

For more information about other syntaxes, refer to the syntax in **CREATE TABLE** statement.

Description

When executing CREATE TABLE AS SELECT, if a column including a NOT NULL constraint is specified in S ELECT list, the NOT NULL constraint is also created in the new table.
However, if the NOT NULL constraint is deferrable, then NOT NULL constraint is not created in the new ta ble.

On the other hand, the NOT NULL constraint is not created in the new table if NOT NULL constraint was n ot explicitly created but there is NOT NULL property such as primary key column or identity column.

Examples

The following is an example of executing CREATE TABLE AS SELECT statement.

```
gSQL> CREATE TABLE recent_orders
                AS SELECT order_id, order_item, order_date
                   FROM orders
                   WHERE order_date >= '2015-03-03'
Table created.
```

The following is an example of specifying the column name.

```
gSQL> CREATE TABLE recent_orders ( order_id, order_item, order_date )
                AS SELECT order_id, order_item, order_date
                   FROM orders
                   WHERE order_date >= '2015-03-03'
Table created.
```

The following is an example of a function in SELECT list.

```
gSQL> CREATE TABLE recent_orders ( order_id, order_item, order_date )
                AS SELECT order_date, COUNT(*)
                   FROM orders
                   WHERE order_date >= '2015-03-03'
                   GROUP BY order_date;
Table created.
```

The following is an example of the statement including WITH DATA.

```
gSQL>CREATE TABLE orders
(
    order_id   NUMBER
  , order_item VARCHAR(128)
  , order_date DATE
);
gSQL> COMMIT;
gSQL> INSERT INTO orders VALUES ( 1, 'Pen', '2010-01-01' );
gSQL> INSERT INTO orders VALUES ( 2, 'Book', '2015-03-03' );
gSQL> COMMIT;
gSQL> CREATE TABLE recent_orders
                AS SELECT order_id, order_item, order_date
                   FROM orders
                   WHERE order_date >= '2015-03-03'
      WITH DATA;
Table created.
gSQL> SELECT COUNT(*) FROM recent_orders;
COUNT(*)
--------
       1
1 row selected.
```

The following is an example of the statement including WITH NO DATA.

```
gSQL>CREATE TABLE orders
(
    order_id   NUMBER
  , order_item VARCHAR(128)
  , order_date DATE
);
gSQL> COMMIT;
gSQL> INSERT INTO orders VALUES ( 1, 'Pen', '2010-01-01' );
gSQL> INSERT INTO orders VALUES ( 2, 'Book', '2015-03-03' );
gSQL> COMMIT;
gSQL> CREATE TABLE recent_orders
                AS SELECT order_id, order_item, order_date
                   FROM orders
                   WHERE order_date >= '2015-03-03'
      WITH NO DATA;
Table created.
gSQL> SELECT COUNT(*) FROM recent_orders;
COUNT(*)
--------
       0
1 row selected.
```

Compatibility

CREATE TABLE AS SELECT statement follows SQL standard. However, the following is an extension of SQ L standard.

- SQL standard require parentheses outside SELECT clause, but it is optional in GOLDILOCKS.
- SQL standard require WITH [NO] DATA clause, but it is optional in GOLDILOCKS.
- The concepts of tablespace in GOLDILOCKS is an extended concept, and it is not supported in SQL st andard.

Table 19-12 SQL standard compatibility

Feature ID	Description	Compatibility
T172	AS subquery clause in table definition	O

For More Information

Refer to the followings.

- CREATE TABLE
- SELECT

19.19 CREATE TABLESPACE

Function

It creates a tablespace.

Syntax

```
<create tablespace statement> ::=
      <memory data tablespace statement>
    | <memory temporary tablespace statement>
    ;
```

Invocation and Access Rules

CREATE TABLESPACE ON DATABASE privilege is required to perform <create tablespace statement>.

The user who performed the statement has CREATE OBJECT ON TABLESPACE privilege on the created tablespace.

One of the following privileges are required to create the objects on the created tablespace.

- CREATE OBJECT ON TABLESPACE for that tablespace
- USAGE TABLESPACE ON DATABASE

Syntax Rules and Parameters

<memory data tablespace statement>

- [MEMORY] TEMPORARY

It is a memory temporary tablespace to store the no logging indexes or the temporary objects such as intermediate results which are generated during the query processing.
The reserved word MEMORY can be omitted.

〈memory data tablespace clause〉

It defines a memory data tablespace.
For more information, refer to CREATE MEMORY DATA TABLESPACE.

〈memory temporary tablespace definition〉

It defines a memory temporary tablespace.
For more information, refer to CREATE MEMORY TEMPORARY TABLESPACE.

Description

For more information, refer to the description of each detailed statement.

Example

For more information, refer to usage example of each detailed statement.

Compatibility

The SQL standard does not cover the concepts of the tablespace.

For More Information

Refer to the followings.

- DROP TABLESPACE
- ALTER TABLESPACE

19.20 CREATE USER

Function

It defines a database user.

Syntax

```
<user definition> ::=
    CREATE USER user_identifier IDENTIFIED BY password
    [ PROFILE { profile_name ¦ DEFAULT ¦ NULL } ]
    [ PASSWORD EXPIRE ]
    [ ACCOUNT { LOCK ¦ UNLOCK } ]
    [ DEFAULT TABLESPACE tablespace_name ]
    [ TEMPORARY TABLESPACE tablespace_name ]
    [ INDEX TABLESPACE { tablespace_name ¦ NULL } ]
    [ <schema clause> ]
    ;
<schema clause> ::=
      WITH SCHEMA [schema_name]
    ¦ WITHOUT SCHEMA
```

Invocation and Access Rules

CREATE USER ON DATABASE privilege is required to perform <user definition>.

The created user, user_identifier, has the privilege, which is the owner the schema created by using <schema clause>.

A separate privilege is not granted to the created user_identifier.
The appropriate privileges should be granted to user_identifier to access and perform SQL statements.

Syntax Rules and Parameters

user_identifier

It is the username to be created.
The identical username (user identifier) or role (role name) should not exist.
The length of user_identifier should be shorter than 128 bytes.

password

It is the user's password to be created. It is encrypted and stored.
The length of password should be shorter than 128 bytes.
The password is case sensitive.
The password should start with an alphabetic character, and it can include alphabetic characters, number s, underscore (_), and $.
The other special characters should be enclosed in double quotes (").

PROFILE { profile_name | DEFAULT | NULL }

The profile for password management policy is assigned.

- PROFILE profile_name
  - It allocates the profile_name which is created by a user.
- PROFILE DEFAULT
  - It allocates the default profile "DEFAULT".
- PROFILE NULL
  - It does not allocate the profile.

If PROFILE clause is omitted, it is as same as PROFILE NULL, and the profile is not applied.
For more information about the password management policy, refer to **CREATE PROFILE**.

PASSWORD EXPIRE

It expires the user's password.
It is used when a user attempts to change the password by force before login.

ACCOUNT { LOCK | UNLOCK }

- ACCOUNT LOCK
  - It locks the user account.
- ACCOUNT UNLOCK
  - It unlocks the user account.

DEFAULT TABLESPACE tablespace_name

It specifies the default TABLESPACE to store objects such as the table created by the user, the indexes (wi th NOLOGGING option).
If DEFAULT TABLESPACE clause is omitted, default data tablespace (MEM_DATA_TBS) is specified, which was defined when creating DATABASE.

TEMPORARY TABLESPACE tablespace_name

It specifies the TABLESPACE which stores the temporary tables created by a user, indexes (NO LOGGING), and the intermediate results generated by the query processing.
If TEMPORARY TABLESPACE clause is omitted, default temporary tablespace (MEM_TEMP_TBS) is specifi ed, which was defined when creating DATABASE.

INDEX TABLESPACE { tablespace_name | NULL }

It specifies the default TABLESPACE which stores the index objects created by a user.

- Specifying INDEX TABLESPACE tablespace_name
  - If it specifies the data tablespace, then it becomes the LOGGING index.
  - If it specifies the temporary tablespace, then it becomes the NOLOGGING index.

- INDEX TABLESPACE NULL
  - It does not specify the index tablespace.

If INDEX TABLESPACE clause is omitted, then it is INDEX TABLESPACE NULL.

〈schema clause〉

It creates a schema which a user uses by default.
The schema name should be unique in the database.

- WITH SCHEMA [schema_name]
  - If schema_name is not assigned, the schema is created whose name is as same as user_identifier.

    - SCHEMA PATH of the user is set as follows.
        - schema_name, PUBLIC
- WITHOUT SCHEMA
    - It does not create the schema which is to be owned by a user.
    - SCHEMA PATH of the user is set as PUBLIC.

If <schema clause> is not specified, the default value is WITH SCHEMA and the schema is created whose name is as same as user_identifier.
The schema to be owned by the user can be additionally created by using **CREATE SCHEMA** statement.

Description

A user is an authorization object which consists of a set of privileges.

When <user definition> statement is executed for the first time, a user without any privilege is created, an d the appropriate privileges should be granted as follows.

In GOLDILOCKS, the relationship between user and schema is 1 : N.
In other words, a user does not own any schema, or a user can own multiple schemas.

The SQL standard does not explicitly define the relationship of the non-schema objects such as a user, a s chema, or a database. Each DBMS defines the relationship of non-schema objects in different concept as follows.

The relationship between user and schema in other DBMS.

- Oracle
    - User : schema = 1 : 1.

- DB2
    - It is as same as the OS user.
    - The separate SQL statements which creates or deletes a user do not exist.

- Postgres
    - User : schema = 1 : N.

- MySQL
  - Database : schema = 1 : 1.
  - User is a subordinate object of database (schema).

Examples

At least the following privileges should be granted to create a user, and for the created user to create the objects, manipulate data.

The following is an example of creating a user and granting privileges.

- Create a user.

```
gSQL> CREATE USER u1 IDENTIFIED BY u1_password
             DEFAULT   TABLESPACE mem_data_tbs
             TEMPORARY TABLESPACE mem_temp_tbs
             INDEX TABLESPACE NULL;
User created.
gSQL> COMMIT;
Commit complete.
```

- Grant database privileges.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO u1;
Grant succeeded.
COMMIT;
Commit complete.
```

- Grant schema privileges.

```
GRANT CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, ADD CONSTRAINT
      ON SCHEMA u1 TO u1;
Grant succeeded.
COMMIT;
Commit complete.
```

- Grant tablespace privileges.

```
GRANT CREATE OBJECT ON TABLESPACE mem_data_tbs TO u1;
Grant succeeded.
```

```
GRANT CREATE OBJECT ON TABLESPACE mem_temp_tbs TO u1;
Grant succeeded.
COMMIT;
Commit complete.
```

The following is an example of creating objects by the user.

- It needs CREATE SESSION ON DATABASE.

```
gSQL> \connect u1 u1_password
```

- It needs CREATE TABLE ON SCHEMA u1.
- It needs CREATE OBJECT ON TABLESPACE mem_data_tbs.

```
gSQL> CREATE TABLE u1.t1 ( c1 INTEGER, c2 INTEGER ) TABLESPACE mem_data_tbs;
Table created.
gSQL> COMMIT;
```

- It needs CREATE INDEX ON SCHEMA u1.
- It needs CREATE OBJECT ON TABLESPACE mem_temp_tbs.

```
gSQL> CREATE INDEX u1.idx ON t1 (c2) TABLESPACE mem_temp_tbs;
Index created.
gSQL> COMMIT;
```

- It needs ADD CONSTRAINT ON SCHEMA u1.

```
gSQL> ALTER TABLE t1 ADD CONSTRAINT u1.t1_pk PRIMARY KEY (c1) ;
Table altered.
gSQL> COMMIT;
```

- It needs CREATE SEQUENCE ON SCHEMA u1.

```
gSQL> CREATE SEQUENCE u1.seq;
Sequence created.
gSQL> COMMIT;
gSQL> INSERT INTO u1.t1 VALUES ( u1.seq.NEXTVAL, u1.seq.NEXTVAL );
1 row created
gSQL> COMMIT;
```

Compatibility

The SQL standard covers the concepts of the user, but it does not define the SQL statements associated with the creation and deletion of user.

For More Information

Refer to the followings.

- DROP USER
- ALTER USER
- CREATE SCHEMA

19.21 CREATE VIEW

Function

It defines a view.

Syntax

```
<view definition> ::=
    CREATE [ OR REPLACE ] [ FORCE ¦ NO FORCE ]
        VIEW view_name [ ( column_name [, ...] ) ]
        AS <query expression>
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <view definition> statement.

- One of the following privileges is required to create a view.
  - (CREATE VIEW or CONTROL SCHEMA) ON SCHEMA for the schema to which the view belongs
  - CREATE ANY VIEW ON DATABASE

- When using OR REPLACE clause, if a view already exists, then one of the following privileges is required to remove the existing view.
  - The owner of that view
  - CONTROL TABLE ON TABLE for that view.
  - (DROP VIEW or CONTROL SCHEMA) ON SCHEMA for the schema to which the view belongs
  - DROP ANY VIEW ON DATABASE

- One of the following privileges is required for all tables used in <Query expression>.
  - SELECT(columns) ON TABLE for all columns used in the statement among table columns
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- The owner of the created view is determined as follows.

    - The owner of the schema to which the view belongs.
    - If the schema to which the view belongs is PUBLIC, then it is the user who executed the statemen t.

- The owner of the view has the following privileges for the created view.
    - SELECT ON TABLE WITH GRANT OPTION
    - INSERT ON TABLE WITH GRANT OPTION
    - UPDATE ON TABLE WITH GRANT OPTION
    - DELETE ON TABLE WITH GRANT OPTION
    - TRIGGER ON TABLE
    - LOCK ON TABLE WITH GRANT OPTION
    - ALTER ON TABLE WITH GRANT OPTION

Syntax Rules and Parameters

[OR REPLACE]

It replaces the existing view when a view already exists.

[FORCE | NO FORCE]

- FORCE
    - A view is created regardless of the validity of <query expression>.
- NO FORCE
    - A view is created when <Query expression> is valid.
- The default value is NO FORCE.

view_name

It is the view name to be created, and it should be a unique name within the schema.
The schema to which the view belongs, such as schema_name.view_name, can be defined. If schema_na me is omitted, the default schema name of the user performing the statement is used.
The length of the view name must be shorter than 128 bytes.

[(column_name [, ...])]

It defines a column name which will configure the view.
Each column name should be unique within the view.

The number of columns should be as same as the number of result columns in SELECT clause.

If the list of column names is omitted, the column names of SELECT clause in 〈query expression〉 are used.

AS 〈query expression〉

It is the **SELECT** query which will create a view.

〈query expression〉 can not include the following variables.

- Host parameter
- SQL parameter
- Dynamic parameter
- Embedded variable
- SEQUENCE object

Description

A view is the object which gave a name to the query, and it is used in the similar way of a table.

When executing a query including the view, that view is interpreted as the query included in the view defi nition. If the table referenced by the view is altered, as the following example, the asterisk (*) included in the view definition is automatically interpreted based on the altered table information.

```
gSQL> CREATE VIEW v1 AS SELECT * FROM t1;
gSQL> COMMIT;
gSQL> SELECT * FROM v1;
ID NAME
-- ---------
 1 leekmo
 2 mkkim
 3 egonspace
3 rows selected.
gSQL> ALTER TABLE t1 ADD COLUMN ( dept_id  INTEGER,  addr  VARCHAR(1024) );
gSQL> COMMIT;
gSQL> select * from v1;
ID NAME      DEPT_ID ADDR
-- --------- ------- ----
 1 leekmo       null null
 2 mkkim        null null
 3 egonspace    null null
```

```
3 rows selected.
```

The view is affected if the view is created on the query including errors by using FORCE option, the tables referred by the view, or views are altered or deleted.

This information can be retrieved from INFORMATION_SCHEMA.VIEWS information.

- IS_COMPILED column
  - TRUE: The view is normally created.
  - FALSE: The view is created having an error by using FORCE option.
- IS_AFFECTED column
  - TRUE : The referenced tables by a view or view is altered.
  - FALSE: After a view is created and compiled, the referenced tables or views are not altered.

The maximum number of creating views and the maximum number of columns to be created within a vie w is not limited. Therefore, they can be created as many as the storage space is available.

Examples

The following is an example of creating a view.

```
gSQL> CREATE VIEW v1 AS SELECT * FROM t1 WHERE dept_id = 101;
View created.
```

The following is an example of defining the column names when defining a view.

```
gSQL> CREATE VIEW v1 ( v_id, v_name )
          AS SELECT id, name FROM t1 WHERE dept_id = 101;
View created.
```

The following is an example of removing the existing view and creating a new view by using REPLACE op tion.

```
gSQL> CREATE OR REPLACE VIEW v1(id, name)
             AS SELECT id, name FROM t1;
View created.
```

The following is an example of forcing to create a view by using FORCE option even when the referenced object by the view does not exist.

```
gSQL> CREATE FORCE VIEW v1
          AS SELECT * FROM t1 WHERE dept_id = 101;
ERR-01000(16243): Warning: View created with compilation errors
ERR-42000(16040): table or view does not exist :
    AS SELECT * FROM t1 WHERE dept_id = 101
                      *
ERROR at line 2:
View created.
```

Compatibility

The SQL standard does not define the following clauses.

- [OR REPLACE] clause
- [FORCE | NO FORCE] clause

Table 19-13 SQL standard compatibility

Feature ID	Description	Compatibility
T131	Recursive query	O
F751	View CHECK enhancements	X
S043	Enhanced reference types	X
T111	Updatable joins, unions, and columns	X
F852	Top-level <order by clause> in views	O
F864	Top-level <result offset clause> in views	O
F859	Top-level <fetch first clause> in views	O
S081	Subtables	X

For More Information

Refer to the followings.

- DROP VIEW
- ALTER VIEW
- SELECT

19.22 DECLARE cursor_name

Function

It declares a cursor.

Syntax

```
<declare cursor> ::=
    DECLARE cursor_name <cursor properties> { FOR ¦ IS } <cursor specification>
    ;
<cursor properties> ::=
      [ <cursor sensitivity> ] [ <cursor scrollability>] ] CURSOR [ <cursor holdability> ]
    ¦ [ <odbc cursor type] CURSOR [ <cursor holdability> ]
<cursor sensitivity> ::=
      INSENSITIVE
    ¦ SENSITIVE
    ¦ ASENSITIVE
<cursor scrollability> ::=
      NO SCROLL
    ¦ SCROLL
<cursor holdability> ::=
      WITH HOLD
    ¦ WITHOUT HOLD
<odbc cursor type> ::=
      STATIC
    ¦ KEYSET
<cursor specification> ::=
      statement_name
    ¦ <cursor query>  [ <updatability clause> ]
<cursor query> ::=
      <select statement>
    ¦ <insert returning query statement>
    ¦ <update returning query statement>
    ¦ <delete returning query statement>
<updatability clause> ::=
      FOR READ ONLY
```

```
    ¦ FOR UPDATE [ OF <column name list> ] [ <lock wait mode> ]
<lock wait mode> ::=
    ¦ WAIT
    ¦ WAIT second
    ¦ NOWAIT
```

Invocation and Access Rules

The dynamic cursor which uses statement_name can be used in an embedded SQL.

An appropriate access privilege is required depending on <cursor query> types.
For more information about the access privileges, refer to the followings.

- The access privilege of a **SELECT** statement
- The access privilege of a **SELECT .. FOR UPDATE** statement
- The access privilege of a **INSERT INTO name RETURNING** statement
- The access privilege of a **UPDATE name RETURNING** statement
- The access privilege of a **DELETE FROM name RETURNING** statement

Syntax Rules and Parameters

cursor_name

It is the cursor name to be declared.
It should be a unique name within the session.
The length of cursor name should be shorter than 128 bytes.

{ FOR | IS }

Either FOR or IS is used as a syntax keyword in SQL standard.

<cursor properties>

It defines the cursor properties.

- If <cursor sensitivity> is not specified, the default value is INSENSITIVE.
- If <cursor scrollability> is not specified, the default value is NO SCROLL.
- If <cursor holdability> is not specified, the default value is determined by <cursor updatability>.

updatable query

To use a cursor property such as SENSITIVE or FOR UPDATE, a query of the cursor should identify changes in rows of the base table, or it should be the updatable query which can acquire a lock on the row.

The updatable query should satisfy all of the following conditions.

- DISTINCT should not exist at the top level query.
  - (X) SELECT DISTINCT * FROM t1;
- GROUP BY, HAVING, aggregation function should not exist at the top level query.
  - (X) SELECT MAX(c1) FROM t1;
- It should not be a returning query.
  - (X) DELETE FROM t1 RETURNING c1;
- Set operator should not exist.
  - (X) SELECT * FROM t1 UNION ALL SELECT * FROM t2;
- At least one updatable column is required on the listed tables in FROM clause.
  - The columns of the tables, which are included in join operations and are not used in the cross joi n, are not the updatable columns.
    - FULL OUTER JOIN is not cross join.
    - NATURAL JOIN is not cross join.
    - If INNER JOIN uses USING phrase, it is not cross join.
  - The columns of the following tables are not the updatable columns.
    - Dictionary table, fixed table, performance view
  - The columns of the view are not updatable tables.

〈cursor sensitivity〉

It determines whether the following data changes which affects the query results can be queried when o perating the cursor.

- INSENSITIVE
  - It can not detect the data updated during the cursor operation.
- SENSITIVE
  - 〈cursor query〉 should be an updatable query.
  - It detects the updated and deleted data in the transaction as same as that of the cursor.
  - It detects the data updated and deleted through COMMIT of other transactions.
- ASENSITIVE
  - INSENSITIVE or SENSITIVE is determined depending on the type of 〈cursor query〉.
    - For the updatable query, it is SENSITIVE.
    - For no updatable query, it is INSENSITIVE.
- If it is not specified, the default value is INSENSITIVE.

〈cursor scrollability〉

It specifies whether the result set of the cursor can be fetched sequentially or non-sequentially.

- NO SCROLL
  - Only sequential FETCH (FETCH NEXT) is possible.
- SCROLL
  - Non-sequential FETCH is possible.
- If not specified, the default value is NO SCROLL.

〈cursor holdability〉

It determines whether the cursor is maintained after the cursor is OPEN and the transaction is committed.

- WITH HOLD
  - The cursor is maintained after the transaction is committed.
  - It can not be used together with FOR UPDATE statement.
  - It can not be used together with **INSERT INTO name RETURNING** statement.
  - It can not be used together with **UPDATE name RETURNING** statement.
  - It can not be used together with **DELETE FROM name RETURNING** statement.
  - It can not be used in the query including the global temporary table whose table commit action is ON COMMIT DELETE ROWS.

- WITHOUT HOLD
  - When the transaction is committed or rolled back, the cursor is closed.

- Rollback and cursor
  - It closes a cursor included in a transaction when rolling back the transaction.
  - It closes a cursor created since the savepoint when rolling back up to the savepoint.

- If not specified, the default value of 〈cursor holdability〉 is determined by 〈cursor updatability〉.
  - If it is FOR READ ONLY or 〈cursor updatability〉 is not specified, the default value is WITH HOLD.
  - If it is used together with FOR UPDATE statement, the default value is WITHOUT HOLD.

〈odbc cursor type〉

It is the cursor type in the ODBC standard, and it has the SCROLL property.

- STATIC CURSOR
  - It is as same as INSENSITIVE SCROLL in SQL standard.
  - Non-sequential FETCH is possible.
  - It is the static scroll cursor in the ODBC standard.
- KEYSET CURSOR

- It is as same as ASENSITIVE SCROLL in SQL standard.
- It is the keyset-driven scroll cursor in the ODBC standard.
- The property of sensitivity is determined according to the following characteristics.

Table 19-14 Sensitivity according to FOR [UPDATE / READ ONLY] statement and the query type

Updatability	Query type	Sensitivity
FOR UPDATE	Updatable query	SENSITIVE
FOR UPDATE	Non-updatable query	Query error
FOR READ ONLY	Any query	INSENSITIVE
N/A	Updatable query	SENSITIVE
N/A	Non-updatable query	INSENSITIVE

〈cursor specification〉

It defines a query which is a target of the cursor.
If statement_name is used, a dynamic cursor whose query has not been defined is declared.
If 〈cursor query〉 is used, a standing cursor whose query is defined is declared.

statement_name

It is a statement_name to be referenced by the cursor, and it can be used in an embedded SQL.

statement_name should exist before performing 〈declare cursor〉 statement, and the SQL statement refe renced by statement_name should be the query prepared by **PREPARE statement_name** statement.

If it is not a query, an error occurs when executing **OPEN cursor_name** statement.

〈cursor query〉

For more information about available query types in the cursor, refer to the followings.

- SELECT
- SELECT .. FOR UPDATE
- INSERT INTO name RETURNING
- UPDATE name RETURNING
- DELETE FROM name RETURNING

〈updatability clause〉

It specifies whether to change rows by using the cursor.

- FOR READ ONLY
  - It declares a read-only cursor.
- FOR UPDATE
  - It declares a writable cursor.
  - When opening the cursor, the x lock for the corresponding rows is acquired to prevent the chang e by other transactions until the transaction is completed.
  - It can not be used together with WITH HOLD statement.
  - 〈cursor query〉 should be an updatable query.
- If not specified, the default value is FOR READ ONLY.

FOR UPDATE OF …

It lists the columns associated with the lock obtaining when OPENing the cursor.

- If it is the columns listed in FOR UPDATE OF statement
  - It should be an updatable column of the table listed in FROM clause of 〈select statement〉.
  - It acquires the lock for the table of listed columns.
- If only FOR UPDATE statement is used
  - It is the same meaning as listing all updatable columns of the table in FROM clause of 〈select stat ement〉.
  - It acquires the lock for the table of all columns.

〈lock wait mode〉

It is used together with FOR UPDATE clause, and it specifies the lock acquisition method.

- WAIT
  - It acquires the lock for all rows of the query result when OPENing the cursor.
  - It waits until acquiring the lock.
- WAIT second
  - It acquires the lock for all rows of the query result when OPENing the cursor.
  - An error occurs if the lock is not acquired within the specified time.
  - The wait time is in seconds, and it can use the value between 0 and 1000000000.
- NOWAIT
  - It acquires the lock for all rows of the query result when OPENing the cursor.
  - An error occurs if the lock is not immediately acquired.
- If not specified, the default value is WAIT.

Description

When controlling the query property, using DECLARE CURSOR, OPEN, FETCH, CLOSE statements have th e performance burden compared to using the cursor with the ODBC or JDBC statements. It is because usi ng DECLARE CURSOR, OPEN, FETCH, CLOSE statements control the cursor of the server.

Before executing the query, the cursor property can be controlled by ODBC statement and JDBC stateme nt. The SQL cursor property control method by DECLARE CURSOR statement, and cursor property control method by the ODBC standard and the JDBC standard are as follows.

Table 19-15 Controlling the cursor property of ODBC/ JDBC

Property	GOLDILOCKS cursor property	ODBC standard cursor property	JDBC standard cursor property
Sensitivity	INSENSITIVE	SQLSetStmtAttr(stmt, SQL_ATTR_C URSOR_SENSITIVITY, SQL_INSENSITI VE, len)	It can not be set.
	SENSITIVE	SQLSetStmtAttr(stmt, SQL_ATTR_C URSOR_SENSITIVITY, SQL_SENSITIV E, len)	It can not be set.
	ASENSITIVE	SQLSetStmtAttr(stmt, SQL_ATTR_C URSOR_SENSITIVITY, SQL_UNSPECI FIED, len)	It can not be set.
Scrollability	NO SCROLL	SQLSetStmtAttr(stmt, SQL_ATTR_C URSOR_SCROLLABLE, SQL_NONSC ROLLABLE, len)	It can not be set.
	SCROLL	SQLSetStmtAttr(stmt, SQL_ATTR_C URSOR_SCROLLABLE, SQL_SCROLL ABLE, len)	It can not be set.
Holdability	WITHOUT HOLD	It can not be set.	java.sql.Connection::prepareState ment(query, type, conc, ResultSet. CLOSE_CURSORS_AT_COMMIT)
	WITH HOLD	It can not be set.	java.sql.Connection::prepareState ment(query, type, conc, ResultSet. HOLD_CURSORS_OVER_COMMIT)

SQL cursor declaration corresponding to ODBC cursor type is as follows.

Table 19-16 SQL cursor declaration corresponding to ODBC cursor type

ODBC cursor type	SQL cursor declaration
SQLSetStmtAttr(stmt, SQL_ATTR_CURSOR_TYPE, SQL_CURSOR_FORWARD_ONLY, le n)	NO SCROLL CURSOR

ODBC cursor type	SQL cursor declaration
SQLSetStmtAttr(stmt, SQL_ATTR_CURSOR_TYPE, SQL_CURSOR_STATIC, len)	STATIC CURSOR
SQLSetStmtAttr(stmt, SQL_ATTR_CURSOR_TYPE, SQL_CURSOR_KEYSET_DRIVEN, len)	KEYSET CURSOR

SQL cursor declaration corresponding to JDBC cursor type is as follows.

Table 19-17 SQL cursor declaration corresponding to JDBC cursor type

JDBC cursor type	SQL cursor declaration
java.sql.Connection::prepareStatement(query, ResultSet.TYPE_FORWARD_ONLY, conc, hold)	INSENSITIVE NO SCROLL CURSOR
java.sql.Connection::prepareStatement(query, ResultSet.TYPE_SCROLL_INSENSITIVE, conc, hold)	INSENSITIVE SCROLL CURSOR
java.sql.Connection::prepareStatement(query, ResultSet.TYPE_SCROLL_SENSITIVE, conc, hold)	KEYSET CURSOR

Examples

The following is an example of declaring the cursor by using interactive SQL (gsql), and using it.

```
gSQL> DECLARE cur1 CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
```

```
   3 data_3
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   4 data_4
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
no rows fetched.
gSQL> CLOSE cur1;
Cursor closed.
```

The following is an example of declaring KEYSET cursor, sequentially searching, then completing the tran saction of UPDATE, DELETE statements, and searching for it in the reverse direction.

```
gSQL> DECLARE cur_keyset KEYSET CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur_keyset;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
```

```
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   4 data_4
1 row fetched.
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH NEXT cur_keyset INTO :v_id, :v_data;
no rows fetched.
gSQL> UPDATE t1 SET data = 'new data_2' WHERE id = 2;
1 row updated.
gSQL> COMMIT;
Commit complete.
gSQL> DELETE FROM t1 WHERE id = 4;
1 row deleted.
gSQL> COMMIT;
Commit complete.
gSQL> FETCH PRIOR cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH PRIOR cur_keyset INTO :v_id, :v_data;
no rows fetched.
gSQL> FETCH PRIOR cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH PRIOR cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ----------
   2 new data_2
1 row fetched.
gSQL> FETCH PRIOR cur_keyset INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
```

```
1 row fetched.
gSQL> CLOSE cur_keyset;
Cursor closed.
```

The following is an example of declaring SCROLL cursor, and using the cursor through the fetch orientati on.

```
gSQL> DECLARE cur_scroll SCROLL CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur_scroll;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH LAST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH PRIOR cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   4 data_4
1 row fetched.
gSQL> FETCH FIRST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH ABSOLUTE 3 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH RELATIVE -1 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH ABSOLUTE 3 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
```

```
   3 data_3
1 row fetched.
gSQL> CLOSE cur_scroll;
Cursor closed.
```

Compatibility

<declare cursor> statement has the following differences compared to the SQL standard.

- In SQL standard, the default value of <cursor sensitivity> is ASENSITIVE, but in GOLDILOCKS, the default value is INSENSITIVE.
- The SQL standard does not cover the following <odbc cursor type>.
  - STATIC CURSOR
  - KEYSET CURSOR
- In SQL standard, the default value of <cursor holdability> is WITHOUT HOLD, but in GOLDILOCKS, the default value depends on <cursor updatability>.
- SQL standard can use only <select statement> as <cursor query>, but GOLDILOCKS can use the returning query as follows.
  - **INSERT INTO name RETURNING**
  - **UPDATE name RETURNING**
  - **DELETE FROM name RETURNING**
- In SQL standard, the default value of <cursor updatability> is determined by <select statement>, but in GOLDILOCKS the default value is FOR READ ONLY.
- In SQL standard, <lock wait mode> statement does not exist.

Table 19-18 SQL standard compatibility

Feature ID	Description	Compatibility
F831	Full cursor update	O
T231	Sensitive cursors	O
F791	Insensitive cursors	O
F431	Read-only scrollable cursors	O
T471	Result sets return value	X
T551	Optional key words for default syntax	O
T111	Updatable joins, unions, and columns	X
B031	Basic dynamic SQL	O

For More Information

Refer to the followings.

- OPEN cursor_name
- FETCH cursor_name
- CLOSE cursor_name
- PREPARE statement_name
- SELECT
- SELECT .. FOR UPDATE
- INSERT INTO name RETURNING
- UPDATE name RETURNING
- DELETE FROM name RETURNING

19.23 DELETE FROM

Function

It deletes rows in a table.

Syntax

```
<delete statement: searched> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
    ;
<result offset clause> ::=
    OFFSET skip_count [ ROW ¦ ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    ¦ <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST ¦ NEXT ] [ row_count ] [ ROW ONLY ¦ ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count ¦ offset_row_count, fetch_row_count ¦ ALL }
```

Invocation and Access Rules

One of the following privileges is required to perform <delete statement: searched>.

- (DELETE or CONTROL TABLE) ON TABLE for the table
- (DELETE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- DELETE ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be deleted.
It defines the schema to which the table belongs such as schema_name.table_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.

[AS alias_name]

It is the alias of table_name.

WHERE 〈search condition〉

It deletes the rows which satisfy WHERE condition.
If WHERE condition is omitted, it deletes all rows.
For more information about WHERE condition, refer to **where clause** of **SELECT** statement.

〈result offset clause〉

It specifies the number of rows to be skipped among the query result.
For more information, refer to **offset limit clause** of **SELECT** statement.

〈fetch limit clause〉

The following two ways are used to specify the number of rows to be fetched.

- 〈fetch first clause〉
  - It specifies the number of rows to be fetched.
  - For more information, refer to **〈fetch first clause〉** of **SELECT** statement.
- 〈limit clause〉
  - It specifies the number of rows to be fetched, or it simultaneously specifies both the number of r ows to be skipped and the number of rows to be fetched.
  - For more information, refer to **〈limit clause〉** of **SELECT** statement.

Description

Differences among DELETE-related Statements

- **DELETE FROM**
  - It deletes multiple rows which satisfy conditions.
  - e.g. DELETE FROM t1 WHERE c1 = 0;
- **DELETE FROM name WHERE CURRENT OF cursor_name**
  - It deletes the row which the current cursor indicates.
  - e.g. DELETE FROM t1 WHERE CURRENT OF cursor;
- **DELETE FROM name RETURNING**
  - It deletes multiple rows which satisfy the conditions, and the deleted rows can be retrieved in the same way as **SELECT** statement (API such as SQLFetch ()).
  - e.g. DELETE FROM t1 WHERE c1 = 0 RETURNING c2;
- **DELETE FROM name RETURNING .. INTO**
  - It deletes row equal to or less than one, and if one row is deleted, the value is obtained into the h ost variable of RETURNING INTO clause.
  - e.g. DELETE FROM t1 WHERE c1 = 0 RETURNING c2 INTO :v1;

Examples

The following is an example of DELETE statement.

```
gSQL> DELETE FROM t1 WHERE id > 3;
2 rows deleted.
```

The following is an example of skipping some rows (two rows) and deleting some rows (two rows) amon g the rows which satisfy the conditions by using <result offset clause> and <fetch first clause> clauses.

```
gSQL> DELETE FROM t1 OFFSET 2 FETCH 2;
2 rows deleted.
gSQL> SELECT * FROM t1 ORDER BY 1;
ID DATA
-- ------
 1 data_1
 2 data_2
 5 data_5
3 rows selected.
```

Compatibility

The SQL standard does not define the following clauses of DELETE statement.

- 〈result offset clause〉
- 〈fetch limit clause〉

Table 19-19 SQL standard compatibility

Feature ID	Description	Compatibility
F781	Self-referencing operations	X
T111	Updatable joins, unions, and columns	X

For More Information

Refer to the followings.

- **DELETE FROM name WHERE CURRENT OF cursor_name**
- **DELETE FROM name RETURNING**
- **DELETE FROM name RETURNING .. INTO**
- **SELECT**

19.24 DELETE FROM name RETURNING

Function

It deletes rows of the table, and retrieves the deleted rows.

Syntax

```
<delete returning query statement> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        <returning clause>
    ;
<result offset clause> ::=
    OFFSET skip_count [ ROW ¦ ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    ¦ <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST ¦ NEXT ] [ row_count ] [ ROW ONLY ¦ ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count ¦ offset_row_count, fetch_row_count ¦ ALL }
<returning clause> ::=
    { RETURN ¦ RETURNING } { * ¦ { <value expression> [ [AS] alias_name] } [, ...] }
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <delete returning query statement>.

- One of the following privileges is required to perform DELETE statement.
  - (DELETE or CONTROL TABLE) ON TABLE for the table
  - (DELETE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - DELETE ANY TABLE ON DATABASE

- One of the following privileges is required for all the columns used in RETURNING clause.
  - SELECT(columns) ON TABLE for all columns used in RETURNING clause.
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be deleted.

[AS alias_name]

It is the alias of table_name.

WHERE 〈search condition〉

It deletes the rows which satisfy WHERE condition.
For more information, refer to **DELETE FROM** statement.

〈result offset clause〉

It specifies the number of rows to be skipped among the query result.
For more information, refer to **DELETE FROM** statement.

〈fetch first clause〉

It specifies the number of rows to be fetched.
For more information, refer to **DELETE FROM** statement.

〈limit clause〉

It specifies the number of rows to be fetched, or it simultaneously specifies both the number of rows to b e skipped and the number of rows to be fetched.
For more information, refer to **DELETE FROM** statement.

〈returning clause〉

It sets the deleted rows as a result set, and it specifies the columns to be searched from the set.

- RETURNING clause returns the rows deleted by DELETE statement as a result set.
- 〈value expression〉
  - It is as same as 〈select list〉 of SELECT statement, but it can not use aggregation.
- [[AS] alias_name]
  - It can give the name to the value expression by using AS clause.

The keywords RETURNING and RETURN have the same meaning.

Description

For more information, refer to **Differences among DELETE-related Statements**.

Examples

The following is an example of deleting rows which satisfy the condition, and searching for the deleted rows.

```
gSQL> DELETE FROM t1 WHERE id > 3 RETURNING *;
ID DATA
-- ------
 4 data_4
 5 data_5
2 rows deleted.
```

The following is an example of querying information of the deleted rows by using operation in RETURNING clause.

```
gSQL> DELETE FROM t1
             WHERE id > 3
             RETURNING 'ID: ' || id || ', DATA: ' || data AS id_data;
ID_DATA
--------------------
ID: 4, DATA: data_4
ID: 5, DATA: data_5
2 rows deleted.
```

Compatibility

The SQL standard does not cover <delete returning query statement>.

For More Information

Refer to the followings.

- DELETE FROM
- DELETE FROM name WHERE CURRENT OF cursor_name
- DELETE FROM name RETURNING .. INTO
- SELECT

19.25 DELETE FROM name RETURNING .. INTO

Function

It deletes a single row from the table, and the value of the deleted row is obtained into the host variable.

Syntax

```
<delete returning query statement> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        <returning into clause>
    ;
<result offset clause> ::=
    OFFSET skip_count [ ROW ¦ ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    ¦ <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST ¦ NEXT ] [ row_count ] [ ROW ONLY ¦ ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count ¦ offset_row_count, fetch_row_count ¦ ALL }
<returning into clause> ::=
    { RETURN ¦ RETURNING } { * ¦ { <value expression> [ [AS] alias_name] } [, ...] } INTO
variable_name [, ...]
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <delete returning into statement>.

- One of the following privileges is required to perform DELETE statement.
  - (DELETE or CONTROL TABLE) ON TABLE for the table
  - (DELETE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs

    - DELETE ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
    - SELECT(columns) ON TABLE for all columns used in RETURNING clause
    - (SELECT or CONTROL TABLE) ON TABLE for the table
    - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
    - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be deleted.

[AS alias_name]

It is the alias of table_name.

WHERE 〈search condition〉

It deletes the rows which satisfy WHERE condition.
For more information, refer to **DELETE FROM** statement.

〈result offset clause〉

It specifies the number of rows to be skipped among the query result.
For more information, refer to **DELETE FROM** statement.

〈fetch first clause〉

It specifies the number of rows to be fetched.
For more information, refer to **DELETE FROM** statement.

〈limit clause〉

It specifies the number of rows to be fetched, or it simultaneously specifies both the number of rows to b e skipped and the number of rows to be fetched.
For more information, refer to **DELETE FROM** statement.

〈returning into clause〉

- RETURNING .. AS ..
  - For more information, refer to 〈returning clause〉 of **DELETE FROM name RETURNING** statement.
- INTO variable_name [, ...]
  - The number of variables specified in INTO clause should be equal to the number of the expressio ns specified in RETURNING clause.

Description

The number of rows to be deleted should be equal to or less than one.
If two or more rows are deleted, then an error occurs.

For more information, refer to **Differences among DELETE-related Statements**.

Example

The following is an example of deleting rows and obtaining the value of deleted rows into the host variab le in an interactive SQL (gsql).

```
gSQL> \var v_id    INTEGER
gSQL> \var v_data  VARCHAR(128)
gSQL> DELETE FROM t1 WHERE id = 3 RETURNING id, data INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row deleted.
```

Compatibility

The SQL standard does not cover 〈delete returning into statement〉.

For More Information

Refer to the followings.

- DELETE FROM
- DELETE FROM name WHERE CURRENT OF cursor_name
- DELETE FROM name RETURNING
- SELECT

19.26 DELETE FROM name WHERE CURRENT OF cursor_name

Function

It deletes a single row which the cursor indicates.

Syntax

```
<delete statement: positioned> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        WHERE CURRENT OF cursor_name
    ;
```

Invocation and Access Rules

The privilege to perform **DELETE FROM** statement is required to perform <delete statement: positioned>.

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be deleted.

[AS alias_name]

It is the alias of table_name.

cursor_name

The cursor corresponding to cursor_name should satisfy the following conditions.

- The cursor should be OPEN. (Refer to **OPEN cursor_name**.)

- Fetched rows by using the cursor should exist. (Refer to **FETCH cursor_name**.)
- The query used for the cursor should identify table_name. (Refer to **DECLARE cursor_name**.)
- The cursor should be updatable for table_name. (Refer to **DECLARE cursor_name**.)

Description

For more information, refer to **Differences among DELETE-related Statements**.

Example

The following is an example of declaring the FOR UPDATE cursor, and deleting rows by using the cursor i n interactive SQL (gsql).

```
gSQL> DECLARE cur1 CURSOR FOR SELECT id, data FROM t1 FOR UPDATE;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> DELETE FROM t1 WHERE CURRENT OF cur1;
1 row deleted.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
```

```
---- ------
   4 data_4
1 row fetched.
gSQL> DELETE FROM t1 WHERE CURRENT OF cur1;
1 row deleted.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
no rows fetched.
gSQL> CLOSE cur1;
Cursor closed.
gSQL> SELECT id, data FROM t1 ORDER BY 1;
ID DATA
-- ------
 1 data_1
 3 data_3
 5 data_5
3 rows selected.
```

Compatibility

Table 19-20 SQL standard compatibility

Feature ID	Description	Compatibility
S111	ONLY in query expressions	X
B031	Basic dynamic SQL	O

For More Information

Refer to the followings.

- DECLARE cursor_name
- OPEN cursor_name
- FETCH cursor_name
- DELETE FROM
- DELETE FROM name RETURNING

- DELETE FROM name RETURNING .. INTO

19.27 DROP AUDIT POLICY

Function

It drops an audit policy.

Syntax

```
<drop audit policy statement> ::=
    DROP AUDIT POLICY [ IF EXISTS ] policy_name
;
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <drop audit policy statement>.

Syntax Rules and Parameters

IF EXISTS

An error does not occur even when a policy_name does not exist.

policy_name

It is the name of an audit policy object to be dropped.

Description

The audit policy object which is already activated can not be dropped. In this case, the audit policy should be deactivated by using NOAUDIT POLICY statement.

Examples

The following is an example of dropping an audit policy.

```
DROP AUDIT POLICY policy_table;
```

Compatibility

In the SQL standard, an audit policy does not exist.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**
- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**
- Retrieving audit trail: **AUDIT_TRAIL**
- Clearing audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

19.28 DROP CLUSTER GROUP

Function

It drops a cluster group from a cluster system.

Syntax

```
<drop cluster group statement> ::=
    DROP CLUSTER GROUP [IF EXISTS] group_name
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.
ADMINISTRATION ON DATABASE privilege is required to perform <drop cluster group statement>.

Syntax Rules and Parameters

[IF EXISTS]

An error does not occur even when a cluster group does not exist.

group_name

It is the name of a cluster group.
A cluster group without any shard can be dropped.

Description

A cluster group can be dropped only when dropping the cluster group does not cause the data loss.

All members in the target cluster group should be inactive.
Otherwise, the following error occurs.

```
gSQL> DROP CLUSTER GROUP g3;
ERR-42000(16582): there are active cluster members in the target cluster group 'G3'
```

Examples

The following is an example of dropping a cluster group.

```
gSQL> DROP CLUSTER GROUP g3;
Cluster Group dropped.
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to **CREATE CLUSTER GROUP**.

19.29 DROP CLUSTER LOCATION

Function

It drops the access information of a cluster member.

Syntax

```
<drop cluster location statement> ::=
    DROP CLUSTER LOCATION member_name
    ;
```

Invocation and Access Rules

It can be performed in a cluster system.
ADMINISTRATION ON DATABASE privilege is required to perform <drop cluster location statement>.

Syntax Rules and Parameters

member_name

It is the name of a cluster member.
The same cluster member name should exist in a registered cluster location information.
The length of the name should be shorter than 128 bytes.

Description

Generally, the information of the cluster location is automatically created by using the connection inform ation provided when creating the cluster group or adding the cluster member. The created information is deleted together when deleting the cluster member and the cluster group.

If the access information of the cluster location is modified, then the connection information can be modi

fied by using **ALTER CLUSTER LOCATION** without deleting or recreating the cluster member.

Example

```
gSQL>
DROP CLUSTER LOCATION g1n2
;
Created
```

Compatibility

The SQL standard does not define the concepts of the cluster.

For More Information

Refer to the followings.

- **CREATE CLUSTER LOCATION**
- **ALTER CLUSTER LOCATION**

19.30 DROP INDEX

Function

It drops an index.

Syntax

```
<drop index statement> ::=
    DROP INDEX [ IF EXISTS ] index_name
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <drop index statement>.

- The owner of that index
- The owner of the table to which the index belongs
- CONTROL TABLE ON TABLE for the table to which the index belongs
- (DROP INDEX or CONTROL SCHEMA) ON SCHEMA for the schema to which the index belongs
- DROP ANY INDEX ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the index does not exist, an error does not occur.

index_name

It is the index name to be dropped.
It can define schema to which the index belongs such as schema_name.index_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

The indexes created for UNIQUE constraint, PRIMARY KEY constraint can not be dropped.
To drop the indexes created for the constraints above, the constraints should be removed through **ALTER TABLE name DROP CONSTRAINT** statement.

Description

Data Definition Language (DDL) statement such as DROP INDEX can be rolled back if it is before when th e transaction is committed.

Examples

The following is an example of dropping an index.

```
gSQL> DROP INDEX idx_t1_id;
Index dropped.
```

The following is an example of preventing an error even when the index does not exist by using IF EXISTS statement.

```
gSQL> DROP INDEX IF EXISTS not_exist_index;
Index dropped.
```

Compatibility

The SQL standard does not cover the concepts of the index.

For More Information

Refer to the followings.

- **CREATE INDEX**
- **DROP TABLE**
- **ALTER TABLE name DROP CONSTRAINT**

19.31 DROP PROFILE

Function

It drops a profile.

Syntax

```
<drop profile statement> ::=
    DROP PROFILE [ IF EXISTS ] profile_name [ CASCADE ] ;
```

Invocation and Access Rules

DROP PROFILE ON DATABASE privilege is required to perform <drop profile statement>.

Syntax Rules and Parameters

IF EXISTS

Even when the profile does not exist, an error does not occur.

profile_name

It specifies the profile name to be dropped.
It can not drop the DEFAULT profile.

CASCADE

If the profile has already been assigned to users, CASCADE clause should be explicitly specified to drop th e profile.
The profile which is assigned to users and to be dropped is changed to DEFAULT profile.

Example

The following is an example of dropping a profile by using CASCADE statement.

```
gSQL> DROP PROFILE prof CASCADE;
Profile dropped.
gSQL> COMMIT;
Commit complete.
```

Compatibility

The SQL standard does not cover the concepts of the profile.

For More Information

Refer to the followings.

- CREATE PROFILE
- ALTER PROFILE

19.32 DROP SCHEMA

Function

It drops a schema.

Syntax

```
<drop schema statement> ::=
    DROP SCHEMA [ IF EXISTS ] schema_name
        [ <drop behavior> ]
    ;
<drop behavior> ::=
      RESTRICT
    | CASCADE
```

Invocation and Access Rules

One of the following privileges is required to perform <drop schema statement>.

- The owner of that schema
- CONTROL SCHEMA ON SCHEMA for the schema
- DROP SCHEMA ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the schema does not exist, an error does not occur.

schema_name

It is the schema name to be dropped.
However, it can not drop the built-in schema such as "DICTIONARY_SCHEMA", "INFORMATION_SCHEMA" and "PUBLIC" which are automatically created when creating the database.

〈drop behavior〉

- When it is RESTRICT
  - Objects should not exist within the schema.
- When it is CASCADE
  - It drops all objects in the schema together.
- When it is omitted, the default value is RESTRICT.

Description

Data Definition Language (DDL) statement such as DROP SCHEMA can be rolled back if it is before when the transaction is committed. In this case, recycle bin objects which are included in the schema to be dropped are also dropped.

Examples

The following is an example of dropping a schema and all objects which exist within the schema.

```
gSQL> DROP SCHEMA s1 CASCADE;
Schema dropped.
```

The following is an example of preventing an error even when the schema does not exist by using IF EXISTS statement.

```
gSQL> DROP SCHEMA IF EXISTS not_exist_schema;
Schema dropped.
```

Compatibility

The SQL standard does not define IF EXISTS clause.

Table 19-21 SQL standard compatibility

Feature ID	Description	Compatibility
F032	CASCADE drop behavior	O
F381	Extended schema manipulation	O

For More Information

Refer to **CREATE SCHEMA**.

19.33 DROP SEQUENCE

Function

It drops a sequence.

Syntax

```
<drop sequence generator statement> ::=
    DROP SEQUENCE [ IF EXISTS ] [schema_name.] sequence_name
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <drop sequence generator statement>.

- The owner of that sequence
- (DROP SEQUENCE or CONTROL SCHEMA) ON SCHEMA for the schema to which the sequence belon gs
- DROP ANY SEQUENCE ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the sequence does not exist, an error does not occur.

sequence_name

It is the sequence name to be dropped.
It can define schema to which the sequence belongs such as schema_name.sequence_name and if schem a_name is omitted, the default schema name of the user performing the statement is used.

Description

Data Definition Language (DDL) statement such as DROP SEQUENCE can be rolled back if it is before wh
en the transaction is committed.

Examples

The following is an example of dropping a sequence.

```
gSQL> DROP SEQUENCE seq1;
Sequence dropped.
```

The following is an example of preventing an error even when the sequence does not exist by using IF EXI
STS statement.

```
gSQL> DROP SEQUENCE invalid_sequence;
ERR-42000(16044): sequence does not exist :
DROP SEQUENCE invalid_sequence
              *
ERROR at line 1:
gSQL> DROP SEQUENCE IF EXISTS invalid_sequence;
Sequence dropped.
```

Compatibility

The SQL standard does not define IF EXISTS clause.

Table 19-22 SQL standard compatibility

Feature ID	Description	Compatibility
T176	Sequence generator support	O

For More Information

Refer to the followings.

- CREATE SEQUENCE

- ALTER SEQUENCE

19.34 DROP SYNONYM

Function

It drops a synonym.

Syntax

```
<drop synonym statement> ::=
    DROP [ PUBLIC ] SYNONYM [ IF EXISTS ] [schema_name.]synonym_name
    ;
```

Invocation and Access Rules

DROP PUBLIC SYNONYM ON DATABASE privilege is required to drop a public synonym by specifying PUB LIC.

One of the following privileges is required to drop a private synonym.

- The owner of that synonym
- (DROP SYNONYM or CONTROL SCHEMA) ON SCHEMA for the schema to which the synonym belon gs
- DROP ANY SYNONYM ON DATABASE

Syntax Rules and Parameters

[PUBLIC]

It is specified when dropping the public synonym.
If this clause is omitted, the private synonym is dropped.

IF EXISTS

Even when the synonym does not exist, an error does not occur.

synonym_name

It is the synonym name to be dropped.
It can define schema to which the synonym belongs such as schema_name.synonym_name and if schema _name is omitted, the default schema name of the user performing the statement is used.
If PUBLIC is explicitly specified, the schema name can not be specified.

Description

Data Definition Language (DDL) statement such as DROP SYNONYM can be rolled back if it is before whe n the transaction is committed.

Examples

The following is an example of dropping a private synonym.

```
gSQL> DROP SYNONYM MyEmp;
Synonym dropped.
```

The following is an example of dropping a public synonym.

```
gSQL> DROP PUBLIC SYNONYM MainEmp;
Synonym dropped.
```

Compatibility

The SQL standard does not define DROP SYNONYM statement.

For More Information

Refer to **CREATE SYNONYM**.

19.35 DROP TABLE

Function

It drops a table.

If the recycle bin feature is activated, the table is not completely dropped but it is stored in the r ecycle bin.

Syntax

```
<drop table statement> ::=
    DROP TABLE [ IF EXISTS ] table_name
    [ <drop behavior> ]
    [ PURGE ]
    ;
<drop behavior> ::=
      RESTRICT
    ¦ CASCADE
    ¦ CASCADE CONSTRAINTS
```

Invocation and Access Rules

One of the following privileges is required to perform <drop table statement>.

- The owner of that table
- CONTROL TABLE ON TABLE for that table
- (DROP TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- DROP ANY TABLE ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the table does not exist, an error does not occur.

table_name

It is the table name to be dropped.
It can define schema to which the table belongs such as schema_name.table_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

The following tables which are automatically created during creating the database, can not be dropped.

- The tables in "DEFINITION_SCHEMA" schema
- The tables in "FIXED_TABLE_SCHEMA" schema

It also drops constraints and indexes created in the table.

drop behavior

Currently, both RESTRICT and CASCADE are operated same.
When it is omitted, the default value is RESTRICT.

purge

It immediately drops a table instead of storing it in the recyclebin even when the recyclebin feature is activated.

Description

Data Definition Language (DDL) statement such as DROP TABLE can be rolled back if it is before when the transaction is committed.

Examples

The following is an example of dropping an ordinary table.

```
gSQL> DROP TABLE region;
Table dropped.
```

The following is an example of preventing an error even when the table does not exist by using IF EXISTS statement.

```
gSQL> DROP TABLE IF EXISTS invalid_table;
Table dropped.
```

The following is an example of rolling back the dropped table.

```
gSQL> SELECT r_regionkey, r_name FROM region;
R_REGIONKEY R_NAME
----------- -------------------------
          0 AFRICA
          1 AMERICA
          2 ASIA
          3 EUROPE
          4 MIDDLE EAST
5 rows selected.
gSQL> DROP TABLE region;
Table dropped.
gSQL> SELECT r_regionkey, r_name FROM region;
ERR-42000(16040): table or view does not exist :
SELECT r_regionkey, r_name FROM region
                               *
ERROR at line 1:
gSQL> ROLLBACK;
Rollback complete.
gSQL> SELECT r_regionkey, r_name FROM region;
R_REGIONKEY R_NAME
----------- -------------------------
          0 AFRICA
          1 AMERICA
          2 ASIA
          3 EUROPE
          4 MIDDLE EAST
```

```
5 rows selected.
```

Compatibility

The SQL standard does not define the following clauses.

- IF EXISTS
- CASCADE CONSTRAINTS

Table 19-23 SQL standard compatibility

Feature ID	Description	Compatibility
F032	CASCADE drop behavior	O

For More Information

Refer to **CREATE TABLE**.

19.36 DROP TABLESPACE

Function

It drops a tablespace.

Syntax

```
<drop tablespace statement> ::=
    DROP TABLESPACE [ IF EXISTS ] tablespace_name
        [ INCLUDING CONTENTS ]
        [ { AND | KEEP } DATAFILES ]
        [ <drop behavior> ]
    ;
<drop behavior> ::=
      RESTRICT
    | CASCADE
    | CASCADE CONSTRAINTS
```

Invocation and Access Rules

DROP TABLESPACE ON DATABASE privilege is required to perform <drop tablespace definition>.

Syntax Rules and Parameters

IF EXISTS

Even when the tablespace does not exist, an error does not occur.

tablespace_name

It is the tablespace name to be dropped.
The following system tablespaces which are automatically created during creating the database, can not

be dropped.

- DICTIONARY_TBS: system tablespace for dictionary management
- MEM_UNDO_TBS: system tablespace for default undo tablespace
- MEM_DATA_TBS: system tablespace for default user data tablespace
- MEM_TEMP_TBS: system tablespace for default temporary tablespace

If tablespace_name was used as a default tablespace of a user, the space for the objects can not be allocated after dropping the tablespace.
After dropping the tablespace, the default tablespace should be changed by using **ALTER USER** statement.

INCLUDING CONTENTS

It drops objects (table, index, key constraint) which belong to the tablespace. If the index or key constrain t which refers to the table which belongs to the tablespace exists outside of the tablespace, then it is also dropped.

If INCLUDING CONTENTS clause is not used, then any object which belongs to the tablespace should not exist.

[{ AND | KEEP } DATAFILES]

It specifies whether to drop the datafiles which configure the tablespace together.
The datafiles are not in the memory temporary tablespace, so the clause is ignored.

- AND DATAFILES
  - It drops the datafiles together.
- KEEP DATAFILES
  - It does not drop the datafiles, but keeps them.
- If it is not specified, the default value is KEEP DATAFILES.

drop behavior

Currently, both RESTRICT and CASCADE are operated same.
When it is omitted, the default value is RESTRICT.

Description

Unlike other Data Definition Language (DDL), DROP TABLESPACE statement can not be rolled back and t he executed transaction is automatically committed. In this case, recycle bin objects which are included in the tablespace to be dropped are also dropped.

Examples

The following is an example of dropping a tablespace together with all objects in the tablespace and data files which configure the tablespace.

```
gSQL> DROP TABLESPACE space1 INCLUDING CONTENTS AND DATAFILES CASCADE CONSTRAINTS;
Tablespace dropped.
```

The following is an example of preventing an error even when the tablespace does not exist by using IF E XISTS statement.

```
gSQL> DROP TABLESPACE IF EXISTS not_exist_tablespace;
Tablespace dropped.
```

Compatibility

The SQL standard does not cover the concepts of the tablespace.

For More Information

Refer to the followings.

- CREATE MEMORY DATA TABLESPACE
- CREATE MEMORY TEMPORARY TABLESPACE
- ALTER TABLESPACE

19.37 DROP USER

Function

It drops a database user.

Syntax

```
<drop user statement> ::=
    DROP USER [ IF EXISTS ] user_identifier [ <drop behavior> ]
    ;
<drop behavior> ::=
      RESTRICT
    ¦ CASCADE
```

Invocation and Access Rules

DROP USER ON DATABASE privilege is required to perform <drop user statement>.

The schema owned by user_identifier should not exist.
For more information about dropping the schema, refer to **DROP SCHEMA**.

Syntax Rules and Parameters

IF EXISTS

Even when the user does not exist, an error does not occur.

user_identifier

It is the database username to be dropped.
However, the user which is automatically created during creating the database such as "SYS", can not be

dropped.

It does not drop the object which is created by user_identifier but is not an owner as follows.

- Role
- Tablespace

〈drop behavior〉

- RESTRICT
  - There should not be the following user owned SQL schema objects.
    - Table, view
    - Index
    - Sequence
    - Table constraint
- CASCADE
  - It drops all the following user owned SQL schema objects.
    - Table, view
    - Index
    - Sequence
    - Table constraint
- When it is omitted, the default value is RESTRICT.

The relationship between user and schema in other DBMS

- Oracle
  - User : schema = 1 : 1.
  - When CASCADE, the schema is also dropped.
- DB2
  - It is as same as the OS user.
  - The separate SQL statements which create or delete a user do not exist.
- Postgres
  - User : schema = 1 : N.
  - It does not support CASCADE option, and a user can be dropped after dropping all the objects owned by the user and all the privileges granted to other users.

> - MySQL
>   - Database : schema = 1 : 1.
>   - User is a subordinate object of database(schema), and it does not support CASCADE option.

Description

In GOLDILOCKS, relationship between the user and the schema is 1 : N. A user does not own a schema, or the user can have multiple schemas.

To drop a user, all schema owned by the user should be dropped. In this case, recycle bin objects of the user to be dropped are also dropped.

Examples

The following is an example of dropping all schema owned by the user and then dropping the user.

```
gSQL> DROP SCHEMA u1 CASCADE;
Schema dropped.
gSQL> DROP USER u1 CASCADE;
User dropped.
```

The following is an example of preventing an error even when the user does not exist by using IF EXISTS statement.

```
gSQL> DROP USER IF EXISTS not_exist_user;
User dropped.
```

Compatibility

The SQL standard covers the concepts of the user, but it does not define the SQL statements related to creating or dropping a user.

For More Information

Refer to the followings.

- CREATE USER
- ALTER USER
- DROP SCHEMA

19.38 DROP VIEW

Function

It drops a view.

Syntax

```
<drop view statement> ::=
    DROP VIEW [ IF EXISTS ] view_name
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <drop view statement>.

- The owner of that view
- CONTROL TABLE ON TABLE for that view
- (DROP VIEW or CONTROL SCHEMA) ON SCHEMA for the schema to which the view belongs
- DROP ANY VIEW ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the view does not exist, an error does not occur.

view_name

It is the view name to be dropped.
The schema to which the table belongs, such as schema_name.view_name, can be defined. If schema_name is omitted, the default schema name of the user performing the statement is used.

Description

Data Definition Language (DDL) statement such as DROP VIEW can be rolled back if it is before when the transaction is committed.

Examples

The following is an example of dropping a view.

```
gSQL> DROP VIEW v1;
View dropped.
```

The following is an example of preventing an error even when the view does not exist by using IF EXISTS statement.

```
gSQL> DROP VIEW IF EXISTS not_exist_view;
View dropped.
```

Compatibility

The SQL standard does not define IF EXISTS clause.

Table 19-24 SQL standard compatibility

Feature ID	Description	Compatibility
F032	CASCADE drop behavior	X

For More Information

Refer to the followings.

- CREATE VIEW
- ALTER VIEW

19.39 EXECUTE IMMEDIATE 'sql_string'

Function

It executes a dynamic SQL statement which was not defined when writing a program.

Syntax

```
<execute immediate statement> ::=
    EXECUTE IMMEDIATE <SQL statement variable>
    ;
<SQL statement variable> ::=
      variable_name
    ¦ 'sql statement'
    ¦ "sql statement"
    ¦ sql statement
```

Invocation and Access Rules

It can be used in an embedded SQL.
An appropriate privilege according to the type of a dynamic SQL statement is required.

Syntax Rules and Parameters

<SQL statement variable>

The dynamic SQL statement referenced by <SQL statement variable> can not use a host variable (:var) or parameter marker (?).

The following four types of <SQL statement variable> can be used.

- variable_name: It is a variable in which an SQL statement is stored.
- 'sql statement': It is an SQL statement which is enclosed with a single quote (').
- "sql statement": It is an SQL statement which is enclosed with double quotes (").

- sql statement: It is an SQL statement without quote.

The single quote (') is used twice as follows to represent string data within a single-quoted string.

```
{
    ...
    EXEC SQL EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES ( ''literal data'' )';
    ...
}
```

If the SQL statement is a query including a query result, it is successfully executed, but the result can not be obtained.

variable_name

The type corresponding to the variable_name should be a character string.
The dynamic SQL statement defined in the variable_name should be valid.

sql statement

The dynamic SQL statement defined in the sql statement should be valid.

Description

EXECUTE IMMEDIATE 'sql_string' statement can be used as the non-query SQL without a host variable in dynamic embedded SQL application. It is appropriate to execute DDL, DML as one-off because it does not require separate preparation procedure.

For more information, refer to **Embedded Dynamic SQL**.

Example

The following is an example of using EXECUTE IMMEDIATE 'sql_string' in the embedded SQL source cod e.

```
{
    ...
    sprintf(sSqlStmt, "INSERT INTO EMP_RND\n"
```

```
            "SELECT *\n"
            "FROM   EMP\n"
            "WHERE  JOB = 'RND'\n" );
    EXEC SQL EXECUTE IMMEDIATE :sSqlStmt;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    ...
}
```

The full source code in which EXECUTE IMMEDIATE 'sql_string' was used can be viewed in **Dynamic Embedded SQL Example Program**.

Compatibility

Table 19-25 SQL standard compatibility

Feature ID	Description	Compatibility
B031	Basic Dynamic SQL	O

For More Information

Refer to the followings.

- **PREPARE statement_name**
- **EXECUTE statement_name**
- **Embedded Dynamic SQL**

19.40 EXECUTE statement_name

Function

It executes the prepared statement.

Syntax

```
<execute statement> ::=
    EXECUTE statement_name [ <parameter using clause> ] [ <result into clause> ]
    ;
<parameter using clause> ::=
      <using parameter arguments>
<using parameter arguments> ::=
    USING variable_name [, ...]
<result into clause> ::=
      <into result arguments>
<into result arguments> ::=
    INTO variable_name [, ...]
```

Invocation and Access Rules

It can be used in an embedded SQL.
An appropriate privilege according to the type of a dynamic SQL statement is required.

Syntax Rules and Parameters

statement_name

It is the name of a prepared statement.
Statement_name should be prepared by using **PREPARE statement_name**.

If the dynamic SQL statement referenced by statement_name contains a dynamic parameter, <parameter using clause> should explicitly be specified.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'DELETE FROM t1 WHERE c1 > ?';
    EXEC SQL EXECUTE stmt1 USING :sValue;
    ...
}
```

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'SELECT COUNT(*) INTO :v1 FROM t1';
    EXEC SQL EXECUTE stmt1 USING :sValue;
    ...
}
```

If the dynamic SQL statement referenced by statement_name is a query or a stored function including the result, <result into clause> should explicitly be specified.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'SELECT COUNT(*) FROM t1';
    EXEC SQL EXECUTE stmt1 INTO :sValue;
    ...
}
```

If there are multiple queries they are normally executed, but only the first query can get the result.
To get multiple results, the following statements related to the cursor should be used.

- DECLARE cursor_name
- OPEN cursor_name
- FETCH cursor_name
- CLOSE cursor_name

If there is not any query result, it is completed as NO DATA.

[<parameter using clause>] [<result into clause>]

<parameter using clause> and <result into clause> can be specified in any order, but they should not be repeated.

〈parameter using clause〉

If any parameter exists in a dynamic SQL statement referenced by statement_name, the parameter inform ation is specified with 〈using parameter arguments〉 clause.

〈using parameter arguments〉

If 〈using parameter arguments〉 statement is used, the number of variable_name should be equal to the number of the parameter included in the dynamic SQL statement referenced by statement_name.

The listed variable_name corresponds to the dynamic parameter in an order of its description.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'DELETE FROM t1 WHERE c1 IN ( ?, ?, ? )';
    EXEC SQL EXECUTE stmt1 USING :sValue1, :sValue2, :sValue3;
    ...
}
```

〈result into clause〉

If the dynamic SQL statement referenced by statement_name is a query, the information about the result columns is specified with 〈into result arguments〉 clause.

If the result is null and INDICATOR is not specified, [DATA EXCEPTION, NULL VALUE, NO INDICATOR PAR AMETER] error occurs.

〈into result arguments〉

If 〈into result arguments〉 clause is used, the number of variable_name should be equal to the number of the result column in the dynamic SQL statement referenced by statement_name.

The listed variable_name corresponds to the dynamic parameter in an order of its description.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'SELECT MIN(salary), MAX(salary), AVG(salary) FROM employee';
    EXEC SQL EXECUTE stmt1 INTO :sMinValue, :sMaxValue, :sAvgValue;
    ...
}
```

Description

Statement_name is an identifier which informs the precompiler the statement in an embedded SQL sourc e code.
A separate type or declaration is not required because statement_name is not a host variable. EXECUTE st atement_name should be written after PREPARE statement_name.

For more information, refer to **Embedded Dynamic SQL**.

Example

The following is an example of using EXECUTE statement_name in an embedded SQL source code.

```
{
    ...
    sprintf( sUpdateSql, "UPDATE EMP SET sal = sal * :v1 WHERE JOB = 'SALES'");
    EXEC SQL PREPARE UPDATE_STMT FROM :sUpdateSql;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    sRatio = 1.1;
    EXEC SQL EXECUTE UPDATE_STMT USING :sRatio;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    ...
}
```

The full source code in which EXECUTE statement_name was used can be viewed in **Dynamic Embedded SQL Example Program**.

Compatibility

Table 19-26 SQL standard compatibility

Feature ID	Description	Compatibility
B031	Basic Dynamic SQL	O
B032	Extended dynamic SQL	X

For More Information

Refer to the followings.

- **PREPARE statement_name**
- **DECLARE cursor_name**
- **OPEN cursor_name**
- **FETCH cursor_name**
- **CLOSE cursor_name**
- **Embedded Dynamic SQL**

19.41 FETCH cursor_name

Function

It locates the cursor on a specific row of result set, and obtains the value of that row to a host variable.

Syntax

```
<fetch statement> ::=
    FETCH [ <fetch orientation> ] [ FROM ] cursor_name
        <result into clause>
    ;
<fetch orientation> ::=
      NEXT
    ¦ PRIOR
    ¦ FIRST
    ¦ LAST
    ¦ CURRENT
    ¦ ABSOLUTE position
    ¦ RELATIVE position
<result into clause> ::=
      <into result arguments>
<into result arguments> ::=
    INTO variable_name [, ...]
```

Syntax Rules and Parameters

[FROM] cursor_name

It should be an open cursor in a session.
FROM can be omitted.

〈fetch orientation〉

To use 〈fetch orientation〉 other than FETCH NEXT, a scrollable cursor should be used.
If 〈fetch orientation〉 is omitted, the default value is NEXT.

The open cursor has the cursor position information for the result set as follows.

Figure 1 The position of cursor

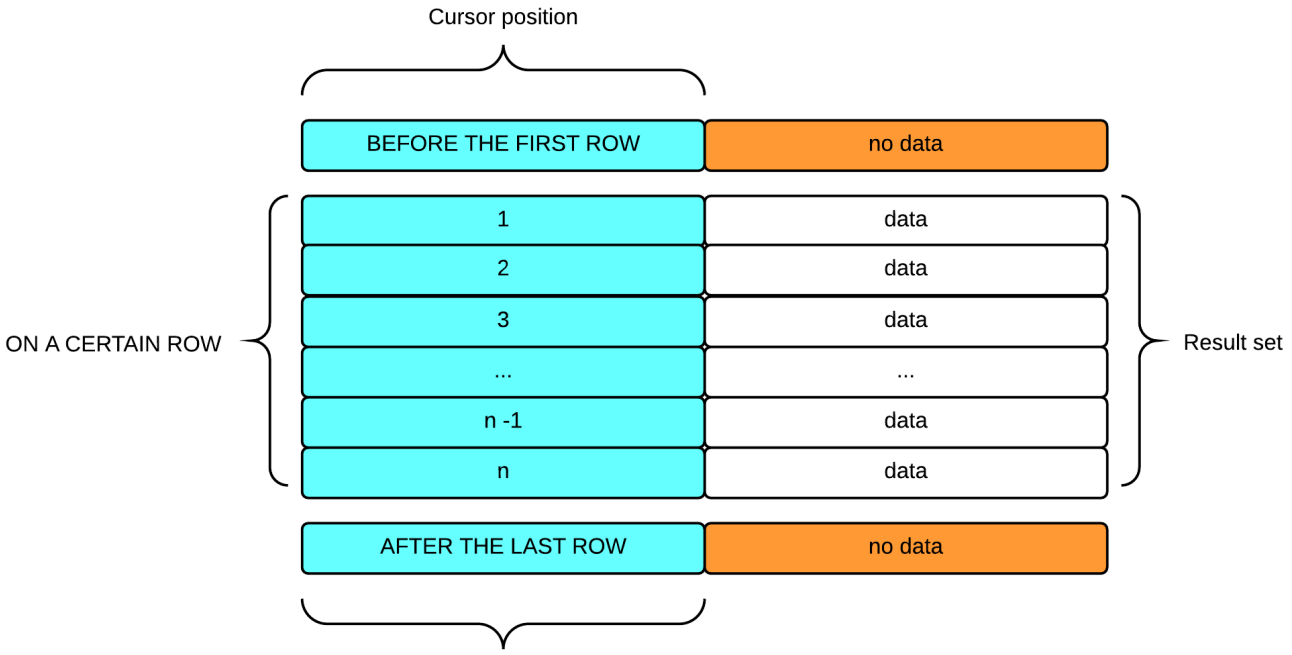

Table 19-27 The position of cursor

Cursor position	Description
BEFORE THE FIRST ROW	The cursor is positioned before the first row of the result set. It is also the cursor positi on when opening it.
ON A CERTAIN ROW	The cursor is positioned on a certain row of the result set through FETCH.
AFTER THE LAST ROW	The cursor is positioned after the last row of the result set.

Each 〈fetch orientation〉 operates based on the cursor position as follows.

- NEXT: It searches for the row next to the current position.
- PRIOR: It searches for the row prior to the current position.
- FIRST: It searches for the first row of the result set.
- LAST: It searches for the last row of the result set.
- CURRENT: It searches for the row in the current position.
- ABSOLUTE position
  - It searches for the row corresponding to the position from the result set.
  - If the position value is negative, it searches for the row at previous position from AFTER THE LAS T ROW.

- RELATIVE position
  - It searches for the row apart as much as position from the current position.

〈result into clause〉

The variable information to obtain the result column is specified by using 〈into result arguments〉.

If the result is null and INDICATOR is not specified, [DATA EXCEPTION, NULL VALUE, NO INDICATOR PAR AMETER] error occurs.

〈into result arguments〉

The number of variables in INTO clause should be as same as the number of columns in the result set of t he cursor.

Description

If the cursor is BEFORE THE FIRST ROW or AFTER THE LAST ROW after performing FETCH, it is positioned at the same position regardless of the entered position in 〈fetch orientation〉.

Example

The following is an example of declaring SCROLL cursor by using the interactive SQL (gsql), then operatin g the various 〈fetch orientation〉.

```
gSQL> DECLARE cur_scroll SCROLL CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur_scroll;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH NEXT cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH NEXT cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
```

```
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH PRIOR cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH PRIOR cur_scroll INTO :v_id, :v_data;
no rows fetched.
gSQL> FETCH FIRST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH FIRST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH LAST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH LAST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH FIRST cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH CURRENT cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH LAST cur_scroll INTO :v_id, :v_data;
```

```
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH CURRENT cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH ABSOLUTE 3 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH CURRENT cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH ABSOLUTE 1 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH ABSOLUTE -1 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH ABSOLUTE 6 cur_scroll INTO :v_id, :v_data;
no rows fetched.
gSQL> FETCH ABSOLUTE -6 cur_scroll INTO :v_id, :v_data;
no rows fetched.
gSQL> FETCH ABSOLUTE 3 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH ABSOLUTE -3 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
```

```
   3 data_3
1 row fetched.
gSQL> FETCH RELATIVE 1 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   4 data_4
1 row fetched.
gSQL> FETCH RELATIVE -1 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH RELATIVE 5 cur_scroll INTO :v_id, :v_data;
no rows fetched.
gSQL> FETCH RELATIVE -5 cur_scroll INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> CLOSE cur_scroll;
Cursor closed.
```

Compatibility

The SQL standard does not define CURRENT among <fetch orientation>.

Table 19-28 SQL standard compatibility

Feature ID	Description	Compatibility
F431	Read-only scrollable cursors	O
B031	Basic dynamic SQL	O

For More Information

Refer to the followings.

- **DECLARE cursor_name**
- **OPEN cursor_name**
- **CLOSE cursor_name**

19.42 FLASHBACK TABLE

Function

It restores the table object which is stored in the recycle bin.

Syntax

```
<flashback table statement> ::=
    FLASHBACK TABLE table_name
    TO BEFORE DROP [ RENAME TO new_table_name ]
    ;
```

Invocation and Access Rules

One of the following privileges is required to perform <flashback table statement>.

- The owner of that table
- CONTROL TABLE ON TABLE for that table
- (DROP TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- DROP ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of the object stored or of the dropped table in the recycle bin.
It can define the schema to which the table belongs in the dropped table name, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

new_table_name

It is a new name of the table to be restored.
The duplicate table name should not exist within a single schema.

Description

It restores the table object which is stored in the recycle bin by using the object name or the dropped tabl e name stored in the recycle bin. If the name which is as same as that of the dropped table exists, then th e newest table object is restored.

If the name which is as same as that of the table object to be restored exists, then an error occurs, but it c an be restored with the new name by using RENAME TO clause. The constraints and the indexes of the re stored tables are restored in its name of when before they were dropped. However, if their names of whe n before the constraints and the indexes were dropped already exist, then the object is restored in the na me of when it is stored in the recycle bin.

Unlike other Data Definition Language (DDL), FLASHBACK TABLE statement can not be rolled back and t he executed transaction is automatically committed.

Example

The following is an example of restoring a table with the name of the object stored in the recycle bin.

```
gSQL> SELECT SCHEMA_NAME, OBJECT_NAME, ORIGINAL_NAME, OBJECT_TYPE FROM USER_RECYCLEBIN;
SCHEMA_NAME OBJECT_NAME                          ORIGINAL_NAME OBJECT_TYPE
----------- ------------------------------------ ------------- -----------
PUBLIC      BIN$106A4F90165D11EA9C5C835D3E4BBBF7 T1            TABLE
1 row selected.
gSQL> FLASHBACK TABLE "BIN$106A4F90165D11EA9C5C835D3E4BBBF7" TO BEFORE DROP;
Flashback complete.
```

The following is an example of restoring the table from the recycle bin in the name of when before it is dr opped.

```
gSQL> SELECT SCHEMA_NAME, OBJECT_NAME, ORIGINAL_NAME, OBJECT_TYPE FROM USER_RECYCLEBIN;
SCHEMA_NAME OBJECT_NAME                          ORIGINAL_NAME OBJECT_TYPE
----------- ------------------------------------ ------------- -----------
PUBLIC      BIN$106A4F90165D11EA9C5C835D3E4BBBF7 T1            TABLE
```

```
gSQL> FLASHBACK TABLE T1 TO BEFORE DROP;
Flashback complete.
```

Compatibility

The SQL standard does not define <flashback table statement>.

For More Information

Refer to the followings.

- **Managing Recycle Bin of Table**
- **PURGE**

19.43 GRANT privileges TO

Function

It grants privileges to a user.

Syntax

```
<grant privilege statement> ::=
    GRANT <privilege> TO <grantee> [, ...]
        [ WITH GRANT OPTION ]
    ;
<grantee> ::=
      PUBLIC
    ¦ user_identifier
    ;

<privilege> ::=
      <database privilege>
    ¦ <tablespace privilege>
    ¦ <schema privilege>
    ¦ <table privilege>
    ¦ <sequence privilege>
    ¦ <procedure privilege>
<database privilege> ::=

    ¦ <procedure action> ON PROCEDURE procedure_name
<procedure action> ::=
    EXECUTE
<package privilege> ::=
      ALL [ PRIVILEGES ] ON PACKAGE package_name
    ¦ <package action> ON PACKAGE package_name
<package action> ::=
    EXECUTE
```

Syntax Rules and Parameters

〈grantee〉

It is the user to be granted the privileges.

- user_identifier
  - It grants the privilege to a user.
- PUBLIC
  - It is an authorization object which means all users.

WITH GRANT OPTION

It allows the grantee to grant the privilege to other users.

When the same 〈privilege〉 is granted as follows, WITH GRANT OPTION is maintained.

- GRANT SELECT ON t1 TO u1 WITH GRANT OPTION;
- GRANT SELECT ON t1 TO u1;

〈privilege〉

It is a privilege which is to be granted to a grantee (the user to be granted the privilege).

The grantor (the user to perform the statement) should satisfy one of the following conditions.

- The grantor owns that 〈privilege〉 by using WITH GRANT OPTION.
  - The grantor is the user who performs the statement.
- The grantor owns the ACCESS CONTROL ON DATABASE privilege.
  - The grantor is the object owner.
    - 〈database privilege〉: _SYSTEM account
    - 〈tablespace privilege〉: _SYSTEM account
    - 〈schema privilege〉: _SYSTEM account
    - 〈table privilege〉: The owner of the table
    - 〈sequence privilege〉: The owner of the sequence
    - 〈procedure privilege〉: The owner of the procedure/function
    - 〈package privilege〉: The owner of the package

〈database privilege〉

It is the privilege for the database objects.
[ON DATABASE] statement can be omitted.

The database action which can be defined with the database privilege is as follows.

- ALL [PRIVILEGES] [ON DATABASE]
  - All privileges for the database which the grantor (the user who performs the statement) owns by using WITH GRANT OPTION.

Table 19-29 Database privilege

〈database action〉	Description
ADMINISTRATION	Privilege for starting or terminating the server
ALTER DATABASE	Privilege for executing ALTER DATABASE
ALTER SYSTEM	Privilege for executing ALTER SYSTEM
AUDIT SYSTEM	Privilege for controlling the audit policy
ACCESS CONTROL	Privilege for controlling all the privileges
CREATE SESSION	Privilege for connecting to the database
CREATE PROFILE	Privilege for creating profiles in the database
ALTER PROFILE	Privilege for altering any profile in the database
DROP PROFILE	Privilege for dropping any profile in the database
CREATE USER	Privilege for creating users in the database
ALTER USER	Privilege for altering any user in the database
DROP USER	Privilege for dropping any user in the database
CREATE ROLE	Privilege for creating roles in the database
ALTER ROLE	Privilege for altering any role in the database
DROP ROLE	Privilege for dropping any role in the database
CREATE TABLESPACE	Privilege for creating tablespaces in the database
ALTER TABLESPACE	Privilege for altering any tablespace in the database
DROP TABLESPACE	Privilege for dropping any tablespace in the database
USAGE TABLESPACE	Privilege for using any tablespace in the database
CREATE SCHEMA	Privilege for creating schemas in the database
ALTER SCHEMA	Privilege for altering any schema in the database
DROP SCHEMA	Privilege for dropping any schema in the database
CREATE PUBLIC SYNONYM	Privilege for creating public synonyms in the database
DROP PUBLIC SYNONYM	Privilege for dropping any public synonym in the database
CREATE ANY TABLE	Privilege for creating tables in any schema of the database
ALTER ANY TABLE	Privilege for altering any table in the database
DROP ANY TABLE	Privilege for dropping any table in the database
SELECT ANY TABLE	Privilege for querying rows of any table in the database
INSERT ANY TABLE	Privilege for creating rows of any table in the database
DELETE ANY TABLE	Privilege for deleting rows of any table in the database
UPDATE ANY TABLE	Privilege for updating rows of any table in the database
LOCK ANY TABLE	Privilege for locking any table in the database
CREATE ANY VIEW	Privilege for creating views in any schema of the database

〈database action〉	Description
DROP ANY VIEW	Privilege for dropping any view in the database
CREATE ANY SEQUENCE	Privilege for creating sequences in any schema of the database
ALTER ANY SEQUENCE	Privilege for altering any sequence of the database
DROP ANY SEQUENCE	Privilege for dropping any sequence of the database
USAGE ANY SEQUENCE	Privilege for using any sequence of the database
CREATE ANY INDEX	Privilege for creating indexes in any schema of the database
ALTER ANY INDEX	Privilege for altering any index in the database
DROP ANY INDEX	Privilege for dropping any index in the database
CREATE ANY SYNONYM	Privilege for creating synonyms in the database
DROP ANY SYNONYM	Privilege for dropping any synonym in the database
CREATE ANY PROCEDURE	Privilege for creating any procedure/function in any schema of the database
ALTER ANY PROCEDURE	Privilege for altering any procedure/function in the database
DROP ANY PROCEDURE	Privilege for dropping any procedure/function in the database
EXECUTE ANY PROCEDURE	Privilege for executing any procedure/function in the database
CREATE ANY PACKAGE	Privilege for creating any package in any schema of the database
ALTER ANY PACKAGE	Privilege for altering any package in the database
DROP ANY PACKAGE	Privilege for dropping any package in the database
EXECUTE ANY PACKAGE	Privilege for executing any package in the database
PURGE DBA_RECYCLEBIN	Privilege for dropping any package in the database

〈tablespace privilege〉

It is the privilege for the tablespace objects.

The tablespace action which can be defined with the tablespace privilege is as follows.

- ALL [PRIVILEGES] ON TABLESPACE tablespace_name
  - All privileges for the tablespace which the grantor (the user who performs the statement) owns by using WITH GRANT OPTION.

Table 19-30 Tablespace privilege

〈tablespace action〉	Description
CREATE OBJECT	Privilege for creating objects in the tablespace

〈schema privilege〉

It is the privilege for the schema objects.

- Whether to omit [ON SCHEMA schema_name]

- If multiple <grantee> exist, [ON SCHEMA schema_name] statement can not be omitted.
- If ALL [PRIVILEGES] is used, [ON SCHEMA schema_name] statement can not be omitted.
- If [ON SCHEMA schema_name] statement is omitted, <grantee> can use only one user_identifier, and the privilege on the first schema in the schema search path of <grantee> is granted.

The schema action which can be defined with the schema privilege is as follows.

- ALL [PRIVILEGES] ON SCHEMA schema_name
  - All privileges for the schema which the grantor (the user who performs the statement) owns by u sing WITH GRANT OPTION

Table 19-31 Schema privilege

<schema action>	Description
CONTROL SCHEMA	All privileges for that schema
CREATE TABLE	Privilege for creating tables in the schema
ALTER TABLE	Privilege for altering any table in the schema
DROP TABLE	Privilege for dropping any table in the schema
SELECT TABLE	Privilege for querying rows of any table in the schema
INSERT TABLE	Privilege for creating rows of any table in the schema
DELETE TABLE	Privilege for deleting rows of any table in the schema
UPDATE TABLE	Privilege for updating rows of any table in the schema
LOCK TABLE	Privilege for locking any table of the schema
CREATE VIEW	Privilege for creating views in the schema
DROP VIEW	Privilege for dropping any view of the schema
CREATE SEQUENCE	Privilege for creating sequences in the schema
ALTER SEQUENCE	Privilege for altering any sequence of the schema
DROP SEQUENCE	Privilege for dropping any sequence of the schema
USAGE SEQUENCE	Privilege for using any sequence of the schema
CREATE INDEX	Privilege for creating indexes in the schema
ALTER INDEX	Privilege for altering any index in the schema
DROP INDEX	Privilege for dropping any index in the schema
ADD CONSTRAINT	Privilege for creating constraints in the schema
CREATE SYNONYM	Privilege for creating synonyms in the schema
DROP SYNONYM	Privilege for dropping any synonym of the schema
CREATE PROCEDURE	Privilege for creating any procedure/function in the schema
ALTER PROCEDURE	Privilege for altering any procedure/function in the schema
DROP PROCEDURE	Privilege for dropping any procedure/function in the schema
EXECUTE PROCEDURE	Privilege for executing any procedure/function in the schema
CREATE PACKAGE	Privilege for creating any package in the schema
ALTER PACKAGE	Privilege for altering any package in the schema
DROP PACKAGE	Privilege for dropping any package in the schema
EXECUTE PACKAGE	Privilege for executing any package in the schema

〈table privilege〉

It is the privilege for the table object or the view object.
[TABLE] statement can be omitted.

The table action which can be defined with the table privilege is as follows.

- ALL [PRIVILEGES] ON [TABLE] table_name
  - All privileges for the table which the grantor (the user who performs the statement) owns by usin g WITH GRANT OPTION

Table 19-32 Table privilege

〈table action〉	Description
CONTROL TABLE	All privileges for that table
SELECT	Privilege for querying rows of the table
INSERT	Privilege for creating rows into the table
UPDATE	Privilege for updating rows in the table
DELETE	Privilege for deleting rows from the table
REFERENCES	Privilege for creating referential constraints which refers to the table
LOCK	Privilege for locking the table
INDEX	Privilege for creating indexes in the table
ALTER	Privilege for altering the table

For SELECT, INSERT, UPDATE, REFERENCES, additional privileges are granted to all columns of the table.

The column action which can be defined with the table privilege is as follows. However, the column actio n is applicable only to the base table.

Table 19-33 Column privilege

〈column action〉	Description
SELECT (columns)	Privilege for querying that columns
INSERT (columns)	Privilege for creating rows including that columns
UPDATE (columns)	Privilege for updating that columns
REFERENCES (columns)	Privilege for creating referential constraints which refers to that columns

〈sequence privilege〉

It is the privilege for the sequence object.

The sequence action which can be defined with the sequence privilege is as follows.

- ALL [PRIVILEGES] ON SEQUENCE sequence_name

- All privileges for the sequence which the grantor (the user who performs the statement) owns by using WITH GRANT OPTION.

Table 19-34 Sequence privilege

〈sequence action〉	Description
USAGE	Privilege for using the sequence

〈procedure privilege〉

It is the privilege for the procedure/ function object.

The action which can be defined with the procedure privilege is as follows.

- ALL [PRIVILEGES] ON PROCEDURE procedure_name
  - All privileges for the procedure/ function which the grantor (the user who performs the statemen t) owns by using WITH GRANT OPTION

Table 19-35 Procedure privilege

〈procedure action〉	Description
EXECUTE	Privilege for executing the procedure/function

〈package privilege〉

It is the privilege for the package object.

The action which can be defined with the package privilege is as follows.

- ALL [PRIVILEGES] ON PACKAGE package_name
  - All privileges for the package which is given to the grantor (the user who performs the statement) by using WITH GRANT OPTION

Table 19-36 Package privilege

〈package action〉	Description
EXECUTE	Privilege for executing the package

Description

Data Definition Language (DDL) such as GRANT privilege can be rolled back if it is before when the trans action is committed.

The owner who created SQL schema object, such as table, sequence, has certain privileges without being granted any separate privilege for the object.
For more information, refer to the following CREATE statements.

- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- ALTER TABLE name ADD COLUMN
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE PACKAGE

The owner who created non-schema object such as schema, tablespace, does not automatically have any privilege for the object. Therefore, the privilege should be separately granted.
For more information, refer to the following CREATE statements.

- CREATE SCHEMA
- CREATE TABLESPACE
- CREATE USER

Examples

The following is an example of granting SELECT ON TABLE t1 privilege to the user u1.

```
gSQL> GRANT SELECT ON t1 TO u1;
Grant succeeded.
```

The following is an example of granting SELECT ON TABLE t1 privilege to the PUBLIC account (all users).

```
gSQL> GRANT SELECT ON t1 TO PUBLIC;
Grant succeeded.
```

The following is an example that the user u1 grants the privilege to the other user by using WITH GRANT OPTION.

```
gSQL> GRANT SELECT ON t1 TO u1 WITH GRANT OPTION;
Grant succeeded.
```

The following is the example that the user executing the statement grants all privileges on the TABLE t1 t o user u1 by using WITH GRANT OPTION.

```
gSQL> GRANT ALL PRIVILEGES ON TABLE t1 TO u1;
Grant succeeded.
```

The following is an example of granting CREATE SESSION ON DATABASE privilege which is a privilege for connecting to the database.

```
gSQL> GRANT CREATE SESSION ON DATABASE TO u1;
Grant succeeded.
```

The following is an example of granting multiple privileges for creating objects such as the table, view, in dex, sequence, constraint in the SCHEMA s1 to the user u1.

```
gSQL> GRANT CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, ADD CONSTRAINT ON SCHEMA
s1 TO u1;
Grant succeeded.
```

The following is an example of granting the privileges for creating objects in TABLESPACE mem_data_tb to the user u1.

```
gSQL> GRANT CREATE OBJECT ON TABLESPACE mem_data_tbs TO u1;
Grant succeeded.
```

The following is an example of granting the privilege for querying some columns in the TABLE t1 to the u ser u1.

```
gSQL> GRANT SELECT( id, name ) ON TABLE t1 TO u1;
Grant succeeded.
```

The following is an example of granting the privilege to the user u1 for using NEXTVAL(), CURRVAL() fun ctions in the SEQUENCE seq1.

```
gSQL> GRANT USAGE ON SEQUENCE seq1 TO u1;
Grant succeeded.
```

Compatibility

The SQL standard does not define the following privileges.

- 〈database privilege〉
- 〈tablespace privilege〉
- 〈schema privilege〉

Table 19-37 SQL standard compatibility

Feature ID	Description	Compatibility
S023	Basic structured types	X
S024	Enhanced structured types	X
S081	Subtables	X
T211	Basic trigger capability	X
T281	SELECT privilege with column granularity	O
T332	Extended Roles	X
F731	INSERT column privileges	O

For More Information

Refer to the followings.

- **REVOKE privileges FROM**
- **CREATE USER**
- **DROP USER**
- **ALTER USER**

20.

SQL References (H~Z)

20.1 INSERT INTO

Function

It creates new rows in a table.

Syntax

```
<insert statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
    ;
<insert source> ::=
      <values clause>
    ¦ <from subquery>
    ¦ <from default>
<values clause> ::=
    VALUES { ( { <value expression> ¦ DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<from default> ::=
    DEFAULT VALUES
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <Insert statement>.

- One of the following privileges is required to perform the INSERT statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - INSERT ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in <from subquery>.
  - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
  - (SELECT or CONTROL TABLE) ON TABLE for the table

- (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.
It can define schema to which the table belongs such as schema_name.table_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

[(column_name [, ...])]

It is the column name of a table.
The column list can be omitted.
The number of columns and the number of 〈insert source〉 values should be same, and DEFAULT value is assigned to the omitted column.

〈values clause〉

It is the list of values to be assigned to the corresponding columns.

- 〈value expression〉
  - It is the value or expression to be assigned to the corresponding column.
- DEFAULT
  - The value of corresponding column will use the default value which were defined through **CREATE TABLE**.
  - If it is not defined, NULL will be assigned.

Multiple rows can be created as follows.

```
INSERT INTO table_name VALUES ( 1, 'A' ), ( 2, 'B' ), ( 3, 'C' )
```

〈from subquery〉

It is the query to create rows.
For more information, refer to **query expression** clause of **SELECT** statement.

DEFAULT VALUES

It fills every column with default value.

DEFAULT VALUES clause means as same as the following.

```
VALUES ( DEFAULT, DEFAULT, ..., DEFAULT )
```

Description

Differences among INSERT-related Statements

- **INSERT INTO**
  - It creates one or multiple rows into the table.
  - e.g. INSERT INTO t1 SELECT * FROM t1;
- **INSERT INTO name RETURNING**
  - It creates one or multiple rows into the table, then the created rows can be retrieved in the same way as SELECT statement(API such as SQLFetch()).
  - e.g. INSERT INTO t1 SELECT * FROM t1 RETURNING c1;
- **INSERT INTO name RETURNING .. INTO**
  - It creates one or less row, and if a single row is created, it obtains the value to the host variable o f RETURNING INTO clause.
  - e.g. INSERT INTO t1 DEFAULT VALUES RETURNING c1 INTO :v1;

Examples

The following is an example of creating a single row by using INSERT statement.

```
gSQL> INSERT INTO region VALUES ( 0, 'AFRICA' );
1 row created.
```

The following is an example of using the DEFAULT value or identity value of the column in INSERT statem ent.

```
gSQL> CREATE TABLE region
(
    r_regionkey   BIGINT    GENERATED BY DEFAULT AS IDENTITY
  , r_name        CHAR(25)  DEFAULT 'N/A'
);
```

```
Table created.
gSQL> COMMIT;
Commit complete.
```

- DEFAULT is inserted into all columns.

```
gSQL> INSERT INTO region DEFAULT VALUES;
1 row created.
```

- DEFAULT is inserted into all columns.

```
gSQL> INSERT INTO region VALUES (DEFAULT, DEFAULT);
1 row created.
```

- If a column is omitted, the DEFAULT value of r_name column is used.

```
gSQL> INSERT INTO region(r_regionkey) VALUES (-100);
1 row created.
```

- If a column is omitted, the identity value of r_regionkey column is used.

```
gSQL> INSERT INTO region(r_name) VALUES ('ASIA');
1 row created.
gSQL> SELECT * FROM region;
R_REGIONKEY R_NAME
----------- -------------------------
          1 N/A
          2 N/A
       -100 N/A
          3 ASIA
4 rows selected.
```

The following is an example of creating multiple rows by describing them in VALUES clause.

```
gSQL> INSERT INTO region
       VALUES ( 1, 'AFRICA' ),
              ( 2, 'ASIA'   ),
              ( 3, 'EUROPE' );
3 rows created.
```

The following is an example of creating multiple rows by using a subquery.

```
gSQL> INSERT INTO region SELECT r_regionkey, r_name FROM tmp_region WHERE r_regionkey < 3;
3 rows created.
```

Compatibility

Table 20-1 SQL standard compatibility

Feature ID	Description	Compatibility
F781	Self-referencing operations	X
F222	INSERT statement: DEFAULT VALUES clause	O
S204	Enhanced structured types	X
S043	Enhanced reference types	X
T111	Updatable joins, unions, and columns	X

For More Information

Refer to the followings.

- **SELECT**
- **INSERT INTO name RETURNING**
- **INSERT INTO name RETURNING .. INTO**

20.2 INSERT INTO name RETURNING

Function

It creates new rows in the table, and retrieves them.

Syntax

```
<insert statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <returning clause>
    ;
<insert source> ::=
      <values clause>
    | <from subquery>
    | <from default>
<values clause> ::=
    VALUES { ( { <value expression> | DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<from default> ::=
    DEFAULT VALUES
<returning clause> ::=
      [ RETURN | RETURNING ] { * | { <value expression> [ [AS] alias_name ] } [, ...]
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <insert returning query statement>.

- One of the following privileges is required to perform INSERT statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - INSERT ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in <from subquery>.
  - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
  - SELECT(columns) ON TABLE for all columns which were used in RETURNING clause.
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.

[(column_name [, ...])]

It is the column name of a table.
For more information, refer to **INSERT INTO**.

<values clause>

It is the list of values to be assigned to the corresponding columns.
For more information, refer to **INSERT INTO**.

<from subquery>

It is the query to create rows.
For more information, refer to **INSERT INTO**.

DEFAULT VALUES

It fills every column with default value.
For more information, refer to **INSERT INTO**.

〈returning clause〉

It returns the inserted rows.

- It sets the inserted rows as a result set, and specifies the rows to be retrieved.
  - RETURNING clause returns the rows which were inserted by INSERT statement, and which is a res ult set.
  - 〈value expression〉
    - It is as same as 〈select list〉 in SELECT statement, but it can not use the aggregation.
  - [[AS] alias_name]
    - It can name a value expression by using AS clause.

The keywords RETURNING and RETURN have the same meaning.

Description

For more information, refer to **Differences among INSERT-related Statements**.

Examples

The following is an example of retrieving the column values created by using INSERT statement.

```
gSQL> CREATE TABLE region
(
    r_regionkey   BIGINT    GENERATED BY DEFAULT AS IDENTITY
  , r_name        CHAR(25)  DEFAULT 'N/A'
);
Table created.
gSQL> COMMIT;
Commit complete.
```

- The following is an example of returning the created DEFAULT value (RETURNING).

```
gSQL> INSERT INTO region VALUES ( DEFAULT, DEFAULT ) RETURNING r_regionkey, r_name;
R_REGIONKEY R_NAME
----------- -------------------------
          1 N/A
1 row created.
```

- The following is an example of returning the omitted column value (RETURNING).

```
gSQL> INSERT INTO region(r_name) VALUES ('ASIA') RETURNING r_regionkey;
R_REGIONKEY
-----------
          2
1 row created.
```

The following is an example of retrieving the rows created by using the subquery.

```
gSQL> INSERT INTO region
      SELECT r_regionkey, r_name FROM tmp_region WHERE r_regionkey < 3
      RETURNING r_regionkey, r_name;
R_REGIONKEY R_NAME
----------- -------------------------
          0 AFRICA
          1 AMERICA
          2 ASIA
3 rows created.
```

Compatibility

The SQL standard does not define <insert returning query statement>.

For More Information

Refer to the followings.

- **INSERT INTO**
- **INSERT INTO name RETURNING .. INTO**

20.3 INSERT INTO name RETURNING .. INTO

Function

It creates a single row in a table, and obtains the value of the created row into a host variable.

Syntax

```
<insert statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <returning into clause>
    ;
<insert source> ::=
      <values clause>
    | <from subquery>
    | <from default>
<values clause> ::=
    VALUES { ( { <value expression> | DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<from default> ::=
    DEFAULT VALUES
<returning into clause> ::=
      [ RETURN | RETURNING ] { * | { <value expression> [ [AS] alias_name ] } [, ...] INTO
variable_name [, ...]
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <insert returning into statement>.

- One of the following privileges is required to perform INSERT statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert.
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs

    - INSERT ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in 〈from subquery〉.
    - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
    - (SELECT or CONTROL TABLE) ON TABLE for the table
    - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
    - SELECT ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
    - SELECT(columns) ON TABLE for all columns which were used in RETURNING clause
    - (SELECT or CONTROL TABLE) ON TABLE for the table
    - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
    - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.

[(column_name [, ...])]

It is the column name of a table.
For more information, refer to **INSERT INTO**.

〈values clause〉

It is the list of values to be assigned to the corresponding columns.
For more information, refer to **INSERT INTO**.

〈from subquery〉

It is the query to create rows.
For more information, refer to **INSERT INTO**.

DEFAULT VALUES

It fills every column with default value.
For more information, refer to **INSERT INTO**.

〈returning clause〉

It returns the inserted rows.
For more information, refer to **〈returning clause〉** in **INSERT INTO name RETURNING** statement.

INTO variable_name [, ...]

The number of variables in INTO clause should be equal to the number of the expressions in RETURNING clause.
The row to be created should be one or less. If two or more rows are created, an error occurs.

Description

For more information, refer to **Differences among INSERT-related Statements**.

Example

The following is an example of obtaining the value of the created row into a host variable.

```
gSQL> CREATE TABLE region
(
    r_regionkey   BIGINT    GENERATED BY DEFAULT AS IDENTITY
  , r_name        CHAR(25)  DEFAULT 'N/A'
);
Table created.
gSQL> COMMIT;
Commit complete.
```

- The host variables are declared.

```
\VAR v_key  BIGINT
\VAR v_name VARCHAR(128)
```

- The created DEFAULT values are obtained into the host variables.

```
gSQL> INSERT INTO region
      VALUES ( DEFAULT, DEFAULT )
      RETURNING r_regionkey, r_name
      INTO :v_key, :v_name;
V_KEY V_NAME
----- -------------------------
    1 N/A
1 row created.
```

- The omitted column value is obtained into the host variable.

```
gSQL> INSERT INTO region(r_name)
      VALUES ('ASIA')
      RETURNING r_regionkey
      INTO :v_key;
V_KEY
-----
    2
1 row created.
```

Compatibility

The SQL standard does not define <insert returning into statement>.

For More Information

Refer to the followings.

- **INSERT INTO**
- **INSERT INTO name RETURNING**

20.4 INSERT INTO name ... UPDATE

Function

It creates new rows in a table. If it violates the unique constraint, then it updates the existing rows.

Syntax

```
<upsert statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <duplicate key clause>
    ;
<insert source> ::=
      <values clause>
    | <from subquery>
    | DEFAULT VALUES
<values clause> ::=
    VALUES { ( { <value expression> | DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<duplicate key clause>
    ON DUPLICATE KEY { DO NOTHING | <do update clause> }
<do update clause> ::=
    [DO] UPDATE [SET] <set clause>  [, ...]
<set value clause> ::=
      <value expression>
    | DEFAULT
    | VALUES( column_name )
<set clause> ::=
      column_name = <set value clause>
    | ( column_name [, ...] ) = ( <set value clause> [, ...] )
    | ( column_name [, ...] ) = ( <query expression> )
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <upsert statement>.

- One of the following privileges is required to perform the corresponding statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - INSERT ANY TABLE ON DATABASE
  - UPDATE(columns) ON TABLE for all columns which are targets of update
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in <from subquery>.
  - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
  - SELECT(columns) ON TABLE for all columns which were used in RETURNING clause
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.
Or, it is the name of a target table to be updated when they are updated because it violates the unique c onstraint.
It can define schema to which the table belongs such as schema_name.table_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

[(column_name [, ...])]

It is the column name of a table.
For more information, refer to **[(column_name [, ...])]** clause of **INSERT INTO** statement.

〈values clause〉

It is the list of values to be assigned to the corresponding columns.
For more information, refer to **〈values clause〉** of **INSERT INTO** statement.

〈from subquery〉

It is the query to create rows.
For more information, refer to **query expression** clause of **SELECT** statement.

DEFAULT VALUES

It fills every column with default value.
For more information, refer to **DEFAULT VALUES** clause of **INSERT INTO** statement.

〈duplicate key clause〉

It defines the action to perform when it violates the unique constraint.

DO NOTHING

It does not perform any operation when it violates the unique constraint.

〈do update clause〉

It updates the values in columns according to 〈set clause〉 when it violates the unique constraint.

〈set value clause〉

It defines the values to assign to the columns to be updated.

It can be defined as follows.

- column_name = 〈value expression〉

```
DO UPDATE SET column1 = value1, column2 = value2, column3 = value3
```

- column_name = DEFAULT

```
DO UPDATE SET column1 = DEFAULT, column2 = DEFAULT, column3 = DEFAULT
```

- column_name = VALUES(column_name)

<insert source> value is used to update the value.

```
DO UPDATE SET column1 = VALUES(column1), column2 = VALUES(column2), column3 = VALUES(column2)
```

<set clause>

It defines the columns to be updated and the values to be assigned, and the number of columns in <set clause> and the number of values should be same.

It can be defined as follows.

- column_name = { <set value clause> }

```
ON DUPLICATE KEY
   DO UPDATE SET column1 = value1, column2 = value2, column3 = value3
```

- (column_name [, ...]) = (<set value clause> } [, ...])

```
ON DUPLICATE KEY
   DO UPDATE SET ( column1, column2, column3 ) = ( value1, value2, value3 )
```

- (column_name [, ...]) = (<query expression>)

```
ON DUPLICATE KEY
   DO UPDATE SET column1 = ( SELECT max(value1) FROM other_table_name )
```

<query expression> should be a query creating a single row.

If DEFAULT is used as a column value, it uses the default value (refer to **<default clause>**.) defined when performing **CREATE TABLE**, and NULL value is assigned when it is not defined.

Description

Differences among INSERT INTO name ... UPDATE-related Statements

- **INSERT INTO name ... UPDATE**
  - It creates rows in a table. If it violates the unique constraint, then it updates the existing rows.
  - e.g. INSERT INTO t1 VALUES (1, 1) ON DUPLICATE KEY UPDATE c2 = c2 + 1;
- **INSERT INTO name ... UPDATE RETURNING**
  - It creates rows in a table or updates the existing rows. The inserted rows or the updated rows ca n be retrieved in the same way as SELECT statement (API such as SQLFetch()).
  - e.g. INSERT INTO t1 VALUES (1, 1) ON DUPLICATE KEY UPDATE c2 = c2 + 1 RETURNING c2;
- **INSERT INTO name ... UPDATE RETURNING ... INTO**
  - It creates or updates one or less row. If the created row or the updated row is a single row, then i t obtains the value into a host variable of RETURNING INTO clause.
  - e.g. INSERT INTO t1 VALUES (1, 1) ON DUPLICATE KEY UPDATE c2 = c2 + 1 RETURNING c2 INT O :v1;

〈upsert statement〉 is a deterministic statement.

The results of the two equivalent and different UPSERT statements should be same as follows.

- INSERT INTO t1 VALUES(1),(2),(3) ON DUPLICATE KEY UPDATE c1 = c1 + 1;
- INSERT INTO t1 VALUES(3),(2),(1) ON DUPLICATE KEY UPDATE c1 = c1 + 1;

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 ),( 2 ),( 3 );
3 rows created.
gSQL> INSERT INTO t1 VALUES( 1 ),( 2 ),( 3 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1;
3 rows created.
gSQL> SELECT * FROM t1;
C1
--
 2
 3
 4
3 rows selected.
```

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 ),( 2 ),( 3 );
```

```
3 rows created.
gSQL> INSERT INTO t1 VALUES( 3 ),( 2 ),( 1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1;
3 rows created.
gSQL> SELECT * FROM t1;
C1
--
 2
 3
 4
3 rows selected.
```

Examples

The following is an example of updating a single row because it violates the unique constraint.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 );
1 row created.
gSQL> INSERT INTO t1 VALUES( 1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1;
1 row created.
gSQL> SELECT * FROM t1;
C1
--
 2
1 row selected.
```

The following is an example of not updating a row even when it violates the unique constraint.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 );
1 row created.
gSQL> INSERT INTO t1 VALUES( 1 ) ON DUPLICATE KEY DO NOTHING;
no rows created.
gSQL> SELECT * FROM t1;
C1
--
 1
1 row selected.
```

The following is an example of inserting or updating multiple rows by using a subquery.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 ),( 2 ),( 3 ),( 4 );
4 rows created.
gSQL> INSERT INTO t1 ( SELECT c1 FROM t1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1;
4 rows created.
gSQL> SELECT * FROM t1;
C1
--
 2
 3
 4
 5
4 rows selected.
```

Compatibility

The SQL standard does not define <upsert statement>.

For More Information

Refer to the followings.

- INSERT INTO
- INSERT INTO name ... UPDATE RETURNING
- INSERT INTO name ... UPDATE RETURNING ... INTO
- UPDATE

20.5 INSERT INTO name ... UPDATE RETURNING

Function

It creates new rows in a table. If it violates the unique constraint, then it updates the existing rows. Then, it retrieves the created rows or the updated rows.

Syntax

```
<upsert returning statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <duplicate key clause>
        <returning clause>
    ;
<insert source> ::=
      <values clause>
    | <from subquery>
    | DEFAULT VALUES
<values clause> ::=
    VALUES { ( { <value expression> | DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<duplicate key clause>
    ON DUPLICATE KEY { DO NOTHING | <do update clause> }
<do update clause> ::=
    [DO] UPDATE [SET] <set clause>  [, ...]
<set value clause> ::=
      <value expression>
    | DEFAULT
    | VALUES( column_name )
<set clause> ::=
      column_name = <set value clause>
    | ( column_name [, ...] ) = ( <set value clause> [, ...] )
    | ( column_name [, ...] ) = ( <query expression> )
<returning clause> ::=
    [ RETURN | RETURNING ] { * | { <value expression> [ [AS] alias_name ] } [, ...]
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <upsert returning statement>.

- One of the following privileges is required to perform the corresponding statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - INSERT ANY TABLE ON DATABASE
  - UPDATE(columns) ON TABLE for all columns which are targets of update
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in <from subquery>.
  - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
  - SELECT(columns) ON TABLE for all columns which were used in RETURNING clause
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.
Or, it is the name of a target table to be updated when they are updated because it violates the unique c onstraint.
For more information, refer to **table_name** clause of **INSERT INTO name ... UPDATE** statement.

[(column_name [, ...])]

It is the column name of a table.
For more information, refer to **[(column_name [, ...])]** clause of **INSERT INTO** statement.

〈values clause〉

It is the list of values to be assigned to the corresponding columns.
For more information, refer to **〈values clause〉** of **INSERT INTO** statement.

〈from subquery〉

It is the query to create rows.
For more information, refer to **query expression** clause of **SELECT** statement.

DEFAULT VALUES

It fills every column with default value.
For more information, refer to **DEFAULT VALUES** clause of **INSERT INTO** statement.

〈duplicate key clause〉

It defines the action to perform when it violates the unique constraint.

DO NOTHING

It does not perform any operation when it violates the unique constraint.

〈do update clause〉

It updates the values in columns according to 〈set clause〉 when it violates the unique constraint.

〈set value clause〉

It defines the values to assign to the columns to be updated.
For more information, refer to **〈set value clause〉** of **INSERT INTO name ... UPDATE** statement.

〈set clause〉

It defines the columns to be updated and the values to be assigned, and the number of columns in 〈set clause〉 and the number of values should be same.
For more information, refer to **〈set clause〉** of **INSERT INTO name ... UPDATE**.

〈returning clause〉

It returns the inserted rows or the updated rows.

- It sets the created rows as a result set, and specifies the rows to be retrieved.
  - RETURNING clause returns the result which sets inserted rows or updated rows as a result set.
  - 〈value expression〉
    - It is as same as 〈select list〉 in SELECT statement, but it can not use the aggregation.
  - [[AS] alias_name]
    - It can name a value expression by using AS clause.

Description

For more information, refer to **Differences among INSERT INTO name ... UPDATE-related Statements**.

The following is an example of inserting four rows, and returning the inserted results.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 ), ( 2 ), ( 3 ), ( 4 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1
RETURNING c1;
C1
--
 1
 2
 3
 4
4 rows created.
```

The following is an example of updating rows because it violates the unique constraint, and returning the updated results.

```
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
```

```
gSQL> INSERT INTO t1 VALUES( 1 ),( 2 ),( 3 ),( 4 );
4 rows created.
gSQL> INSERT INTO t1 ( SELECT c1 FROM t1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1 RETURNING c1;
C1
--
 2
 3
 4
 5
4 rows created.
```

Compatibility

The SQL standard does not define <upsert returning statement>.

For More Information

Refer to the followings.

- **INSERT INTO name ... UPDATE**
- **INSERT INTO name ... UPDATE RETURNING ... INTO**

20.6 INSERT INTO name ... UPDATE RETURNING ... INTO

Function

It creates a single row in a table. If it violates the unique constraint, then it updates the existing rows. Then, it obtains the created rows or the updated rows as the host variable.

Syntax

```
<upsert returning into statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <duplicate key clause>
        <returning clause>
        <into clause>
    ;
<insert source> ::=
      <values clause>
    ¦ <from subquery>
    ¦ DEFAULT VALUES
<values clause> ::=
    VALUES { ( { <value expression> ¦ DEFAULT } [, ...] ) } [, ...]
<from subquery> ::=
    <query expression>
<duplicate key clause>
    ON DUPLICATE KEY { DO NOTHING ¦ <do update clause> }
<do update clause> ::=
    [DO] UPDATE [SET] <set clause>  [, ...]
<set value clause> ::=
      <value expression>
    ¦ DEFAULT
    ¦ VALUES( column_name )
<set clause> ::=
      column_name = <set value clause>
    ¦ ( column_name [, ...] ) = ( <set value clause> [, ...] )
```

```
    ¦ ( column_name [, ...] ) = ( <query expression> )
<returning clause> ::=
    [ RETURN ¦ RETURNING ] { * ¦ { <value expression> [ [AS] alias_name ] } [, ...]
<into clause> ::= INTO variable_name [, ...]
```

Invocation and Access Rules

A user should satisfy the following conditions to perform <upsert returning into statement>.

- One of the following privileges is required to perform the corresponding statement.
  - INSERT(columns) ON TABLE for all columns which are targets of insert
  - (INSERT or CONTROL TABLE) ON TABLE for the table
  - (INSERT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - INSERT ANY TABLE ON DATABASE
  - UPDATE(columns) ON TABLE for all columns which are targets of update
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

- One of the following privileges is required for all tables used in <from subquery>.
  - SELECT(columns) ON TABLE for all columns of tables which were used in the statement
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- One of the following privileges is required for all columns used in RETURNING clause.
  - SELECT(columns) ON TABLE for all columns which were used in RETURNING clause
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table in which the row is to be created.
Or, it is the name of a target table to be updated when they are updated because it violates the unique c onstraint.

For more information, refer to **table_name** clause of **INSERT INTO name ... UPDATE** statement.

[(column_name [, ...])]

It is the column name of a table.
For more information, refer to **[(column_name [, ...])]** clause of **INSERT INTO** statement.

〈values clause〉

It is the list of values to be assigned to the corresponding columns.
For more information, refer to **〈values clause〉** of **INSERT INTO** statement.

〈from subquery〉

It is the query to create rows.
For more information, refer to **query expression** clause of **SELECT** statement.

DEFAULT VALUES

It fills every column with default value.
For more information, refer to **DEFAULT VALUES** clause of **INSERT INTO** statement.

〈duplicate key clause〉

It defines the action to perform when it violates the unique constraint.

DO NOTHING

It does not perform any operation when it violates the unique constraint.

〈do update clause〉

It updates the values in columns according to 〈set clause〉 when it violates the unique constraint.

〈set value clause〉

It defines the values to assign to the columns to be updated.
For more information, refer to **〈set value clause〉** of **INSERT INTO name ... UPDATE** statement.

〈set clause〉

It defines the columns to be updated and the values to be assigned, and the number of columns in 〈set clause〉 and the number of values should be same.
For more information, refer to **〈set clause〉** of **INSERT INTO name ... UPDATE**.

〈returning clause〉

It returns the inserted rows or the updated rows.
For more information, refer to **〈returning clause〉** of **INSERT INTO name ... UPDATE RETURNING**.

〈into clause〉

The number of variables specified in INTO clause should be same as the number of expressions specified in RETURNING clause.
The row should be created one or less. If two or more rows are created, then an error occurs.

Description

For more information, refer to **Differences among INSERT INTO name ... UPDATE-related Statements**.

The following is an example of inserting a single row, then obtaining the inserted result as the host variable.

```
gSQL> \VAR v_c1 INTEGER;
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1 RETURNING c1 INTO :v_c1;
V_C1
----
   1
1 row created.
```

The following is an example of updating a single row because it violates the unique constraint, then obtaining the updated result as the host variable.

```
gSQL> \VAR v_c1 INTEGER;
gSQL> CREATE TABLE t1 ( c1 INTEGER UNIQUE );
Table created.
gSQL> INSERT INTO t1 VALUES( 1 );
1 row created.
gSQL> INSERT INTO t1 VALUES( 1 ) ON DUPLICATE KEY UPDATE c1 = c1 + 1 RETURNING c1 INTO :v_c1;
V_C1
----
   2
1 row created.
```

Compatibility

The SQL standard does not define <upsert returning into statement>.

For More Information

Refer to the followings.

- **INSERT INTO name ... UPDATE**
- **INSERT INTO name ... UPDATE RETURNING**

20.7 LOCK TABLE

Function

It locks one or more tables.

Syntax

```
<lock table statement> ::=
    LOCK TABLE lock target [, ...]
    IN <lock mode> MODE [<wait clause>]
    ;
<lock mode> ::=
    SHARE
    ¦ EXCLUSIVE
    ¦ ROW SHARE
    ¦ ROW EXCLUSIVE
    ¦ SHARE ROW EXCLUSIVE
<wait clause> ::=
    NOWAIT
    ¦ WAIT time
```

Invocation and Access Rules

One of the following privileges is required to perform <lock table statement>.

- (LOCK or CONTROL TABLE) ON TABLE for the table
- (LOCK TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- LOCK ANY TABLE ON DATABASE

Syntax Rules and Parameters

〈lock target〉

It specifies the target table to be locked.

〈lock mode〉

It specifies the LOCK mode.

- SHARE
  - It allows concurrent queries for the locked table, but prohibits updating the table.
- EXCLUSIVE
  - It allows exclusive queries for the locked table.
- ROW SHARE
  - It allows concurrent access to the locked table, but prohibits locking the entire table for exclusive access.
- ROW EXCLUSIVE
  - It allows concurrent access to the locked table, but prohibits locking the entire table for exclusive access.
  - If ROW EXCLUSIVE mode is set, it prohibits locking in SHARE mode.
  - ROW EXCLUSIVE mode is automatically obtained when updating, inserting, deleting.
- SHARE ROW EXCLUSIVE
  - It is used to search for the entire table or to make other users search for the rows in the table.
  - It prohibits other users from accessing the locked tables in SHARE mode or accessing the rows be ing updated.

〈wait clause〉

It specifies the waiting time to acquire the lock.

- NOWAIT
  - It immediately acquires the lock contol for the object.
  - If the lock is already set by another user, the control is immediately handed over.
    - In this case, the database generates a message.
- WAIT time
  - It sets the waiting time for acquiring the lock.
  - It is specified in seconds, and its value is from 0 to 1,000,000,000.
- If it is not specified, it waits indefinitely until acquiring the lock.

Description

If the transaction is committed or rolled back all acquired locks are automatically released. When using R OLLBACK TO SAVEPOINT statement, all locks acquired since that savepoint are released.

Examples

The following is an example of locking the TABLE t1 to prevent any updating operation by another transa ction.

```
gSQL> LOCK TABLE t1 IN EXCLUSIVE MODE;
Table locked.
```

The following is an example of performing LOCK statement for multiple tables.

```
gSQL> LOCK TABLE t1, t2 IN EXCLUSIVE MODE;
Table locked.
```

The following is an example of acquiring SHARE ROW EXCLUSIVE lock for the TABLE t1.

```
gSQL> LOCK TABLE t1 IN SHARE ROW EXCLUSIVE MODE;
Table locked.
```

The following statement is performed only when the lock can be immediately acquired for the table. If th e lock can not be acquired, an error occurs.

```
gSQL> LOCK TABLE t1 IN EXCLUSIVE MODE NOWAIT;
Table locked.
```

The following is an example of waiting 10 seconds to acquire the lock.

```
gSQL> LOCK TABLE t1 IN EXCLUSIVE MODE WAIT 10;
Table locked.
```

Compatibility

The SQL standard does not cover the concepts of the lock table.

For More Information

Refer to the followings.

- COMMIT
- ROLLBACK

20.8 NOAUDIT POLICY

Function

It deactivates the audit policy.

Syntax

```
<noaudit policy statement> ::=
    NOAUDIT POLICY policy_name
    [ <specified_user_option> ]
    ;
<specified_user_option> ::=
      BY user_name [, ...]
```

Invocation and Access Rules

AUDIT SYSTEM ON DATABASE privilege is required to perform <noaudit policy statement>.

Syntax Rules and Parameters

policy_name

It is the name of the audit policy object to be deactivated.
The deactivated audit policy does not effect on the existing session, and it effects only on the newly creat ed session.

<specified_user_option>

It specifies the user to be excluded from the auditing target.

Unlike AUDIT POLICY statement, NOAUDIT POLICY does not have EXCEPT option.

If AUDIT POLICY name BY clause is used, NOAUDIT POLICY name BY statement should be used to deacti vate it.
If AUDIT POLICY name EXCEPT clause is used, NOAUDIT POLICY name statement without BY clause shou ld be used to deactivate it.

NOAUDIT POLICY statement should be used as follows according to the usage of AUDIT POLICY stateme nt to deactivate it.

Table 20-2 Activating/ deactivating audit policy

Type	AUDIT POLICY statement	NOAUDIT POLICY statement
All users	AUDIT POLICY p1	NOAUDIT POLICY p1
Using BY	AUDIT POLICY p1 BY u1	NOAUDIT POLICY p1 BY u1
Using EXCEPT	AUDIT POLICY p1 EXCEPT u1	NOAUDIT POLICY p1

When deactivating all activated users, the audit policy object is completely deactivated.

Description

The information about activationthe audit policy object is retrieved as follows.

```
SELECT policy_name
     , enabled_opt
     , user_name
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
```

NOAUDIT POLICY statement deletes each created information about activationaccording to the AUDIT P OLICY specifying method.
If the information activated through the query above does not exist, then the audit policy is completely d eactivated.

If all users are activated as follows, NOAUDIT POLICY BY clause does not does not affect it.

```
AUDIT POLICY p1;
```

- It does not does not affect any.

```
NOAUDIT POLICY p1 BY u1;
```

- It should be deactivated as follows.

```
NOAUDIT POLICY p1;
```

If one or more users are separately activated, use NOAUDIT POLICY statement according to the AUDIT PO LICY specifying method.

When Activated by Using BY

If the audit policy is activated as follows,

```
AUDIT POLICY p1 WHENEVER NOT SUCCESSFUL;
AUDIT POLICY p1 BY u1;
AUDIT POLICY p1 BY u2;
```

the information about activation is as follows.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME  ENABLED_OPT  USER_NAME    WHEN_SUCCESS  WHEN_FAILURE
-----------  -----------  ---------    ------------  ------------
P1           BY           ALL USERS    NO            YES
P1           BY           U1           YES           YES
P1           BY           U2           YES           YES
```

The following is an example of performing NOAUDIT statement and the information about activation.

```
NOAUDIT POLICY p1;
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME  ENABLED_OPT  USER_NAME    WHEN_SUCCESS    WHEN_FAILURE
-----------  -----------  ---------    ------------    ------------
P1           BY           U1           YES             YES
P1           BY           U2           YES             YES
```

The auditing for a failure for ALL USERS is deactivated, but the auditing for user u1, u2 is still activated.

If NOAUDIT POLICY statement is additionally used through BY option as follows, then audit policy p1 is c ompletely deactivated.

```
NOAUDIT POLICY p1 BY u1, u2;
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
no rows selected.
```

When Activated by Using EXCEPT

If the audit policy is activated as follows,

```
AUDIT POLICY p1 EXCEPT u1, sys;
```

the information about activation is as follows.

```
SELECT policy_name
     , enabled_opt
     , user_name
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
POLICY_NAME  ENABLED_OPT  USER_NAME    WHEN_SUCCESS    WHEN_FAILURE
-----------  -----------  ---------    ------------    ------------
P1           EXCEPT       U1           YES             YES
P1           EXCEPT       SYS          YES             YES
```

Unlike AUDIT POLICY statement, NOAUDIT POLICY does not have EXCEPT option, so execute the statem ent without an option as follows.

```
NOAUDIT POLICY p1;
SELECT policy_name
     , enabled_opt
     , user_name
```

```
     , when_success
     , when_failure
  FROM audit_policy_enabled
 WHERE policy_name = 'P1';
no rows selected.
```

In other words, if the audit policy is activated by using EXCEPT option, each user can not be activated aga in by using NOAUDIT POLICY statement.

Examples

The following is an example of deactivating all users.

```
NOAUDIT POLICY table_pol;
```

The following is an example of deactivating a specific activated user by using BY.

```
NOAUDIT POLICY table_pol BY u1;
```

Compatibility

The SQL standard does not have the audit policy.

For More Information

Refer to the followings.

- Managing audit policy object
  - **CREATE AUDIT POLICY**
  - **DROP AUDIT POLICY**
  - **ALTER AUDIT POLICY**
- Activating/ deactivating audit policy
  - **AUDIT POLICY**
  - **NOAUDIT POLICY**
- Viewing audit trail: **AUDIT_TRAIL**

- Clearing audit trail: **ALTER DATABASE CLEAR AUDIT TRAIL**

20.9 OPEN cursor_name

Function

It opens a cursor.

Syntax

```
<open statement> ::=
    OPEN cursor_name [ <parameter using clause> ]
    ;
<parameter using clause> ::=
      <using parameter arguments>
<using parameter arguments> ::=
    USING variable_name [, ...]
```

Invocation and Access Rules

If cursor_name is a dynamic cursor which is declared by using **PREPARE statement_name** and **DECLARE c ursor_name**, it can be used in an embedded SQL.

It is same with the privilege of **<cursor query>** included in **DECLARE cursor_name** which declared cursor_n ame.

Syntax Rules and Parameters

cursor_name

It should be a cursor declared with **DECLARE cursor_name** within the session.

〈parameter using clause〉

It can be used in an embedded SQL.

When 〈parameter using clause〉 is used, cursor_name should be a dynamic cursor declared by using **PREP ARE statement_name** and **DECLARE cursor_name**.

〈using parameter arguments〉

When 〈using parameter arguments〉 is used, the number of variable_name should be equal to the numb er of the parameter included in a query which is referenced by **PREPARE statement_name**.

The listed variable_name corresponds to the dynamic parameter in an order of its description.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'SELECT c1, c2 FROM t1 WHERE c1 IN ( ?, ?, ? )';
    EXEC SQL DECLARE cur1 CURSOR FOR stmt1;
    EXEC SQL OPEN cur1 USING :sValue1, :sValue2, :sValue3;
    ...
    EXEC SQL WHENEVER NOT FOUND DO break;
    for(;;)
    {
        EXEC SQL FETCH cur1 INTO :sC1, :sC2;
    }
    EXEC SQL WHENEVER NOT FOUND CONTINUE;
    ...
    EXEC SQL CLOSE cur1;
    ...
}
```

Description

The cursor is a distinguishable object in a session. The cursor being used in the current session has nothin g to do with the cursor being used in another session.

To use OPEN cursor_name statement, it should be a cursor declared with **DECLARE cursor_name**, and it s hould be a closed cursor.

Examples

The following is an example of declaring a cursor and using OPEN cursor statement in an interactive SQL (gsql).

```
gSQL> DECLARE cur1 CURSOR FOR SELECT id, data FROM t1;
Cursor declared.
gSQL> OPEN cur1;
Cursor is open.
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   1 data_1
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   2 data_2
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   3 data_3
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   4 data_4
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
V_ID V_DATA
---- ------
   5 data_5
1 row fetched.
gSQL> FETCH cur1 INTO :v_id, :v_data;
no rows fetched.
gSQL> CLOSE cur1;
Cursor closed.
```

Compatibility

Table 20-3 SQL standard compatibility

Feature ID	Description	Compatibility
B031	Basic Dynamic SQL	O

For More Information

Refer to the followings.

- **DECLARE cursor_name**
- **FETCH cursor_name**
- **CLOSE cursor_name**
- **PREPARE statement_name**

20.10 PREPARE statement_name

Function

It prepares a dynamic SQL statement for a repeated execution.

Syntax

```
<prepare statement> ::=
    PREPARE statement_name FROM <SQL statement variable>
    ;
<SQL statement variable> ::=
      variable_name
    ¦ 'sql statement'
    ¦ "sql statement"
    ¦ sql statement
```

Invocation and Access Rules

It can be used in an embedded SQL.
An appropriate privilege according to the type of a dynamic SQL statement is required.

Syntax Rules and Parameters

statement_name

It is the name of the statement to be prepared.
The length of the statement name should be shorter than 128 bytes.
EXECUTE statement_name and **DECLARE cursor_name**, which are to be performed later, refers to the sta tement_name.
If the same statement_name exists, the previously prepared dynamic SQL is dropped.

```
{
    ...
    EXEC SQL PREPARE stmt1 FROM 'DELETE FROM t1';
    ...
    EXEC SQL PREPARE stmt1 FROM 'UPDATE t1 SET c1 = c1 + 10';
    ...
}
```

〈SQL statement variable〉

〈SQL statement variable〉 can be used as following four types.

- variable_name: It is a variable in which an SQL statement is stored.
- 'sql statement': It is an SQL statement which is enclosed with single quote (').
- "sql statement": It is an SQL statement which is enclosed with double quotes (").
- sql statement: It is an SQL statement without quote.

The single quote (') is used twice as follows to represent string data within single-quoted string.

```
{
    ...
    PREPARE stmt_name FROM 'INSERT INTO t1 VALUES ( ''literal data'' )';
    ...
}
```

The dynamic SQL statement referenced by 〈SQL statement variable〉 can use a host variable (:var) or para meter marker (?).
However, if the unquoted SQL statement is used, the parameter marker (?) can not be used.

Depending on the characteristics of the referenced dynamic SQL statements, the variable can be either in put or output dynamic parameter.
The dynamic parameter described in the dynamic SQL statement does not have a meaning for the variabl e name, and it is identified by the specified order regardless of its type.

- Example 1

```
{
    ...
    int sValue1;
    int sValue2;
    ...
    EXEC SQL PREPARE stmt1 FROM 'DELETE FROM t1 WHERE c1 BETWEEN ? AND ?';
```

```
    EXEC SQL EXECUTE stmt1 USING :sValue1, :sValue2;
    ...
}
```

- All parameter markers are the input dynamic parameters.
- The order to identify
  - No. 1 - BETWEEN ?
    - Input dynamic parameter
    - It uses the value of :sValue1.
  - No. 2 - AND ?
    - Input dynamic parameter
    - It uses the value of :sValue2.

- Example 2

```
{
    ...
    int sValue1;
    int sValue2;
    ...
    EXEC SQL PREPARE stmt1 FROM 'SELECT SUM(c2) INTO :v1 FROM t1 WHERE c1 > :v2';
    EXEC SQL EXECUTE stmt1 USING :sValue1, :sValue2;
    ...
}
```

- The input dynamic parameter and the output dynamic parameter exist.
- The order to identify
  - No. 1 - :v1
    - Output dynamic parameter
    - It stores the value in :sValue1.
  - No. 2 - :v2
    - Input dynamic parameter
    - It uses the value of :sValue2.

variable_name

The type corresponding to variable_name should be a character string.
The dynamic SQL statement defined in variable_name should be valid.

sql statement

The dynamic SQL statement defined in the sql statement should be valid.

Description

PREPARE statement_name FROM sql_string statement analyzes SQL statement to use EXECUTE or cursor statement. Statement_name is an identifier which informs the precompiler the statement in an embedde d SQL source code. A separate type or declaration is not required because statement_name is not a host variable.

For more information, refer to **Embedded Dynamic SQL**.

Example

The following is an example of using PREPARE statement_name in an embedded SQL source code.

```
{
    ...
    sprintf( sUpdateSql, "UPDATE EMP SET sal = sal * :v1 WHERE JOB = 'SALES'");
    EXEC SQL PREPARE UPDATE_STMT FROM :sUpdateSql;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    sRatio = 1.1;
    EXEC SQL EXECUTE UPDATE_STMT USING :sRatio;
    if(sqlca.sqlcode != 0)
    {
        goto fail_exit;
    }
    ...
}
```

The full source code in which PREPARE statement_name was used can be viewed in **Dynamic Embedded SQL Example Program**.

Compatibility

Table 20-4 SQL standard compatibility

Feature ID	Description	Compatibility
B031	Basic Dynamic SQL	O
B034	Dynamic specification of cursor attributes	X

For More Information

Refer to the followings.

- **EXECUTE statement_name**
- **DECLARE cursor_name**
- **EXECUTE IMMEDIATE 'sql_string'**
- **Embedded Dynamic SQL**

20.11 PURGE

Function

It permanently drops objects stored in the recycle bin.

Syntax

```
<purge statement> :==
    PURGE <purge action>
    ;
<purge action> :==
     TABLE table_name
   ¦ INDEX index_name
   ¦ CONSTRAINT constraint_name
   ¦ TABLESPACE tablespace_name [ USER user_name ]
   ¦ RECYCLEBIN
   ¦ USER_RECYCLEBIN
   ¦ DBA_RECYCLEBIN
```

Invocation and Access Rules

One of the following privilege is required for a user to perform <purge statement>.

- The owner of that table
- CONTROL TABLE ON TABLE for that table
- (DROP TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- DROP ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of the object stored or of the dropped table in the recycle bin.
It can define the schema to which the table belongs in the dropped table name, such as schema_name.table_name. If schema_name is omitted, the default schema name of the user performing the statement is used. In this case, indexes and constraints which are related to the table are also dropped.

index_name

It is the name of the object stored or of the dropped index in the recycle bin.
It can define the schema to which the index belongs such as schema_name.index_name.
If schema_name is omitted, the default schema name of the user performing the statement is used.
The key index which is created with a constraint should be dropped with the constraint.

constraint_name

It is the name of the object stored or of the dropped constraint in the recycle bin.

tablespace_name

It is the name of the tablespace.
When assigning USER, DROP ANY TABLE ON DATABASE privilege is required.

user_name

It is the name of the user.

recyclebin

It is the alias of user_recyclebin.

user_recyclebin

It drops all recycle bins owned by a user.

dba_recyclebin

It drops all recycle bins in the database.
PURGE DBA_RECYCLEBIN ON DATABASE privilege is required.

Description

It permanently drops objects stored in the recycle bin by using the object name or the dropped table nam e stored in the recycle bin. If the name which is as same as that of the dropped table exists, then the olde st table object is dropped.

When specifying a tablespace in the recycle bin object owned by a user, then only the objects included in the tablespace are dropped. In this case, if a user is assigned, then only the objects included in the specifi ed tablespace owned by the user are dropped.

PURGE TABLE, INDEX, CONSTRAINT statements can be rolled back if it is before when the transaction is committed. However, PURGE TABLESPACE, RECYCLEBIN, DBA_RECYCLEBIN statements can not be rolle d back, and the transaction which performed the statement is automatically committed.

Example

The following is an example of dropping a table stored in the recycle bin.

```
gSQL> SELECT OBJECT_NAME, ORIGINAL_NAME, OBJECT_TYPE FROM USER_RECYCLEBIN;
OBJECT_NAME                          ORIGINAL_NAME        OBJECT_TYPE
------------------------------------ -------------------- -----------
BIN$135B9908166111EA9C5C835D3E4BBBF7 T1                   TABLE
BIN$135B993A166111EA9C5C835D3E4BBBF7 T1_PRIMARY_KEY       CONSTRAINT
BIN$135B991C166111EA9C5C835D3E4BBBF7 T1_PRIMARY_KEY_INDEX INDEX
BIN$135B9926166111EA9C5C835D3E4BBBF7 T1_IDX1              INDEX
4 rows selected.
gSQL> PURGE TABLE t1;
Table purged.
```

The following is an example of dropping an index stored in the recycle bin.

```
gSQL> SELECT OBJECT_NAME, ORIGINAL_NAME, OBJECT_TYPE FROM USER_RECYCLEBIN;
OBJECT_NAME                          ORIGINAL_NAME        OBJECT_TYPE
------------------------------------ -------------------- -----------
```

DBA Recyclebin purged.
```

Compatibility

The SQL standard does not define <purge statement>.

For More Information

Refer to the followings.

- **Managing Recycle Bin of Table**
- **FLASHBACK TABLE**

20.12 RELEASE SAVEPOINT savepoint_specifier

Function

It releases a savepoint.

Syntax

```
<release savepoint statement> ::=
    RELEASE SAVEPOINT savepoint_name
    ;
```

Syntax Rules and Parameters

savepoint_name

It is a name of the savepoint, and it should exist.
The length of the savepoint name should be shorter than 128 bytes.

Description

If multiple savepoints are defined and RELEASE SAVEPOINT savepoint_name statement is performed, all s avepoints defined since the savepoint_name are also released.

Example

The following is an example of releasing a savepoint.

```
gSQL> RELEASE SAVEPOINT sp2;
Savepoint dropped.
```

Compatibility

Table 20-5 SQL standard compatibility

Feature ID	Description	Compatibility
T271	Savepoints	O

For More Information

Refer to the followings.

- **COMMIT**
- **ROLLBACK**
- **SAVEPOINT savepoint_specifier**

20.13 REVOKE privileges FROM

Function

It revokes the granted privilege from a user.

Syntax

```
<revoke privilege statement> ::=
    REVOKE [ <revoke option extention> ] <privilege>
      FROM <grantee> [, ...]
      [ <revoke behavior> ]
    ;
<revoke option extention> ::=
      GRANT OPTION FOR
<revoke behavior> ::=
      RESTRICT
    ¦ CASCADE
    ¦ CASCADE CONSTRAINTS
```

Syntax Rules and Parameters

<privilege>

It is a privilege which is to be revoked from the revokee (the user whose privilege is to be revoked).

The revoker (the user who performs the statement) should satisfy one of the following conditions.

- If it is <privilege> which the revoker grants to the revokee.
  - Only the <privilege> which the revoker grants to the revokee is revoked.
- If the revoker owns ACCESS CONTROL ON DATABASE privilege.
  - The <privilege> which other grantors grant to the revokee is revoked.

When using ALL [PRIVILEGES], it succeeds even when the satisfying <privilege> does not exist.

For more information about the types of <privilege>, refer to **<privilege>** clause of **GRANT privileges TO** st atement.

<grantee>

It is a user whose privilege is to be revoked.

- user_identifier
  - It revokes the privilege of that user.
- PUBLIC
  - They are authorization objects which mean all users.

GRANT OPTION FOR

It revokes WITH GRANT OPTION included in the privilege.
It also revokes WITH GRANT OPTION of the dependent privilege.

The privilege is maintained.

<revoke behavior>

- Dependent privilege: It is as same as the <privilege> which was granted to the revokee by using WITH GRANT OPTION and granted to another user by the revokee.
- RESTRICT
  - If the dependent privilege exists, it can not be revoked.
- CASCADE
  - The dependent privilege should also be revoked.
- CASCADE CONSTRAINTS
  - The dependent privilege should also be revoked.
- If it is omitted, the default value is CASCADE.

Description

Data Definition Language (DDL) such as REVOKE privilege can be rolled back if it is before when the trans action is committed.

When performing the following DROP statement, all privilege information related to the object is revoked even without performing any separate REVOKE statement.

- DROP statement related to SQL schema object

    - DROP TABLE
    - DROP VIEW
    - DROP SEQUENCE
    - ALTER TABLE name SET UNUSED COLUMN
    - DROP FUNCTION
    - DROP PROCEDURE
    - DROP PACKAGE

- DROP statement related to non-schema object
    - DROP SCHEMA
    - DROP TABLESPACE
    - DROP USER

Examples

The following is an example of revoking multiple privileges for the table t1.

```
gSQL> REVOKE INSERT, UPDATE, DELETE, LOCK, ALTER, INDEX ON t1 FROM u1;
Revoke succeeded.
```

The following is an example of revoking SELECT ON TABLE t1 privilege granted to the PUBLIC account, w hich means all users. However, only the privilege for PUBLIC account is revoked, and SELECT ON TABLE t1 privilege which was explicitly granted to a specific user is not revoked.

```
gSQL> REVOKE SELECT ON t1 FROM PUBLIC;
Revoke succeeded.
```

The following is an example that SELECT ON TABLE t1 privilege granted to user u1 is remained, and only REVOKE GRANT OPTION which can grant the privilege to another user is revoked.

```
gSQL> REVOKE GRANT OPTION FOR SELECT ON t1 FROM u1;
Revoke succeeded.
```

The following is an example that an error occurs when the privilege granted to the user u1 is revoked by using RESTRICT option and the user u1 grants it to another user. CASCADE option is used to revoke these dependent privileges as well.

```
gSQL> REVOKE SELECT ON t1 FROM u1 RESTRICT;
ERR-2B000(16235): dependent privilege descriptors still exist
gSQL> REVOKE SELECT ON t1 FROM u1 CASCADE;
Revoke succeeded.
```

Compatibility

The SQL standard does not define the following privileges.

- 〈database privilege〉
- 〈tablespace privilege〉
- 〈schema privilege〉

〈revoke behavior〉 of the SQL standard has the following differences.

- The default value of the SQL standard is RESTRICT.
- The SQL standard does not cover CASCADE CONSTRAINTS.

Table 20-6 SQL standard compatibility

Feature ID	Description	Compatibility
T311	Basic roles	X
F034	Extended REVOKE statement	X
S081	Subtables	X

For More Information

Refer to the followings.

- **GRANT privileges TO**
- **〈database privilege〉**
- **〈tablespace privilege〉**
- **〈schema privilege〉**
- **〈table privilege〉**
- **Column privilege**
- **〈sequence privilege〉**

20.14 ROLLBACK

Function

It rolls back a transaction, or the operation after the savepoint.

Syntax

```
<rollback statement> ::=
    ROLLBACK [ WORK ] [ <rollback force clause> ¦ <savepoint clause> ]
    ;
<rollback force clause> ::=
    FORCE 'xid_string' [ COMMENT 'comment_string' ]
<savepoint clause> ::=
    TO SAVEPOINT savepoint_name
```

Syntax Rules and Parameters

WORK

It is a reserved word which does not affect the operation.

<rollback force clause>

It is used to manually rollback the distributed transaction.

- FORCE 'xid_string'
  - It rolls back the distributed transaction corresponding to 'xid_string'.
  - 'xid_string' consists of 'format_id.transaction_id.branch_id'.
- COMMENT 'comment_string'
  - It specifies the comment on a transaction when rolling back the distributed transaction.

〈savepoint clause〉

It specifies the rollback scope of the current transaction.

- If it is omitted
  - It undoes all operations of the current transaction.
  - It ends the transaction.
  - It deletes all savepoints.
  - It releases all transaction locks.

- TO SAVEPOINT savepoint_name
  - It undoes the operations of the current transaction since savepoint_name.
  - It does not end the transaction.
  - It deletes all savepoints since savepoint_name.
  - It releases all transaction locks acquired since savepoint_name.

Description

ROLLBACK statement undoes the following statements performed in the transaction.

- Data Manipulation Language (DML) statement
  - The statements to update data, such as INSERT, UPDATE and DELETE
- Data Definition Language (DDL) statement
  - The statements to alter the structure and definition of the object such as CREATE, DROP, ALTER, TRUNCATE, GRANT and REVOKE

Exceptionally, the following statements of DDL which deals with OS resources or alters the DATA TYPE ca n not be rolled back, but are automatically committed when executing the statement.

- **CREATE TABLESPACE**
- **DROP TABLESPACE**
- **ALTER TABLESPACE**
- ALTER TABLE .. ALTER COLUMN .. SET DATA TYPE: **〈alter column data type clause〉**

Examples

The following is an example of rolling back the INSERT statement.

```
gSQL> INSERT INTO t1 VALUES ( 1, 'anonymous' );
1 row created.
gSQL> SELECT * FROM t1;
ID DATA
-- ---------
 1 anonymous
1 row selected.
gSQL> ROLLBACK;
Rollback complete.
gSQL> SELECT * FROM t1;
no rows selected.
```

The following is an example of ROLLBACK after performing the DROP TABLE statement.

```
gSQL> DROP TABLE t1;
Table dropped.
gSQL> SELECT * FROM t1;
ERR-42000(16040): table or view does not exist :
SELECT * FROM t1
              *
ERROR at line 1:
gSQL> ROLLBACK;
Rollback complete.
gSQL> SELECT * FROM t1;
ID DATA
-- ---------
 1 anonymous
1 row selected.
```

Compatibility

Table 20-7 SQL standard compatibility

Feature ID	Description	Compatibility
T271	Savepoints	O
T261	Chained transactions	X

For More Information

Refer to the followings.

- COMMIT
- SAVEPOINT savepoint_specifier

20.15 SAVEPOINT savepoint_specifier

Function

It defines a savepoint.

Syntax

```
<savepoint statement> ::=
    SAVEPOINT savepoint_name
    ;
```

Syntax Rules and Parameters

savepoint_name

It is a name of the savepoint.
If the savepoint name is as same as the existing savepoint name, then the existing savepoint is deleted.
The length of the savepoint name should be shorter than 128 bytes.

Description

The defined savepoint is used by ROLLBACK TO SAVEPOINT statement (refer to **ROLLBACK**.), and DML or DDL statement which has been performed up to the savepoint is rolled back. Then the locks acquired by using that statement are released, too.

The defined savepoint is automatically deleted when the transaction is committed or rolled back, or it can be explicitly deleted by using **RELEASE SAVEPOINT savepoint_specifier**.

Example

The following is an example of defining the savepoint and using ROLLBACK TO SAVEPOINT statement.

```
gSQL> SAVEPOINT sp1;
Savepoint created.
gSQL> INSERT INTO t1 VALUES ( 1, 'anonymous' );
1 row created.
gSQL> SAVEPOINT sp2;
Savepoint created.
gSQL> INSERT INTO t1 VALUES ( 2, 'someone' );
1 row created.
gSQL> SAVEPOINT sp3;
Savepoint created.
gSQL> INSERT INTO t1 VALUES ( 3, 'anyone' );
1 row created.
gSQL> SELECT * FROM t1;
ID DATA
-- ---------
 1 anonymous
 2 someone
 3 anyone
3 rows selected.
gSQL> ROLLBACK TO SAVEPOINT sp3;
Rollback complete.
gSQL> SELECT * FROM t1;
ID DATA
-- ---------
 1 anonymous
 2 someone
2 rows selected.
gSQL> ROLLBACK TO SAVEPOINT sp2;
Rollback complete.
gSQL> SELECT * FROM t1;
ID DATA
-- ---------
 1 anonymous
1 row selected.
gSQL> ROLLBACK TO SAVEPOINT sp1;
Rollback complete.
```

```
gSQL> SELECT * FROM t1;
no rows selected.
```

Compatibility

Table 20-8 SQL standard compatibility

Feature ID	Description	Compatibility

For More Information

Refer to the followings.

- **COMMIT**
- **ROLLBACK**
- **RELEASE SAVEPOINT savepoint_specifier**

20.16 SELECT

query expression

Function

It retrieves desired rows from one or more tables or views.

Syntax

```
<query expression> ::=
    [ <with clause> ] <query expression body> [ <order by clause> ] [ <offset limit clause> ]
<query expression body> ::=
      <query term>
    ¦ <set operator>
<query term> ::=
      <query specification>
    ¦ <left paren> <query expression body> [ <order by clause> ] [ <offset limit clause> ]
<right paren>
```

Invocation and Access Rules

One of the following privileges for all tables used in the statement is required for a user to perform <query expression>.

- SELECT(columns) ON TABLE for all used columns of table in the statement
- (SELECT or CONTROL TABLE) ON TABLE for the table
- (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

<with clause>

<with clause> defines the temporary result set, and it refers to that result set.
For more information, refer to **with clause**.

〈set operator〉

It performs a set operation among the subqueries.
For more information, refer to **set operator**.

〈query specification〉

It specifies a single subquery.
For more information, refer to **〈query specification〉**.

〈order by clause〉

It specifies sorting information of a query result.
For more information, refer to **order by clause**.

〈offset limit clause〉

It specifies the number of rows to skip and the number of rows to fetch from the query result set.
For more information, refer to **offset limit clause**.

Description

It specifies a query with SELECT statement.
〈with clause〉, 〈order by clause〉, 〈offset limit clause〉 can be omitted.
Two or more subqueries can be specified by using 〈set operator〉.

Examples

The following is an example of SELECT statement.

```
gSQL> SELECT s_name, s_nation FROM supplier;
S_NAME                    S_NATION
------------------------- -------------
Supplier#1                FRANCE
Supplier#2                KOREA
Supplier#3                GERMANY
Supplier#4                UNITED STATES
Supplier#5                CANADA
5 rows selected.
```

The following is an example of the SELECT statement which uses 〈order by clause〉.

```
gSQL> SELECT s_name, s_nation FROM supplier ORDER BY s_name DESC;
S_NAME                    S_NATION
------------------------- -------------
Supplier#5                CANADA
Supplier#4                UNITED STATES
Supplier#3                GERMANY
Supplier#2                KOREA
Supplier#1                FRANCE
5 rows selected.
```

The following is an example of the SELECT statement which uses <offset limit clause>.

```
gSQL> SELECT s_name, s_nation FROM supplier OFFSET 1;
S_NAME                    S_NATION
------------------------- -------------
Supplier#2                KOREA
Supplier#3                GERMANY
Supplier#4                UNITED STATES
Supplier#5                CANADA
4 rows selected.
gSQL> SELECT s_name, s_nation FROM supplier LIMIT 1;
S_NAME                    S_NATION
------------------------- --------
Supplier#1                FRANCE
1 row selected.
```

The following is an example of the SELECT statement which uses <order by clause> and <offset limit claus e>.

```
gSQL> SELECT s_name, s_nation FROM supplier ORDER BY s_name DESC OFFSET 3 LIMIT 1;
S_NAME                    S_NATION
------------------------- --------
Supplier#2                KOREA
1 row selected.
```

The following is an example of SELECT statement which uses <with clause>.

```
* Non Recursive CTE
gSQL> WITH revenue ( supplier_no, total_revenue ) AS
      (
            SELECT
                  l_suppkey,

with clause

Function

<with clause> defines the temporary result set, and it refers to that result set.
The result set a temporary result set with a given name, and it is defined and referred in SELECT statemen t. It is called as Common Table Expression (CTE).

Syntax

```
<with clause> ::=
    WITH <with list>
<with list> ::=
    <with list element> [ { <comma> <with list element> }... ]
<with list element> ::=
    <query name> [ <left paren> <with column list> <right paren> ]
        AS <table subquery> [ <search or cycle clause> ]
<with column list> ::=
    <column name list>

<search or cycle clause> ::=
    <search clause>
  ¦ <cycle clause>
  ¦ <search clause> <cycle clause>
<search clause> ::=
    SEARCH <recursive search order> SET <sequence column>
<recursive search order> ::=
    DEPTH FIRST BY <ordering column list>
  ¦ BREADTH FIRST BY <ordering column list>
<ordering column list> ::=
    <ordering column> [ { <comma> <ordering column> }... ]
<ordering column> ::=
    <column name> [ ASC ¦ DESC ] [ NULLS FIRST ¦ NULLS LAST ]
<sequence column> ::=
    <column name>
<cycle clause> ::=
    CYCLE <cycle column list> SET <cycle mark column> TO <cycle mark value>
        DEFAULT <non-cycle mark value>
<cycle column list> ::=
    <cycle column> [ { <comma> <cycle column> }... ]
```

```
<cycle column> ::=
    <column name>

<cycle mark column> ::=
    <column name>

<cycle mark value> ::=
    <value expression>
<non-cycle mark value> ::=
    <value expression>
```

Invocation and Access Rules

It is supported in <query expression> statement, and the user should satisfy the access privilege of <query expression> to perform it.
For more information, refer to **query expression**.

Syntax Rules and Parameters

<with list>

It can define multiple <with list element>.

<with list element>

It defines the temporary result set of specified <query name>.
<with list element> is called as Common Table Expression (CTE).
CTE is divided into a recursive CTE and a non-recursive CTE.
For more information, refer to **Description**.

- Referring to CTE
  - Referring to CTE is restricted according to the described sequence.
  - CTE described before the current CTE can be referenced.
  - CTE described after the current CTE can not be referenced.
- Non-recursive CTE
  - CTE described before the current CTE can be referenced in <with list element>.
- Recursive CTE
  - Either self CTE, or CTE described before the current CTE can be referenced in <with list element>.
  - Self-reference CTE is allowed only once within CTE.

```
--# success : non recursive CTE
WITH CTE_1( c1 ) AS
    (
         SELECT i1
           FROM t1
    ),
    CTE_2( c2 ) AS
    (
         SELECT c1
           FROM CTE_1       ❶ Referring to the leading CTE
    )
SELECT c2 FROM CTE_2;
--# error : non recursive CTE
WITH CTE_1( c1 ) AS
    (
         SELECT c2
           FROM CTE_2       ❷ Referring to the trailing CTE
    ),
    CTE_2( c2 ) AS
    (
         SELECT i1
           FROM t1
    )
SELECT c1 FROM CTE_1;
```

```
--# success : recursive CTE
WITH CTE_1( c1 ) AS
     (
          SELECT i1
            FROM t1
     ),
     CTE_2( c2 ) AS
     (
          SELECT c1
            FROM CTE_1          ❶ Referring to the leading CTE
     ),
     CTE_3( c3 ) AS
     (
          SELECT 1
            FROM CTE_1
          UNION ALL
```

```
          SELECT 1
           FROM CTE_2, CTE_3      ❷ Referring to the leading CTE or self CTE
     )
SELECT c3 FROM CTE_3;
--# error : recursive CTE
WITH CTE_RECURSIVE( c1 ) AS
   (
          SELECT i1
            FROM t1
          WHERE i1 IS NULL
          UNION ALL
          SELECT 1
            FROM CTE_RECURSIVE A, CTE_RECURSIVE B    ❸ Self-reference CTE is allowed only once
          WHERE 1 = 0
     )
SELECT c1 FROM CTE_RECURSIVE;
```

〈query name〉

〈query name〉 should not be duplicated within WITH clause.

〈with column list〉

Recursive CTE can not omit 〈with column list〉.

〈search clause〉

- Non-recursive CTE
  - It can not describe 〈search clause〉.
- Recursive CTE
  - It describes the sort order of CTE result records.

- 〈recursive search order〉
  - DEPTH FIRST BY
    - Child rows are returned before sibling rows are returned.
  - BREADTH FIRST BY
    - Sibling rows are returned before child rows are returned.

- 〈ordering column list〉
  - It specifies the ordering of column list.
  - Sort order
    - ASC

        - DESC
        - If not specified, the default value is ASC.
    - Null ordering
        - NULLS FIRST
        - NULLS LAST
        - If not specified, the default value is NULLS LAST.
    - It should describe <with column list> declared in <with list element>.
    - It does not support LONG type (LONG VARCHAR, LONG VARBINARY).

- <sequence column>
    - It stores the sequence of CTE result records.
    - <column name> should not be a duplicate of following items.
        - The column name declared in <with column list> of <with list element>
        - The column name declared in <cycle column list> of <cycle clause>

<cycle clause>

- Non-recursive CTE
    - It can not describe <cycle clause>.
- Recursive CTE
    - If <cycle clause> is omitted, it returns an error when cycle occurs.

It stores <cycle mark value> or <non-cycle mark value> in <cycle mark column> according to whether cycle occurs.

- <cycle column list>
    - It should describe <with column list> declared in <with list element>.

- <cycle mark column>
    - <column name> should not be a duplicate of following items.
        - The column name declared in <with column list> of <with list element>
        - The column name declared in <sequence column> of <search clause>

- <cycle mark value> or <non-cycle mark value>
    - It can describe 1 byte character only.

Description

<with clause> defines a temporary result set, and it can refer to that result set.
It is defined and referenced within SELECT statement, and it is a temporary result set with a given name.
It is called as Common Table Expression (CTE).
CTE is classified into recursive CTE and non-recursive CTE.

- Recursive CTE: It refers to CTE which is currently defined within CTE (self-reference CTE).

```
WITH RECURSIVE_CTE ( c1 ) AS
     (
          SELECT 1
            FROM dual
          UNION ALL
          SELECT c1 + 1
            FROM RECURSIVE_CTE
           WHERE c1 < 10
     )
SELECT c1 FROM RECURSIVE_CTE;
```

- Non-recursive CTE: It is CTE other than recursive CTE.

```
WITH NON_RECURSIVE_CTE ( c1 ) AS
     (
          SELECT i1
            FROM t1
          UNION ALL
          SELECT i1
            FROM t2
     )
SELECT c1 FROM NON_RECURSIVE_CTE;
```

〈with clause〉 can be described in SELECT, INSERT, UPDATE, DELETE, CREATE TABLE AS SELECT, CREAT E VIEW statement.

〈with list element〉

It defines the temporary result set of the described 〈query name〉.
〈with list element〉 is called as Common Table Expression (CTE).
CTE is classified into recursive CTE and non-recursive CTE.

- Recursive CTE
  - It refers to CTE which is currently defined within CTE (self-reference CTE).
  - The query block including the self-reference CTE is called as a recursive member query.
  - The query block other than a recursive member query is called as an anchor member query.
  - The recursive member query and the anchor member query should be composed of UNION ALL.
  - Only one recursive member query can be described.

- Non-recursive CTE: It is CTE other than recursive CTE.

```
WITH CTE_RECURSIVE( c1, c2 ) AS
    (
         SELECT i1, i2                          ❶ Anchor member query
           FROM t1
          WHERE i2 IS NULL
         UNION ALL
         SELECT i1, i2                          ❷ Recursive member query
           FROM CTE_RECURSIVE, t1       ❸ Self reference
          WHERE CTE_RECURSIVE.c1 = t1.i2
    )
SELECT c1, c2 FROM CTE_RECURSIVE;
```

- The recursive member query can not include the following items.
  - GROUP BY or DISTINCT clause
    - (X) SELECT i1, i2 FROM CTE_RECURSIVE, t1 WHERE CTE_RECURSIVE.c1 = t1.i2 GROUP BY i1, i2
    - (X) SELECT DISTINCT i1, i2 FROM CTE_RECURSIVE, t1 WHERE CTE_RECURSIVE.c1 = t1.i2
  - Referring to CTE in the inner part of LEFT, RIGHT, OUTER JOIN
    - (X) SELECT i1, i2 FROM t1 LEFT OUTER JOIN CTE_RECURSIVE ON t1.i2 = CTE_RECURSIVE.c1
  - Aggregation function
    - (X) SELECT MAX(i1), MAX(i2) FROM CTE_RECURSIVE, t1 WHERE CTE_RECURSIVE.c1 = t1.i2
  - Subquery including self-reference CTE
    - (X) SELECT i1, i2 FROM (SELECT * FROM CTE_RECURSIVE) cte, t1 WHERE cte.c1 = t1.i2

〈search clause〉

It describes the sort order of CTE result records.
Sibling rows are sorted with 〈ordering column list〉, it specifies the returning order of sibling rows and child rows for the sorted records.
The sequence of result records are stored in 〈sequence column〉.

- DEPTH FIRST BY
  - Child rows are returned before sibling rows are returned.
- BREADTH FIRST BY
  - Sibling rows are returned before child rows are returned.

```
gSQL>
SELECT * FROM t1;

ABX  AB       5
AC   A        6
ACX  AC       7
7 rows selected.
```

〈cycle clause〉

If 〈cycle clause〉 statement is not described, then an error occurs when cycle occurs.

〈cycle column list〉 is used to check cycle.
It stores 〈cycle mark value〉 or 〈non-cycle mark value〉 in 〈cycle mark column〉 according to whether cycle occurs.
Only 1 byte character can be described in 〈cycle mark value〉 or 〈non-cycle mark value〉.
〈cycle mark value〉 is stored in 〈cycle mark column〉 of the record where cycle occurred. In this case, it sto ps further recursion, and returns only until the record where cycle occurred
The recursion continuously proceeds for sibling rows where cycle does not occurred.

```
gSQL>
SELECT * FROM t1;
I1  I2
--- ---
A   ---
AA  A
AB  A
AC  A
AA  AA
AAX AA
ABX AB
ACX AC
8 rows selected.
```

```

Examples

The following is an example of SELECT statement which uses WITH clause.

- Non-recursive CTE

```
gSQL>
WITH revenue ( supplier_no, total_revenue ) AS
      (
            SELECT
                  l_suppkey,
                  SUM(l_extendedprice * (1 - l_discount))
             FROM lineitem
            WHERE l_shipdate >= DATE '1996-01-01'
              AND l_shipdate < DATE '1996-01-01' + INTERVAL '3' MONTH
            GROUP BY
                  l_suppkey
      )
select
       s_suppkey,
       s_name,
       s_address,
       s_phone,
       ROUND( total_revenue, 2 ) as total_revenue
  from
       supplier,
       revenue
 where
       s_suppkey = supplier_no
   and total_revenue = (
                           select
                                 max(total_revenue)
                             from
                                 revenue
                       )
order by
      s_suppkey;
S_SUPPKEY S_NAME                    S_ADDRESS         S_PHONE         TOTAL_REVENUE
```

```
--------- ------------------------- ------------------ --------------- -------------
     8449 Supplier#000008449        Wp34zim9qYFbVctdW 20-469-856-8873    1772627.21
1 row selected.
```

- Recursive CTE

```
gSQL>
WITH GenerateRecord ( c1, c2 ) AS
     (
          SELECT 1, 11
            FROM dual
          UNION ALL
          SELECT c1 + 1, c2 + 1
            FROM GenerateRecord
           WHERE c1 < 10
     )
SELECT c1, c2 FROM GenerateRecord;
C1 C2
-- --
 1 11
 2 12
 3 13
 4 14
 5 15
 6 16
 7 17
 8 18
 9 19
10 20
10 rows selected.
```

The following is the result of retrieving record in emp table which will be used in the example of WITH cla use.

```
gSQL>
SELECT * FROM emp;
NAME    MGR
------- -------
Kelly   null
Bill    Kelly
Jackson Kelly
Joe     Kelly
```

```
Scott   Bill
Larry   Bill
Paul    Jackson
Bill    Bill
8 rows selected.
```

The following is an example of using SEARCH BREADTH FIRST BY.

- Cycle occurred

```
gSQL>
WITH w_emp( w_name, w_mgr ) AS
     (
         SELECT name, mgr
           FROM emp
          WHERE mgr IS NULL
         UNION ALL
         SELECT name, mgr
           FROM emp, w_emp
          WHERE mgr = w_emp.w_name
     ) SEARCH BREADTH FIRST BY w_name SET w_seq
SELECT w_name, w_mgr, w_seq
  FROM w_emp;
ERR-42000(16511): cycle detected while executing recursive WITH query
```

- Retrieve the data by describing cycle clause in the statement above after cycle occurred.

```
gSQL>
WITH w_emp( w_name, w_mgr ) AS
     (
         SELECT name, mgr
           FROM emp
          WHERE mgr IS NULL
         UNION ALL
         SELECT name, mgr
           FROM emp, w_emp
          WHERE mgr = w_emp.w_name
     ) SEARCH BREADTH FIRST BY w_name SET w_seq
       CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
SELECT w_name, w_mgr, w_seq, w_cycle
  FROM w_emp;
W_NAME  W_MGR   W_SEQ W_CYCLE
```

```
------- ------- ----- -------
Kelly   null        1 F
Bill    Kelly       2 F
Jackson Kelly       3 F
Joe     Kelly       4 F
Bill    Bill        5 T
Larry   Bill        6 F
Paul    Jackson     7 F
Scott   Bill        8 F
8 rows selected.
```

The following is an example of using SEARCH DEPTH FIRST BY.

```
gSQL>
WITH w_emp( w_name, w_mgr ) AS
     (
          SELECT name, mgr
            FROM emp
           WHERE mgr IS NULL
          UNION ALL
          SELECT name, mgr
            FROM emp, w_emp
           WHERE mgr = w_emp.w_name
     ) SEARCH DEPTH FIRST BY w_name SET w_seq
       CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
SELECT w_name, w_mgr, w_seq, w_cycle
  FROM w_emp;
W_NAME  W_MGR   W_SEQ W_CYCLE
------- ------- ----- -------
Kelly   null        1 F
Bill    Kelly       2 F
Bill    Bill        3 T
Larry   Bill        4 F
Scott   Bill        5 F
Jackson Kelly       6 F
Paul    Jackson     7 F
Joe     Kelly       8 F
8 rows selected.
```

The following is an example of using *with clause* in CREATE TABLE AS SELECT statement.

```
gSQL>
CREATE TABLE new_emp AS
WITH w_emp( w_name, w_mgr ) AS
     (
          SELECT name, mgr
            FROM emp
           WHERE mgr IS NULL
          UNION ALL
          SELECT name, mgr
            FROM emp, w_emp
           WHERE mgr = w_emp.w_name
     ) SEARCH BREADTH FIRST BY w_name SET w_seq
       CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
SELECT w_name, w_mgr, w_seq, w_cycle
  FROM w_emp;
Table created.
```

The following is an example of using *with clause* in INSERT statement.

```
gSQL>
INSERT INTO new_emp
WITH w_emp( w_name, w_mgr ) AS
     (
          SELECT name, mgr
            FROM emp
           WHERE mgr = 'Bill'
          UNION ALL
          SELECT name, mgr
            FROM emp, w_emp
           WHERE mgr = w_emp.w_name
     ) SEARCH BREADTH FIRST BY w_name SET w_seq
       CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
SELECT w_name, w_mgr, w_seq, w_cycle
  FROM w_emp;
6 rows created.
```

The following is an example of using *with clause* in UPDATE statement.

```
gSQL>
UPDATE new_emp SET w_name = NULL
 WHERE ( w_name, w_mgr )
```

```
       IN ( WITH w_emp( w_name, w_mgr ) AS
                (
                    SELECT name, mgr
                      FROM emp
                     WHERE mgr = 'Bill'
                    UNION ALL
                    SELECT name, mgr
                      FROM emp, w_emp
                     WHERE mgr = w_emp.w_name
                ) SEARCH BREADTH FIRST BY w_name SET w_seq
                  CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
             SELECT w_name, w_mgr
               FROM w_emp );
9 rows updated.
```

The following is an example of using *with clause* in DELETE statement.

```
gSQL>
DELETE FROM new_emp
WHERE ( w_mgr )
      IN ( WITH w_emp( w_name, w_mgr ) AS
                (
                    SELECT name, mgr
                      FROM emp
                     WHERE mgr = 'Bill'
                    UNION ALL
                    SELECT name, mgr
                      FROM emp, w_emp
                     WHERE mgr = w_emp.w_name
                ) SEARCH BREADTH FIRST BY w_name SET w_seq
                  CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
           SELECT w_mgr
             FROM w_emp );
9 rows deleted.
```

The following is an example of using *with clause* in CREATE VIEW statement.

```
gSQL>
CREATE VIEW v_emp AS
WITH w_emp( w_name, w_mgr ) AS
     (
          SELECT name, mgr
```

```
            FROM emp
           WHERE mgr IS NULL
          UNION ALL
          SELECT name, mgr
            FROM emp, w_emp
           WHERE mgr = w_emp.w_name
     ) SEARCH BREADTH FIRST BY w_name SET w_seq
       CYCLE w_name SET w_cycle TO 'T' DEFAULT 'F'
SELECT w_name, w_mgr, w_seq, w_cycle
  FROM w_emp;
View created.
```

query specification

Function

It specifies the table which is derived from the result of <table expression>.

Syntax

```
<query specification> ::=
    SELECT [ <hint clause> ] [ <set quantifier> ] <select list> <table expression>
<set quantifier> ::=
      ALL
    ¦ DISTINCT
<table expression> ::=
      <from clause> [ <where clause> ] [ <hierarchical query clause> ] [ <group by clause> ] [
<having clause> ] [ <window clause> ]
```

Invocation and Access Rules

The user should satisfy one of the following conditions to perform <query specification>.

- The owner of that table
- SELECT privilege for the table
- The user owns one of SELECT TABLE, CONTROL TABLE, CONTROL privileges for the schema to which the table belongs
- The user owns the SELECT TABLE privilege for the database

Syntax Rules and Parameters

<hint clause>

It specifies the hint for query execution.
For more information, refer to **SQL Hint**.

<set quantifier>

It specifies whether to remove a duplicate of the query result.
If it is omitted, it operates in the same way as ALL.

〈select list〉

It specifies the column to be retrieved among query results.
For more information, refer to **select list**.

〈from clause〉

It specifies the tables to be retrieved.
For more information, refer to **from clause**.

〈where clause〉

It specifies conditions for retrieving.
For more information, refer to **where clause**.

〈hierarchical query clause〉

It specifies to retrieve the hierarchical model data in a hierarchy.
For more information, refer to **hierarchical query clause**.

〈group by clause〉

It specifies grouping of the query result.
For more information, refer to **group by clause**.

〈having clause〉

It specifies conditions for the grouping result.
For more information, refer to **having clause**.

〈window clause〉

It defines the execution range of the window function.
For more information, refer to **window clause**.

Description

〈hint clause〉

〈hint clause〉 is a comment which the user uses to directly command an optimizer how to execute SQL st
atement.

The optimizer of GOLDILOCKS preferentially applies 〈hint clause〉 specified by a user.
If it is not applicable, the optimizer selects the best execution plan through the cost calculation.

Even when a syntactic error occurs in 〈hint clause〉, GOLDILOCKS is set to ignore and perform it by defaul t. Set **HINT_ERROR** property to *on*, then execute the query to check if a syntactic error exist in 〈hint claus e〉.

〈set quantifier〉

〈set quantifier〉 sets whether to remove duplicates from the result set consisting of the 〈select list〉 expre ssions.

- ALL: It does not remove the duplicates from the result set.
- DISTINCT: It removes the duplicates from the result set.
- If it is omitted, it is operated by default which is as same as ALL.

〈select list〉

It specifies columns to be retrieved from the query result.
They are listed by separating by a comma (,).
An asterisk (*) is used to specify all columns in 〈from clause〉.

〈from clause〉

〈from clause〉 specifies the tables or views to be retrieved.

〈where clause〉

〈where clause〉 specifies the conditions to get only the desired results from the result obtained from 〈fro m clause〉.

〈hierarchical query clause〉

It specifies to retrieve the hierarchical model data in a hierarchy.
It returns table records in a hierarchy of depth-first sequence by using the launch condition and sub-conn ectivity condition.

〈group by clause〉

〈group by clause〉 specifies the method of grouping the result set to which 〈where clause〉 was applied.

When 〈group by clause〉 is specified, the following expressions can be used in 〈select list〉.

- Constant number

- Expression specified in *group by*
- Operation expression specified in *group by*
- Aggregation function for an expression belonging to a group

〈having clause〉

〈having clause〉 specifies the retrieving condition for the grouped result set.
It is generally used together with 〈group by clause〉.

〈window clause〉

It specifies the execution range of the window function described in *select list* and *order by* clause

Examples

The following is an example of SELECT statement which uses 〈hint clause〉.

```
gSQL> SELECT /*+ INDEX_DESC(supplier, supplier_pk_index) */ s_name, s_nation FROM supplier;
S_NAME                    S_NATION
------------------------- -------------
Supplier#5                CANADA
Supplier#4                UNITED STATES
Supplier#3                GERMANY
Supplier#2                KOREA
Supplier#1                FRANCE
5 rows selected.
```

The following is an example of SELECT statement which uses 〈set quantifier〉.

```
gSQL> SELECT ALL p_type FROM part;
P_TYPE
------
COPPER
NICKEL
STEEL
NICKEL
STEEL
5 rows selected.
gSQL> SELECT DISTINCT p_type FROM part;
P_TYPE
------
COPPER
```

```
STEEL
NICKEL
3 rows selected.
```

The following is an example of SELECT statement which uses <where clause>.

```
gSQL> SELECT p_name, p_brand, p_type, p_size FROM part where p_size < 10;
P_NAME P_BRAND    P_TYPE P_SIZE
------ ---------- ------ ------
Part#1 Brand#1    COPPER      7
Part#2 Brand#1    NICKEL      1
2 rows selected.
```

The following is an example of retrieving the hierarchy data of SELECT statement by using <hierarchical query clause>.

```
gSQL> SELECT *
        FROM emp
      START WITH mgr IS NULL
      CONNECT BY NOCYCLE mgr = PRIOR name
      ORDER SIBLINGS BY name;
NAME    MGR
------- -------
Kelly   null
Bill    Kelly
Larry   Bill
Scott   Bill
Jackson Kelly
Paul    Jackson
Joe     Kelly
7 rows selected.
```

The following is an example of SELECT statement which uses <group by clause>.

```
gSQL> SELECT ps_partkey, SUM(ps_availqty) FROM partsupp GROUP BY ps_partkey;
PS_PARTKEY SUM(PS_AVAILQTY)
---------- ----------------
         1            11401
         2             8025
         3            13864
         4            11564
         5             8744
```

```
5 rows selected.
```

The following is an example of SELECT statement which uses <having clause>.

```
gSQL> SELECT ps_partkey, SUM(ps_availqty) FROM partsupp GROUP BY ps_partkey having
SUM(ps_availqty) > 10000;
PS_PARTKEY SUM(PS_AVAILQTY)
---------- ----------------
         1            11401
         3            13864
         4            11564
3 rows selected.
```

The following is an example of SELECT statement which uses <window clause>.

```
gSQL>
SELECT item_no,
       sales_date,
       sales,
       SUM( sales ) OVER W1 cumulative_sales,
       AVG( sales ) OVER w1 avg_sales
  FROM store
WINDOW w1 AS ( PARTITION BY item_no
               ORDER BY sales_date
               ROWS BETWEEN UNBOUNDED PRECEDING
                        AND CURRENT ROW );
ITEM_NO SALES_DATE SALES CUMULATIVE_SALES AVG_SALES
------- ---------- ----- ---------------- ---------
    100 2001-01-01   150              150       150
    100 2001-01-02   100              250       125
    100 2001-01-03   170              420       140
    100 2001-01-04    90              510     127.5
    100 2001-01-05   200              710       142
    235 2001-01-01    70               70        70
    235 2001-01-02   130              200       100
    235 2001-01-03   190              390       130
    235 2001-01-04   150              540       135
    235 2001-01-05    50              590       118
10 rows selected.
```

Compatibility

Table 20-10 SQL standard compatibility

Feature ID	Description	Compatibility
F801	Full set function	X
T051	Row types	X
T301	Functional dependencies	X
T325	Qualified SQL parameter references	X
T053	Explicit aliases for all-fields reference	O
T285	Enhanced derived column names	O

For More Information

Refer to **query expression**.

select list

Function

It specifies the columns to be retrieved from the query result.

Syntax

```
<select list> ::=
      <asterisk>
    ¦ <select sublist> [ { <comma> <select sublist> } ... ]
<select sublist> ::=
      <derived column>
    ¦ <qualified asterisk>
<qualified asterisk> ::=
      <asterisked identifier chain> <period> <asterisk>
<asterisked identifier chain> ::=
    <asterisked identifier> [ { <period> <asterisked identifier> } ... ]
<derived column> ::=
    <value expression> [ <as clause> ]
<as clause> ::=
    [ AS ] <column name>
```

Invocation and Access Rules

If columns or subqueries exist in <select list> statement, the user should satisfy the followings.

- The access privileges for the columns
- The access privileges for the table and columns of the subqueries

Syntax Rules and Parameters

<select list>

It has <asterisk> or <select sublist>.

〈asterisk〉

- 〈asterisk〉 can be used only alone in 〈select list〉.
  - (O) SELECT * FROM t1;
  - (X) SELECT *, c1 FROM t1;

〈select sublist〉

- It has 〈derived column〉 or 〈qualified asterisk〉.
  - SELECT c1, c2 FROM t1;
  - SELECT t1.* FROM t1;
- 〈derived column〉 can change the output name by using *AS*, and *AS* can be omitted.
  - SELECT c1 AS col1, c2 AS col2 AS FROM t1;
  - SELECT c1 col1, c2 col2 FROM t1;
- If two or more 〈select sublist〉 are specified, each 〈select sublist〉 should be separated by a comma (,).
  - (O) SELECT c1, c2 FROM t1;
  - (O) SELECT c1, c2, t1.* FROM t1;
  - (X) SELECT c1 c2 FROM t1;
    - c2 is processed as ALIAS.
  - (X) SELECT c1 c2 c3 FROM t1;

Description

〈select list〉

〈select list〉 specifies the columns to be included in the result set.

〈asterisk〉

〈asterisk〉 sets all columns in 〈from clause〉 as a select list.

〈select sublist〉

〈select sublist〉 has 〈derived column〉 or 〈qualified asterisk〉.

- 〈qualified asterisk〉
  - It sets all columns belonging to a specific table or a view as a select list.
- 〈derived column〉
  - It can specifies a column or 〈value expression〉.
  - The column name can be updated by using 〈as clause〉, and *AS* can be omitted.
  - If 〈from clause〉 has tables with the same column name, then the table name or the table alias sh ould be specified to refer to that columns.

    - SELECT T1.C1, T2.C1 FROM T1, T2;
    - SELECT A.C1, B.C1 FROM T1 A, T2 B;

If two or more <select sublist> are specified, each <select sublist> should be separated by a comma (',').

Names to Be Set in select list

- When <column name> is specified in <derived column>, that name is set as a select list name
  - SELECT i1 AS name FROM t1;
- When <column name> is not specified in <derived column>
  - When <derived column> is a single column reference
    - The column name of a single column is set as a select list name.
    - SELECT i1 FROM t1;
  - If <derived column> is not a column but it is an expression
    - The select list name is not set.
    - SELECT i1 + 100 FROM t1;
    - If it is written in CREATE TABLE AS SELECT clause, the column name should be specified.
    - CREATE TABLE t2 AS SELECT i1 + 100 AS sum_i1 FROM t1;

Examples

The following is an example of SELECT statement which uses <asterisk>.

```
gSQL> SELECT * FROM supplier;
S_SUPPKEY S_NAME                    S_NATION      S_PHONE
--------- ------------------------- ------------- ---------------
        1 Supplier#1                FRANCE        27-918-335-1736
        2 Supplier#2                KOREA         15-679-861-2259
        3 Supplier#3                GERMANY       11-383-516-1199
        4 Supplier#4                UNITED STATES 25-843-787-7479
        5 Supplier#5                CANADA        21-151-690-3663
5 rows selected.
```

The following is an example of SELECT statement which uses <select sublist>.

```
gSQL> SELECT revenue.* FROM revenue;
SUPPLIER_NO TOTAL_REVENUE
----------- -------------
          1      11978.64
          2       20321.5
          3      41844.68
3 rows selected.
```

```
gSQL> SELECT supplier_no suppno, total_revenue AS TOTAL FROM revenue;
SUPPNO    TOTAL
------ --------
     1 11978.64
     2  20321.5
     3 41844.68
3 rows selected.
gSQL> SELECT 1, revenue.*, CAST( total_revenue AS NATIVE_INTEGER ) TOTAL FROM revenue;
1 SUPPLIER_NO TOTAL_REVENUE TOTAL
- ----------- ------------- -----
1           1      11978.64 11979
1           2       20321.5 20322
1           3      41844.68 41845
3 rows selected.
```

For More Information

Refer to **query specification**.

from clause

Function

It specifies the table which is derived from one or more tables.

Syntax

```
<from clause> ::=
    FROM <table reference list>
<table reference list> ::=
    <table reference> [ { , <table reference> } ... ]
<table reference> ::=
      <table factor>
    ¦ <joined table>
<table factor> ::=
    <table primary>
<table primary> ::=
      <table name> [ <cluster domain> ] [ [ AS ] <correlation name> ]
    ¦ <derived table> [ <cluster domain> ] [ [ AS ] <correlation name> [ <left paren> <derived
column list> <right paren> ] ]
    ¦ <lateral derived table> [ <cluster domain> ] [ [ AS ] <correlation name> [ <left paren>
<derived column list> <right paren> ] ]
    ¦ <table function derived table> [ [ AS ] <correlation name> ]
    ¦ <parenthesized joined table>
<derived table> ::=
    <table subquery>
<lateral derived table> ::=
    LATERAL <table subquery>
<parenthesized joined table> ::=
      <left paren> <parenthesized joined table> <right paren>
    ¦ <left paren> <joined table> <right paren>
<derived column list> ::=
    <column name list>
<cluster domain> ::=
    @ <cluster domain name>
<cluster domain name> ::=
      GLOBAL
    ¦ LOCAL
    ¦ LOCAL_OFFLINE
```

```
    ¦ <identifier>
<table function derived table> ::=
      TABLE <left paren> <table function expression> <right paren>
<table function expression> ::=
      <table function name> <left paren> [ <table function argument list> ] <right paren>
<table function argument list> ::=
      <value expression> [ <comma> ... ]
```

Invocation and Access Rules

The access privilege for the table or view specified in <table reference list> is required.

Syntax Rules and Parameters

<table reference list>

- One or more tables can be specified in <table reference list> by using a comma (,).
- When two or more tables are specified
  - The evaluation order for the tables is from left to right.
  - When * is specified in <select list>, the columns are sequentially mapped in <select list> from the l eft table to the right table.

<table primary>

- An alias name can be specified by using <correlation name>.
  - SELECT * FROM t1 AS a, t2 AS b;
  - SELECT * FROM (SELECT i1 FROM t1) AS a;

- <derived table> as known as <table subquery>
  - can specify an alias name by using <correlation name>.
    - SELECT * FROM (SELECT i1, i2, i3 FROM t1) AS a;
  - can specify <derived column list>.
    - SELECT * FROM (SELECT i1, i2, i3 FROM t1) AS a(col1, col2, col3);
    - The number of <column name> in <derived column list> should be same as the number of tar gets in <select list> specified in <table subquery>.
    - It is sequentially mapped 1 :1 to the target in <select list> specified in <table subquery>.
    - It should use <column name> specified in <derived column list> to refer to <select list> of <ta ble subquery> in that <derived table>.

```
SELECT col1, col2
FROM ( SELECT i1, i2 FROM t1 ) AS a( col1, col2 )
```

```
WHERE col1 = 1 AND col2 = 1;
```

- 〈lateral derived table〉
  - If LATERAL is specified in front of 〈table subquery〉, then it becomes the lateral inline view.
  - The lateral inline view can refer to tables listed in FROM clause of the main query in all clauses wit hin 〈table subquery〉.
    - However, it can refer to only the table which was specified before the lateral inline view. If it i s RIGHT OUTER JOIN or FULL OUTER JOIN, then it can not refer to the table even when it was specified beforehand.

- 〈table function derived table〉
  - table function derived table is a logical table which consists of the result sets of executing the tab le function. For more information about the table function derived table, refer to **Table Function Derived Table**.
  - table function derived table specifies TABLE and the table function name to execute.
  - 〈table function argument list〉 of 〈table function expression〉 can refer to the columns of the tabl e listed before 〈table function derived table〉 in FROM clause.
    - However, if it is RIGHT OUTER JOIN or FULL OUTER JOIN, then it can not be referred even wh en the table is specified beforehand.

```
SELECT t1.col1, ft.rf2
FROM t1, TABLE( tablefunc( t1.col1 ) );
```

〈correlation name〉

- The same 〈correlation name〉 should not exist two or more in 〈table reference list〉.
- When 〈correlation name〉 is specified, 〈correlation name〉 should be used to refer to 〈table name〉 o r 〈derived table〉.
  - SELECT a.i1 FROM t1 AS a WHERE a.i1 > 3;
  - (X) SELECT t1.i1 FROM t1 AS a WHERE t1.i1 > 3;
- When specifying 〈correlation name〉, AS can be omitted.
  - SELECT a.i1 FROM t1 a;

〈derived column list〉

The same 〈column name〉 should not exist two or more in 〈derived column list〉.

〈cluster domain〉

- 〈cluster domain〉 can be specified in a table, a view, or a table subquery.
  - SELECT * FROM t1@G1;
  - It can not be specified in 〈parenthesized joined table〉.
    - (X) SELECT * FROM (t1 INNER JOIN t2 ON t1.sk = t2.sk)@G2;

- <cluster domain> can not be specified in a table or a view whose structure or data is to be altered.
  - (X) DELETE FROM t2@GLOBAL;
  - (X) UPDATE t1@GLOBAL SET i1 = 1;
  - (X) INSERT INTO t1@GLOBAL VALUES (1, 10);
  - (X) SELECT * FROM t1@GLOBAL FOR UPDATE;
  - (X) CREATE INDEX t1_idx ON t1@GLOBAL(i1);

<cluster domain name>

Only a cluster group name or a cluster member name can be <identifier> of <cluster domain name>.

- cluster group name
  - SELECT * FROM t1@G1;
- cluster member name
  - SELECT * FROM t1@G1N1;

Description

<table reference list>

Two or more tables can be specified in <table reference list> by using a comma (,).

- If two or more tables are specified, it operates in the same way as cross join each table from left to ri ght.
  - SELECT * FROM t1, t2;
  - <=> SELECT * FROM t1 CROSS JOIN t2;
- If the conditions to join two tables exist in <where clause>, the two tables operate in the same way as inner join which has <where clause> as a join condition.
  - SELECT * FROM t1, t2 WHERE t1.I1 = t2.I1;
  - <=> SELECT * FROM t1 INNER JOIN t2 ON t1.i1 = t2.i1;
- If outer join operator (+) is used in <where clause>, it operates in the same way as outer join.
  - For more information about outer join operator (+), refer to **OUTER JOIN**.

<table reference>

A single table, or view, table subquery, joined table can be <table reference>. Others except for the joine d table can have a correlation name.

For more information about joined table, refer to **joined table**.

〈table primary〉

The tables, views, table subqueries and 〈parenthesized joined table〉 can be 〈table primary〉.

The table, view, table subquery can have a correlation name, and AS can be omitted. If the correlation na me is specified, it should be used in everywhere referring to the table, view, table subquery such as 〈selec t list〉, 〈where clause〉.

The table subquery can specify 〈derived column list〉. The name specified in 〈derived column list〉 should be used in everywhere referring to table subquery column as like correlation name. To use 〈derived colu mn list〉 in the table subquery, the correlation name should be specified.

〈parenthesized joined table〉 specifies the logical join order for the table participating in the join operatio n. At this time, if all join operations for the tables enclosed with parentheses are cross join, inner join, the join order can be changed by an optimizer.

〈cluster domain〉

When 〈cluster domain〉 is omitted, it means the same as using GLOBAL as 〈cluster domain name〉.
For more information, refer to **Cluster Domain**.

〈cluster domain name〉

The reserved words defined in 〈cluster domain name〉 mean as follows.

- GLOBAL
  - It selects all cluster groups as a cluster domain.
- LOCAL
  - It selects only the server performing the user query as a cluster domain.
    - It brings data of G2N1 when performing the following query in G2N1.
    - SELECT * FROM t1@LOCAL;
- LOCAL_OFFLINE
  - It selects only the server performing the user query as a cluster domain to retrieve the offline tabl e data.
    - It brings data of offline table T1 in G2N1 when performing the following query in G2N1.
    - SELECT * FROM t1@LOCAL_OFFLINE;
  - If LOCAL_OFFLINE domain is specified in an online table, then an error occurs.

If 〈identifier〉 is specified in 〈cluster domain name〉, a cluster group or a cluster member with the corresp onding name is selected as **Cluster Domain**.

Examples

The following is an example of SELECT statement to query a single table by using <table name>.

```
gSQL> SELECT c_name, c_nation FROM customer;
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
Customer#3 KOREA
Customer#4 GERMANY
Customer#5 UNITED STATES
5 rows selected.
```

The following is an example of SELECT statement which uses <derived table>.

```
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer);
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
Customer#3 KOREA
Customer#4 GERMANY
Customer#5 UNITED STATES
5 rows selected.
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer) AS CUST ("CUSTOMER_NAME",
"CUSTOMER_NATION");
CUSTOMER_NAME CUSTOMER_NATION
------------- ---------------
Customer#1    KOREA
Customer#2    CANADA
Customer#3    KOREA
Customer#4    GERMANY
Customer#5    UNITED STATES
5 rows selected.
```

The following is an example of SELECT statement using <lateral derived table>.

```
gSQL> SELECT r_name, n_name
  FROM region, (  SELECT n_name
                    FROM nation
                   WHERE n_regionkey = r_regionkey
```

```
               ) v_nation
 WHERE r_name = 'ASIA';
ERR-42000(16036): 'R_REGIONKEY': invalid identifier :
                  WHERE n_regionkey = r_regionkey
                                      *
gSQL> SELECT r_name, n_name
  FROM region, LATERAL (  SELECT n_name
                            FROM nation
                           WHERE n_regionkey = r_regionkey
                       ) v_nation
 WHERE r_name = 'ASIA';
R_NAME                    N_NAME
------------------------- -------------------------
ASIA                      INDIA
ASIA                      INDONESIA
ASIA                      JAPAN
ASIA                      CHINA
ASIA                      VIETNAM
5 rows selected.
```

The following is an example of SELECT statement for a joined table which uses parentheses.

```
gSQL> SELECT customer.c_name, o_totalprice FROM (customer INNER JOIN orders ON
customer.c_custkey = orders.o_custkey);
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1    173665.47
Customer#2     46929.18
Customer#4    193846.25
Customer#3     32151.78
Customer#5     144659.2
5 rows selected.
```

The following is an example of SELECT statement which uses two table separated by a comma (,).

```
gSQL> SELECT c_name, o_totalprice FROM customer, orders;
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1    173665.47
Customer#1     46929.18
Customer#1    193846.25
Customer#1     32151.78
```

```
Customer#1     144659.2
Customer#2    173665.47
Customer#2     46929.18
Customer#2    193846.25
Customer#2     32151.78
Customer#2     144659.2
Customer#3    173665.47
Customer#3     46929.18
Customer#3    193846.25
Customer#3     32151.78
Customer#3     144659.2
Customer#4    173665.47
Customer#4     46929.18
Customer#4    193846.25
Customer#4     32151.78
Customer#4     144659.2
C_NAME     O_TOTALPRICE
---------- ------------
Customer#5    173665.47
Customer#5     46929.18
Customer#5    193846.25
Customer#5     32151.78
Customer#5     144659.2
25 rows selected.
```

The following is an example of SELECT statement which uses <cluster domain>.

- Using the reserved word GLOBAL

```
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer@GLOBAL);
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
Customer#3 KOREA
Customer#4 GERMANY
Customer#5 UNITED STATES
5 rows selected.
```

- Using the reserved word LOCAL

```
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer)@LOCAL;
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
2 rows selected.
```

- Using the cluster group name G1

```
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer@G1);
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
2 rows selected.
```

- Using the cluster member name G2N1

```
gSQL> SELECT * FROM (SELECT c_name, c_nation FROM customer@G2N1);
C_NAME     C_NATION
---------- -------------
Customer#3 KOREA
Customer#4 GERMANY
2 rows selected.
```

For More Information

Refer to **subquery**.

joined table

Function

It specifies the table derived from a cartesian product, inner join, outer join.

Syntax

```
<joined table> ::=
      <cross join>
    ¦ <qualified join>
    ¦ <natural join>
<cross join> ::=
    <table reference> CROSS JOIN <table factor>
<qualified join> ::=
    <table reference> [ <join type> ] JOIN <table reference> <join specification>
<natural join> ::=
    <table reference> NATURAL [ <join type> ] JOIN <table factor>
<join specification> ::=
      <join condition>
    ¦ <named columns join>
<join condition> ::=
    ON <search condition>
<named columns join> ::=
    USING ( <join column list> )
<join type> ::=
      INNER
    ¦ { LEFT ¦ RIGHT ¦ FULL } [ OUTER ]
<join column list> ::=
    <column name list>
```

Invocation and Access Rules

The access privilege for all tables and views specified in a joined table is required.

Syntax Rules and Parameters

〈cross join〉

〈join specification〉 specifying the join condition does not appear at the location of 〈cross join〉.
A single table, 〈table subquery〉 or 〈parenthesized joined table〉 can appear on the right of 〈cross join〉.

〈qualified join〉

- 〈join specification〉 specifying the join condition should be specified.
  - SELECT * FROM t1 INNER JOIN t2 ON t1.i1 = t2.i1;
  - SELECT * FROM t1 INNER JOIN t2 USING (i1);
- 〈join type〉 can be omitted, and it is processed as INNER when omitted.
  - SELECT * FROM t1 JOIN t2 ON t1.i1 = t2.i1;
  - 〈=〉 SELECT * FROM t1 INNER JOIN t2 ON t1.i1 = t2.i1;
- OUTER can be omitted in 〈join type〉.
  - SELECT * FROM t1 LEFT JOIN t2 ON t1.i1 = t2.i1;
  - 〈=〉 SELECT * FROM t1 LEFT OUTER JOIN t2 ON t1.i1 = t2.i1;
- If 〈join type〉 is OUTER JOIN, then only 〈join condition〉 can appear on 〈join specification〉.
  - SELECT * FROM t1 FULL OUTER JOIN t2 ON t1.i1 = t2.i1;
  - (X) SELECT * FROM t1 FULL OUTER JOIN t2 USING (i1);

〈natural join〉

- 〈join specification〉 specifying the join condition does not appear at the location of 〈natural join〉.
- A single table, 〈table subquery〉 or 〈parenthesized joined table〉 can appear on the right of 〈natural j oin〉.
- 〈join type〉 can be omitted. When it is omitted, it performs INNER.
  - SELECT * FROM t1 NATURAL JOIN t2;
  - 〈=〉 SELECT * FROM t1 NATURAL INNER JOIN t2;
- It does not allow OUTER in 〈join type〉.
  - (X) SELECT * FROM t1 NATURAL LEFT OUTER JOIN t2;
- If the same 〈column name〉 does not exist between the left row and right row of NATURAL JOIN, it p erforms 〈cross join〉.
  - t1(c1 INTEGER, c2 INTEGER);
  - t2(c3 INTEGER, c4 INTEGER);
  - SELECT * FROM t1 NATURAL INNER JOIN t2;
  - 〈=〉 SELECT * FROM t1 CROSS JOIN t2;
- If the same 〈column name〉 exists between the left row and right row of NATURAL JOIN, it is perfor med as if USING clause is specified.
  - t1(c1 INTEGER, c2 INTEGER);
  - t2(c2 INTEGER, c3 INTEGER);
  - SELECT * FROM t1 NATURAL INNER JOIN t2;
  - 〈=〉 SELECT * FROM t1 INNER JOIN t2 USING(c2);

〈join specification〉

- Only one of 〈join condition〉 or 〈named columns join〉 can be specified.
  - 〈join condition〉
    - SELECT * FROM t1 INNER JOIN t2 ON t1.i1 = t2.i1;
  - 〈named columns join〉
    - SELECT * FROM t1 INNER JOIN t2 USING (i1);
- When 〈named columns join〉 is specified
  - One or more column name should be specified in 〈join column list〉.
    - SELECT * FROM t1 INNER JOIN t2 USING (i1);
  - The column name can not be specified such as 〈table name〉.〈column name〉.
    - (X) SELECT * FROM t1 INNER JOIN t2 USING (t1.i1);
  - The listed columns in 〈join column list〉 should be on the left row and right row of JOIN, and they should be able to be compared.
    - t1(c1 INTEGER, c2 INTEGER);
    - t2(c2 INTEGER, c3 INTEGER);
    - SELECT * FROM t1 INNER JOIN t2 USING (c2);
  - If * is used in 〈select list〉, then the records are configured as follows.

    1) Columns specified in 〈join column list〉

    2) Columns which does not correspond to 〈join column list〉 among left rows.

    3) Columns which does not correspond to 〈join column list〉 among right rows.
    - t1(c1 INTEGER, c2 INTEGER);
    - t2(c2 INTEGER, c3 INTEGER);
    - SELECT * FROM t1 INNER JOIN t2 USING (c2);
    - Record configuration: C2, C1, C3
  - 〈column name〉 specified in 〈join column list〉 can not be referenced together with 〈table name〉.〈column name〉, but it can be referenced only by the 〈column name〉.
    - SELECT c2 FROM t1 INNER JOIN t2 USING (c2) WHERE c2 > 3;
    - (X) SELECT t1.c2 FROM t1 INNER JOIN t2 USING (c2);
    - (X) SELECT * FROM t1 INNER JOIN t2 USING (c2) WHERE t1.c2 > 3;
  - Processing the join condition of 〈join column list〉
    - For each column listed in 〈join column list〉
    - The condition 〈left table name〉.〈column name〉 = 〈right table name〉.〈column name〉 is generated
    - and the conditions to process each 〈column name〉 condition using AND are generated.
    - t1(c1 INTEGER, c2 INTEGER);
    - t2(c1 INTEGER, c2 INTEGER);
    - SELECT * FROM t1 INNER JOIN t2 USING (c1, c2);
    - Join condition: t1.c1 = t2.c1 AND t1.c2 = t2.c2
  - 〈table name〉.* statement which returns all the row for a particular table can not be used in 〈select list〉.
    - (X) SELECT t1.*, t2.* FROM t1 INNER JOIN t2 USING (c1, c2);

Description

〈cross join〉

〈cross join〉 returns a result which combines each left row with all right rows.

```
T1 ( 1, 1 ), ( 2, 2 )
T2 ( 2, 2 ), ( 3, 3 )
gSQL> SELECT * FROM t1 CROSS JOIN t2;
C1 C2 C1 C2
-- -- -- --
 1  1  2  2
 1  1  3  3
 2  2  2  2
 2  2  3  3
4 rows selected.
```

The explicit join condition can not be specified in 〈cross join〉, but the join condition for the two tables ca n be specified in 〈where clause〉. In this case, it performs inner join.

- SELECT * FROM t1 CROSS JOIN t2 WHERE t1.c1 = t2.c1;
- 〈=〉 SELECT * FROM t1 INNER JOIN t2 ON t1.c1 = t2.c1;

```
T1 ( 1, 1 ), ( 2, 2 )
T2 ( 2, 2 ), ( 3, 3 )
gSQL> SELECT * FROM t1 CROSS JOIN t2 WHERE t1.c1 = t2.c1;
C1 C2 C1 C2
-- -- -- --
 2  2  2  2
1 row selected.
```

〈qualified join〉

〈qualified join〉 combines each left row with all right rows, then returns only the rows satisfying the join c ondition as a result.

If 〈where clause〉 exists in 〈table expression〉, then conditions in 〈where clause〉 are applied to the result set of 〈qualified join〉.

The result is same, even when inner join processes the conditions in 〈where clause〉 as join conditions. Bu t result differs when outer join processes the conditions in 〈where clause〉 as join conditions.

INNER JOIN

```
t1 ( 1, 1 ), ( 2, 2 ), ( 3, 3 ), ( 4, 4 ), ( 5, 5 )
t2 ( 2, 2 ), ( 3, 3 )
```

- When a condition exists only on ON clause

```
gSQL> SELECT * FROM t1 INNER JOIN t2 ON t1.c1 = t2.c1 AND t1.c2 = t2.c2;
C1 C2 C1 C2
-- -- -- --
 2  2  2  2
 3  3  3  3
2 rows selected.
```

- When a condition exists on ON clause and WHERE clause
  - It applies WHERE condition t1.c2 = t2.c2 to the result set to which JOIN condition ON t1.c1 = t2.c1 is applied.

```
gSQL> SELECT * FROM t1 INNER JOIN t2 ON t1.c1 = t2.c1 WHERE t1.c2 = t2.c2;
C1 C2 C1 C2
-- -- -- --
 2  2  2  2
 3  3  3  3
2 rows selected.
```

  - The result set to which JOIN condition ON t1.c1 = t2.c1 is applied → Apply WHERE condition t1.c2 = t2.c2

```
( 2,  2,    2,    2 )                    ( 2,  2,    2,    2 )
  ( 3,  3,    3,    3 )                →   ( 3,  3,    3,    3 )
```

OUTER JOIN

```
t1 ( 1, 1 ), ( 2, 2 ), ( 3, 3 ), ( 4, 4 ), ( 5, 5 )
t2 ( 2, 2 ), ( 3, 3 )
```

- When a condition exists only on ON clause

```
gSQL> SELECT * FROM t1 LEFT OUTER JOIN t2 ON t1.c1 = t2.c1 AND t1.c2 = t2.c2;
C1 C2   C1   C2
-- -- ---- ----
 1  1 null null
 2  2    2    2
```

```
 3  3    3    3
 4  4 null null
 5  5 null null
5 rows selected.
```

- When a condition exists on ON clause and WHERE clause
  - It applies WHERE condition t1.c2 = t2.c2 to the result set to which JOIN condition ON t1.c1 = t2.c1 is applied.

```
gSQL> SELECT * FROM t1 LEFT OUTER JOIN t2 ON t1.c1 = t2.c1 WHERE t1.c2 = t2.c2;
C1 C2 C1 C2
-- -- -- --
 2  2  2  2
 3  3  3  3
2 rows selected.
```

  - The result set to which JOIN condition ON t1.c1 = t2.c1 is applied → Apply WHERE condition t1.c2 = t2.c2

```
( 1,  1, null, null )
  ( 2,  2,    2,    2 )                    ( 2,  2,    2,    2 )
  ( 3,  3,    3,    3 )          →         ( 3,  3,    3,    3 )
  ( 4,  4, null, null )
  ( 5,  5, null, null )
```

Left outer join combines right rows satisfying the join condition for the left rows, then returns the combined rows as a result. If right rows satisfying the join condition does not exist, then it returns the result whose left row values are as they are and whose right row values are filled with NULL.

LEFT OUTER JOIN

```
t1 ( 1, 1 ), ( 2, 2 )
t2 ( 2, 2 ), ( 3, 3 )
gSQL> SELECT * FROM t1 LEFT OUTER JOIN t2 ON t1.c1 = t2.c1;
C1 C2   C1   C2
-- -- ---- ----
 1  1 null null
 2  2    2    2
2 rows selected.
```

Right outer join is operated in an opposite way of left outer join.

```
RIGHT OUTER JOIN
t1 ( 1, 1 ), ( 2, 2 )
t2 ( 2, 2 ), ( 3, 3 )
gSQL> SELECT * FROM t1 RIGHT OUTER JOIN t2 ON t1.c1 = t2.c1;
  C1   C2 C1 C2
---- ---- -- --
   2    2  2  2
null null  3  3
2 rows selected.
```

Full outer join returns the left rows filled with NULL for all right rows which do not satisfy the join conditi on together with left outer join results.

```
FULL OUTER JOIN
t1 ( 1, 1 ), ( 2, 2 )
t2 ( 2, 2 ), ( 3, 3 )
gSQL> SELECT * FROM t1 FULL OUTER JOIN t2 ON t1.c1 = t2.c1;
  C1   C2   C1   C2
---- ---- ---- ----
   1    1 null null
   2    2    2    2
null null    3    3
3 rows selected.
```

〈natural join〉

〈natural join〉 joins all columns with same names in two tables participating in join as equal. In other wor ds, it is as same as specifying all columns with same names of two tables participating in join in USING cla use of inner join.

```
t1 ( C1 INTEGER, C2 INTEGER )
t2 ( C1 INTEGER, C3 INTEGER )
t1 ( 1, 10 ), ( 2, 20 ), ( 3, 30 )
t2 ( 1, 100 ), ( 2, 200 ), ( 3, 300 )
gSQL> SELECT * FROM t1 NATURAL JOIN t2;
C1 C2  C3
-- -- ---
 1 10 100
 2 20 200
 3 30 300
3 rows selected.
gSQL> SELECT * FROM t1 INNER JOIN t2 USING ( c1 );
```

```
C1 C2  C3
-- -- ---
 1 10 100
 2 20 200
 3 30 300
3 rows selected.
```

〈join specification〉

It specifies the join condition.
〈join condition〉 specifies the condition for joining left rows and right rows of a join statement.
〈named columns join〉 specifies the join condition by listing that 〈column name〉, if the same 〈column name〉 exist in left rows and right rows.

```
t1 ( C1 INTEGER, C2 INTEGER )
t2 ( C1 INTEGER, C3 INTEGER )
t1 ( 1, 10 ), ( 2, 20 ), ( 3, 30 )
t2 ( 1, 100 ), ( 2, 200 ), ( 3, 300 )
• 〈join condition〉
gSQL> SELECT * FROM t1 INNER JOIN t2 ON t1.c1 = t2.c1;
C1 C2 C1  C3
-- -- -- ---
 1 10  1 100
 2 20  2 200
 3 30  3 300
3 rows selected.
• 〈named columns join〉
gSQL> SELECT * FROM t1 INNER JOIN t2 USING ( c1 );
C1 C2  C3
-- -- ---
 1 10 100
 2 20 200
 3 30 300
3 rows selected.
```

Examples

The following is an example of SELECT statement which uses 〈cross join〉.

```
gSQL> SELECT c_name, o_totalprice FROM customer CROSS JOIN orders;
C_NAME     O_TOTALPRICE
```

```
---------- ------------
Customer#1    173665.47
Customer#1     46929.18
Customer#1    193846.25
Customer#1     32151.78
Customer#1     144659.2
Customer#2    173665.47
Customer#2     46929.18
Customer#2    193846.25
Customer#2     32151.78
Customer#2     144659.2
Customer#3    173665.47
Customer#3     46929.18
Customer#3    193846.25
Customer#3     32151.78
Customer#3     144659.2
Customer#4    173665.47
Customer#4     46929.18
Customer#4    193846.25
Customer#4     32151.78
Customer#4     144659.2
C_NAME     O_TOTALPRICE
---------- ------------
Customer#5    173665.47
Customer#5     46929.18
Customer#5    193846.25
Customer#5     32151.78
Customer#5     144659.2
25 rows selected.
```

The following is an example of SELECT statement which uses inner join.

```
gSQL> SELECT c_name, o_totalprice FROM customer INNER JOIN orders ON c_custkey = o_custkey;
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1    173665.47
Customer#2     46929.18
Customer#4    193846.25
Customer#3     32151.78
Customer#5     144659.2
5 rows selected.
```

The following is an example of SELECT statement which uses outer join.

```
gSQL> SELECT c_name, o_totalprice FROM customer LEFT OUTER JOIN orders ON c_custkey =
o_custkey AND o_orderdate < '1996-01-01';
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1         null
Customer#2         null
Customer#3     32151.78
Customer#4    193846.25
Customer#5     144659.2
5 rows selected.
gSQL> SELECT c_name, o_totalprice FROM customer RIGHT OUTER JOIN orders ON c_custkey =
o_custkey AND c_nation = 'KOREA';
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1    173665.47
null           46929.18
null          193846.25
Customer#3     32151.78
null           144659.2
5 rows selected.
gSQL> SELECT c_name, o_totalprice FROM customer FULL OUTER JOIN orders ON c_custkey =
o_custkey AND c_nation = 'KOREA' AND o_orderdate < '1996-01-01';
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1         null
Customer#2         null
Customer#3     32151.78
Customer#4         null
Customer#5         null
null          173665.47
null           46929.18
null          193846.25
null           144659.2
9 rows selected.
```

The following is an example of SELECT statement which uses natural join.

```
gSQL> SELECT c_name, o_totalprice FROM (SELECT c_custkey custkey, c_name FROM customer)
NATURAL JOIN (SELECT o_custkey custkey, o_totalprice FROM orders);
```

```
C_NAME     O_TOTALPRICE
---------- ------------
Customer#1    173665.47
Customer#2     46929.18
Customer#4    193846.25
Customer#3     32151.78
Customer#5     144659.2
5 rows selected.
```

Compatibility

Table 20-11 SQL standard compatibility

Feature ID	Description	Compatibility
F401	Extended joined table	O

F403	Partitioned join tables	X

For More Information

Refer to **from clause**.

where clause

Function

It applies <search condition> to the result of <from clause>.

Syntax

```
<where clause> ::=
    WHERE <search condition>
```

Syntax Rules and Parameters

<where clause>

<search condition> which returns a boolean type is required after WHERE keyword.

Description

For more information about <where clause>, refer to **Conditions**.

Example

The following is an example of SELECT statement which uses <where clause>.

```
gSQL> SELECT s_name, s_nation FROM supplier WHERE s_nation = 'KOREA';
S_NAME                    S_NATION
------------------------- --------
Supplier#2                KOREA
1 row selected.
gSQL> SELECT s_name, ps_availqty, ps_supplycost FROM supplier, partsupp WHERE s_nation =
'KOREA' AND s_suppkey = ps_suppkey;
S_NAME                    PS_AVAILQTY PS_SUPPLYCOST
------------------------- ----------- -------------
Supplier#2                       8076        993.49
Supplier#2                       4069        357.84
2 rows selected.
```

Compatibility

Table 20-12 SQL standard compatibility

Feature ID	Description	Compatibility
F441	Extended set function support	O

For More Information

Refer to **query specification**.

hierarchical query clause

Function

It specifies to retrieve the hierarchical model data in a hierarchy.
It returns table records in a hierarchy of depth-first sequence by using the launch condition and sub-connectivity condition.

Syntax

```
<hierarchical query clause> ::=
    <start with connect by clause> [ <order siblings by clause> ]
<start with connect by clause> ::=
    <start with clause> <connect by clause>
    | <connect by clause> <start with clause>
    | <connect by clause>
<start with clause> ::=
    START WITH <start_with_condition>
<connect by clause> ::=
    CONNECT BY [NOCYCLE] <connect_by_condition>
<order siblings by clause> ::=
    ORDER SIBLINGS BY <ordering element> [ { <comma> <ordering element> }... ]
<ordering element> ::=
    <value expression> [ASC | DESC] [NULLS FIRST | NULLS LAST]
<hierarchy expression> ::=
    LEVEL
    | CONNECT_BY_ISCYCLE
    | CONNECT_BY_ISLEAF
    | PRIOR <value expression>
    | CONNECT_BY_ROOT <value expression>
    | SYS_CONNECT_BY_PATH <left paren> <value expression> <comma> <character string literal>
<right paren>
```

Invocation and Access Rules

It is supported in <query specification> statement, and the user should satisfy the access privilege of <query specification> to perform it.
For more information, refer to **query specification**.

Syntax Rules and Parameters

〈hierarchical query clause〉

〈connect by clause〉 should be described.
〈start with clause〉 or 〈order siblings by clause〉 is described when it is required.

〈start with clause〉

It specifies the condition of root record in data hierarchy.
When it is not specified, then all records of from clause become targets of root records.
It can be described only once within SELECT statement.

〈connect by clause〉

It describes the relation between the parent record and the child record.
It expresses the relation between the parent record and the child record by using PRIOR operator which r epresenting the column value of the parent record.
If the condition of connecting the parent record and the child record is not specified by using PRIOR oper ator, then an infinite loop may occur.
It can be described only once within SELECT statement.

- NOCYCLE
  - When NOCYCLE option is not specified
    - When cycle occurs, then that query causes an error and the execution stops.
  - When NOCYCLE option is specified
    - When cycle occurs, then that query does not cause an error.
    - The record which caused cycle stops retrieving the child record and it is not included in the re sult record.
    - The query continuously proceeds for sibling rows where cycle does not occur.
    - 1 is stored in CONNECT_BY_ISCYCLE of the parent record of the record which caused cycle.
    - 0 is stored in CONNECT_BY_ISCYCLE of the parent record of the record which has not cause d cycle.

〈order siblings by clause〉

It specifies the order of fetching sibling records of the same parent records.

- Sort order
  - ASC
  - DESC
  - If not specified, the default value is ASC.

- Null ordering
  - NULLS FIRST
  - NULLS LAST
  - If not specified, the default value is NULLS LAST.

〈hierarchy expression〉

- The following hierarchy information is acquired when configuring the hierarchy query.
  - LEVEL
  - CONNECT_BY_ISCYCLE
  - CONNECT_BY_ISLEAF
  - PRIOR
  - CONNECT_BY_ROOT
  - SYS_CONNECT_BY_PATH

Table 20-13 Result type of 〈hierarchy expression〉

Expression	Result DataType
LEVEL	NATIVE_BIGINT
CONNECT_BY_ISCYCLE	NATIVE_BIGINT
CONNECT_BY_ISLEAF	NATIVE_BIGINT
PRIOR expr	expr의 DataType
CONNECT_BY_ROOT expr	expr의 DataType
SYS_CONNECT_BY_PATH(expr, literal)	VARCHAR(4000 characters)

〈hierarchy expression〉 can be described in the following statements.

Expression₩clause	FROM	START WITH	CONNECT BY	ORDER SIBLINGS BY	WHERE/ GROUP BY/ HAVING	ORDER BY/ SELECT TARGET
LEVEL	X	O	O	X	O	O
CONNECT_BY_ISCYCLE	X	X	X	X	O	O
CONNECT_BY_ISLEAF	X	X	X	X	O	O
PRIOR	X	X	O	X	O	O
CONNECT_BY_ROOT	X	X	X	X	O	O
SYS_CONNECT_BY_PATH	X	X	X	X	O	O

Whether 〈hierarchy expression〉 can be used as an argument of 〈hierarchy expression〉 is described in the following table.

Expression₩Argument(expr)	LEVEL	CONNECT_BY_ISCYCLE	CONNECT_BY_ISLEAF	PRIOR	CONNECT_BY_ROOT	SYS_CONNECT_BY_PARTH
PRIOR expr	X	X	X	X	X	X
CONNECT_BY_ROOT expr	X	X	X	X	X	X
SYS_CONNECT_BY_PARTH (expr,literal)	O	O	O	O	O	O

Description

〈hierarchical query clause〉 retrieves the hierarchical model data in a hierarchy.
It returns table records in a hierarchy of depth-first sequence by using the launch condition and sub-connectivity condition.

When 〈hierarchical query clause〉 is described in SELECT, then it is processed in the following order.

1. ON condition in FROM clause
2. START WITH
3. CONNECT BY
4. WHERE

- When only a single table exists in *from* clause

```
SELECT *
 FROM r_region
WHERE r_population > 10000000            ❸ Condition in WHERE clause
START WITH r_name = 'EARTH'              ❶ START WITH
CONNECT BY r_domain = PRIOR r_name       ❷ CONNECT BY
```

- When join condition configured with multiple tables exists in *from* clause
    - When join condition is described in ON clause of FROM clause

```
SELECT *
  FROM r_region INNER JOIN s_region
       ON r_id = s_id                     ❶ Join condition in ON clause
 WHERE r_population > 10000000            ❹ Condition in WHERE clause
START WITH r_name = 'EARTH'              ❷ START WITH
CONNECT BY r_domain = PRIOR r_name       ❸ CONNECT BY
```

    - When join condition is described in WHERE clause

```
SELECT *
  FROM r_region, s_region
 WHERE r_population > 10000000          ❸ Condition in WHERE clause
   AND r_id = s_id                      ❸ Join condition in WHERE clause
START WITH r_name = 'EARTH'             ❶ START WITH
CONNECT BY r_domain = PRIOR r_name      ❷ CONNECT BY
```

- When join condition is described in both ON clause of FROM and in WHERE clause

```
SELECT *
  FROM r_region INNER JOIN s_region
       ON r_name = s_name               ❶ Join condition in ON clause
 WHERE r_population > 10000000          ❹ Condition in WHERE clause
   AND r_id = s_id                      ❹ Join condition in WHERE clause
START WITH r_name = 'EARTH'             ❷ START WITH
CONNECT BY r_domain = PRIOR r_name      ❸ CONNECT BY
```

〈order siblings by clause〉

It specifies the order of fetching sibling records of the same parent records within 〈hierarchical query clause〉.
〈order siblings by clause〉 is a statement distinct from 〈order by clause〉.

```
gSQL>
SELECT * FROM t1;
I1  I2
--- ----
A   null
AA  A
AB  A
fAA AA
eAA AA
bAA AA
dAB AB
cAB AB
aAB AB
9 rows selected.
```

- The following is an example of defining the order of fetching sibling records of the same parent records.

```
gSQL>
SELECT LEVEL, i1, i2
  FROM t1
START WITH i1 = 'A'
CONNECT BY i2 = PRIOR i1
ORDER SIBLINGS BY i1;
LEVEL I1  I2
----- --- ----
    1 A   null
    2 AA  A
    3 bAA AA
    3 eAA AA
    3 fAA AA
    2 AB  A
    3 aAB AB
    3 cAB AB
    3 dAB AB
9 rows selected.
```

- The following is an example of sorting all results retrieved in a hierarchy by using ORDER BY claus e in an order of LEVEL.

```
gSQL>
SELECT LEVEL, i1, i2
  FROM t1
START WITH i1 = 'A'
CONNECT BY i2 = PRIOR i1
ORDER SIBLINGS BY i1
ORDER BY LEVEL;
LEVEL I1  I2
----- --- ----
    1 A   null
    2 AA  A
    2 AB  A
    3 bAA AA
    3 eAA AA
    3 fAA AA
    3 aAB AB
    3 cAB AB
    3 dAB AB
9 rows selected.
```

〈hierarchy expression〉

The followings are features of the hierarchy expression.

- PRIOR
  - It acquires the information based on the parent record of the current record.
  - PRIOR is a unary operator, and its priority is as same as that of a unary operator +,-.

```
gSQL>
SELECT i1, i2
  FROM t1
START WITH i1 = 'X'
CONNECT BY i2 = PRIOR i1;
I1    I2
----- ----
X     null
XA    X
XXA   XA
XXXA  XXA
XXXXA XXXA
5 rows selected.
```

- LEVEL
  - It is the hierarchical value in which the record belongs.
  - LEVEL of the root record is 1, and LEVEL of the child record of the root is 2.
  - LEVEL increases by 1 as it goes down to the child record.

```
gSQL>
SELECT LEVEL, i1, i2
  FROM t1
START WITH i1 = 'X'
CONNECT BY i2 = prior i1;
LEVEL I1    I2
----- ----- ----
    1 X     null
    2 XA    X
    3 XXA   XA
    4 XXXA  XXA
    5 XXXXA XXXA
5 rows selected.
```

- CONNECT_BY_ISCYCLE

- It acquires the information about whether the record causing cycle exists among child records related to the current record.
- It is available only when NOCYCLE exists in CONNECT BY statement.

```
gSQL>
SELECT * FROM t1;
I1 I2
-- ----
A  null
AA A
AB A
AC A
AA AA
AB AA
6 rows selected.
gSQL>
SELECT i1, i2, CONNECT_BY_ISCYCLE
  FROM t1
START WITH i1 = 'A'
CONNECT BY NOCYCLE i2 = prior i1;
I1 I2   CONNECT_BY_ISCYCLE
-- ---- ------------------
A  null                 0
AA A                    1
AB AA                   0
AB A                    0
AC A                    0
5 rows selected.
```

- CONNECT_BY_ISLEAF
  - It acquires the information about whether the child record related to the current record exists.
  - If the child record related to the current record does not exist, then it returns 1.

```
gSQL>
SELECT i1, i2, CONNECT_BY_ISLEAF
  FROM t1
START WITH i1 = 'X'
CONNECT BY i2 = prior i1;
I1    I2   CONNECT_BY_ISLEAF
----- ---- -----------------
X     null                0
XA    X                   0
```

```
XXA   XA                  0
XXXA  XXA                 0
XXXXA XXXA                1
5 rows selected.
```

- CONNECT_BY_ROOT
  - It acquires the information based on the root record of the current record.

```
gSQL>
SELECT i1, i2, CONNECT_BY_ROOT i1
  FROM t1
START WITH i1 = 'X'
CONNECT BY i2 = prior i1;
I1    I2   CONNECT_BY_ROOT I1
----- ---- ------------------
X     null X
XA    X    X
XXA   XA   X
XXXA  XXA  X
XXXXA XXXA X
5 rows selected.
```

- SYS_CONNECT_BY_PATH
  - It acquires the information by recursively searching along the parent record of the current record.

```
gSQL>
SELECT i1, i2, SYS_CONNECT_BY_PATH( i1, '/' )
  FROM t1
START WITH i1 = 'X'
CONNECT BY i2 = prior i1;
I1    I2   SYS_CONNECT_BY_PATH( I1, '/' )
----- ---- ------------------------------
X     null /X
XA    X    /X/XA
XXA   XA   /X/XA/XXA
XXXA  XXA  /X/XA/XXA/XXXA
XXXXA XXXA /X/XA/XXA/XXXA/XXXXA
5 rows selected.
```

Examples

The following is the result of retrieving record in emp table which will be used in the example of hierarchi cal query clause.

```
gSQL>
SELECT * FROM emp;
NAME    MGR
------- -------
Kelly   null
Bill    Kelly
Jackson Kelly
Joe     Kelly
Scott   Bill
Larry   Bill
Paul    Jackson
Bill    Bill
8 rows selected.
```

The following is an example of when cycle occurs.

```
gSQL>
SELECT *
  FROM emp
START WITH mgr IS NULL
CONNECT BY mgr = PRIOR name
ORDER SIBLINGS BY name;
ERR-42000(16511): cycle detected while executing recursive WITH query
```

The following is an example of executing the query by using CONNECT BY NOCYCLE statement.

```
gSQL>
SELECT *
  FROM emp
START WITH mgr IS NULL
CONNECT BY NOCYCLE mgr = PRIOR name
ORDER SIBLINGS BY name;
NAME    MGR
------- -------
Kelly   null
Bill    Kelly
Larry   Bill
```

```
Scott   Bill
Jackson Kelly
Paul    Jackson
Joe     Kelly
7 rows selected.
```

The following is an example of retrieving the information about the hierarchical data by using the hierarchy expression.

```
gSQL>
SELECT name,
       mgr,
       PRIOR name AS prior_mgr,
       LEVEL,
       CONNECT_BY_ISCYCLE AS iscycle,
       CONNECT_BY_ISLEAF AS isleaf,
       CONNECT_BY_ROOT mgr AS root_mgr,
       SYS_CONNECT_BY_PATH( mgr, '/' ) AS path
  FROM emp
START WITH mgr IS NULL
CONNECT BY NOCYCLE mgr = PRIOR name
ORDER SIBLINGS BY name;
NAME    MGR     PRIOR_MGR LEVEL ISCYCLE ISLEAF ROOT_MGR PATH
------- ------- --------- ----- ------- ------ -------- ---------------
Kelly   null    null          1       0      0 null     /
Bill    Kelly   Kelly         2       1      0 null     //Kelly
Larry   Bill    Bill          3       0      1 null     //Kelly/Bill
Scott   Bill    Bill          3       0      1 null     //Kelly/Bill
Jackson Kelly   Kelly         2       0      0 null     //Kelly
Paul    Jackson Jackson       3       0      1 null     //Kelly/Jackson
Joe     Kelly   Kelly         2       0      1 null     //Kelly
7 rows selected.
```

group by clause

Function

It specifies the grouped table of which <group by clause> was applied to the result processed by the previous statements.

Syntax

```
<group by clause> ::=
    GROUP BY <grouping element list>
<grouping element list> ::=
    <grouping element> [ { , <grouping element> } ... ]
<grouping element> ::=
      <ordinary grouping set>
    ¦ <empty grouping set>
<ordinary grouping set> ::=
      <grouping column reference>
<grouping column reference> ::=
    <column reference>
    ¦ <value_expression>
<empty grouping set> ::=
    <left paren> <right paren>
```

Invocation and Access Rules

Any separate access privilege is not required for a user to perform <group by clause>.

Syntax Rules and Parameters

<ordinary grouping set>

It consists of one or more <grouping column reference>.
It does not support LONG type (LONG VARCHAR, LONG VARBINARY).

- SELECT c1, sum(c2) FROM t1 GROUP BY c1;
- SELECT sum(c1) FROM t1 GROUP BY NULL;

〈empty grouping set〉

It can be specified by using only parentheses.

- SELECT sum(c1) FROM t1 GROUP BY ();

Description

〈grouping element list〉

It groups 〈grouping element list〉 specified in 〈group by clause〉 into a GROUPING SET. If all values of 〈grouping element〉 in GROUPING SET are matched, it is processed as the same group.

- If 〈group by clause〉 is specified, the following expressions can appear in 〈select list〉.
  - Constant number
  - 〈grouping column reference〉 specified in 〈group by clause〉
  - Operation expression including 〈grouping column reference〉 specified in 〈group by clause〉
  - Aggregation function of a column which is not specified in 〈group by clause〉
  - SELECT c1, sum(c2) FROM t1 GROUP BY c1;

〈grouping column reference〉

〈column reference〉 or 〈value expression〉 can appear in 〈grouping column reference〉.

- 〈column reference〉
  - Only the columns belonging to 〈from clause〉 of 〈query specification〉 can be referenced.
    - SELECT c1 FROM t1 GROUP BY c1;
  - If same column names exist, then clearly specify the column name by using a table name.
    - SELECT t1.c1, t2.c1 FROM t1, t2 GROUP BY t1.c1, t2.c1;

- 〈value expression〉
  - It is an expression which includes 〈column reference〉.
    - It can be divided into several groups by using 〈column reference〉
    - SELECT sum(c2) FROM t1 GROUP BY c1 + 10;
  - It is an expression which does not include 〈column reference〉.
    - Values in 〈value expression〉 are all same constants, so all records are configured into a single group.
    - If null is specified in 〈value expression〉, the null values are treated as the same value, so all records are configured into a single group.
    - SELECT sum(c1), sum(c2) FROM t1 GROUP BY NULL;

〈empty grouping set〉

All records in 〈empty grouping set〉 are configured into a single group.

- SELECT sum(c1), sum(c2) FROM t1 GROUP BY ();

Example

The following is an example of SELECT statement which uses GROUP BY clause.

```
gSQL> SELECT c_nation, COUNT(c_name) FROM customer GROUP BY c_nation;
C_NATION      COUNT(C_NAME)
------------- -------------
UNITED STATES             1
CANADA                    1
KOREA                     2
GERMANY                   1
4 rows selected.
gSQL> SELECT COUNT(c_name) FROM customer GROUP BY NULL;
COUNT(C_NAME)
-------------
            5
1 row selected.
gSQL> SELECT COUNT(c_name) FROM customer GROUP BY ();
COUNT(C_NAME)
-------------
            5
1 row selected.
```

Compatibility

Table 20-14 SQL standard compatibility

Feature ID	Description	Compatibility

T432	Nested and concatenated GROUPING SETS	X
T434	GROUP BY DISTINCT	X

For More Information

Refer to the followings.

- having clause
- query specification

having clause

Function

It specifies grouped tables having removed groups which do not satisfy <search condition>.

Syntax

```
<having clause> ::=
    HAVING <search condition>
```

Invocation and Access Rules

Any separate access privilege is not required for a user to perform <having clause>.

Syntax Rules and Parameters

<having clause>

- What can be used without aggregate functions in <search condition> is only <grouping column reference> specified in <group by clause>.
  - SELECT c1, sum(c2) FROM t1 GROUP BY c1 HAVING c1 > 3;
- The columns which are not specified in <group by clause> can be specified by using aggregate functions.
  - SELECT c1, sum(c2) FROM t1 GROUP BY c1 HAVING sum(c2) > 100;

Description

<having clause>

<having clause> specifies search conditions for the grouped data.

Generally, it is used together with <group by clause>. When <having clause> is used without <group by clause>, it is considered as if <empty grouping set> exists.

- SELECT sum(c1), sum(c2) FROM t1 HAVING sum(c1) > 0;
- <=> SELECT sum(c1), sum(c2) FROM t1 GROUP BY () HAVING sum(c1) > 0;

<grouping column reference> specified in <group by clause> can be specified in <having clause>.
The columns which are not specified in <group by clause> can be specified by using aggregate functions.

- SELECT c1, sum(c2) FROM t1 GROUP BY c1 HAVING c1 > 3 AND sum(c2) > 100;

Example

The following is an example of SELECT statement which uses <having clause>.

```
gSQL> SELECT c_nation, COUNT(c_name) FROM customer GROUP BY c_nation HAVING COUNT(c_name) > 1;
C_NATION COUNT(C_NAME)
-------- -------------
KOREA                2
1 row selected.
gSQL> SELECT COUNT(c_name) FROM customer HAVING COUNT(c_name) > 1;
COUNT(C_NAME)
-------------
            5
1 row selected.
```

For More Information

Refer to the followings.

- **group by clause**
- **Conditions**

window clause

Function

It defines the execution range of the window function described in select list and order by clause.

Syntax

```
<window clause> ::=
     WINDOW <window definition list>
<window definition list> ::=
     <window definition> [ { <comma> <window definition> }... ]
<window definition> ::=
     <new window name> AS <window specification>
<new window name> ::=
     <window name>
<window specification> ::=
     <left paren> <window specification details> <right paren>
<window specification details> ::=
     [ <existing window name> ]
          [ <window partition clause> ]
          [ <window order clause> ]
          [ <window frame clause> ]
<existing window name> ::=
     <window name>
<window partition clause> ::=
     PARTITION BY <window partition column reference list>
<window partition column reference list> ::=
     <window partition column reference>
          [ { <comma> <window partition column reference> }... ]
<window partition column reference> ::=
     <column reference>
<window order clause> ::=
     ORDER BY <sort specification list>
<sort specification list> ::=
     <sort specification> [ { <comma> <sort specification> }... ]
<sort specification> ::=
     <sort key> [ <ordering specification> ] [ <null ordering> ]
<sort key> ::=
     <value expression>
```

```
<ordering specification> ::=
       ASC
     | DESC
<null ordering> ::=
      NULLS FIRST
    | NULLS LAST
<window frame clause> ::=
     <window frame units> <window frame extent>
          [ <window frame exclusion> ]
<window frame units> ::=
       ROWS
     | RANGE
     | GROUPS
<window frame extent> ::=
       <window frame start>
     | <window frame between>
<window frame start> ::=
       UNBOUNDED PRECEDING
     | <window frame preceding>
     | CURRENT ROW
<window frame preceding> ::=
     <unsigned value specification> PRECEDING
<window frame between> ::=
     BETWEEN <window frame bound 1> AND <window frame bound 2>
<window frame bound 1> ::=
     <window frame bound>
<window frame bound 2> ::=
     <window frame bound>
<window frame bound> ::=
       <window frame start>
     | UNBOUNDED FOLLOWING
     | <window frame following>
<window frame following> ::=
     <unsigned value specification> FOLLOWING
<window frame exclusion> ::=
       EXCLUDE CURRENT ROW
     | EXCLUDE GROUP
     | EXCLUDE TIES
     | EXCLUDE NO OTHERS
```

Invocation and Access Rules

The access privilege for a column is required if the column exist in a window clause.

Syntax Rules and Parameters

〈window clause〉

The window function is not allowed in a window clause.

〈window definition list〉

It can define multiple 〈window definition〉.

〈window definition〉

It describes the execution range of window function with 〈new window name〉.

〈new window name〉 should not be a duplicate in 〈window clause〉.
〈new window name〉 can be referred in *over* clause in the window function.

```
SELECT SUM(i2) OVER w1
  FROM t1
WINDOW w1 AS ( PARTITION BY i1 ORDER BY i2 );
```

〈window specification〉

It defines the execution range of window function.

It can redefine 〈window specification〉 by referring to 〈existing window name〉 and adding it to the pred efined information.
〈existing window name〉 can refer to 〈new window name〉 which was predefined in 〈window definition list〉 only.

```
• Referred in window clause
SELECT SUM(i2) OVER w2
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2 ),
       w2 AS ( w1 ROWS BETWEEN UNBOUNDED PRECEDING  <---
                          AND CURRENT ROW );
• Referred in over clause of window function
SELECT SUM(i2) OVER ( w1 ROWS BETWEEN UNBOUNDED PRECEDING  <---
```

```
                                    AND CURRENT ROW )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2 );
```

When redefining <window specification>by referring to <existing window name>

```
• <window partition clause> is not allowed in the redefinition.
SELECT SUM(i2) OVER ( w1 PARTITION BY i1 )  <--- ( X )
  FROM t1
WINDOW w1 AS ( );
• If order by clause is described in <existing window name>,
  order by clause is not allowed in the redefinition.
SELECT SUM(i2) OVER ( w1 ORDER BY i3 ) <--- ( X )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2 );
• window frame clause is not allowed in <existing window name>.
SELECT SUM(i2) OVER ( w1 )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2
               ROWS BETWEEN UNBOUNDED PRECEDING  <--- ( X )
                        AND CURRENT ROW );
```

<window frame start>

If frame end is omitted, then <window frame start> is as same as <window frame start> AND CURRENT R OW.

- UNBOUNDED PRECEDING
  - UNBOUNDED PRECEDING AND CURRENT ROW
- *offset* PRECEDING
  - *offset* PRECEDING AND CURRENT ROW
    - 3 PRECEDING AND CURRENT ROW
- CURRENT ROW
  - CURRENT ROW AND CURRENT ROW

<window frame between>

- UNBOUNDED FOLLOWING is not allowed in frame start.
  - BETWEEN *UNBOUNDED FOLLOWING* AND UNBOUNDED FOLLOWING (X)

- UNBOUNDED PRECEDING is not allowed in frame end.
  - BETWEEN UNBOUNDED PRECEDING AND *UNBOUNDED PRECEDING* (X)
- If frame start is CURRENT ROW, then <window frame preceding> is not allowed in frame end.
  - BETWEEN CURRENT ROW AND *1 PRECEDING* (X)
- If frame start is <window frame following>, then neither <window frame preceding> nor CURRENT ROW is allowed in frame end.
  - BETWEEN 3 FOLLOWING AND *1 PRECEDING* (X)
  - BETWEEN 3 FOLLOWING AND *CURRENT ROW* (X)

<window frame following> / <window frame preceding>

offset PRECEDING / *offset* FOLLOWING

- Neither a negative number nor NULL is allowed in offset.
  - *NULL* PRECEDING (X)
  - *-1* PRECEDING (X)
  - *NULL* FOLLOWING (X)
  - *-1* FOLLOWING (X)

- When frame unit is RANGE
  - If the sort key of window ORDER BY is a numeric type, then describe a numeric type in offset.
    - ORDER BY orderkey RANGE BETWEEN 3 PRECEDING AND 5 FOLLOWING
  - If the sort key of window ORDER BY is a datetime type or an interval type, then describe an interval type in offset.
    - ORDER BY orderdate RANGE BETWEEN INTERVAL'3'DAY PRECEDING AND INTERVAL'5'day FOLLOWING
- When frame unit is ROWS/GROUPS, then describe an integer type number in offset.
  - ORDER BY orderkey ROWS BETWEEN 3 PRECEDING AND 5 FOLLOWING
  - ORDER BY orderkey GROUPS BETWEEN 3 PRECEDING AND 5 FOLLOWING

Description

WINDOW clause describes the execution range of window function described in select list and order by clause.

<window partition clause> divides groups.
<window order clause> sorts the records in the group.
<window frame clause> defines the range of window function's target record for the sorted records in the group.

WINDOW clause is executed for the result sets after FROM, WHERE, GROUP BY, HAVING clauses are executed.
When using an aggregate, GROUP BY, HAVING clauses in a query, then describe the group column inste

ad of the column from the original table in WINDOW clause.

〈window specification〉

It describes the execution range of window function for each record.

It can redefine 〈window specification〉 by referring to 〈existing window name〉 and adding it to the pred efined information.

```
SELECT SUM(i2) OVER ( w1
                      ORDER BY i2
                      ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1 ),
       w2 AS ( w1 ORDER BY i3 );
   → It is the same statement.
SELECT SUM(i2) OVER ( PARTITION BY i1
                      ORDER BY i2
                      ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1 ),
       w2 AS ( PARTITION BY i1
               ORDER BY i3 );
```

When referring to 〈window name〉 wname in window function OVER clause, then OVER wname and OV ER (wname) is not same.

- OVER wname

```
* Referring to 〈window specification〉 information defined with wname
ex) Referring to w1
SELECT SUM(i2) OVER w1
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW );
```

- OVER(wname)

```
* It redefines 〈window specification〉 by adding it to the predefined information,
  and it can not define 〈window frame clause〉 in the existing information.
ex) Referring to w1
```

```
SELECT SUM(i2) OVER ( w1 ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2 );
ex) Referring to w1 ( Error : It can not define <window frame clause> in the existing
information. )
SELECT SUM(i2) OVER ( w1 )
  FROM t1
WINDOW w1 AS ( PARTITION BY i1
               ORDER BY i2
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW );  <---
```

<window partition clause>

It divides the query result set into groups based on <window partition column reference list> by using PA RTITION BY.
If this clause is omitted, then the function processes all rows in the result set as a single group.

- When <window partition clause> is described

```
gSQL>
SELECT orderdate,
       orderkey,
       totalprice,
       SUM( totalprice ) OVER( PARTITION BY orderdate ) AS SUM_OVER_RESULT
FROM orders;
ORDERDATE  ORDERKEY TOTALPRICE SUM_OVER_RESULT

<window order clause>

It specifies the method of sorting the data in the partition based on <sort specification list> by using ORD ER BY.

- <ordering specification>
  - It specifies whether to sort in ascending order or in descending order.
    - ASC
    - DESC
    - If it is omitted, the default value is ASC.

- <null ordering>
  - It specifies an order between the NULL values and non-NULL values.
    - NULLS FIRST
    - NULLS LAST
    - If it is omitted, the default value is NULLS LAST.

- When <window frame units> of <window frame clause> is RANGE,
  - If offset PRECEDING or offset FOLLOWING is described, then it can specify only a single sort key.
    - ORDER BY I1 RANGE 3 PRECEDING

        - ORDER BY I1 RANGE BETWEEN CURRENT ROW AND 3 FOLLOWING
    - Otherwise, it can specify multiple sort keys.
        - ORDER BY I1, I2 RANGE UNBOUNDED PRECEDING
        - ORDER BY I1, I2 RANGE CURRENT ROW
        - ORDER BY I1, i2 RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING
        - ORDER BY I1, i2 RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWIN G

〈window frame clause〉

It specifies window frame which is the record range of window function's target.

window frame is the record range related to each row (current row) of the query.
The target of window frame is records sorted in the current partition.
window frame can specify the scope (ROWS/ RANGE/ GROUPS), starting point and ending point, and ex cluded records.

If it is omitted, then it applies RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW.

- RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
    - Starting point: From the record at the beginning of the partition
    - Ending point: Until all peer records of the current record

- peer: The records whose sorting order of window ORDER BY clause is same

<window frame units>

ROWS/ RANGE/ GROUPS are units of window frame scope.

<window frame extent>

It defines window frame start (the starting point) and window frame end (ending point).

- UNBOUNDED PRECEDING
  - From the record at the beginning of the partition
- UNBOUNDED FOLLOWING

    - Until the record at the end of the partition
- CURRENT ROW
    - When it is <window frame units> ROWS,
        - it is the current record.
    - When it is <window frame units> RANGE/ GROUPS
        - they are all peer records in the current record.
- offset PRECEDING/ offset FOLLOWING
    - When it is <window frame units> ROWS
        - it is the range of the number of offset records before and after the current record.
    - When it is <window frame units> GROUPS
        - it is the range of the number of offset groups before and after the current record group.
    - When it is <window frame units> RANGE
        - it is the range of offset values before and after the current record.
        - When sorting ORDER BY column in ASC order
        - ··· offset PRECEDING → The record whose value is above (sort key value of the current recor d - offset)
        - ··· offset FOLLOWING → The record whose value is below (sort key value of the current recor d + offset)
        - When sorting ORDER BY column in DESC order
        - ··· offset PRECEDING → The record whose value is below (sort key value of the current recor d + offset)
        - ··· offset FOLLOWING → The record whose value is above (sort key value of the current recor d - offset)
- For more information, refer to **Example of Using <window frame extent>**.

<window frame exclusion>

It defines records to exclude from window frame.

- EXCLUDE CURRENT ROW: It excludes the current record.
- EXCLUDE GROUP: It excludes the current record and all peer records.
- EXCLUDE TIES: It maintains the current record but excludes all peer records.
- EXCLUDE NO OTHERS: It does not exclude any record.
- If it is not specified, the default value is EXCLUDE NO OTHERS.
- For more information, refer to **Example of Using <window frame exclusion>**.

Example of Using <window frame extent>

- order by clause
- Window Function

order by clause

Function

It specifies the sorting order of the query results.

Syntax

```
<order by clause> ::=
    ORDER BY <sort specification list>
<sort specification list> ::=
    <sort specification> [ { <comma> <sort specification> }... ]
<sort specification> ::=
    <sort key> [ <ordering specification> ] [ <null ordering> ]
<sort key> ::=
    <value expression>
<ordering specification> ::=
      ASC
    ¦ DESC
<null ordering> ::=
      NULLS FIRST
    ¦ NULLS LAST
```

Invocation and Access Rules

The access privilege for a column is required if the column exist in a sort key specified for sorting.

Syntax Rules and Parameters

<order by clause>

- When <set quantifier> DISTINCT is specified in <query specification>, then only the expression specifie d in <select list> can appear in <sort key>.
  - SELECT DISTINCT c1, c2 FROM t1 ORDER BY c1;
  - (X) SELECT DISTINCT c1, c2 FROM t1 ORDER BY c5;
- When one or more <set function specification> are specified in <select list> of <query specification>, t hen only the expression specified in <select list> can appear in <sort key>.
  - SELECT c1, sum(c2) FROM t1 GROUP BY c1 ORDER BY c1;
  - (X) SELECT c1, sum(c2) FROM t1 GROUP BY c1 ORDER BY c5;

- If <order by clause> is specified in <set operator>, <sort key> is analysed based on the firstly specified <query specification>.
  - SELECT c1, c2 FROM t1 UNION SELECT i1, i2 FROM t3 ORDER BY c1, c2;
  - (X) SELECT c1, c2 FROM t1 UNION SELECT i1, i2 FROM t3 ORDER BY i1, i2;

<sort specification list>

- <ordering specification>
  - ASC
  - DESC
  - If it is not specified, the default value is ASC.
- <null ordering>
  - NULLS FIRST
  - NULLS LAST
  - If it is not specified, the default value is NULLS LAST.

<sort key>

- If <value expression> of <sort key> is the positive integer value, the value is used as a sort key index.
  - The i-th <select sublist> of <query specification> which corresponds to the value is used as a sort key.
    - SELECT c1, c2 FROM t1 ORDER BY 1;
    - C1 is sorted by the sort key.
  - If the i-th <select sublist> of <query specification> >which corresponds to the value does not exist, it returns an error.
    - (X) SELECT c1, c2 FROM t1 ORDER BY 3;
- A row subquery or relation subquery is not supported as <value expression>.
  - (X) SELECT c1, c2 FROM t1 ORDER BY (SELECT i1, i2 FROM t2 FETCH FIRST ROW ONLY);
  - Multiple records exist in T2.
    - (X) SELECT c1, c2 FROM t1 ORDER BY (SELECT i1 FROM t2);
- Other <value expression> are used as sort keys.

Description

<order by clause>

<order by clause> specifies a method to sort the query results.

<sort key> can be listed in <order by clause> by using a comma (,), and <sort key> of each records are co mpared and listed in order.

```
SELECT c1, c2 FROM t1 ORDER BY c1, c2;
```

<ordering specification> which specifies an ascending order or an descending order can be specified in <sort key>. If it is omitted, then they are sorted in an ascending order.

```
gSQL> SELECT c1 FROM t1;
C1
--
 2
 3
 1
3 rows selected.
```

- Ascending order (ASC)

```
gSQL> SELECT c1 FROM t1 ORDER BY c1;
C1
--
 1
 2
 3
3 rows selected.
gSQL> SELECT c1 FROM t1 ORDER BY c1 ASC;
C1
--
 1
 2
 3
3 rows selected.
```

- Descending order (DESC)

```
gSQL> SELECT c1 FROM t1 ORDER BY c1 DESC;
C1
--
 3
 2
 1
3 rows selected.
```

<null ordering> specifies an order between the non-NULL values and NULL values in <sort key>. If it is omi tted, then they are sorted as NULLS LAST.

```
gSQL> SELECT c1 FROM t1;
  C1
----
   2
null
   1
3 rows selected.
```

- NULLS LAST

```
gSQL> SELECT c1 FROM t1 ORDER BY c1;
  C1
----
   1
   2
null
3 rows selected.
gSQL> SELECT c1 FROM t1 ORDER BY c1 NULLS LAST;
  C1
----
   1
   2
null
3 rows selected.
```

- NULLS FIRST

```
gSQL> SELECT c1 FROM t1 ORDER BY c1 NULLS FIRST;
  C1
----
null
   1
   2
3 rows selected.
```

If a constant value is specified in <sort key>, the expression positioned in the location corresponding to th e order of the corresponding value in <select list> is regarded as <sort key>. In this case, the constant is an integer bigger than 0, and it should be equal or smaller than the total number of expression in <select list> .

```
gSQL> SELECT c1 FROM t1 ORDER BY 1;
  C1
----
   1
   2
null
3 rows selected.
```

LONG (LONG VARCHAR, LONG VARBINARY) type can not be specified in <sort key>.

Comparison of Null Value

- The comparison between null values is regarded as the same value.
- The comparison between non-null value and null value is subject to the following rules.
  - When it is NULLS FIRST and ASC: null value < not null value
  - When it is NULLS LAST and ASC: null value > not null value
  - When it is NULLS FIRST and DESC: null value > not null value
  - When it is NULLS LAST and DESC: null value < not null value
- If the comparison result between null values is UNKNOWN, it is sorted according to the scan order.

Sorting Rows Which Have Same Sort Key Value

Peers are rows which can not be distinguished by a sort key, and the peers are sorted according to the sc an order.

<aggregation function> Which Is Used As <sort key>

If <aggregation function> is used in <query specification>, or <group by clause> is specified, <aggregation function> can be used as <sort key>.
However, the nested aggregation function can be used as <sort key> only when <group by clause> is spec ified.

```
gSQL> SELECT c1, c2 FROM t1;
C1 C2
-- --
 2  1
 3  5
 1  2
 2 10
 3 10
5 rows selected.
gSQL> SELECT sum(c1) FROM t1 ORDER BY sum(c1);
```

```
SUM(C1)
-------
     11
1 row selected.
gSQL> SELECT c1, sum(c2) FROM t1 GROUP BY c1 ORDER BY sum(c2);
C1 SUM(C2)
-- -------
 1       2
 2      11
 3      15
3 rows selected.
gSQL> SELECT sum(c1) FROM t1 GROUP BY c1 ORDER BY sum(sum(c1));
SUM(C1)
-------
      6
1 row selected.
```

Example

The following is an example of SELECT statement which uses ORDER BY clause.

```
gSQL> SELECT c_name, c_nation FROM customer ORDER BY c_nation;
C_NAME     C_NATION
---------- -------------
Customer#2 CANADA
Customer#4 GERMANY
Customer#1 KOREA
Customer#3 KOREA
Customer#5 UNITED STATES
5 rows selected.
gSQL> SELECT c_name, c_nation FROM customer ORDER BY c_nation DESC;
C_NAME     C_NATION
---------- -------------
Customer#5 UNITED STATES
Customer#1 KOREA
Customer#3 KOREA
Customer#4 GERMANY
Customer#2 CANADA
5 rows selected.
gSQL> SELECT c_name, c_nation FROM customer ORDER BY 2 DESC;
C_NAME     C_NATION
```

```
---------- -------------
Customer#5 UNITED STATES
Customer#1 KOREA
Customer#3 KOREA
Customer#4 GERMANY
Customer#2 CANADA
5 rows selected.
```

Compatibility

Table 20-17 SQL standard compatibility

Feature ID	Description	Compatibility
F850	Top-level <order by clause> in <query expression>	O
F851	<order by clause> in subqueries	O
F852	Top-level <order by clause> in views	O
F855	Nested <order by clause> in <query expression>	O

For More Information

Refer to **query expression**.

offset limit clause

Function

It specifies the number of rows to skip and the number of rows to fetch from the query results.

Syntax

```
<offset limit clause> ::=
      <result offset clause>
    ¦ <fetch limit clause>
    ¦ <result offset clause> <fetch limit clause>
<result offset clause> ::=
    OFFSET <offset row count> [ { ROW ¦ ROWS } ]
<fetch limit clause> ::=
      <fetch first clause>
    ¦ <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST ¦ NEXT ] [ <fetch row count> ] [ ROW ONLY ¦ ROWS ONLY ]
<limit clause> ::=
    LIMIT { <fetch row count> ¦ <offset row count> , <fetch row count> ¦ ALL }
```

Invocation and Access Rules

The access privilege for <offset limit clause> is not required.

Syntax Rules and Parameters

<result offset clause>

- <offset row count> value should be a positive integer which is equal to or bigger than zero.
- ROW and ROWS are keywords with the same meaning and they can be omitted.
- If the statement is omitted, it means as same as *OFFSET 0 ROWS*.

<fetch limit clause>

- It specifies the number of rows to skip in the query result.
- If the statement is omitted, it means as same as *LIMIT ALL*.

〈fetch first clause〉

- It specifies the number of rows to fetch from the query result.
- It can not be used together with 〈limit clause〉.
- FIRST and NEXT are keywords with the same meaning and they can be omitted.
- ROW ONLY and ROWS ONLY are keywords with the same meaning and they can be omitted.
- 〈fetch row count〉
  - It should be a positive integer which is bigger than zero.
  - It can be omitted and if it is omitted, its value is one.

〈limit clause〉

- It specifies the number of rows to fetch.
- It can simultaneously specify both the number of rows to fetch and the number of rows to be skippe d from query results .
- It can not be used together with 〈fetch first clause〉.
- When it is used as LIMIT 〈fetch row count〉
  - 〈fetch row count〉 should be a positive integer which is bigger than zero.
  - The statement means same as *FETCH FIRST 〈fetch row count〉 ROWS ONLY*.
- When it is used as LIMIT 〈offset row count〉, 〈fetch row count〉
  - It can not be used together with 〈result offset clause〉.
  - 〈offset row count〉 should be a positive integer which is equal to or bigger than zero.
  - 〈fetch row count〉 should be a positive integer which is bigger than zero.
  - The statement means same as *OFFSET 〈offset row count〉 ROWS FETCH FIRST 〈fetch row count〉 ROWS ONLY*.
- When it is used as LIMIT ALL
  - It does not limit the number of rows to fetch.

Description

〈result offset clause〉

It fetches rows from the 〈offset row count〉th of the query results. If the result which 〈offset row count〉 queried is equal to or greater than the number of rows, the number of fetch rows is 0.

```
gSQL> SELECT c1 FROM t1;
C1
--
 1
 2
 3
3 rows selected.
```

```
gSQL> SELECT c1 FROM t1 OFFSET 1;
C1
--
 2
 3
2 rows selected.
gSQL> SELECT c1 FROM t1 OFFSET 3;
no rows selected.
```

〈fetch first clause〉

It fetches the query results as many as the number of 〈fetch row count〉.

```
gSQL> SELECT c1 FROM t1;
C1
--
 1
 2
 3
3 rows selected.
gSQL> SELECT c1 FROM t1 FETCH FIRST 2 ROWS ONLY;
C1
--
 1
 2
2 rows selected.
```

〈limit clause〉

When LIMIT 〈fetch_row_count〉 is used, it fetches the query results as many as the number of 〈fetch row count〉.

When LIMIT 〈offset row count〉 is used, 〈fetch row count〉, it fetches the query results as many as the nu mber of 〈fetch row count〉 from the 〈offset row count〉th row.

When LIMIT ALL is used, it returns the query results to a user without limit of the number.

```
gSQL> SELECT c1 FROM t1;
C1
--
 1
 2
 3
```

```
3 rows selected.
• LIMIT <fetch_row_count>
gSQL> SELECT c1 FROM t1 LIMIT 2;
C1
--
 1
 2
2 rows selected.
• LIMIT <offset row count>, <fetch_row_count>
gSQL> SELECT c1 FROM t1 LIMIT 1, 1;
C1
--
 2
1 row selected.
• LIMIT ALL
gSQL> SELECT c1 FROM t1 LIMIT ALL;
C1
--
 1
 2
 3
3 rows selected.
```

Examples

The following is an example of SELECT statement which uses <result offset clause>.

```
gSQL> SELECT c_name, c_nation FROM customer OFFSET 1;
C_NAME     C_NATION
---------- -------------
Customer#2 CANADA
Customer#3 KOREA
Customer#4 GERMANY
Customer#5 UNITED STATES
4 rows selected.
```

The following is an example of SELECT statement which uses <fetch first clause>.

```
gSQL> SELECT c_name, c_nation FROM customer FETCH FIRST ROW ONLY;
C_NAME     C_NATION
---------- --------
```

```
Customer#1 KOREA
1 row selected.
gSQL> SELECT c_name, c_nation FROM customer FETCH FIRST 2 ROW ONLY;
C_NAME     C_NATION
---------- --------
Customer#1 KOREA
Customer#2 CANADA
2 rows selected.
```

The following is an example of SELECT statement which uses <limit clause>.

```
gSQL> SELECT c_name, c_nation FROM customer LIMIT 1;
C_NAME     C_NATION
---------- --------
Customer#1 KOREA
1 row selected.
gSQL> SELECT c_name, c_nation FROM customer LIMIT 1, 2;
C_NAME     C_NATION
---------- --------
Customer#2 CANADA
Customer#3 KOREA
2 rows selected.
gSQL> SELECT c_name, c_nation FROM customer LIMIT ALL;
C_NAME     C_NATION
---------- -------------
Customer#1 KOREA
Customer#2 CANADA
Customer#3 KOREA
Customer#4 GERMANY
Customer#5 UNITED STATES
5 rows selected.
```

The following is an example of SELECT statement which uses <result offset clause> and <fetch limit clause>
.

```
gSQL> SELECT c_name, c_nation FROM customer OFFSET 1 FETCH 2;
C_NAME     C_NATION
---------- --------
Customer#2 CANADA
Customer#3 KOREA
2 rows selected.
gSQL> SELECT c_name, c_nation FROM customer OFFSET 1 LIMIT 2;
```

```
C_NAME     C_NATION
---------- --------
Customer#2 CANADA
Customer#3 KOREA
2 rows selected.
```

Compatibility

Table 20-18 SQL standard compatibility

Feature ID	Description	Compatibility
F861	Top-level <result offset clause> in <query expression>	O
F862	<result offset clause> in subqueries	O
F863	Nested <result offset clause> in <query expression>	O
F864	Top-level <result offset clause> in views	O
F865	dynamic <offset row count> in <result offset clause>	X

set operator

Function

It performs a set operation for results of the subquery.

Syntax

```
<set operator> ::=
      <set operator term>
    ¦ <query expression body> UNION [ ALL ¦ DISTINCT ] <set operator term>
    ¦ <query expression body> EXCEPT [ ALL ¦ DISTINCT ] <set operator term>
    ¦ <query expression body> MINUS [ ALL ¦ DISTINCT ] <set operator term>
<set operator term> ::=
      <query term>
    ¦ <set operator term> INTERSECT [ ALL ¦ DISTINCT ] <set operator term>
```

Invocation and Access Rules

All access privileges for the <query expression> in each <set operator term> are required for using <set operator> statement.

Syntax Rules and Parameters

<set operator>

- It specifies the set operations among the subqueries.
- The number of the target in <select list> of each subquery should be same, and all matched targets should belong to the same data type group.
- The representative name of the result target of <set operator> is the target name of <select list> of the first subquery.
  - gSQL> SELECT c1 AS NAME FROM t1 UNION SELECT i1 FROM t2;
    NAME

    1
    2
    2 rows selected.
- If the processing order is not explicitly specified by using parentheses it processes by evaluating specified subqueries from the left to the the right.
- The meaning of each operator in <set operator> is as follows.

- UNION
  - UNION ALL: It is a union of all subquery results without removing the duplicates.
  - UNION DISTINCT: It is a union of all subquery results, which removed the duplicates.
  - If at least one of ALL and DISTINCT is not specified, it is operated as same as when DISTINCT i s specified.
- EXCEPT
  - EXCEPT ALL: It returns the difference of all rows for the subquery result including all duplicat es.
  - EXCEPT DISTINCT: It returns the difference of all rows for the subquery result excluding all du plicates.
  - If at least one of ALL and DISTINCT is not specified, it is operated as same as when DISTINCT i s specified.
- MINUS
  - It is an alias of EXCEPT and, it is operated as same as EXCEPT.
- INTERSECT
  - INTERSECT ALL: It is a intersection of all subquery results without removing the duplicates.
  - INTERSECT DISTINCT: It is a intersection of all subquery results, which removed the duplicates.
  - If at least one of ALL and DISTINCT is not specified, it is operated as same as when DISTINCT i s specified.

〈query term〉

It specifies the single subquery.
For more information, refer to **query expression**.

Description

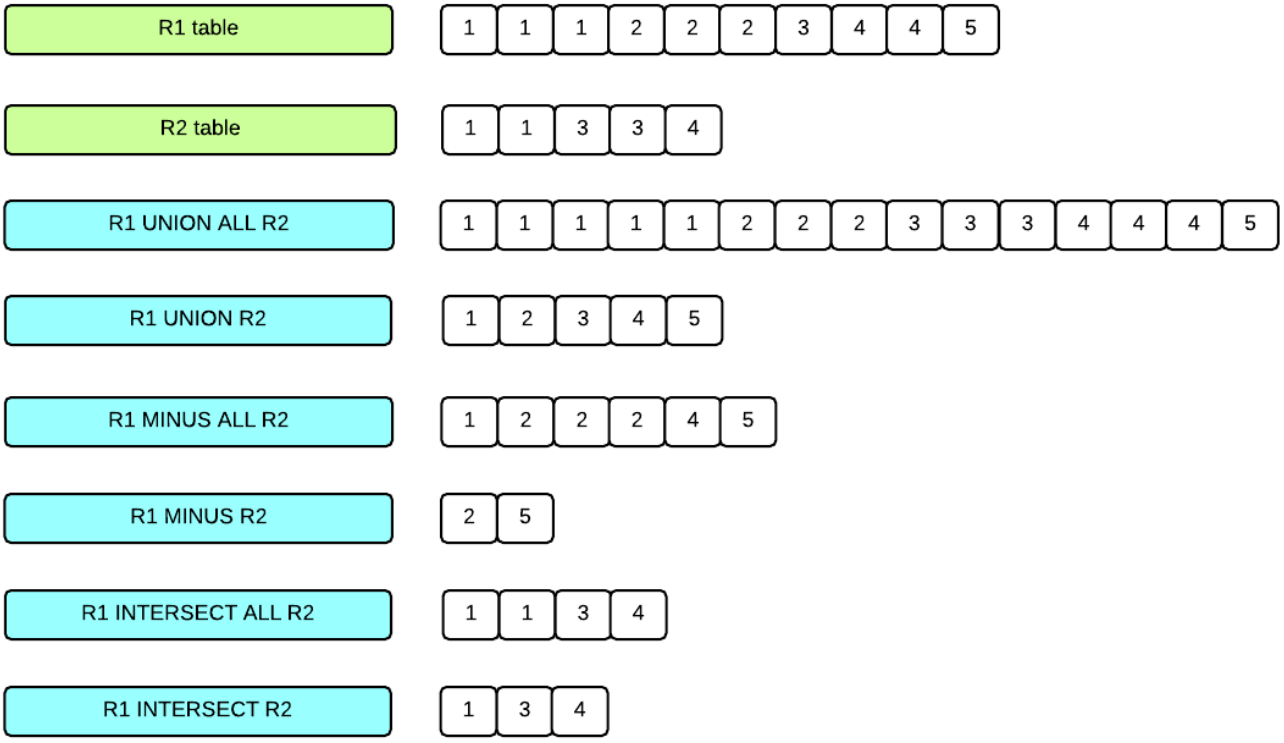
The Differences between ALL and DISTINCT in 〈set operator〉

For example, if the data of the table R1 and R2 is given as follows, the result of each 〈set operator 〉 is as follows.

- TABLE data
  - R1 TABLE = {1, 1, 1, 2, 2, 2, 3, 4, 4, 5}
  - R2 TABLE = {1, 1, 3, 3, 4}
- SELECT * FROM R1 UNION ALL SELECT * FROM R2;
  - result = {1, 1, 1, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 4, 5}
- SELECT * FROM R1 UNION DISTINCT SELECT * FROM R2;
  - result = {1, 2, 3, 4, 5}
- SELECT * FROM R1 MINUS ALL SELECT * FROM R2;
  - result = {1, 2, 2, 2, 4, 5}
- SELECT * FROM R1 MINUS DISTINCT SELECT * FROM R2;

    - result = {2, 5}
- SELECT * FROM R1 INTERSECT ALL SELECT * FROM R2;
    - result = {1, 1, 3, 4}
- SELECT * FROM R1 INTERSECT DISTINCT SELECT * FROM R2;
    - result = {1, 3, 4}

Figure 1 SET operation results



Operator Precedence

The operator precedence of <set operator> is as follows.

- Parentheses ( ) has a priority.
- INTERSECT has a priority.
- For UNION and EXCEPT, the precedence is according to an order listed from left to right within an ex pression.

Result Type of <set operator>

The i-th column of all subqueries in <set operator> should be a data type of the same family, and its result type is determined by **Result Type Combination Rule**.
However, LONG VARCHAR and LONG VARBINARY types can only use UNION ALL.

ORDER BY Clause

When <set operator> is used together with ORDER BY, and the column names are different among subq ueries, then it can be used as follows.

- ORDER BY indicator
  - It specifies the order of result columns.
    SELECT c1 FROM t1
    UNION ALL
    SELECT c2 FROM t2
    ORDER BY 1;
- ORDER BY left_column_name
  - It specifies the column name of the first subquery.
    SELECT c1 FROM t1
    UNION ALL
    SELECT c2 FROM t2
    ORDER BY c1;

Examples

The following is an example of SELECT statement which uses UNION operator.

```
gSQL> SELECT s_nation nation FROM supplier UNION ALL SELECT c_nation FROM customer;
NATION
-------------
FRANCE
KOREA
GERMANY
UNITED STATES
CANADA
KOREA
CANADA
KOREA
GERMANY
UNITED STATES
10 rows selected.
gSQL> SELECT s_nation nation FROM supplier UNION DISTINCT SELECT c_nation FROM customer;
NATION
-------------
UNITED STATES
CANADA
KOREA
```

```
GERMANY
FRANCE
5 rows selected.
```

The following is an example of SELECT statement which uses EXCEPT operator.

```
gSQL> SELECT c_nation nation FROM customer EXCEPT ALL SELECT s_nation FROM supplier;
NATION
------
KOREA
1 row selected.
gSQL> SELECT c_nation nation FROM customer EXCEPT DISTINCT SELECT s_nation FROM supplier;
no rows selected.
```

The following is an example of SELECT statement which uses INTERSECT operator.

```
gSQL> SELECT c_nation nation FROM customer INTERSECT ALL SELECT s_nation FROM supplier;
NATION
--------------
UNITED STATES
CANADA
KOREA
GERMANY
4 rows selected.
gSQL> SELECT c_nation nation FROM customer INTERSECT DISTINCT SELECT s_nation FROM supplier;
NATION
--------------
UNITED STATES
CANADA
KOREA
GERMANY
4 rows selected.
```

Compatibility

Table 20-19 SQL standard compatibility

Feature ID	Description	Compatibility
F302	INTERSECT table operator	O
F301	CORRESPONDING	X
T551	Optional key words for default syntax	O
F304	EXCEPT ALL table operator	O

For More Information

Refer to **query expression**.

subquery

Function

It specifies the scalar value, row, table which are derived from <query expression>.

Syntax

```
<scalar subquery> ::=
    <subquery>
<row subquery> ::=
    <subquery>
<table subquery> ::=
    <subquery>
<subquery> ::=
    ( <query expression> )
```

Invocation and Access Rules

The access privilege for <query expression> in <subquery> is required.

Syntax Rules and Parameters

<scalar subquery>

- The number of targets in <query expression> should be one.
- The result value according to the number of rows returned from <query expression> is as follows.
  - If the number of returned rows is zero, the result value is NULL.
  - If the number of returned rows is one, the result value is a value contained in the row.
  - If the number of returned rows is two or more, an exception error occurs.

<row subquery>

- The number of target in <query expression> should be two or more.
- The result value according to the number of rows returned from <query expression> is as follows.
  - If the number of returned rows is zero, the result value is a row all of whose columns are NULL.
  - If the number of returned rows is one, the result value is that row.
  - If the number of returned rows is two or more, an exception error occurs.

〈table subquery〉

- The number of target in 〈query expression〉 should be one or more.
- The result according to the number of rows returned from 〈query expression〉 is as follows.
  - If the number of returned rows is zero, the result value is *no rows*.
  - If the number of returned rows is one or more, the result value is that row.

Description

〈scalar subquery〉

〈scalar subquery〉 returns one row which has one column as a result. The target of 〈scalar subquery〉 should be only one, and the result data type depends on the data type of the target.

〈scalar subquery〉 can be used alone in the target of 〈select list〉, and it can be used in the operator which has a single column.

〈row subquery〉

〈row subquery〉 returns one row which has two or more columns as a result. The targets of 〈row subquery〉 should be two or more, and the result data type depends on the data type of each target.

〈row subquery〉 can not be used alone in the target of 〈select list〉, and it can only be used in the row operator which has two or more columns.

〈table subquery〉

〈table subquery〉 returns one or more rows which have one or more columns as a result. The targets of 〈table subquery〉 should be one or more, and the result data type depends on the data type of each target.

〈table subquery〉 can not be used alone in the target of 〈select list〉, but it can be used in the operators such as IN, NOT IN, EXISTS, NOT EXISTS, quantify operator.

Examples

The following is an example of SELECT statement which uses 〈scalar subquery〉.

```
gSQL> SELECT (SELECT c_name FROM dual)  FROM customer;
(SELECT C_NAME FROM DUAL)
-------------------------
Customer#1
Customer#2
Customer#3
Customer#4
```

```
Customer#5
5 rows selected.
gSQL> SELECT c_name, c_nation FROM customer WHERE c_nation = (SELECT 'CANADA' FROM dual);
C_NAME     C_NATION
---------- --------
Customer#2 CANADA
1 row selected.
```

The following is an example of SELECT statement which uses <row subquery>.

```
gSQL> SELECT p_name, p_brand, p_type FROM part WHERE (p_brand, p_type) = (SELECT 'Brand#1',
'NICKEL' FROM dual);
P_NAME P_BRAND    P_TYPE
------ ---------- ------
Part#2 Brand#1    NICKEL
1 row selected.
```

The following is an example of SELECT statement which uses <table subquery>.

```
gSQL> SELECT s_name, s_nation FROM supplier WHERE s_nation IN (SELECT c_nation FROM customer);
S_NAME                    S_NATION
------------------------- -------------
Supplier#2                KOREA
Supplier#3                GERMANY
Supplier#4                UNITED STATES
Supplier#5                CANADA
4 rows selected.
gSQL> SELECT * FROM (SELECT s_name, s_nation FROM supplier);
S_NAME                    S_NATION
------------------------- -------------
Supplier#1                FRANCE
Supplier#2                KOREA
Supplier#3                GERMANY
Supplier#4                UNITED STATES
Supplier#5                CANADA
5 rows selected.
```

Compatibility

Table 20-20 SQL standard compatibility

Feature ID	Description	Compatibility
F471	Scalar subquery values	O
F641	Row and table constructors	X
T501	Enhanced EXISTS predicate	O
E061-11	Subqueries in IN predicate	O
E061-12	Subqueries in quantified comparison predicate	O
E061-12	Correlated subqueries	O

For More Information

Refer to the followings.

- **from clause**
- **where clause**

hint clause

It specifies a hint to be used for a query execution.
For more information, refer to **SQL Hint**.

20.17 SELECT .. FOR UPDATE

Function

It sets whether or not to update the result set of SELECT statement.

Syntax

```
<select for update statement> ::=
    <query expression>  <updatability clause>
    ;
<updatability clause> ::=
      FOR READ ONLY
    ¦ FOR UPDATE [ OF <column name list> ] [ <lock wait mode> ]
<lock wait mode> ::=
    ¦ WAIT
    ¦ WAIT second
    ¦ NOWAIT
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <select for update statement>.

- One of the following privileges for all tables used in the statement is required for a user to perform <query expression>.
  - SELECT(columns) ON TABLE for all columns used in the statement among the table columns
  - (SELECT or CONTROL TABLE) ON TABLE for that table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

- If FOR UPDATE clause is used, one of the following privileges for the tables to be locked is required.
  - (LOCK or CONTROL TABLE) ON TABLE for that table
  - (LOCK TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - LOCK ANY TABLE ON DATABASE

Syntax Rules and Parameters

〈query expression〉

INTO clause should not exist in SELECT statement.

To use FOR UPDATE, the query should identify the row updates of the base table, or it should be an upda table query which can acquire the lock into the row.

The updatable query should satisfy all of following conditions.

- DISTINCT should not exist in the top-level query.
  - (X) SELECT DISTINCT * FROM t1;
- GROUP BY, HAVING, aggregation function should not exist in the top-level query.
  - (X) SELECT MAX(c1) FROM t1;
- Set operators should not exist.
  - (X) SELECT * FROM t1 UNION ALL SELECT * FROM t2;
- There should be at least one updatable column in the table listed in FROM clause.
  - The column of the table which is not for cross join among the tables included in join is not an up datable column.
    - OUTER JOIN is not the cross join.
    - NATURAL JOIN is not the cross join.
    - If USING clause is is used in INNER JOIN, it is not the cross join.
  - The column of the following tables is not an updatable column.
    - Dictionary table, fixed table, performance view
  - The column of a view is not an updatable table.

For more information about SELECT statement, refer to **query expression**.

〈updatability clause〉

It specifies whether or not to update the row for the result set.

- FOR READ ONLY
  - The read-only query is declared.
- FOR UPDATE
  - The writable query is declared.
  - x lock is acquired for the rows until the end of the transaction to prevent other transactions from updating the rows when executing the query.
  - 〈query expression〉 should be an updatable query.

FOR UPDATE OF …

It lists the columns relating to acquiring lock when executing the query.

- The column listed in FOR UPDATE OF statement.
  - It should be updatable columns of the table listed in the FROM clause of <query expression>.
  - It acquires a lock for the table of the listed column.
- Only FOR UPDATE is used
  - It means the same as listing all updatable columns of the table in FROM clause of <query expression>.
  - It acquires a lock for the table of all columns.

<lock wait mode>

It is used together with FOR UPDATE statement, and it specifies the lock acquisition method.

- WAIT
  - It acquires a lock for all rows of the query result before obtaining the query result.
  - It waits until acquiring a lock.
- WAIT second
  - It acquires a lock for all rows of the query result before acquiring the query result.
  - If the lock is not acquired for a specified time, an error occurs.
  - The wait time is in seconds and it can use the value between 0 and 1,000,000,000.
- NOWAIT
  - It acquires a lock for all rows of the query result before acquiring the query result.
  - If the lock is not immediately acquired, an error occurs.
- If it is not specified, the default value is WAIT.

Description

SELECT statement keep fetching the rows regardless of whether the transaction ends. However, SELECT .. FOR UPDATE statement can not fetch the rows when the transaction ends because the statement acquires the lock for the rows.

Cursor holdability

- WITH HOLD
  - It can keep fetching regardless of whether the transaction ends.
  - It is also known as fetch across commit.

- WITHOUT HOLD
  - When the transaction ends, it can not fetch.

Examples

The following is an example of acquiring a lock for the row by using FOR UPDATE statement.

```
gSQL> SELECT id, data FROM t1 WHERE id = 3 FOR UPDATE;
ID DATA
-- ------
 3 data_3
1 row selected.
```

The following uses join and ORDER BY clause but it is an updatable query, so FOR UPDATE statement can be used.

```
gSQL> SELECT t1.id, t1.name, t2.addr
        FROM t1, t2
       WHERE t1.id = t2.id
       ORDER BY 1
         FOR UPDATE;
ID NAME    ADDR
-- ------- -------------
 1 someone somewhere
 2 anyone  anywhere
 3 unknown N/A
 4 leekmo  leekmo's home
 5 mkkim   seoul
5 rows selected.
```

The following is a non-updatable query, so FOR UPDATE statement can not be used.

```
gSQL> SELECT id, COUNT(*)
        FROM t1
       GROUP BY id
         FOR UPDATE;
ERR-42000(16112): query expression is not updatable
```

Compatibility

In the SQL standard, <select for update statement> is not defined, but it can be defined by using **DECLARE cursor_name** statement.

20.18 SELECT .. INTO

Function

It retrieves a single row by using a query, then obtains the value of retrieved row into the host variable.

Syntax

```
<select statement: single row> ::=
    SELECT [ <hint clause> ] [ <set quantifier> ] <select list>
        INTO <select target list>
        <table expression>
    ;
<select target list> ::=
    variable_name [, ...]
```

Invocation and Access Rules

One of the following privileges for all tables used in the statement is required for a user to perform <select statement: single row>.

- SELECT(columns) ON TABLE for all columns used in the statement among the table columns
- (SELECT or CONTROL TABLE) ON TABLE for that table
- (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

<hint clause>

It specifies hints for query execution.
For more information, refer to **hint clause** of **SELECT** statement.

〈set quantifier〉

It specifies whether to remove duplicates from the query result.
For more information, refer to **query specification** clause.

〈select list〉

It specifies the columns to be retrieved from the query result.
For more information, refer to **select list** clause.

INTO 〈select target list〉

The number of the variable specified in INTO clause should be equal to the number of the expression spe cified in 〈select list〉.

〈table expression〉

It specifies the query information such as a search condition.
For more information, refer to **query specification** clause.

Description

The rows to be retrieved should be one or less.
If two or more rows are retrieved, an error occurs.

Differences among SELECT-related Statements

- 〈select statement〉
  - It retrieves multiple rows which satisfy the condition, and the retrieved rows can be retrieved by u sing API such as SQLFetch ().
  - e.g. SELECT c1 FROM t1 WHERE c1 > 0;
- 〈select statement: single row〉
  - It can retrieve one or less row which satisfies the condition, then obtains the value into the host v ariable in INTO clause when the retrieved row is a single row.
  - e.g. SELECT c2 INTO :v1 FROM t1 WHERE c1 = 0;

Example

The following is an example of obtaining the value into the host variable by using interactive SQL (gsql).

```
gSQL> \var v_id   INTEGER
gSLQ> \var v_data VARCHAR(128)
gSQL> SELECT id, data INTO :v_id, :v_data FROM t1 WHERE id = 3;
V_ID V_DATA
---- ------
   3 data_3
1 row selected.
```

20.19 SELECT .. INTO .. FOR UPDATE

Function

It sets whether to update the row by retrieving a single row through the query, then obtains the value of retrieved row into the host variable.

Syntax

```
<select for update statement: single row> ::=
    SELECT [ <hint clause> ] [ <set quantifier> ] <select list>
        INTO <select target list>
        <table expression>  <updatability clause>
    ;
<select target list> ::=
    variable_name [, ...]
<updatability clause> ::=
      FOR READ ONLY
    | FOR UPDATE [ OF <column name list> ] [ <lock wait mode> ]
<lock wait mode> ::=
    | WAIT
    | WAIT second
    | NOWAIT
```

Invocation and Access Rules

One of the following privileges for all tables used in the statement is required for a user to perform <select statement: single row>.

- SELECT(columns) ON TABLE for all columns used in the statement among the table columns
- (SELECT or CONTROL TABLE) ON TABLE for that table
- (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- SELECT ANY TABLE ON DATABASE

If FOR UPDATE clause is used, one of the following privileges for the tables to be locked is required.

- (LOCK or CONTROL TABLE) ON TABLE for that table
- (LOCK TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- LOCK ANY TABLE ON DATABASE

Syntax Rules and Parameters

〈select for update statement: single row〉

To use FOR UPDATE, the query should identify the row updates of the base table, or it should be an upda table query which can acquire the lock into the row.

The updatable query should satisfy all of following conditions.

- DISTINCT should not exist in the top-level query.
  - (X) SELECT DISTINCT * FROM t1;
- GROUP BY, HAVING, aggregation function should not exist in the top-level query.
  - (X) SELECT MAX(c1) FROM t1;
- Set operators should not exist.
  - (X) SELECT * FROM t1 UNION ALL SELECT * FROM t2;
- There should be at least one updatable column in the table listed in FROM clause.
  - The column of the table which is not for cross join among the tables included in join is not an up datable column.
    - FULL OUTER JOIN is not the cross join.
    - NATURAL JOIN is not the cross join.
    - If USING clause is is used in INNER JOIN, it is not the cross join.
  - The column of the following tables is not an updatable column.
    - Dictionary table, fixed table, performance view
  - The column of a view is not an updatable table.

〈updatability clause〉

It specifies whether or not to update the row for the result set.

- FOR READ ONLY
  - The read-only query is declared.
- FOR UPDATE
  - The writable query is declared.
  - x lock is acquired for the rows until the end of the transaction to prevent other transactions from updating the rows when executing the query.
  - 〈query expression〉 should be an updatable query.

FOR UPDATE OF …

It lists the columns relating to acquiring lock when executing the query.

- The column listed in FOR UPDATE OF statement.
  - It should be updatable columns of the table listed in the FROM clause of 〈query expression〉.
  - It acquires a lock for the table of the listed column.
- Only FOR UPDATE is used
  - It means the same as listing all updatable columns of the table in FROM clause of 〈query expression〉.
  - It acquires a lock for the table of all columns.

〈lock wait mode〉

It is used together with FOR UPDATE statement, and it specifies the lock acquisition method.

- WAIT
  - It acquires a lock for all rows of the query result before obtaining the query result.
  - It waits until acquiring a lock.
- WAIT second
  - It acquires a lock for all rows of the query result before acquiring the query result.
  - If the lock is not acquired for a specified time, an error occurs.
  - The wait time is in seconds and it can use the value between 0 and 1,000,000,000.
- NOWAIT
  - It acquires a lock for all rows of the query result before acquiring the query result.
  - If the lock is not immediately acquired, an error occurs.
- If it is not specified, the default value is WAIT.

〈hint clause〉

It specifies hints for query execution.
For more information, refer to **hint clause** of **SELECT** statement.

〈set quantifier〉

It specifies whether to remove duplicates from the query result.
For more information, refer to **query specification** clause.

〈select list〉

It specifies the columns to be retrieved from the query result.
For more information, refer to **select list** clause.

INTO 〈select target list〉

The number of the variable specified in INTO clause should be equal to the number of the expression spe cified in 〈select list〉.

〈table expression〉

It specifies the query information such as a search condition.
For more information, refer to **query specification** clause.

Description

The rows to be retrieved should be one or less.
If two or more rows are retrieved, an error occurs.

SELECT statement keep fetching the rows regardless of whether the transaction ends. However, SELECT .. FOR UPDATE statement can not fetch the rows when the transaction ends because the statement acquir es the lock for the rows.

Cursor holdability

- WITH HOLD
  - It can keep fetching regardless of whether the transaction ends.
  - It is also known as fetch across commit.
- WITHOUT HOLD
  - When the transaction ends, it can not fetch.

Differences among SELECT-related Statements

- 〈select for update statement〉
  - It retrieves multiple rows which satisfy the condition, sets whether to update them and the retriev ed rows can be retrieved by using API such as SQLFetch ().
  - e.g. SELECT c1 FROM t1 WHERE c1 > 0 FOR UPDATE;
- 〈select for update statement: single row〉
  - It can retrieve one or less row which satisfies the condition, sets whether to update them then ob tains the value into the host variable in INTO clause when the retrieved row is a single row.
  - e.g. SELECT c2 INTO :v1 FROM t1 WHERE c1 = 0 FOR UPDATE;

Examples

The following is an example of acquiring a lock for the row by using FOR UPDATE statement, and obtaini ng the value into the host variable by using interactive SQL (gsql).

```
gSQL> \var v_id   INTEGER
gSQL> \var v_data VARCHAR(128)
gSQL> SELECT id, data INTO :v_id, :v_data FROM t1 WHERE id = 3 FOR UPDATE;
V_ID V_DATA
---- ------
   3 data_3
1 row selected.
```

The following uses join and ORDER BY clause but it is an updatable query, so FOR UPDATE statement can be used.

```
gSQL> \var v_id   INTEGER
gSQL> \var v_name VARCHAR(128)
gSQL> \var v_addr VARCHAR(128)
gSQL> SELECT t1.id, t1.name, t2.addr
        INTO :v_id, :v_name, :v_addr
        FROM t1, t2
       WHERE t1.id = t2.id
       ORDER BY 1
       LIMIT 1
         FOR UPDATE;
ID NAME    ADDR
-- ------- -------------
 1 someone somewhere
```

```
1 row selected.
```

The following is a non-updatable query, so FOR UPDATE statement can not be used.

```
gSQL> \var v_id    INTEGER
gSQL> \var v_count INTEGER
gSQL> SELECT id, COUNT(*)
        INTO :v_id, :v_count
        FROM t1
       GROUP BY id
         FOR UPDATE;
ERR-42000(16112): query expression is not updatable
```

For More Information

Refer to the followings.

- SELECT .. FOR UPDATE
- SELECT .. INTO

20.20 SET CONSTRAINTS

Function

It sets the check point of deferrable constraint in a transaction to IMMEDIATE or DEFERRED.

Syntax

```
<set constraints mode statement> ::=
    SET { CONSTRAINT ¦ CONSTRAINTS } <constraint name list> { DEFERRED ¦ IMMEDIATE }
    ;
<constraint name list> ::=
      ALL
    ¦ <constraint name> [, ...]
```

Invocation and Access Rules

Any separate access privilege is not required for a user to perform SET CONSTRAINTS.

It is not supported in the cluster system.

Syntax Rules and Parameters

CONSTRAINT | CONSTRAINTS

CONSTRAINT and CONSTRAINTS are the keywords of the same meaning, and the SQL standard uses CONSTRAINTS.

<constraint name list>

It specifies the list of constraint names, or specifies ALL to set all deferrable constraints.
When specifying <constraint name>, it should be the name of the deferrable constraint.

ALL means all deferrable constraints.

DEFERRED | IMMEDIATE

It sets the check point of specified deferrable constraints.

- IMMEDIATE
  - It checks the specified constraints when executing the DML statement.
  - If the transaction violates the constraints, then an error occurs.
- DEFERRED
  - It checks the specified constraints when the transaction is committed.

If the transaction is in progress, the check point of the constraint is set in the current transaction. If the tr ansaction is not in progress, it is set in the next transaction.
After the transaction ends, it does not affect the next transaction.

Description

Deferrable Constraint

DEFERRABLE constraint can change its check point.
The following is an example of creating a table with a deferrable constraint, and inserting data to the tabl e.

```
gSQL> CREATE TABLE t1
(
    id   INTEGER,
    name VARCHAR(128) CONSTRAINT t1_uk UNIQUE
                      DEFERRABLE INITIALLY IMMEDIATE
);
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO t1 VALUES ( 1, 'leekmo' );
1 row created.
gSQL> INSERT INTO t1 VALUES ( 2, 'mkkim' );
1 row created.
gSQL> COMMIT;
Commit complete.
```

In the example above, UNIQUE constraint which is deferrable is created on a name column, and the initial check point is set as INITIALLY IMMEDIATE. Therefore, the constraint is checked whenever DML statemen t is executed.

In this case, if the user tries to exchange the name value of two rows as follows, it violates the constraint because the check point is IMMEDIATE.

```
gSQL> UPDATE t1 SET name = 'mkkim' WHERE id = 1;
ERR-23000(16057): unique constraint (PUBLIC.T1_UK) violated
gSQL> UPDATE t1 SET name = 'leekmo' WHERE id = 2;
ERR-23000(16057): unique constraint (PUBLIC.T1_UK) violated
```

If the check point is changed to DEFERRED as follows, the operation as same as above succeeds because the constraint is checked when the transaction is committed.

```
gSQL> SET CONSTRAINTS t1_uk DEFERRED;
Constraints set.
gSQL> UPDATE t1 SET name = 'mkkim' WHERE id = 1;
1 row updated.
gSQL> UPDATE t1 SET name = 'leekmo' WHERE id = 2;
1 row updated.
gSQL> COMMIT;
Commit complete.
```

If the check point is set to DEFERRED, then the constraint is checked when the transaction is committed. Therefore, if the transaction is committed when the constraint is violated, then the transaction fails and it is rolled back as follows.

```
gSQL> SET CONSTRAINTS t1_uk DEFERRED;
Constraints set.
gSQL> INSERT INTO t1 VALUES ( 3, 'leekmo' );
1 row created.
gSQL> COMMIT;
ERR-40002(16291): transaction rollback: integrity constraint violation : PUBLIC.T1_UK(1)
```

Violation of a Deferred Constraint

Executing the following statements when the transaction violates the constraints set to DEFFFERED, then an error occurs as follows.

- COMMIT
  - An error occurs and the transaction is rolled back.

- SET CONSTRAINTS ALL IMMEDIATE
  - An syntax error occurs.
- DDL
  - An syntax error occurs.

An unexpected ROLLBACK can occur when COMMIT, it is necessary to ensure whether the transaction vi olates the constraint by using SET CONSTRAINTS ALL IMMEDIATE statement.

```
gSQL> SET CONSTRAINTS t1_uk DEFERRED;
Constraints set.
gSQL> INSERT INTO t1 VALUES ( 3, 'leekmo' );
1 row created.
gSQL> SET CONSTRAINTS ALL IMMEDIATE;
ERR-23000(16038): integrity constraint violation : PUBLIC.T1_UK(1)
gSQL> SELECT * FROM t1 ORDER BY id;
ID NAME
-- ------
 1 mkkim

3 rows selected.
gSQL> UPDATE t1 SET name = 'xcom73' WHERE id = 3;
1 row updated.
gSQL> SET CONSTRAINTS ALL IMMEDIATE;
Constraints set.
gSQL> COMMIT;
Commit complete.
```

Transaction Control Language

SET CONSTRAINTS statement is a transaction control language which is used when the transaction is in p rogress such as **SAVEPOINT savepoint_specifier**.
The transaction control such as COMMIT, ROLLBACK, ROLLBACK TO SAVEPOINT statement is applied to SET CONSTRAINTS statement.

The following is an example of a table with multiple deferrable constraints.

```
CREATE TABLE t1
(
   id1 INTEGER CONSTRAINT t1_uk1 UNIQUE DEFERRABLE INITIALLY IMMEDIATE,
   id2 INTEGER CONSTRAINT t1_uk2 UNIQUE DEFERRABLE INITIALLY IMMEDIATE,
```

```
   id3 INTEGER CONSTRAINT t1_uk3 UNIQUE DEFERRABLE INITIALLY IMMEDIATE
);
```

If <set constraints mode statement> statement is performed when the transaction is in progress, the chec k point of deferrable constraints is changed depending on each point as follows.

- result: success

```
INSERT INTO t1 VALUES ( 1, 1, 1 );
1 row created.
COMMIT;
Commit complete.
```

- result: success

```
SAVEPOINT sp1;
Savepoint created.
```

- result: success
- t1_uk1 constraint is DEFERRED

```
SET CONSTRAINTS t1_uk1 DEFERRED;
Constraints set.
```

- result: success

```
SAVEPOINT sp2;
Savepoint created.
```

- result: success
- t1_uk1, t1_uk2 constraints are DEFERRED

```
SET CONSTRAINTS t1_uk2 DEFERRED;
Constraints set.
```

- result: success

```
SAVEPOINT sp3;
Savepoint created.
```

- result: success
- ALL constraints are DEFERRED

```
SET CONSTRAINTS ALL DEFERRED;
Constraints set.
```

- result: success

```
SAVEPOINT sp4;
Savepoint created.
```

- result: success
- ALL constraints are IMMEDIATE

```
SET CONSTRAINTS ALL IMMEDIATE;
Constraints set.
```

When the transaction is partially rolled back by using ROLLBACK TO SAVEPOINT statement as follows, SET CONSTRAINTS statement is also partially rolled back and the check point is changed.

- result: error

```
INSERT INTO t1 VALUES ( 1, 2, 2 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK1) violated
```

- result: error

```
INSERT INTO t1 VALUES ( 3, 1, 3 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK2) violated
```

- result: error

```
INSERT INTO t1 VALUES ( 4, 4, 1 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK3) violated
```

- result: success
- t1_uk1, t1_uk2 constraints are DEFERRED

```
ROLLBACK TO SAVEPOINT sp4;
Rollback complete.
```

- result: success

```
INSERT INTO t1 VALUES ( 1, 2, 2 );
1 row created.
```

- result: success

```
INSERT INTO t1 VALUES ( 3, 1, 3 );
1 row created.
```

- result: success

```
INSERT INTO t1 VALUES ( 4, 4, 1 );
1 row created.
```

- result: success
- t1_uk1, t1_uk2 constraints are DEFERRED

```
ROLLBACK TO SAVEPOINT sp3;
Rollback complete.
```

- result: success

```
INSERT INTO t1 VALUES ( 1, 2, 2 );
1 row created.
```

- result: success

```
INSERT INTO t1 VALUES ( 3, 1, 3 );
1 row created.
```

- result: success

```
INSERT INTO t1 VALUES ( 4, 4, 1 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK3) violated
```

- result: success
- t1_uk1 constraint is DEFERRED

```
ROLLBACK TO SAVEPOINT sp2;
Rollback complete.
```

- result: success

```
INSERT INTO t1 VALUES ( 1, 2, 2 );
1 row created.
```

- result: error

```
INSERT INTO t1 VALUES ( 3, 1, 3 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK2) violated
```

- result: error

```
INSERT INTO t1 VALUES ( 4, 4, 1 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK3) violated
```

- result: success
- all constraint are IMMEDIATE

```
ROLLBACK TO SAVEPOINT sp1;
Rollback complete.
```

- result: error

```
INSERT INTO t1 VALUES ( 1, 2, 2 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK1) violated
```

- result: error

```
INSERT INTO t1 VALUES ( 3, 1, 3 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK2) violated
```

- result: error

```
INSERT INTO t1 VALUES ( 4, 4, 1 );
ERR-23000(16057): unique constraint (PUBLIC.T1_UK3) violated
```

- result: 1 row
- 1 1 1

```
SELECT * FROM t1;
ID1 ID2 ID3
--- --- ---
  1   1   1
1 row selected.
```

When the transaction is committed or rolled back, the effects of SET CONSTRAINTS statement is also ter minated, and all deferrable constraints follows the constraints property which is INITIALLY IMMEDIATE or INITIALLY DEFERRED value.

Examples

The following is an example of changing the check point by specifying the constraint name.

```
gSQL> SET CONSTRAINTS t1_uk1 DEFERRED;
Constraints set.
```

The following is an example of changing the check point of all deferrable constraints.

```
gSQL> SET CONSTRAINTS ALL DEFERRED;
Constraints set.
```

Compatibility

The SQL standard does not define CONSTRAINT keyword clause.

Table 20-21 SQL standard compatibility

Feature ID	Description	Compatibility
F721	Deferrable constraints	O

For More Information

Refer to the followings.

- Adding constraints
  - **CREATE TABLE**
  - **ALTER TABLE name ADD CONSTRAINT**
  - **ALTER TABLE name ADD COLUMN**
  - **ALTER TABLE name ALTER COLUMN**
- Altering constraints: **ALTER TABLE name ALTER CONSTRAINT**
- Controlling the check point of constraints: **SET CONSTRAINTS**

20.21 SET SCHEMA schema_name

Function

It sets the default schema name to be used in the current session.

Syntax

```
<set schema statement> ::=
    SET SCHEMA schema_name
    ;
```

Invocation and Access Rules

N/A

Syntax Rules and Parameters

schema_name

It is the default schema name to be set in the current session.

Description

It sets the default schema name to be used in the current session.
If the schema name of the object is not specified, then it becomes the default schema name to be used in the current session.

- When accessing as the user u1, then retrieve R relation by using the schema path of user u1.

```
% gsql u1 u1
gsql> SELECT * FROM r;
```

- When SET SCHEMA statement is set, then then retrieve R relation by using NEW_SCHEMA.R.

```
gsql> SET SCHEMA new_schema;
gsql> SELECT * FROM r;
```

Examples

The following is an example of when user u1 has schema s1 and s2.

```
CREATE USER u1 IDENTIFIED BY u1 WITHOUT SCHEMA;
CREATE SCHEMA s1 AUTHORIZATION u1;
CREATE SCHEMA s2 AUTHORIZATION u1;
COMMIT;
ALTER USER u1 SCHEMA PATH ( s1, s2 );
GRANT ALL PRIVILEGES TO u1;
COMMIT;
CREATE TABLE s1.t1 ( c1 VARCHAR(32) );
INSERT INTO s1.t1 VALUES ( 'S1.T1' );
COMMIT;
CREATE TABLE s2.t1 ( c1 VARCHAR(32) );
INSERT INTO s2.t1 VALUES ( 'S2.T1' );
COMMIT;
```

It retrieves table S1.T1 by interpreting table t1 using schema path of user u1 when accessing for the first t ime.

```
% gsql u1 u1
gSQL> SELECT current_schema FROM dual;
CURRENT_SCHEMA
--------------
S1
1 row selected.
gSQL> SELECT * FROM t1;
C1
-----
S1.T1
1 row selected.
```

It retrieves table S2.T1 by interpreting table t1 using schema name of the session after SET SCHEMA state ment is used.

```
gSQL> SET SCHEMA s2;
Session set.
gSQL> SELECT current_schema FROM dual;
CURRENT_SCHEMA
--------------
S2
1 row selected.
gSQL> SELECT * FROM t1;
C1
-----
S2.T1
1 row selected.
```

Compatibility

Table 20-22 SQL standard compatibility

Feature ID	Description	Compatibility
F761	Session management	O

20.22 SET SESSION AUTHORIZATION user_identifier

Function

It sets the session user and current user.

Syntax

```
<set session user identifier statement> ::=
    SET SESSION AUTHORIZATION user_identifier
    ;
```

Invocation and Access Rules

ACCESS CONTROL ON DATABASE privilege is required for a logon user to perform <set session user identifier statement>.

The user information is managed in three types as follows.

- Logon user
  - It is a user who performed login, and it is maintained until the connection is closed.
- Session user
  - It is as same as the first logon user, but it can be changed using the SET SESSION AUTHORIZATION statement.
- Current user
  - It is generally as same as the session user, but it is temporarily changed internally in system to control access when using the PSM or view.
  - The session user and current user is similar to the difference between the unix system's real user and the effective user.

Syntax Rules and Parameters

user_identifier

It is the username to be altered.

Description

After performing SET SESSION AUTHORIZATION statement, all statements is performed based on the sess ion user. Therefore, the privilege for the session user is checked and the owner of when creating objects also is the session user.

Example

The following is an example that the user test with ACCESS CONTROL ON DATABASE privilege sets the u ser u1 to the session user.

```
gSQL> SET SESSION AUTHORIZATION u1;
Session set.
gSQL> SELECT LOGON_USER(), SESSION_USER(), CURRENT_USER FROM dual;
LOGON_USER() SESSION_USER() CURRENT_USER
------------ -------------- ------------
TEST         U1             U1
1 row selected.
```

Compatibility

Table 20-23 SQL standard compatibility

Feature ID	Description	Compatibility
F321	User authorization	O

20.23 SET SESSION CHARACTERISTICS AS transaction_mode

Function

It sets the transaction property of a session.

Syntax

```
<set session characteristics statement> ::=
    SET SESSION CHARACTERISTICS AS TRANSACTION <transaction_mode>
    ;
<transaction_mode> ::=
    { <transaction_access_mode> | ISOLATION LEVEL < isolation_level > }
<transaction_access_mode> ::=
    READ { ONLY | WRITE }
< isolation_level > ::=
    { READ COMMITTED | SERIALIZABLE }
```

Syntax Rules and Parameters

<transaction_access_mode>

It is ACCESS MODE of the following transactions.

- READ ONLY
- READ WRITE

<isolation_level>

It is ISOLATION LEVEL of the following transactions.

- READ COMMITTED
- SERIALIZABLE

Description

SET SESSION CHARACTERISTICS sets the transaction property of a session. In other words, properties of a ll transactions created within the session follows these properties.

However, **SET TRANSACTION transaction_mode** statement sets only the property of a single transaction which is performed next.

Examples

The following is an example that all transactions to be created within the session are set to READ ONLY.

```
gSQL> SET SESSION CHARACTERISTICS AS TRANSACTION READ ONLY;
Session set.
```

The following is an example that the isolation level of all transactions to be created within the session is s et to READ COMMITTED.

```
gSQL> SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED;
Session set.
```

Compatibility

Table 20-24 SQL standard compatibility

Feature ID	Description	Compatibility
F761	Session management	O

For More Information

Refer to **SET TRANSACTION transaction_mode**.

20.24 SET TIME ZONE

Function

It sets the TIMEZONE of a session.

Syntax

```
<set local time zone statement> ::=
    SET TIME ZONE <set time zone value>
    ;
<set time zone value> ::=
    { '[+|-]hh:mm' | LOCAL }
```

Syntax Rules and Parameters

<set time zone value>

It is the TIMEZONE value to be set.

- hh:mm: It is a GMT OFFSET of the TIMEZONE to be set.
  - The range of the offset value is '-14:00' ~ '+14:00' .
- LOCAL: It is the TIME ZONE at the time of session creation.
  - TIME ZONE at the time of session creation is set to TIME ZONE of the client OS.

Description

Altering the time zone of the session affects the result value of function such as **CURRENT_TIME**, **CURRENT_TIMESTAMP**.

Example

The following is an example of altering the session time zone to '+09: 00'.

```
gSQL> SET TIME ZONE '+09:00';
Session set.
```

Compatibility

Table 20-25 SQL standard compatibility

Feature ID	Description	Compatibility
F411	Time zone specifications	O

20.25 SET TRANSACTION transaction_mode

Function

It sets the transaction property.

Syntax

```
<set transaction statement> ::=
    SET TRANSACTION <transaction_mode>
    ;
<transaction_mode> ::=
    { <transaction_access_mode> | ISOLATION LEVEL < isolation_level > }
<transaction_access_mode> ::=
    READ { ONLY | WRITE }
< isolation_level > ::=
    { READ COMMITTED | SERIALIZABLE }
```

Syntax Rules and Parameters

<transaction_access_mode>

It is ACCESS MODE of the following transactions.

- READ ONLY
- READ WRITE

<isolation_level>

It is ISOLATION LEVEL of the following transactions.

- READ COMMITTED
- SERIALIZABLE

Description

SET TRANSACTION sets property of the next transaction, and the property is reset to the default value aft
er the next transaction ends.

Example

The following is an example of setting the next transaction to READ ONLY.

```
gSQL> SET TRANSACTION READ ONLY;
Transaction set.
```

Compatibility

Table 20-26 SQL standard compatibility

Feature ID	Description	Compatibility
T251	SET TRANSACTION statement: LOCAL option	X

For More Information

Refer to **SET SESSION CHARACTERISTICS AS transaction_mode**.

20.26 TRUNCATE TABLE

Function

It truncates all rows from a table.

Syntax

```
<truncate table statement> ::=
    TRUNCATE TABLE table_name
        [ RESTART IDENTITY ¦ CONTINUE IDENTITY ]
        [ DROP STORAGE ¦ DROP ALL STORAGE ]
    ;
```

Invocation and Access Rules

One of the following privileges is required for a user to perform <truncate table statement>.

- The owner of that table
- CONTROL TABLE ON TABLE for the table
- (DROP TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- DROP ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be truncated.
It can define schema to which the table belongs such as schema_name.table_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

[RESTART IDENTITY | CONTINUE IDENTITY]

- RESTART IDENTITY
  - If an identity column which has auto created value in that table exists, it automatically restarts val ue.
- CONTINUE IDENTITY
  - If an identity column which has auto created value in that table exists, it does not change the exis ting value.
- If it is not specified, the default value is CONTINUE IDENTITY.

[DROP STORAGE | DROP ALL STORAGE]

- DROP STORAGE
  - It drops allocated extents from the the table excluding the space of MINSIZE.
- DROP ALL STORAGE
  - It drops all extents allocated to the table.
- If it is not specified, the default value is DROP STORAGE.

Description

Data Definition Language (DDL) statement such as TRUNCATE TABLE can be rolled back if it is before wh en the transaction is committed.

Examples

The following is an example of performing TRUNCATE TABLE statement.

```
gSQL> TRUNCATE TABLE t1;
Table truncated.
```

The following is an example of restarting the value of the identity column when performing TRUNCATE T ABLE.

```
TRUNCATE TABLE t1 RESTART IDENTITY;
Table truncated.
```

Compatibility

The SQL standard does not define [DROP STORAGE | DROP ALL STORAGE] clause.

Table 20-27 SQL standard compatibility

Feature ID	Description	Compatibility
F200	TRUNCATE TABLE statement	O
F202	TRUNCATE TABLE: identity column restart option	O

20.27 UPDATE

Function

It updates rows in a table.

Syntax

```
<update statement: searched> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        SET <set clause> [, ...]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
    ;
<set clause> ::=
      column_name = { <value expression> | DEFAULT }
    | ( column_name [, ...] ) = ( { <value expression> | DEFAULT } [, ...] )
    | ( column_name [, ...] ) = ( <query expression> )
<result offset clause> ::=
    OFFSET skip_count [ ROW | ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    | <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST | NEXT ] [ row_count ] [ ROW ONLY | ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count | offset_row_count, fetch_row_count | ALL }
```

Invocation and Access Rules

One of the following privileges is required for a user to perform <update statement: searched>.

- UPDATE(columns) ON TABLE for all columns which are targets to be updated
- (UPDATE or CONTROL TABLE) ON TABLE for the table

- (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
- UPDATE ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be updated.
It can define schema to which the table belongs such as schema_name.table_name and if schema_name is omitted, the default schema name of the user performing the statement is used.

[AS alias_name]

It is the alias of table_name.

〈set clause〉

It defines the columns to be updated and its values to be assigned. The number of columns in 〈set clause 〉 should be as same as the number of values.

It can be defined as follows.

- column_name = { 〈value expression〉 | DEFAULT }

```
UPDATE table_name
   SET column1 = value1, column2 = value2, column3 = value3
```

- (column_name [, ...]) = ({ 〈value expression〉 | DEFAULT } [, ...])

```
UPDATE table_name
   SET ( column1, column2, column3 ) = ( value1, value2, value3 )
```

- (column_name [, ...]) = (〈query expression〉)

```
UPDATE table_name
   SET column1 = ( SELECT max(value1) FROM other_table_name )
```

〈query expression〉 should be a query which creates a single row.

If DEFAULT is defined as a column value, the default values (refer to **〈default clause〉**) defined when exec uting **CREATE TABLE** is used. If it is not defined, NULL value is assigned.

WHERE 〈search condition〉

It updates the rows which satisfy WHERE condition.
If WHERE condition is not specified, all rows are updated.
For more information about WHERE condition, refer to **where clause** of **SELECT**.

〈result offset clause〉

It specifies the number of rows to skip from the query result.
For more information, refer to **〈result offset clause〉** of **SELECT**.

〈fetch limit clause〉

It specifies the number of rows to fetch in two ways, which are 〈fetch first clause〉 and 〈limit clause〉.

- 〈fetch first clause〉
  - It specifies the number of rows to be fetched.
  - For more information, refer to **〈fetch first clause〉** of **SELECT** statement.
- 〈limit clause〉
  - It specifies the number of rows to be fetched, or it simultaneously specifies both the number of r ows to be skipped and the number of rows to be fetched.
  - For more information, refer to **〈limit clause〉** of **SELECT** statement.

Description

Differences among UPDATE-related Statements

- **UPDATE**
  - It updates multiple rows which satisfy the condition.
  - e.g. UPDATE t1 SET c2 = c2 + 1 WHERE c1 > 0;
- **UPDATE name WHERE CURRENT OF cursor_name**
  - It updates the row which the current cursor indicates.
  - e.g. UPDATE t1 WHERE CURRENT OF cursor;
- **UPDATE name RETURNING**
  - It updates multiple rows which satisfy the conditions, and the updated rows can be retrieved in t he same way as **SELECT** statement (API such as SQLFetch ()).

    - e.g. UPDATE t1 SET c2 = c2 + 1 WHERE c1 > 0 RETURNING c2;
- **UPDATE name RETURNING .. INTO**
    - It updates row equal to or less than one, and if a single row is updated, it obtains the value to th e host variable of RETURNING INTO clause.
    - e.g. UPDATE t1 SET c2 = c2 + 1 WHERE c1 = 0 RETURNING c2 INTO :v1;

Examples

The following is an example of updating multiple rows which satisfy the condition.

```
gSQL> UPDATE lineitem
         SET l_shipdate = CURRENT_DATE
       WHERE l_returnflag = 'R';
5 rows updated.
```

The following is an example of updating the value of multiple columns.

```
gSQL> UPDATE lineitem
         SET l_shipdate   = CURRENT_DATE
           , l_returnflag = 'A'
       WHERE l_returnflag = 'R';
5 rows updated.
```

The following is an example of updating multiple columns by enclosing them with parentheses.

```
gSQL> UPDATE lineitem
         SET ( l_shipdate  , l_returnflag )
           = ( CURRENT_DATE, 'A' )
       WHERE l_returnflag = 'R';
5 rows updated.
```

The following is an example of updating the column value by using the subquery.

```
gSQL> UPDATE lineitem
         SET l_discount = ( SELECT MAX(l_discount) + 0.01 FROM lineitem )
       WHERE l_returnflag = 'R';
5 rows updated.
```

The following is an example of updating part of the rows which satisfy the condition by using OFFSET an d FETCH clauses.

```
gSQL> UPDATE lineitem
         SET l_discount = l_discount + 0.01
       WHERE l_returnflag = 'R'
      OFFSET 3
      FETCH 2;
2 rows updated.
```

Compatibility

The SQL standard does not define the following clauses in UPDATE statement.

- 〈result offset clause〉
- 〈fetch limit clause〉

Table 20-28 SQL standard compatibility

Feature ID	Description	Compatibility
F781	Self-referencing operations	X
T111	Updatable joins, unions, and columns	X

20.28 UPDATE name RETURNING

Function

It updates rows in a table, and retrieves the rows of before or after the update.

Syntax

```
<update statement: searched> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        SET <set clause> [, ...]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        <returning clause>
<set clause> ::=
      column_name = { <value expression> | DEFAULT }
    | ( column_name [, ...] ) = ( { <value expression> | DEFAULT } [, ...] )
    | ( column_name [, ...] ) = ( <query expression> )
<result offset clause> ::=
    OFFSET skip_count [ ROW | ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    | <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST | NEXT ] [ row_count ] [ ROW ONLY | ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count | offset_row_count, fetch_row_count | ALL }
<returning clause> ::=
    { RETURN | RETURNING } [ NEW | OLD ] { * | { <value expression> [ [AS] alias_name] } [,
...] }
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <update returning query statement>.

- One of the following privileges is required to perform UPDATE statement.
  - UPDATE(columns) ON TABLE for all columns which are targets to be updated
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

- One of the following privileges for all columns used in RETURNING clause is required.
  - SELECT(columns) ON TABLE for all columns used in RETURNING clause
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be updated.

[AS alias_name]

It is the alias of table_name.

<set clause>

It defines the columns to be updated and its values to be assigned. The number of columns in <set clause > should be as same as the number of values.
For more information, refer to **UPDATE**.

WHERE <search condition>

It updates the rows which satisfy WHERE condition.
If WHERE condition is not specified, all rows are updated.
For more information about WHERE condition, refer to **where clause** of **SELECT**.

〈result offset clause〉

It specifies the number of rows to skip from the query result.
For more information, refer to **〈result offset clause〉** of **SELECT**.

〈fetch limit clause〉

It specifies the number of rows to fetch in two ways, which are 〈fetch first clause〉 and 〈limit clause〉.

- 〈fetch first clause〉
  - It specifies the number of rows to be fetched.
  - For more information, refer to **〈fetch first clause〉** of **SELECT** statement.
- 〈limit clause〉
  - It specifies the number of rows to be fetched, or it simultaneously specifies both the number of r ows to be skipped and the number of rows to be fetched.
  - For more information, refer to **〈limit clause〉** of **SELECT** statement.

〈returning clause〉

It defines the updated rows as a result set, and specifies columns to be retrieved from the result set.

- RETURN and RETURNING are the keywords with the same meaning.
- NEW | OLD
  - NEW: It searches for updated rows based on the row after the update.
  - OLD: It searches for updated rows based on the row before the update.
  - If it is omitted, the default value is NEW.
- 〈value expression〉
  - It is as same as 〈select list〉 in SELECT statement, but aggregation can not be used.
- [[AS] alias_name]
  - It can name 〈value expression〉 by using AS clause.

Description

For more information, refer to **Differences among UPDATE-related Statements**.

Examples

The following is an example of obtaining values of the updated rows by using RETURNING clause.

```
gSQL> UPDATE lineitem
         SET l_discount = l_discount + 0.01
       WHERE l_returnflag = 'R'
   RETURNING l_orderkey, l_linenumber, l_discount;
L_ORDERKEY L_LINENUMBER L_DISCOUNT
---------- ------------ ----------
         8            1        .07
         9            2        .11
        12            5        .05
        15            1        .03
        16            2        .08
5 rows updated.
```

The following is an example of obtaining values before the update for the updated rows by using RETUR NING OLD clause.

```
gSQL> UPDATE lineitem
         SET l_discount = l_discount + 0.01
       WHERE l_returnflag = 'R'
   RETURNING OLD l_orderkey, l_linenumber, l_discount;
L_ORDERKEY L_LINENUMBER L_DISCOUNT
---------- ------------ ----------
         8            1        .06
         9            2         .1
        12            5        .04
        15            1        .02
        16            2        .07
5 rows updated.
```

Compatibility

The SQL standard does not define <update returning query statement>.

20.29 UPDATE name RETURNING .. INTO

Function

It updates a single row of a table, and the updated value is obtained into the host variable.

Syntax

```
<update statement: searched> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        SET <set clause> [, ...]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        <returning into clause>
    ;
<set clause> ::=
      column_name = { <value expression> | DEFAULT }
    | ( column_name [, ...] ) = ( { <value expression> | DEFAULT } [, ...] )
    | ( column_name [, ...] ) = ( <query expression> )
<result offset clause> ::=
    OFFSET skip_count [ ROW | ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    | <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST | NEXT ] [ row_count ] [ ROW ONLY | ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count | offset_row_count, fetch_row_count | ALL }
<returning into clause> ::=
    { RETURN | RETURNING } [ NEW | OLD ] { * | { <value expression> [ [AS] alias_name] } [,
...] } INTO variable_name [, ...]
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <update returning query statement>.

- One of the following privileges is required to perform UPDATE statement.
  - UPDATE(columns) ON TABLE for all columns which are targets to be updated
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

- One of the following privileges for all columns used in RETURNING clause is required.
  - SELECT(columns) ON TABLE for all columns used in RETURNING clause
  - (SELECT or CONTROL TABLE) ON TABLE for the table
  - (SELECT TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - SELECT ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a target table whose rows are to be updated.

[AS alias_name]

It is the alias of table_name.

<set clause>

It defines the columns to be updated and its values to be assigned. The number of columns in <set clause > should be as same as the number of values.
For more information, refer to **UPDATE**.

WHERE <search condition>

It updates the rows which satisfy WHERE condition.
If WHERE condition is not specified, all rows are updated.
For more information about WHERE condition, refer to **where clause** of **SELECT**.

〈result offset clause〉

It specifies the number of rows to skip in the query result.
For more information, refer to **〈result offset clause〉** of **SELECT**.

〈fetch limit clause〉

It specifies the number of rows to fetch in two ways, which are 〈fetch first clause〉 and 〈limit clause〉.

- 〈fetch first clause〉
  - It specifies the number of rows to be fetched.
  - For more information, refer to **〈fetch first clause〉** of **SELECT** statement.
- 〈limit clause〉
  - It specifies the number of rows to be fetched, or it simultaneously specifies both the number of r ows to be skipped and the number of rows to be fetched.
  - For more information, refer to **〈limit clause〉** of **SELECT** statement.

RETURNING .. AS ..

It defines the updated rows as a result set, and specifies columns to be retrieved from the result set.
For more information, refer to **〈returning clause〉** of **UPDATE name RETURNING**.

INTO variable_name [, ...]

The number of variables specified in INTO clause should be equal to the number of the expressions specifi ed in RETURNING clause.
The row to be updated should be one or less. If two or more rows are updated, an error occurs.

Description

For more information, refer to **Differences among UPDATE-related Statements**.

Example

The following is an example of obtaining column values of the updated rows into the host variables.

- Declare the host variable.

```
gSQL> \VAR v_discount NUMBER
gSQL> UPDATE lineitem
         SET l_discount = l_discount + 0.01
       WHERE l_orderkey = 12 AND l_linenumber = 5
   RETURNING l_discount INTO :v_discount;
V_DISCOUNT
----------
       .05
1 row updated.
```

Compatibility

In the SQL standard, <update returning into statement> statement does not exist.

20.30 UPDATE name WHERE CURRENT OF cursor_name

Function

It updates a single row which the current cursor indicates.

Syntax

```
<update statement: positioned> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        SET <set clause> [, ...]
        WHERE CURRENT OF cursor_name
    ;
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <update statement: positioned>.

- One of the following privileges is required to perform UPDATE statement.
  - UPDATE(columns) ON TABLE for all columns which are targets to be updated
  - (UPDATE or CONTROL TABLE) ON TABLE for the table
  - (UPDATE TABLE or CONTROL SCHEMA) ON SCHEMA for the schema to which the table belongs
  - UPDATE ANY TABLE ON DATABASE

Syntax Rules and Parameters

table_name

It is the name of a table whose rows are to be updated.

[AS alias_name]

It is the alias of table_name.

〈set clause〉

It defines the columns to be updated and its values to be assigned. The number of columns in 〈set clause 〉 should be as same as the number of values.
For more information, refer to **UPDATE**.

cursor_name

The cursor corresponding to cursor_name should satisfy the following conditions.

- The cursor should be OPEN. (Refer to **OPEN cursor_name**.)
- Fetched rows by using the cursor should exist. (Refer to **FETCH cursor_name**.)
- The query used for the cursor should identify table_name. (Refer to **DECLARE cursor_name**.)
- The cursor should be updatable for table_name. (Refer to **DECLARE cursor_name**.)

Description

For more information, refer to **Differences among UPDATE-related Statements**.

Examples

The following is an example that 〈update statement: positioned〉 is performed in interactive SQL (gsql) us ing the cursor.

- Declare the host variable.

```
gSQL> \VAR v_discount NUMBER
```

- Declare the cursor.

```
gSQL> DECLARE update_cursor CURSOR FOR
        SELECT l_discount
          FROM lineitem
         WHERE l_orderkey = 8 AND l_linenumber = 1
```

```
           FOR UPDATE;
Cursor declared.
```

- Open the cursor.

```
gSQL> OPEN update_cursor;
Cursor is open.
```

- Fetch the row.

```
gSQL> FETCH update_cursor INTO :v_discount;
V_DISCOUNT
----------
       .06
1 row fetched.
```

- Update the current row.

```
gSQL> UPDATE lineitem
         SET l_discount = l_discount + 0.01
       WHERE CURRENT OF update_cursor;
1 row updated.
```

- Close the cursor.

```
gSQL> CLOSE update_cursor;
Cursor closed.
gSQL> COMMIT;
Commit complete.
```

The following is an example of performing <update statement: positioned> by using the cursor in embed ded SQL program.

```
{
    ...
    EXEC SQL BEGIN DECLARE SECTION;
        ...
        double v_discount;
        ...
    EXEC SQL END DECLARE SECTION;
    ...
    EXEC SQL DECLARE update_cursor CURSOR FOR
```

```
            SELECT l_discount
              FROM lineitem
             WHERE l_orderkey = 8 AND l_linenumber = 1
               FOR UPDATE;
    ...
    EXEC SQL OPEN update_cursor;
    ...
    EXEC SQL FETCH NEXT update_cursor INTO :v_discount;
    ...
    EXEC SQL UPDATE lineitem
                SET l_discount = l_discount + 0.01
              WHERE CURRENT OF update_cursor;
    ...
    EXEC SQL CLOSE update_cursor;
    ...
    EXEC SQL COMMIT WORK;
    ...
}
```

Compatibility

Table 20-29 SQL standard compatibility

Feature ID	Description	Compatibility
F831	Full cursor update	O
B031	Basic dynamic SQL	O

For More Information

Refer to **CLOSE cursor_name**.

Part IV.

PSM Manual

21.

Overview of PSM

21.1 Features of PSM

Closely Interworking with SQL

GOLIDILOCKS PSM can closely interworks with GOLDILOCKS SQL.

- It supports all data types supported by GOLDILOCKS SQL.
- It supports an attribute type (%TYPE, %ROWTYPE), so a flexible tables and column types are availabl e.
- It supports all operators and built-in functions supported by GOLDILOCKS SQL.
- It supports all DML, DCL (COMMIT/ROLLBACK) supported by GOLDILOCKS SQL.
- It supports SQL SELECT statements by declaring a cursor and using OPEN, FETCH, CLOSE statements.
- It supports SQL DDL statements through the dynamic SQL feature.

Improving Performance

GOLDILOCKS PSM is operated only within a server, so it reduces the number of communications between the user application and the DBMS server. Therefore, the overall performance is improved.

Improving Productivity

The language of GOLDILOCKS PSM is quite similar to that of script, a less effort is required to write a cod e for the desired feature. The time of writing a client application can be reduced if the procedure and fun cure is created by modularizing the user's work logic.

Portability

Procedures and functions created by GOLDILOCKS PSM can also be used in ODBC, JDBC, an embedded S QL, and various development tools in the same way. Also, it can be easily transplanted in a different platf orm regardless of the platform type of server or a client.

Easy Maintenance

GOLDILOCKS PSM is implemented into a single module in a server from each similar logics in separate cli ents. Therefore, it is easy to manage, and enable to modify when it is in need even during the module is i n use.

21.2 Language Elements

Data Types

GOLDILOCKS PSM provides all built-in data types provided by GOLDILOCKS SQL, and it even supports use r defined records and collection types.
For more information, refer to **PSM DataTypes**.

Variables

Required variables declared by a user in GOLDILOCKS PSM can be used in all expressions.

For more information, refer to the followings.

- **Declarative Part**
- **Assignment**

Control Structures

GOLDILOCKS PSM supports most of decision branch statements, unconditional branch statements (GOT O), loop statement for repeated executions which were provided by a general script language.
For more information, refer to **PSM Control Statements**.

Subprograms

GOLDILOCKS PSM subprogram is a PSM block with a name and it can be repeatedly performed. If a subp rogramd has an argument, then it can be performed by being given different arguments when each time it is called.
Subprogram is either in a procedure form or a function form, and the function form has a return value. It also supports a nested subprogram which is declared in a specific block and used within it.
For more information, refer to **Using PSM Subprograms**.

21.3 Processing Transaction in PSM

A database transaction is a work unit which consists of one or more of SQL statements and it can not be disassembled. The followings are SQL statements which use transactions in GOLDILOCKS database.

- DML except for SELECT statements
- All DDL

A transaction starts in the following cases.

- When performing SQL which uses a transaction for the first time immediately after the connection.
- When performing SQL which uses a transaction for the first time since COMMIT or ROLLBACK

A transaction ends when a user performs COMMIT or ROLLBACK, or terminates the connection.

A subprogram module created by GOLDILOCKS PSM is a statement which does not uses its own transacti on, so a new transaction does not occur when the subprogram is called.

However, to guarantee atomicity of the SQL statement, the the available SQL types in a subprogram may vary depending on the case of calling the subprogram.

- When a user directly calls a subprogram module by using CALL statement, or performs an anonymou s block
  - A superordinate statement does not exists, so all kinds of SQL can be used within a subprogram and COMMIT/ROLLBACK is also allowed.
- When a subprogram module is used within a DML statement (INSERT/UPDATE/DELETE) except for S ELECT
  - A superordinate statement has a transaction, so all kinds of SQL can be used within a subprogra m. However, to guarantee the atomicity of the superordinate statement, neither COMMIT nor R OLLBACK is allowed.
- When a subprogram module is called within a SELECT statement
  - A superordinate statement does not use a transaction, so any kind of SQL using a transaction can not be used even within a called subprogram, nor is COMMIT/ROLLBACK allowed. Only SELECT s tatement is allowed.

22.

PSM DataTypes

22.1 Built-in Data Types

GOLDILOCKS PSM supports all basic data types provided by GOLDILOCKS SQL in the same way.
The followings are the basic data types.
For more information, refer to **Data Type**.

Numeric Types

- NUMBER
- NUMERIC
- FLOAT
- NATIVE_INTEGER
- NATIVE_DOUBLE

CHARACTER STRING Types

- CHARACTER (CHAR)
- CHARACTER VARYING (VARCHAR, VARCHAR2)
- CHARACTER LONG VARYING (LONG VARCHAR)

Exceptionally, for the compatibility with other database, GOLDILOCKS PSM provides VARCHAR types (VARCHAR2, CHAR VARYING, CHARACTER VARYING) whose precision is not specified, a nd which is not supported by GOLDILOCKS SQL.

This type can not be used when declaring an ordinary variable, but it can be used only when de claring an argument of a subprogram, a return type or an argument of a cursor. If this type is sp ecified, then the argument and the return type is determined as a type with the biggest value a mong VARCHAR types. (precision = 4000)

BINARY STRING Type

- BINARY
- BINARY VARYING (VARBINARY)
- BINARY LONG VARYING (LONG VARBINARY)

DATE/TIME Type

- DATE
- TIME [WITH/WITHOUT TIME ZONE]
- TIMESTAMP [WITH/WITHOUT TIME ZONE]

INTERVAL Type

- INTERVAL YEAR
- INTERVAL MONTH
- INTERVAL YEAR TO MONTH
- INTERVAL DAY
- INTERVAL HOUR
- INTERVAL MINUTE
- INTERVAL SECOND
- INTERVAL DAY TO HOUR
- INTERVAL DAY TO MINUTE
- INTERVAL DAY TO SECOND
- INTERVAL HOUR TO MINUTE
- INTERVAL HOUR TO SECOND
- INTERVAL MINUTE TO SECOND

BOOLEAN Type

BOOLEAN

ROWID Type

ROWID

Declaring Built-in Data Type Variables

A variable can be declared in each declaration section within an anonymous block, a procedure or a funct ion.

```
DECLARE
  V_MSG VARCHAR(20) := 'HELLO, WORLD!';
BEGIN
  DBMS_OUTPUT.PUT_LINE( 'My First Message Is : ' || V_MSG );
END;
/
```

For more information, refer to **Built-in Data Type References**.

22.2 Attribute Data Types

It is a data type which is used when specifying types of other PSM variables, cursors, tables or a specific c olumn in a table.

If an attribute variable or a target object (table) of a function is altered, then PSM (procedure, function) is automatically compiled again according to the altered type and it is applied.

%TYPE

It is used when specifying a type of other variables or a column type of a specific table. The following obj ects can be referenced.

- Scalar type (Including built-in data type) variables
- User defined record type variables
- A specific field of a record type variable
- Collection type variables
- A specific field of a collection type variable
- A specific column of a table

%TYPE is used as follows.

```
CREATE TABLE EMP ( ID INTEGER, NAME VARCHAR(32) );
INSERT INTO EMP VALUES ( 1001, 'Tom Jackson' );
COMMIT;
DECLARE
  V_NAME EMP.NAME%TYPE;
BEGIN
  SELECT NAME INTO V_NAME FROM EMP;
  DBMS_OUTPUT.PUT_LINE( 'EMP.NAME = ' || V_NAME );
END;
/
```

%ROWTYPE

It is used to specify the structure of a specific table, or the record type as same as the returned type of a s pecific cursor. It can refer to the following objects.

- Table
- Cursor
- Cursor variable

Neither the record type variable nor collection type variable can be a target of %ROWTYPE.

The following is an example of using %ROWTYPE.

```
DECLARE
  V_EMP EMP%ROWTYPE;
BEGIN
  SELECT * INTO V_EMP FROM EMP WHERE ID = 1001;
  DBMS_OUTPUT.PUT_LINE( 'Name of ID 1001 Is : ' || V_EMP.NAME );
END;
/
```

Constraint Attributes Inheritance

The constraint attributes of variables declared as an attribute type inherits the constraint attributes of the reference target as follows.

Table 22-1 Whether to inherit constraints of the attribute types

Attribute type	Reference target	NOT NULL	Default value
%TYPE	Scalar variable	O	X
	Record type variable	O	O
	A specific field of a record type variable	O	X
	Collection type variable - scalar element	O	X
	Collection type variable - record element	O	O
	A specific field of a collection type variable	O	X
	A specific column of a table	X	X
%ROWTYPE	Table	X	X
	Cursor	X	X

22.3 User-defined Record Type

The record type variable is a complex structure type which consists of several fields of each different type. A record type variable can be created by copying types of other tables or cursors by using %ROWTYPE, o r by declaring a data structure which is appropriate to a specific purpose by a user.

A user defined record type can be defined by using TYPE keyword in PSM declarative part as follows. Eac h field can optionally specify a NOT NULL constraint and a default value.

```
DECLARE
  TYPE MY_EMP_TYPE IS RECORD
  (
    ID INTEGER := 99999,
    NAME VARCHAR(32) NOT NULL DEFAULT 'anonymous'
  );
  V_EMP MY_EMP_TYPE;
BEGIN
  SELECT ID, NAME INTO V_EMP.ID, V_EMP.NAME FROM EMP;
  DBMS_OUTPUT.PUT_LINE('ID = ' || V_EMP.ID);
  DBMS_OUTPUT.PUT_LINE('NAME = ' || V_EMP.NAME);
END;
/
```

The following is an example of using it in a nested procedure or in a nested function.

```
DECLARE
  TYPE MY_EMP_TYPE IS RECORD
  (
    ID INTEGER := 99999,
    NAME VARCHAR(32) NOT NULL DEFAULT 'anonymous'
  );
  V_EMP MY_EMP_TYPE;
  PROCEDURE SET_EMP( A_EMP IN OUT MY_EMP_TYPE )
  IS
  BEGIN
    DBMS_OUTPUT.PUT_LINE('ID = ' || A_EMP.ID);
    DBMS_OUTPUT.PUT_LINE('NAME = ' || A_EMP.NAME);
    SELECT ID, NAME INTO A_EMP.ID, A_EMP.NAME FROM EMP;
  END;
BEGIN
```

```
  SET_EMP( V_EMP );
  DBMS_OUTPUT.PUT_LINE('ID = ' || V_EMP.ID);
  DBMS_OUTPUT.PUT_LINE('NAME = ' || V_EMP.NAME);
END;
/
```

A user defined record type can be used as an argument or a returned type of a general regional variable, a nested procedure, or a nested function. However, it can not be used as an argument or a returned type of a schema-level procedure or a schema-level function.

22.4 User-defined Collection Type

User defined collection type is a kind of an array structure which stores one or more data. GOLDILOCKS PSM supports an associative array type which can be stored as key/value pair among collection types.

The following is a basic SYNTAX to declare an associative type.

```
TYPE <type_name> IS TABLE OF <element_data_type> INDEX BY <index_key_data_type>
```

- <type_name> is a user defined name for the type.
- <element_data_type> specifies a data type of a value which configures an array.
- <index_key_data_type> specifies a data type of an index key which explores for an element.

For example, if the information corresponding to (number) is in form of (name, age), then a table can be created and stored in a database as follows.

```
CREATE TABLE INFO
(
   NO INTEGER,
   NAME VARCHAR(20),
   AGE INTEGER
)
CREATE UNIQUE INDEX IDX_NO ON INFO (NO)
```

- If the information above is stored as an associative array, then its configuration is as follows.
  - Index_key corresponds to a number (NO).
  - Element_data consists of a name (NAME) and an age (AGE).

An associative array variable to store it is defined within a real PSM as follows.

```
TYPE rec IS RECORD (NAME VARCHAR(20), AGE INTEGER);
TYPE info IS TABLE OF rec INDEX BY INTEGER;
```

For more information, refer to **COLLECTION Variable Declaration**.

Associative Array

An associative array type variable has a data type key specified in an index clause, and it is a PSM variable which can store a value of element data type specified in TABLE OF clause in one or more values in a key/value form.

- The features of an associative array type of GOLDILOCKS PSM is as follows.
  - It has an exploring key in a data type form specified in INDEX BY clause, and it is automatically so rted and stored.
  - It consists of elements specified in TABLE OF clause.
  - It provides exploring functions called as collection methods.
  - It is stored in a replace form when storing an element in an existing index key.
  - The maximum storage size is restricted to the available size of MEMORY_TEMP_TBS_SIZE.

The following is an example of declaring an element type as an SQL data type, and inserting data.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> DECLARE
  TYPE rec IS TABLE OF VARCHAR(20) INDEX BY VARCHAR(10);
  V1 rec;
BEGIN
  V1('aa') := 'Dog';
  V1('bb') := 'Cat';
  INSERT INTO T1 VALUES ( V1('aa'), V1('bb') );
END;
/
Anonymous PL block executed.
gSQL> SELECT * FROM T1;
C1  C2
--- ---
Dog Cat
1 row selected.
```

The following is an example of having a record type as an element.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> DECLARE
  TYPE rec IS TABLE OF T1%ROWTYPE INDEX BY VARCHAR(10);
```

```
  V1 rec;
BEGIN
  V1('person1').C1 := 'seoul';
  V1('person1').C2 := '12';
  V1('person2').C1 := 'busan';
  V1('person2').C2 := '24';
  INSERT INTO T1 VALUES V1('person1'), V1('person2');
END;
/
Anonymous PL block executed.
gSQL> SELECT * FROM T1;
C1    C2
----- --
seoul 12
busan 24
2 rows selected.
```

- The following is a data type which can be specified in an index key of an associative array of GOLDIL OCKS PSM.
  - INTEGER
  - LONG
  - CHAR
  - VARCHAR

- The following is a data type which can be used as an element type of an associative array of GOLDILO CKS PSM.
  - SQL Data Type
  - %TYPE
  - %ROWTYPE
  - User defined Record Type

For more information, refer to **Built-in Data Types**, **%TYPE**, **%ROWTYPE**, **User Defined Record Type**.

Assign Values to Collection Variables

The following rules are applied when assigning values to collection valuables.

- The rules as same as <Assign Statement> is applied to an element assignment.
- To assign values to the entire collection variable, the types of collection variables should be same.
- When assigning an element of a collection variable, it is operated according to the element data type as follows.

- Assigning a user defined type element is allowed among same type.
- Else, it is allowed to assign when data types of a field configuring an element are compatible at a run-time.

The following is an example of an error due to the assignment of a different type.

```
DECLARE
  TYPE udr1 IS RECORD (F1 INTEGER, F2 VARCHAR(20));
  TYPE udr2 IS RECORD (F1 INTEGER, F2 VARCHAR(20));
  TYPE rec1 IS TABLE OF udr1 INDEX BY VARCHAR(10);
  TYPE rec2 IS TABLE OF udr2 INDEX BY VARCHAR(10);
  V1 rec1;
  V2 rec2;
BEGIN
  V2('person1').F1 := 24;
  V2('person1').F2 := 'seoul korea';
  V1 := V2;
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (14:9): ERR-HY000(17007): invalid expression
```

In the example above, configuration of each field of an element which consists of user defined type is same. However, the variable types are different, so the assignment fails.

The following is an example of succeeding in an assignment by using the same type.

```
DECLARE
  TYPE udr1 IS RECORD (F1 INTEGER, F2 VARCHAR(20));
  TYPE rec1 IS TABLE OF udr1 INDEX BY VARCHAR(10);
  V1 rec1;
  V2 rec1;
BEGIN
  V2('person1').F1 := 24;
  V2('person1').F2 := 'seoul korea';
  V1 := V2;
END;
/
Anonymous PL block executed.
```

Assignment of an associative type in an element unit is allowed only when the data types of elements are compatible.

Refer to the following example.

```
gSQL> CREATE TABLE T1
(
  c1 VARCHAR(20),
  c2 VARCHAR(20)
);
Table created.
gSQL> DECLARE
TYPE record_org1 IS RECORD (f1 VARCHAR(20), f2 VARCHAR(20));
TYPE rec1 IS TABLE OF t1%rowtype INDEX BY VARCHAR(10);
TYPE rec2 IS TABLE OF record_org1 INDEX BY VARCHAR(10);
v1 record_org1;
v2 rec1;
v3 rec2;
v4 t1%rowtype;
BEGIN

  -- From record_org1 type to %rowtype
  V2('first') := v1;
  -- From record_org1 type to record_org1 type
  V3('first') := v1;

  -- From t1%rowtype to record_org1 type
  V3('second') := V2('first');
END;
/
Anonymous PL block executed.
```

An associative type variable is stored in a volatile memory space, and the user accessible TEMP TABLESPA CE should be extended when the space is insufficient. The following is an example of an error due to the memory insufficiency.

```
DECLARE
TYPE rec IS TABLE OF t1%rowtype INDEX BY varchar(20);
v1 rec;
BEGIN
  BEGIN
    FOR i IN 1 .. 100000
    LOOP
      v1(i).c1 := i;
```

```
      v1(i).c2 := i;
    END LOOP;
    EXCEPTION WHEN OTHERS THEN
                dbms_output.put_line('error: count=' || v1.count());
                dbms_output.put_line('sqlcode=' || SQLCODE);
                dbms_output.put_line('sqlmsg =' || SQLERRM);
  END;
  dbms_output.put_line('v1.count=' || v1.count());
END;
/
error: count=95004
sqlcode=-14015
sqlmsg =[SUNJESOFT][PSM][GOLDILOCKS]there is no extendible datafile in tablespace
'MEM_TEMP_TBS'
v1.count=95004
Anonymous PL block executed.
```

Collection Method

A collection method is a function or a procedure which is provided to easily operate a collection type variable. Associative array provides the following methods.

Table 22-2 Collection method

Method	Type	Input argument	Return type	Description
FIRST	Function	X	Index key data type	It returns the first index key.
LAST	Function	X	Index key data type	It returns the last index key.
COUNT	Function	X	INTEGER	It returns the number of elements.
EXISTS	Function	O	BOOLEAN	It returns whether an index key exists or not.
PRIOR	Function	O	Index key data type	It returns an index key prior to the input index key.
NEXT	Function	O	Index key data type	It returns an index key next to the input index key.
DELETE	Procedure	O	N/A	It deletes an element corresponding to the input index key.

A collection method is used as follows.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> DECLARE
  TYPE rec IS TABLE OF T1%ROWTYPE INDEX BY VARCHAR(10);
  V1 rec;
BEGIN
  V1('person1').C1 := 'seoul';
  V1('person1').C2 := '12';
  V1('person2').C1 := 'busan';
  V1('person2').C2 := '24';
  V1('person3').C1 := 'Daegu';
  V1('person3').C2 := '36';
  -- First method
  DBMS_OUTPUT.PUT_LINE('First Index Key = ' || V1.first() );
  -- Last method
  DBMS_OUTPUT.PUT_LINE('Last Index Key = ' || V1.last() );
  -- Count method
  DBMS_OUTPUT.PUT_LINE('Count of element = ' || V1.count() );
  -- Prior Method
  DBMS_OUTPUT.PUT_LINE('Prior (person1) = ' || V1.prior('person1') ); -- return NULL
  DBMS_OUTPUT.PUT_LINE('Prior (person3) = ' || V1.prior('person3') );
  -- Next Method
  DBMS_OUTPUT.PUT_LINE('Next (person1) = ' || V1.next('person1') );
  DBMS_OUTPUT.PUT_LINE('Next (person3) = ' || V1.next('person3') ); -- return NULL
  -- Exists Method
  DBMS_OUTPUT.PUT_LINE('Exists (person2) = ' || V1.exists('person2') );
  -- Delete Method
  V1.delete('person2');
  -- Exists Method
  DBMS_OUTPUT.PUT_LINE('After delete, Exists (person2) = ' || V1.exists('person2') );
END;
/
First Index Key = person1
Last Index Key = person3
Count of element = 3
Prior (person1) =
Prior (person3) = person2
```

```
Next (person1) = person2
Next (person3) =
Exists (person2) = TRUE
After delete, Exists (person2) = FALSE
Anonymous PL block executed.
```

If a delete procedure deleting an element can not find an index key corresponding to the input argument, then an error occurs as follows.

```
gSQL> DECLARE
  TYPE rec IS TABLE OF T1%ROWTYPE INDEX BY VARCHAR(10);
  V1 rec;
BEGIN
  V1('person1').C1 := 'seoul';
  V1('person1').C2 := '12';
  -- Call delete procedure
  V1.delete('person2');
END;
/
ERR-HY000(17045): no data found :
  V1.delete('person2');
  *
ERROR at line 9:
Anonymous PL block executed.
```

22.5 SYS_REFCURSOR

SYS_REFCURSOR is a predefined type for a cursor variable, and it is used to declare a cursor variable.

It is used to declare a cursor variable in the following form.

```
cursor_variable_name SYS_REFCURSOR;
```

Cursor variable can be used together with OPEN FOR, FETCH, CLOSE statement as follows.

```
DECLARE
  v1 VARCHAR(20);
  v2 VARCHAR(20);
  cv1 SYS_REFCURSOR;
  cv2 SYS_REFCURSOR;
BEGIN
  OPEN cv1 FOR SELECT * FROM T1;
  cv2 := cv1;
  FETCH cv2 INTO V1, V2;
  DBMS_OUTPUT.PUT_LINE('V1 = ' || V1 || ' , V2 = ' || V2);

END;
/
V1 = Seoul , V2 = 24
Anonymous PL block executed.
```

- The variable declared by using SYS_REFCURSOR is used as follows.
  - It is possible to assign each cursor variable among cursor variables. An existing open cursor of the cursor variable which is on the right of the assign can not be used any more.
  - An explicit cursor can not be assigned to a cursor variable.
  - A variable of a different data type can not be assigned to a cursor variable.
  - A nested function/procedure and schema-level function/procedure can be used as a parameter.

For more information, refer to **Cursor Variable**, **Cursor Variable Declaration**, **OPEN FOR Statement**.

23.

PSM Control Statements

23.1 Assignment

It inserts the calculation value of the right expression into the left variable by using assignment operators (':=').

Assignment Target

An assignment target is on the left side of the assignment operator, and the following items may exist on it.

- Variables (Including an argument of a procedure or a function except for IN type)
- Bind parameter such as '?' or ':V1' (It can be used only in an anonymous PL block.)

Assigning Expression

An expression available on PSM is on the right side of the assignment operator. Expressions available on a PSM expression is as follows.

- Constant
- All operators, built-in functions or pseudo columns provided by GOLDILOCKS SQL
- Bind parameter bound to IN or IN OUT type (It can be used only in an anonymous PL block.)
- PSM variable
- PSM nested function
- Schema-level function

The following is an example of assignment statement per each type.

```
CREATE OR REPLACE FUNCTION ADD_TEN( A1 INTEGER )
RETURN INTEGER
IS
BEGIN
  RETURN A1 + 10;
END;
/
COMMIT;
DECLARE
  FUNCTION ADD_ONE( A1 INTEGER )
```

```
  RETURN INTEGER
  IS
  BEGIN
    RETURN A1 + 1;
  END;
  V_NUM INTEGER;
  V_STR VARCHAR(10);
BEGIN
  V_NUM := 10;                  ❶ Numeric literal
  V_STR := 'ABC';               ❷ String literal
  :V_PARAM := V_STR || 'DEF';   ❸ PSM variable, SQL operator
  V_NUM := ADD_ONE( 100 ) + ADD_TEN( 1000 );
                                ❹ Nested function, Schema-level function
END;
/
```

The following expressions can not be used in an PSM expression.

- Column of a table, view or the corresponding object
- SQL objects such as an index, a sequence or a synonym
- Subquery
- Nested procedure
- Schema-level procedure

The following is an example of an error due to a wrong expression.

```
gSQL> CREATE SEQUENCE SEQ1;
Sequence created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  V1 INTEGER;
BEGIN
  V1 := SEQ1.NEXTVAL;
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (4:9): ERR-42000(16074): sequence number not allowed here
```

To assign an object value of a type which is not available in an PSM expression, use SELECT INTO stateme nt as follows.

```
gSQL> DECLARE
  V1 INTEGER;
BEGIN
  SELECT SEQ1.NEXTVAL INTO V1 FROM DUAL;
END;
/
Anonymous PL block executed.
```

Assignment Compatibility

Even though the statement can use an expression of an assignment statement, it may succeed or fail dep ending on a target type and the final result type of an expression. The available expression types accordin g to a target type is as follows.

Table 23-1 Assignment compatibility

Target type	Final result type of an expression
Scalar type • Scalar type variable • A specific field of a record type variable • Scalar element of a collection variable with a key value	It is allowed only when it is a scalar type with a value conve rsible to a target type.
Attribute record type (%ROWTYPE)	It is allowed only when the number of fields are same and each field value is conversible to the field of the correspon ding order of a target.
User defined record type	Only the exactly same type is allowed.
Collection type • Collection type variable whose key value is not sp ecified	Only the exactly same type is allowed.

Even though the internal structures of user defined record type variables are same, an error occurs if the t ype names are different.

```
gSQL> DECLARE
  TYPE MY_REC1 IS RECORD ( F1 INTEGER := 1, F2 VARCHAR(10) := 'AAA' );
  TYPE MY_REC2 IS RECORD ( F1 INTEGER := 1, F2 VARCHAR(10) := 'AAA' );
  V1 MY_REC1;
  V2 MY_REC2;
BEGIN
  V2 := V1;
END;
```

```
/
ERR-HY000(17032): PSM compilation error :
(1) at (7:9): ERR-HY000(17007): invalid expression
```

Moreover, if a target is an argument variable defined with IN attribute or is a bind parameter bound with IN attribute, an error occurs.

```
gSQL> DECLARE
  FUNCTION ADD_ONE( A1 IN INTEGER )
  RETURN INTEGER
  IS
  BEGIN
    A1 := A1 + 1;
    RETURN A1;
  END;
  V1 INTEGER;
BEGIN
  V1 := ADD_ONE( 10 );
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (6:5): ERR-HY000(17024): (A1) cannot be used as assignment target
```

Assignment compatibility rules are applied same even when assigning the value of an actual parameter to a formal parameter variable while calling a function or a procedure.

23.2 PL Block

A PL block is a basic unit which configures PSM. A PL block can be nested again in another PL block. Item s declared within a PL block can be referenced only within the range of its own block (Including subordin ate blocks)

PL Block Configuration

A single PL block is divided into the following three parts.
For more information, refer to **Block (BEGIN .. END)**.

```
[DECLARE
❶ Declarative part]
BEGIN
❷ Statements
[EXCEPTION
❸ Handlers]
END;
```

Declarative Part

A declarative part is an area in which a local item to be used within a PL block is declared. If an item such as a local variable to be declared does not exist, then a declarative part is not defined, but it starts from a n executable part.

Local items to be declared in a declarative part is as follows.

- Variable (Refer to **PSM DataTypes**.)
- User defined type
- Cursor
- Nested function or a procedure (Subprogram)
- User defined exception

All names of items declared in a single PL block should be unique regardless of their types. For example, a cursor whose name is as same as a name of a variable can not be declared.

```
gSQL> DECLARE
  C1 INTEGER;
  CURSOR C1 IS SELECT * FROM DUAL;
```

```
BEGIN
  OPEN C1;
  FETCH C1 INTO C1;
  CLOSE C1;
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (3:10): ERR-HY000(17027): duplicated identifier
(2) at (5:8): ERR-HY000(17031): mismatch identifier type
(3) at (6:9): ERR-HY000(17031): mismatch identifier type
(4) at (7:9): ERR-HY000(17031): mismatch identifier type
```

However, an item in a subordinate PL block whose name is as same as an item in a superordinate PL bloc k can be declared. In this case, that name means the item found first when exploring from the current loc ation toward the superordinate block.

```
gSQL> <<PP>>
DECLARE     ❶ Parent scope begin
  V1 VARCHAR(10) := 'AAA';
BEGIN
  <<CC>>
  DECLARE   ❷ Child scope begin
    V1 INTEGER := 99;
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'PP.V1 = ' || PP.V1 );
    DBMS_OUTPUT.PUT_LINE( 'CC.V1 = ' || CC.V1 );
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
  END;      ❸ Child scope end
END;        ❹ Parent scope end
/
PP.V1 = AAA
CC.V1 = 99
V1 = 99
Anonymous PL block executed.
```

Executable Part

In an executable part, a declared items are manipulated and included statements are performed. Stateme nts available in an executable parts are as follows.

- Control Statements (Refer to **PSM Control Statements**.)

- Cursor Statements (Refer to **PSM Cursor Statements**.)
- SQL Statements (static/ dynamic) (Refer to **Using SQLs In PSM**.)

Exception Handling Part

It defines handlers which handles multiple exceptions occurring during the execution.

If an exception occurs during executing several statements in an executable part, then it explores from th e location of that PL block to the superordinate PL block to find out whether a handler is registered to ha ndle the exception. If there is the handler, then it performs the contents of that handle, then initializes th at exceptional situation.

```
DECLARE
  V1 INTEGER;
BEGIN
  SELECT C1 INTO V1 FROM T1 WHERE C1 = 100;
EXCEPTION
  WHEN NO_DATA_FOUND THEN
    DBMS_OUTPUT.PUT_LINE('SQL%ISOPEN   = ' || SQL%ISOPEN);
    DBMS_OUTPUT.PUT_LINE('SQL%FOUND    = ' || SQL%FOUND);
    DBMS_OUTPUT.PUT_LINE('SQL%NOTFOUND = ' || SQL%NOTFOUND);
    DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT = ' || SQL%ROWCOUNT);
END;
/
```

If an appropriate handler is not found even after exploring to the top-level PL block, then the occurred ex ception is returned to a caller, and it is terminated.

```
gSQL> DECLARE
  v1 INTEGER;
BEGIN
  v1 := 1/ 0;
END;
/
ERR-HY000(17007): invalid expression :
  v1 := 1/ 0;
        *
ERROR at line 4:
ERR-22012(12122): divisor is equal to zero
```

For more information about declaration of user defined exception, built-in handler types or installing a ha ndler, refer to **Error Handling**.

23.3 NULL Statement

It is used to specify a statement which does not have any role in PSM such as no-op.
For more information, refer to **NULL Statement**.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  IF V1 < 10 THEN
    V1 := V1 + 1;
  ELSE
    NULL;  -- do nothing
  END IF;
END;
/
```

23.4 Testing Conditions

Conditional branch statements perform statements according to true/false of the given condition. GOLDI LOCKS PSM provides two conditional branch statements, which are IF and CASE.

IF

IF statement performs statements which are true among conditions of the given expression. Conditions o f an expression can be specified next to IF and ELSIF. If the condition of an expression is true when checki ng conditions in an order specified when performing, then it performs the statements below THEN clause. If all IF conditions and ELSIF conditions are false, and ELSE clause is specified, then it performs the statem ents below ELSE clause.

IF statement always ends with END IF keyword.
For more information, refer to **IF Statement**.

```
DECLARE
V1 INTEGER := 1;
BEGIN
  -- IF COND
  IF V1 > 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'IF COND' );
  ELSIF V1 = 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'ELSIF COND' );
  ELSE
    DBMS_OUTPUT.PUT_LINE( 'ELSE COND' );
  END IF;
  -- ELSIF COND
  IF V1 = 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'IF COND' );
  ELSIF V1 > 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'ELSIF COND' );
  ELSE
    DBMS_OUTPUT.PUT_LINE( 'ELSE COND' );
  END IF;
  -- ELSE COND
  IF V1 = 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'IF COND' );
```

```
  ELSIF V1 < 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'ELSIF COND' );
  ELSE
    DBMS_OUTPUT.PUT_LINE( 'ELSE COND' );
  END IF;
END;
/
```

ELSIF clause and ELSE clause are optional, so it may or may not be specified.

When ELSE statement is not specified and any conditions of IF or ELSIF is not true, then it does not perfor m any statement, but proceeds to the next statement without causing any exception.

CASE

CASE statement selects a single array among arrays of multiple statements such as IF statement, then per forms it. CASE statement ends with END CASE keyword, and ELSE clause is optional so it may or may not be specified.

If WHEN clause with an appropriate condition can not be found and ELSE clause is specified, then it arra ys statements below ELSE clause. If an appropriate condition does not exist nor is ELSE clause specified, t hen CASE_NOT_FOUND exception occurs.
For more information, refer to **CASE Statement**.

WHEN clauses in CASE is evaluated in an specified order, and if an appropriate WHEN clause is found an d statements of that WHEN clause are arrayed, then all WHEN clauses after that are ignored.

There are two kinds of CASE statements as follows.

- Simple CASE statement
- Searched CASE statement

Simple CASE Statement

A simple CASE statement arrays statements owned by WHEN clause which has the same value as a select or expression among expressions specified next to WHEN clause by using a selector expression specified next to CASE keyword. Then it ends.

```
DECLARE
V1 VARCHAR(1) := '2';
BEGIN
```

```
  CASE V1 WHEN '0' THEN DBMS_OUTPUT.PUT_LINE ('Result = 0');
          WHEN '1' THEN DBMS_OUTPUT.PUT_LINE ('Result = 1');
          WHEN '2' THEN DBMS_OUTPUT.PUT_LINE ('Result = 2');
          ELSE DBMS_OUTPUT.PUT_LINE ('Result = Other');
  END CASE;
END;
/
```

Searched CASE Statement

A searched CASE statement does not have a selector expression, instead a conditional expression which i s evaluated as boolean type per each WHEN clause is specified. When it is executed, it arrays statements owned by the first WHEN clause which is TRUE by evaluating expressions of each WHEN clause. Then it e nds.

```
DECLARE
V1 VARCHAR(1) := '2';
BEGIN
  CASE WHEN V1 = 0 THEN DBMS_OUTPUT.PUT_LINE ('Result = 0');
       WHEN V1 = 1 THEN DBMS_OUTPUT.PUT_LINE ('Result = 1');
       WHEN V1 = 2 THEN DBMS_OUTPUT.PUT_LINE ('Result = 2');
       ELSE DBMS_OUTPUT.PUT_LINE ('Result = OTHER');
  END CASE;
END;
/
```

23.5 Iterative Control

Iterative control statements performs a series of statements several times. GOLDILOCKS PSM provides the following iterative control statements.

- Basic loop
- FOR loop
- WHILE loop

Basic Loop

A basic loop statement encloses a series of statements which are to be performed several times with LOOP and END LOOP keywords. This statement indefinitely performs the inner statements, and it can escape out of the loop by using EXIT or GOTO statements which are sequential control statements.
For more information, refer to **Basic LOOP Statement**.

The following is an example of escaping from a basic loop which has the closest scope from that location by using EXIT WHEN statement.
For more information, refer to **EXIT Statement**.

```
gSQL> DECLARE
  V1 INTEGER := 1;
BEGIN
  LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    V1 := V1 + 1;
    EXIT WHEN V1 > 10;   -- Escape Condition
  END LOOP;
END;
/
V1 = 1
V1 = 2
V1 = 3
V1 = 4
V1 = 5
V1 = 6
V1 = 7
V1 = 8
V1 = 9
```

```
V1 = 10
Anonymous PL block executed.
```

To escape out of a specific loop when multiple loops are nested, specify a label in front of that loop and s pecify that label as a target label in EXIT statement.

```
gSQL> DECLARE
  V1 INTEGER := 1;
BEGIN
  <<OUTER_LOOP>>
  LOOP
    <<INNER_LOOP>>
    LOOP
      DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
      V1 := V1 + 1;
      EXIT OUTER_LOOP WHEN V1 > 5;  -- Escape Condition
    END LOOP INNER_LOOP;
    DBMS_OUTPUT.PUT_LINE( 'END OF INNER LOOP' );
    V1 := V1 + 5;
  END LOOP OUTER_LOOP;
  DBMS_OUTPUT.PUT_LINE( 'END OF OUTER LOOP' );
END;
/
V1 = 1
V1 = 2
V1 = 3
V1 = 4
V1 = 5
END OF OUTER LOOP
Anonymous PL block executed.
```

FOR Loop

FOR loop statement repeatedly performs a series of statements as many times as the number of integers of the given scope.
For more information, refer to **FOR LOOP Statement**.

A user creates an index variable with the name specified next to FOR keyword.
Then, it sets the lower bound specified on the left side of a scope operator (..) which is next to IN keywor d as an initial value of the index variable. Then, it performs a series of statements by increasing the index

variable by 1 per each loop until it becomes as same as the higher bound specified on the right side of a s cope operator (..).

```
BEGIN
  FOR I IN 0 .. 2 LOOP
    DBMS_OUTPUT.PUT_LINE( 'I = ' || I );
  END LOOP;
END;
/
I = 0
I = 1
I = 2
Anonymous PL block executed.
```

When REVERSE keyword is specified in front of the scope, it sets the higher bound specified on the right side of a scope operator (..) as an initial value of the index variable. Then, it performs a series of statemen ts by decreasing the index variable by 1 per each loop until it becomes as same as the lower bound specifi ed on the left side of a scope operator (..).

```
BEGIN
  FOR I IN REVERSE 0 .. 2 LOOP
    DBMS_OUTPUT.PUT_LINE( 'I = ' || I );
  END LOOP;
END;
/
I = 2
I = 1
I = 0
Anonymous PL block executed.
```

WHILE Loop

WHILE loop statement repeatedly performs a series of statements while the given condition is TRUE.
For more information, refer to **WHILE LOOP Statement**.

```
DECLARE
V1 integer := 0;
BEGIN
  WHILE V1 < 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
```

```
    V1 := V1 + 1;
  END LOOP;
END;
/
```

WHILE loop checks given conditions before performing statements of a body so if the condition is FALSE f rom the beginning, then it may not perform statements of a body at all.

23.6 Sequential Control

Sequential control statements move on which a program is performed from the current performing location to another location.

GOLDILOCKS PSM provides the following three sequential control statements.

- GOTO
- CONTINUE
- EXIT

GOTO

GOTO statement moves the performing location to the statement in which the given label is. It can be specified in front of any statement which is executable within PSM of a label. A target label to which GOTO moves can exist before and after the GOTO statement. However, only a visible statement can perform GOTO.
For more information, refer to **GOTO Statement**.

Conditions for a visible statement is as follows.

- Sibling statements located before and after the current performing location
- A superordinate statement of the current location, and sibling statements located before and after that superordinate statement

The following is an example of moving a performing location to a sibling statement of the current location.

```
gSQL> BEGIN
  <<PARENT_PREV>>
  DBMS_OUTPUT.PUT_LINE('PARENT PREV');
  <<PARENT>>
  IF 1 > 0 THEN
    <<SIBLING_PREV>>
    DBMS_OUTPUT.PUT_LINE('SIBLING PREV');
    <<CURRENT_POSITION>>
    GOTO SIBLING_NEXT;
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    <<SIBLING_NEXT>>
```

```
    DBMS_OUTPUT.PUT_LINE('SIBLING NEXT');
  ELSE
    <<NON_SIBLING>>
    DBMS_OUTPUT.PUT_LINE('NON SIBLING');
  END IF;
  <<PARENT_NEXT>>
  DBMS_OUTPUT.PUT_LINE('PARENT NEXT');
END;
/
PARENT PREV
SIBLING PREV
SIBLING NEXT
PARENT NEXT
Anonymous PL block executed.
```

The following is an example of moving a performing location to a superordinate statement of a current lo cation.

```
gSQL> BEGIN
  <<PARENT_PREV>>
  DBMS_OUTPUT.PUT_LINE('PARENT PREV');
  <<PARENT>>
  IF 1 > 0 THEN
    <<SIBLING_PREV>>
    DBMS_OUTPUT.PUT_LINE('SIBLING PREV');
    <<CURRENT_POSITION>>
    GOTO PARENT_NEXT;
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    <<SIBLING_NEXT>>
    DBMS_OUTPUT.PUT_LINE('SIBLING NEXT');
  ELSE
    <<NON_SIBLING>>
    DBMS_OUTPUT.PUT_LINE('NON SIBLING');
  END IF;
  <<PARENT_NEXT>>
  DBMS_OUTPUT.PUT_LINE('PARENT NEXT');
END;
/
PARENT PREV
SIBLING PREV
```

```
PARENT NEXT
Anonymous PL block executed.
```

The following is an example of moving a performing location to a statement which is not a sibling, so an error occurs.

```
gSQL> BEGIN
  <<PARENT_PREV>>
  DBMS_OUTPUT.PUT_LINE('PARENT PREV');
  <<PARENT>>
  IF 1 > 0 THEN
    <<SIBLING_PREV>>
    DBMS_OUTPUT.PUT_LINE('SIBLING PREV');
    <<CURRENT_POSITION>>
    GOTO NON_SIBLING;
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    DBMS_OUTPUT.PUT_LINE('SIBLINGS');
    <<SIBLING_NEXT>>
    DBMS_OUTPUT.PUT_LINE('SIBLING NEXT');
  ELSE
    <<NON_SIBLING>>
    DBMS_OUTPUT.PUT_LINE('NON SIBLING');
  END IF;
  <<PARENT_NEXT>>
  DBMS_OUTPUT.PUT_LINE('PARENT NEXT');
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (12:10): ERR-HY000(17010): can not find label name
```

Likewise, when moving a performing location to a statement which is not a superordinate sibling of the c urrent statement, then an error occurs.

GOTO is a good tool to make a PSM program logic flexible. However, like in other languages, if it is used too much, then it may downgrade the readability, so maintenance becomes difficult. Therefore, it is reco mmended to use loop statements such as FOR or WHILE for an ordinary logics, and use GOTO only when it is necessary.

CONTINUE

CONTINUE statement terminates the current iteration and starts the next iteration within a loop statemen t such as FOR or WHILE.
For more information, refer to **CONTINUE Statement**.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  WHILE V1 <= 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    V1 := V1 + 1;
    IF V1 <= 2 THEN
      DBMS_OUTPUT.PUT_LINE( 'CONTINUE' );
      CONTINUE;
    ELSE
      EXIT;
    END IF;
    DBMS_OUTPUT.PUT_LINE( 'END-OF-WHILE' );
  END LOOP AAA;
END;
/
```

If a target label is specified, it starts the next iteration of a loop which has the corresponding label. If it is not specified, it starts the next iteration of the closest (inner) loop.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  FOR I IN 0..5 LOOP
    <<BBB>>
    WHILE V1 <= 10 LOOP
      DBMS_OUTPUT.PUT_LINE( 'I = ' || I );
      DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
      V1 := V1 + 1;
      IF V1 <= 2 THEN
        CONTINUE BBB;
      ELSE
```

```
        EXIT AAA;
      END IF;
    END LOOP BBB;
  END LOOP AAA;
END;
/
```

WHEN clause can be optionally specified in CONTINUE statement. In this case, it terminates the current it eration and starts the next iteration, only when an expression next to WHEN clause is TRUE.

```
DECLARE
  V1 INTEGER :=0 ;
BEGIN
  LOOP
    V1 := V1 + 1;
    CONTINUE WHEN V1 < 5;
    EXIT;
  END LOOP;
END;
/
```

EXIT

EXIT statement escapes the current loop and performs the next statement.
For more information, refer to **EXIT Statement**.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  WHILE V1 <= 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    IF V1 > 5 THEN
      EXIT;
    END IF;
    V1 := V1 + 1;
  END LOOP;
END;
/
```

If a target loop is specified, then it escapes a loop which has the corresponding label.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  FOR I IN 0..5 LOOP
    <<BBB>>
    WHILE V1 <= 10 LOOP
      DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
      IF V1 >= 5 THEN
        EXIT AAA;
      END IF;
      V1 := V1 + 1;
    END LOOP BBB;
  END LOOP AAA;
END;
/
```

WHEN clause can be optionally specified in EXIT statement, like as in CONTINUE statement. In this case, it performs EXIT, only when the given condition is TRUE.

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  FOR I IN 0..5 LOOP
    <<BBB>>
    WHILE V1 <= 10 LOOP
      DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
      EXIT AAA WHEN V1 >= 5;
      V1 := V1 + 1;
    END LOOP BBB;
  END LOOP AAA;
END;
/
```

23.7 Error Handling

Errors in PSM are as follows depending on the point of time when it occurs.

- Errors at compile time
- Errors at run time

Errors at Compile Time

A compile error outputs an error which occurs during the validation of PSM statement specified in a proc edure/function.

A syntax error outputs only the location of the first found syntax error as follows, so a user should compil e it again to find out if there are any additional errors.

```
CREATE OR REPLACE PROCEDURE PROC1
IS
BEGIN
  V1 = 1;
  V2 = 1;
END;
/
ERR-42000(40000): syntax error:
  V1 = 1;
.....^
Error at line 4
```

If a syntax error does not exist, then GOLDILOCKS performs a validation while compiling a PSM statemen t and the errors occurred in this case are output as follows.

```
CREATE OR REPLACE PROCEDURE PROC1
IS
BEGIN
  V1 := 1;
  V2 := 2;
END;
/
ERR-01000(16409): Warning: Routine definition has compilation errors
ERR-HY000(17032): PSM compilation error :
```

```
(1) at (4:3): ERR-HY000(17006): unknown variable or column name (V1)
(2) at (5:3): ERR-HY000(17006): unknown variable or column name (V2)
Procedure created.
```

Compile errors output the information of errors within the size which is allowed in the error output buffe r of GOLDILOCKS. Therefore, some errors may not be output. If so, it is output in the following form to n otify that there are errors which are not output.

```
CREATE OR REPLACE PROCEDURE PROC1
IS
BEGIN
V1 := 1;
V2 := 2;
V3 := 2;
V4 := 2;
V5 := 2;
V6 := 2;
V7 := 2;
V8 := 2;
V10 := 2;
END;
/
ERR-01000(16409): Warning: Routine definition has compilation errors
ERR-HY000(17032): PSM compilation error :
(1) at (4:3): ERR-HY000(17006): unknown variable or column name (V1)
(2) at (5:3): ERR-HY000(17006): unknown variable or column name (V2)
(3) at (6:3): ERR-HY000(17006): unknown variable or column name (V3)
(4) at (7:3): ERR-HY000(17006): unknown variable or column name (V4)
(5) at (8:3): ERR-HY000(17006): unknown variable or column name (V5)
(6) at (9:3): ERR-HY000(17006): unknown variable or column name (V6)
(7) at (10:3): ERR-HY000(17006): unknown variable or column name (V7)
2 more errors...
```

An error message is output in the following form.

```
(Index) at (Line_Number : Column_Position): ERR-SQLState( Internal_ErrorCode):
Detail_Error_Message
```

- Index
  - It is a sequence of an error occurrence.
- Line_Number
  - It is a location of a line of source in which an error occurred.

- Column_Position
  - It is a location of a column of a source in which an error occurred.
- ERR-SQLState
  - It is a standard SQLState.
- Internal_ErrorCode
  - It is an internal error code.
- Detail_Error_Message
  - It is details of an error message.

Errors at Run-time

An error may occur in a PSM statement for various reasons even when PSM is normally executed. In this case, GOLDILOCKS provides an exception handling to help a user to control the error.

The following is an example of an error occurrence at the time of execution. If an error occurs when executing GOLDILOCKS PMS, then it outputs a location of an error, a PSM error and an internal error together. In other words, one or more errors may occur, so all errors should be retrieved from the database through a function such as SQLGetDiagRec if a user wants to find out the exact error message during the development process such as ODBC.

```
DECLARE
  V1 INTEGER;
BEGIN
  V1 := 1 / 0;
END;
/
ERR-HY000(17007): invalid expression :
  V1 := 1 / 0;
        *
ERROR at line 4:
ERR-22012(12122): divisor is equal to zero
```

If an error occurs at the time of operation, PSM immediately stops the operation and notifies it to a user. However, if a user wants to directly control these errors and keep the program running, the user should perform the exception handling.

The following is an example of definition to run the user program without interruption by performing the exception handling on the location of an error.

```
DECLARE
  V1 INTEGER;
BEGIN
  BEGIN
    V1 := 1 / 0;
  EXCEPTION WHEN OTHERS
            THEN DBMS_OUTPUT.PUT_LINE('SQLCODE = ' || SQLCODE);
                 DBMS_OUTPUT.PUT_LINE('SQLERRM = ' || SQLERRM);
  END;

  DBMS_OUTPUT.PUT_LINE('next code');
END;
/
SQLCODE = -12122
SQLERRM = [SUNJESOFT][PSM][GOLDILOCKS]divisor is equal to zero
next code
Anonymous PL block executed.
```

For more information, refer to **EXCEPTION Handling**, **SQLCODE Function**, **SQLERRM Function**.

Cursor Attributes

Cursor attributes are attributes (variables) which are provided to display the cursor status specified by a us er or to display the inside of the database, while processing PSM.

- Cursors are specified as follows.
  - Implicit cursor
    - It is a cursor which is OPEN/ FETCH/ CLOSE inside of the database when it is required.
  - Explicit cursor
    - It is a cursor which OPEN/ FETCH /CLOSE after when a user explicitly perform declaration/ de finition.

Implicit Cursor Attributes

Implicit cursor attributes in PSM is used to find out the processing status of a SQL statement which was p roximately performed. Each value of attributes can be used in expressions such as a conditional expressio n, so a user can control it such as branching logics of a program through that value.
For more information about attributes, refer to the following table.

Table 23-2 Implicit cursor attributes

Attribute name	Return type	Description
ISOPEN	BOOLEAN	It is always FALSE because it is internally closed.
FOUND	BOOLEAN	If the data is returned by the previous statement, then it is TRUE. Otherwise, it is FALSE.
NOTFOUND	BOOLEAN	It is the opposite value of FOUND.
ROWCOUNT	INTEGER	It is the number of rows affected by the previous statement.

The syntax is used in the following form.

```
SQL%Attribute_name
Attribute_name := ISOPEN ¦ FOUND ¦ NOTFOUND ¦ ROWCOUNT
```

Each attribute can be viewed as the following example.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> INSERT INTO T1 VALUES ('Seoul', '24');
1 row created.
gSQL> INSERT INTO T1 VALUES ('Pusan', '44');
1 row created.
gSQL> BEGIN
    UPDATE T1 SET C2 = C2 + 1;

    DBMS_OUTPUT.PUT_LINE('ISOPEN   = ' ¦¦ SQL%ISOPEN );
    DBMS_OUTPUT.PUT_LINE('FOUND    = ' ¦¦ SQL%FOUND );
    DBMS_OUTPUT.PUT_LINE('NOTFOUND = ' ¦¦ SQL%NOTFOUND );
    DBMS_OUTPUT.PUT_LINE('ROWCOUNT = ' ¦¦ SQL%ROWCOUNT );
END;
/
ISOPEN   = FALSE
FOUND    = TRUE
NOTFOUND = FALSE
ROWCOUNT = 2
Anonymous PL block executed.
```

Explicit Cursor Attributes

Explicit cursor attributes is used to enquire the status of an explicit cursor.
For more information about attributes, refer to the following table.

Table 23-3 Cursor attributes

Attributes	Return type	Description
%ISOPEN	BOOLEAN	It is TRUE only when a cursor is normally open. Otherwise, it is FALSE.
%FOUND	BOOLEAN	It is NULL before FETCH, and it is TRUE when FETCH is normally performed. I t is FALSE when data does not exist, and it is NULL after CLOSE.
%NOTFOUND	BOOLEAN	It is the opposite value of %FOUND.
%ROWCOUNT	INTEGER	It is NULL before OPEN, and it is 0 when it is normally OPEN. It increases by 1 whenever FETCH succeeds.

It is used as follows within PSM.

```
Cursor_Name % Attribute_name
Attribute_name :=  ISOPEN
                 ¦ FOUND
                 ¦ NOTFOUND
                 ¦ ROWCOUNT
```

The following is an example of using an explicit cursor attribute.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> INSERT INTO T1 VALUES ('Seoul', '24');
1 row created.
gSQL> INSERT INTO T1 VALUES ('Pusan', '44');
1 row created.
gSQL> DECLARE
  CURSOR C1 IS SELECT * FROM T1;
  v1 c1%ROWTYPE;
BEGIN
```

- Check if the cursor is open through ISOPEN.

```
IF C1%ISOPEN = FALSE
  THEN
      OPEN C1;
  END IF;
  LOOP
      FETCH C1 INTO v1;
```

- Check if there is any more data through NOTFOUND.

```
EXIT WHEN C1%NOTFOUND;
```

- Find out the number of fetched rows through ROWCOUNT.

```
DBMS_OUTPUT.PUT_LINE('COUNT = ' || C1%ROWCOUNT );
  END LOOP;
  CLOSE C1;

END;
/
COUNT = 1
COUNT = 2
Anonymous PL block executed.
```

EXCEPTION Handling

Exceptions within PSM is a definition of various errors occurred while a user is executing PSM. If an error occurs at the time of operation, PSM immediately stops the operation and returns an error to a user. EXC EPTION handling is a function provided to a user to control EXCEPTION situation and keep the program r unning without interruption.

Exception Handler

An error situation can be controlled through an exception handler defined in PSM BLOCK as follows.

```
DECLARE
  V1 INTEGER;
BEGIN
  BEGIN
    V1 := 1 / 0;
```

- Exception handler

```
EXCEPTION WHEN OTHERS
            THEN DBMS_OUTPUT.PUT_LINE('SQLCODE = ' || SQLCODE);
                 DBMS_OUTPUT.PUT_LINE('SQLERRM = ' || SQLERRM);
  END;

  DBMS_OUTPUT.PUT_LINE('next code');
END;
/
SQLCODE = -12122
SQLERRM = [SUNJESOFT][PSM][GOLDILOCKS]divisor is equal to zero
next code
```

In the example above, the program is stopped by *divide by zero* at the time of execution. However, if an e rror occurred by an exception handler, then only the corresponding BLOCK stops, but the processing cont inues from the next location.

An exception handler is specified as follows.

```
BEGIN
EXCEPTION WHEN exception_name, [exception_name, ...] THEN pl_statements;
         [WHEN exception_name, [exception_name, ...] THEN pl_statements;
END
```

- Features of an exception handler are as follows.
  - A single exception handler is specified in BLOCK.
  - One or more Exception_Name can be specified and its operation can be defined within an except ion handler.
  - Exception_name within an exception handler should not be duplicate.
  - It is operated only for an error within PL BLOCK SCOPE in which an exception handler is specified.
  - OTHERS indicating all exceptional situations should be unique, and should be specified at last.
  - If an exception handler is normally completed, the previous errors are cleared. Therefore, a user s hould store them in a separate PSM variable if in need.

An exception in GOLDILOCKS has the following properties.

Table 23-4 EXCEPTION types

Type	Definer	Error code	Name	Raise implicitly	Raise explicitly
Predefined	Database	O	O	O	Optionally
User defined	User	User-defined	User defined	X	O

For more information about a predefined exception or a user defined exception provided by GO LDILOCKS, refer to **Exception Declaration**.

Propagating Exception

If an appropriate exception handler does not exist in the current BLOCK when an exception occurs, then i t is propagated to an exception handler of the superordinate BLOCK until the exception is processed.

If an error occurred on LINE_1 in the following code, the result varies upon whether an exception handler operates.

```
BEGIN
  ...
  BEGIN
    LINE_1
    EXCEPTION HANDLER_1
  END;
  LINE_2
  EXCEPTION HANDLER_2
END;
/
```

- When it is processed in EXCEPTION_HANDLER_1
  - If the handler operation is normally completed, then it is performed from LINE_2.
- When an appropriate handler does not exist in EXCEPTION_HANDLER_1
  - It can not perform LINE_2, and the currently occurred EXCEPTION is propagated to EXCEPTION_ HANDLER_2.
    - When an appropriate handler exists in EXCEPTION_HANDLER_2, if a handler operation is nor mally completed, then the program ends.
    - If a handler does not exist in EXCEPTION_HANDLER_2, the program stops and the currently occurred error is returned to a user.

If an error occurred in an exception handler which was processing an exception, then the error code is propagated to a superordinate BLOCK.

```
DECLARE
  V1 INTEGER;
  E1 EXCEPTION;
  E2 EXCEPTION;
BEGIN
```

```
  BEGIN
    RAISE E1;
  EXCEPTION WHEN E1 THEN V1 := 1 / 0;    ❶ A new error occurs.
  END;
  EXCEPTION WHEN E1
            THEN DBMS_OUTPUT.PUT_LINE('User Exception');
            WHEN ZERO_DIVIDE
            THEN DBMS_OUTPUT.PUT_LINE('Zero divide');
END;
/
Zero divide
Anonymous PL block executed.
```

User Defined Exception

A user defined exception is an exception used by setting an exception name and an error-code by a user except for a predefined. User defined exception can not implicitly occur, but a user should execute it by e xplicitly using a RAISE statment.

The following is an example of causing an exception by using a RAISE statement.

```
DECLARE
  V1   INTEGER;
  high EXCEPTION;
  low  EXCEPTION;
BEGIN
  BEGIN
      V1 := 10;
      IF V1 > 10
      THEN
          RAISE high;
      ELSE
          RAISE low;
      END IF;
  EXCEPTION WHEN high
            THEN DBMS_OUTPUT.PUT_LINE('High');
            WHEN low
            THEN DBMS_OUTPUT.PUT_LINE('Low');
  END;
END;
/
Low
```

- A user defined exception is processed depending on the following two cases.
  - When an error-code is set
  - When an error-code is not set

It is operated as follows when a user sets an error code.

```
DECLARE
  V1 INTEGER;
  E1 EXCEPTION;
  PRAGMA EXCEPTION_INIT( E1, -12122);
BEGIN
  BEGIN
    V1 := 1 / 0;
  EXCEPTION WHEN E1
            THEN DBMS_OUTPUT.PUT_LINE('SQLCODE = ' || SQLCODE);
                 DBMS_OUTPUT.PUT_LINE('SQLERRM = ' || SQLERRM);
  END;
END;
/
SQLCODE = -12122
SQLERRM = [SUNJESOFT][PSM][GOLDILOCKS]divisor is equal to zero
```

The ZERO_DIVIDE predefined exception exists, but a user sets a handler by setting an error code as E1 ex ception. For the program compatibility between vendors with each different error code as above, an exce ption handler is available of which a user directly resets an error code.

A user defined exception in which an error-code is not set is set as the following error code and message in an exception handler.

```
DECLARE
  V1 INTEGER;
  E1 EXCEPTION;
BEGIN
  BEGIN
    RAISE E1;
  EXCEPTION WHEN E1
            THEN DBMS_OUTPUT.PUT_LINE('SQLCODE = ' || SQLCODE);
                 DBMS_OUTPUT.PUT_LINE('SQLERRM = ' || SQLERRM);
  END;
END;
/
SQLCODE = 1
```

```
SQLERRM = [SUNJESOFT][PSM][GOLDILOCKS]User-Defined Exception
Anonymous PL block executed.
```

A propagation process of a user defined exception is as same as that of a predefined exception. However, if an error-code is not set in a user defined exception, it is propagated as unhandled user exception error to the superordinate BLOCK.

```
DECLARE
  V1 INTEGER;
  E1 EXCEPTION;
  E2 EXCEPTION;
BEGIN
  BEGIN
    RAISE E1;
  EXCEPTION WHEN E2
            THEN DBMS_OUTPUT.PUT_LINE('SQLCODE = ' || SQLCODE);
                 DBMS_OUTPUT.PUT_LINE('SQLERRM = ' || SQLERRM);
  END;
END;
/
ERR-HY000(17017): Unhandled user exception :
    RAISE E1;
          *
ERROR at line 7:
```

An unhandled user exception can be caught by specifying a user defined exception in an exception handler or by using OTHERS which is a predefined exception.

PRAGMA EXCEPTION_INIT

It is used for a user sets a specific DBMS error code when using a user defined exception. DBMS error codes varies depending on vendors, so it can be used for a compatibility of an exception handler of PSM code.

The syntax is as follows.

```
<PRAGMA EXCEPTION_INIT> ::=
    PARAGMA EXCEPTION_INIT ( exception_name, internal_errorcode )
```

- Constraints are as follows.
  - exception_name should be declared in advance.

- exception_name can not use a predefined exception.
- Only an internal error-code of GOLDILOCKS is available for internal_errorcode.
- It can not set 0 which means SUCCESS.

The following is an example of handling an exception of when assigning NULL to V1 (the PSM variable to which NOT NULL constraints are applied) by using a user defined exception.

```
DECLARE
  V1 VARCHAR(20) NOT NULL := 10;
  USER_EXCEPT EXCEPTION;
```

- Declare the PSM NOT NULL constraint error as a user defined exception.

```
PRAGMA EXCEPTION_INIT( USER_EXCEPT, -17009 );
BEGIN
```

- Generate a situation of an exception.

```
V1 := NULL;
  EXCEPTION WHEN USER_EXCEPT THEN DBMS_OUTPUT.PUT_LINE('Check Value');
END;
/
Check Value
Anonymous PL block executed.
```

The following error occurs when setting a value which is not an internal error-code of GOLDILOCKS.

```
DECLARE
  E1 EXCEPTION;
  PRAGMA EXCEPTION_INIT( E1, 99999);
BEGIN
    NULL;
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (3:30): ERR-HY000(17021): Invalid error number for PRAGMA EXCEPTION_INIT
```

DBMS_STANDARD.RAISE_APPLICATION_ERROR

It is used to easily generate an exception through an arbitrary user error code and a message, instead of e xplicitly defining a user exception. It belongs to a DBMS_STANDARD module, and the routines of this mo dule can be called even when omitting a name of that module.

There are three types of arguments as follows.

Table 23-5 RAISE_APPLICATION_ERROR

Argument	Description
error_code IN NATIVE_INT EGER	It is a value of an error code to be arbitrarily generated. Only the value within the rang e of -20000 ~ -20999 can be used.
error_message IN VARCHA R(4000)	It is a message to be stored in SQLERRM when an error occurs.
stack_flag IN BOOLEAN := FALSE	It is a flag of whether to stack on the existing errors (TRUE), or to replace with all exist ing errors (FALSE). The default value is FALSE.

The following is a simple example of using it.

```
CREATE OR REPLACE PROCEDURE PROC1
IS
BEGIN
  RAISE_APPLICATION_ERROR (-20000, 'USER DEFINED ERROR TEST');
END;
/
Procedure created.
BEGIN
  PROC1;
EXCEPTION WHEN OTHERS THEN
  DBMS_OUTPUT.PUT_LINE( 'SQLCODE : ' || SQLCODE || ' SQLERRM : ' || SQLERRM );
END;
/
SQLCODE : -20000 SQLERRM : [SUNJESOFT][PSM][GOLDILOCKS]USER DEFINED ERROR TEST
Anonymous PL block executed.
```

24.

PSM Cursor Statements

24.1 Implicit Cursor

An implicit cursor is defined and managed by PSM statement in the database. PSM statement uses an im plicit cursor whenever executing SELECT statement or DML statement. A user can not control an implicit cursor, but it can obtain the information about the query through an implicit cursor attribute.

Implicit Cursor Attributes

An implicit cursor attributes refer to the execution result of the most recently executed SELECT statement or DML statement. If neither SELECT statement nor is DML statement recently executed, then the attribut es values are NULL.

Table 24-1 Implicit cursor attributes

Attribute name	Return type	Description
SQL%ISOPEN	BOOLEAN	It always returns FALSE, because the most recently executed SELECT statem ent or DML statement is always terminated.
SQL%FOUND	BOOLEAN	It it TRUE when the most recently executed SELECT statement or DML state ment returns a result. Otherwise, it is FALSE.
SQL%NOTFOUN D	BOOLEAN	It has the opposite value of SQL%FOUND.
SQL%ROWCOU NT	INTEGER	It is the number of ROWs returned from the most recently executed SELECT statement or DML statement.

Examples

- When the most recently executed query does not exist

```
gSQL>
BEGIN
  DBMS_OUTPUT.PUT_LINE('SQL%ISOPEN   = ' || SQL%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('SQL%FOUND    = ' || SQL%FOUND);
  DBMS_OUTPUT.PUT_LINE('SQL%NOTFOUND = ' || SQL%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT = ' || SQL%ROWCOUNT);
END;
/
SQL%ISOPEN   = FALSE
```

```
SQL%FOUND    =
SQL%NOTFOUND =
SQL%ROWCOUNT =
Anonymous PL block executed.
```

- When the most recently executed query exists

```
gSQL>
CREATE TABLE t_month( month_char VARCHAR(15) , month_num INTEGER );
Table created.
gSQL>
INSERT INTO t_month VALUES( 'JANUARY' , 1 ), ( 'MARCH' , 3 ),
                          ( 'MAY' , 5 ), ( 'JULY' , 7 ),
                          ( 'SEPTEMBER' , 9 ), ( 'NOVEMBER' , 11 );
6 rows created.
gSQL>
DECLARE
  row_count INTEGER;
BEGIN
  SELECT COUNT(*) INTO row_count FROM t_month;
  DBMS_OUTPUT.PUT_LINE('SQL%ISOPEN   = ' || SQL%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('SQL%FOUND    = ' || SQL%FOUND);
  DBMS_OUTPUT.PUT_LINE('SQL%NOTFOUND = ' || SQL%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT = ' || SQL%ROWCOUNT);
END;
/
SQL%ISOPEN   = FALSE
SQL%FOUND    = TRUE
SQL%NOTFOUND = FALSE
SQL%ROWCOUNT = 1
Anonymous PL block executed.
```

24.2 Explicit Cursor

An explicit cursor is declared, defined and managed by a user. The user specifies the cursor name and sho uld connect to SELECT statement or DML statement.

- Use an explicit cursor as follows.
  - The user open the explicit cursor through open statement, and fetches the query result by execut ing the fetch statement. Last, it closes the cursor with close statement.
  - The explicit cursor is available for *cursor for loop* statement.

The explicit cursor is not available for an expression. In other words, it can not assign the value to the curs or, nor is it used as a parameter of the procedure or the routine.

- Example of Explicit Cursor

```
gSQL>
CREATE TABLE t_month( month_char VARCHAR(15), month_num INTEGER );
Table created.
gSQL>
INSERT INTO t_month VALUES( 'FEBRUARY' , 2 ), ( 'APRIL' , 4 ),
                          ( 'JUNE' , 6 ), ( 'AUGUST' , 8 ),
                          ( 'OCTOBER' , 10 ), ( 'DECEMBER' , 12 );
6 rows created.
gSQL>
DECLARE
  CURSOR cur_month IS SELECT * FROM t_month;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month;                                          ❶ OPEN explicit cursor.
LOOP                                                       ❷ Fetch multiple ROWs by using loop.
    FETCH cur_month INTO v_month_char, v_month_num;        ❸ FETCH explicit cursor.

    EXIT WHEN cur_month%NOTFOUND;                          ❹ Check if all ROWs in the result
set are fetched.

    DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
  END LOOP;

  CLOSE cur_month;                                         ❺ CLOSE explicit cursor.
```

```
END;
/
v_month_char : FEBRUARY , v_month_num : 2
v_month_char : APRIL , v_month_num : 4
v_month_char : JUNE , v_month_num : 6
v_month_char : AUGUST , v_month_num : 8
v_month_char : OCTOBER , v_month_num : 10
v_month_char : DECEMBER , v_month_num : 12
Anonymous PL block executed.
```

Declaring and Defining Explicit Cursors

An explicit cursor should be declared and defined in PSM declare section to use it. The cursor name, the parameter information and the return type of when declaring the explicit cursor should be as same as wh en defining the explicit cursor. For more information about the syntax of the explicit cursor and others, re fer to **Explicit Cursor Declaration and Definition**.

Example of Declaring and Defining Explicit Cursor

```
gSQL>
DECLARE
  CURSOR cur_month1( p1 INTEGER ) RETURN t_month%rowtype;
  CURSOR cur_month1( p1 INTEGER ) RETURN t_month%rowtype IS SELECT * FROM t_month WHERE
month_num = p1;
  CURSOR cur_month2 IS SELECT * FROM t_month;
BEGIN
  NULL;
END;
/
Anonymous PL block executed.
```

Opening and Closing Explicit Cursors

- Perform the cursor query by executing **OPEN Statement** after declaring and defining the explicit curs or.
- If the query of the explicit cursor is SELECT ... FOR UPDATE statement, then it locks the ROW in the re sult set

- If the query of the explicit cursor refers to an explicit cursor parameter or a PSM variable, then it affec ts the query result.
- Close the explicit cursor by using **CLOSE Statement** after using the cursor. It can not fetch the record from the result set after the explicit cursor is closed.
- Once after the explicit cursor is OPENed it can not be reopened, CLOSE it first to OPEN it again.

Example of Explicit Cursor OPEN and CLOSE

```
gSQL>
DECLARE
  CURSOR cur_month( p1 INTEGER ) IS SELECT * FROM t_month WHERE month_num = p1;
BEGIN
  OPEN cur_month( 2 );      -- Explicit Cursor OPEN
  CLOSE cur_month;          -- Explicit Cursor CLOSE
END;
/
Anonymous PL block executed.
```

Fetching Data With Explicit Cursors

- It fetches the row from the result set by executing **FETCH Statement** after OPENing the explicit cursor.
- Fetch statement retrieves the current ROW of the result set and stores the ROW value in PSM variable or in record type variable, then moves the cursor to the next ROW.
- PSM **FETCH Statement** does not throw an exception even when there is not a fetched ROW.
- When performing FETCH in **Basic LOOP Statement**, then use %NOTFOUND property to detect the ter minating condition.

Example of FETCHing Explicit Cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT * FROM t_month;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month;

  LOOP
    FETCH cur_month INTO v_month_char, v_month_num;
```

```
    EXIT WHEN cur_month%NOTFOUND;

    DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
  END LOOP;

  CLOSE cur_month;
END;
/
v_month_char : FEBRUARY , v_month_num : 2
v_month_char : APRIL , v_month_num : 4
v_month_char : JUNE , v_month_num : 6
v_month_char : AUGUST , v_month_num : 8
v_month_char : OCTOBER , v_month_num : 10
v_month_char : DECEMBER , v_month_num : 12
Anonymous PL block executed.
```

When Explicit Cursor Queries Need Column Aliases

If the query of an explicit cursor includes an expression, then the column always needs an alias name. The fetched result is stored in %ROWTYPE variable created by referring to the explicit cursor, and it can be us ed as a reference.

Example of Using Alias in Query of Explicit Cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT month_char, ( ' == ' || month_num ) as equal_month_num FROM
t_month;
  var cur_month%rowtype;
BEGIN
  OPEN cur_month;

  LOOP
    FETCH cur_month INTO var;

    EXIT WHEN cur_month%NOTFOUND;
```

```
    DBMS_OUTPUT.PUT_LINE( var.month_char || var.equal_month_num );
  END LOOP;
  CLOSE cur_month;
END;
/
FEBRUARY == 2
APRIL == 4
JUNE == 6
AUGUST == 8
OCTOBER == 10
DECEMBER == 12
Anonymous PL block executed.
```

Explicit Cursors that Accept Parameters

It can declare and define the explicit cursor having the parameter.

- Parameter of the explicit cursor
  - It allows IN bind type only.
  - It can have DEFAULT value. It is not necessary to specify an argument.
  - It can be referenced in the query of the cursor.
  - If it is out of the explicit cursor's range, then it can not refer to the parameter of the explicit curso r.

Example of Using Explicit Cursor Parameter

```
gSQL>
DECLARE
  CURSOR cur_month( p1 IN INTEGER ) IS SELECT month_char, month_num FROM t_month WHERE
month_num = p1;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month(4);

  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
gSQL>
```

```
  CLOSE cur_month;
END;
/
v_month_char : APRIL , v_month_num : 4
Anonymous PL block executed.
```

- Example of Explicit Cursor Parameter's DEFAULT value

```
gSQL>
DECLARE
  CURSOR cur_month( p1 INTEGER DEFAULT 2 ) IS SELECT month_char, month_num FROM t_month WHERE
month_num = p1;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month;                    ❶ It is allowed to omit the actual parameter.

  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
  CLOSE cur_month;

  OPEN cur_month(4);          ❷ It can be OPENed by specifying the actual parameter.

  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
  CLOSE cur_month;
END;
/
v_month_char : FEBRUARY , v_month_num : 2
v_month_char : APRIL , v_month_num : 4
Anonymous PL block executed.
```

Explicit Cursor Attributes

The explicit cursor attribute describes the status of an explicit cursor. It can be used as an explicit cursor a ttribute by adding the attribute after the cursor name.

Table 24-2 Explicit cursor attributes

Attribute name	Return type	Description
explicit_cursor_name%ISOPEN	BOOLEAN	If the explicit cursor is normally OPEN, then it is TRUE. Otherwise, it is FALSE.
explicit_cursor_name%FOUND	BOOLEAN	If the explicit cursor is not FETCHed yet, then it is NULL. If the data exists, then it is TRUE. If the data does not exist, then it is FALSE. If it is CLOSEd, then it is NULL.
explicit_cursor_name%NOTFOUND	BOOLEAN	It has an opposite value of explicit_cursor_name%FOUND.
explicit_cursor_name%ROWCOUNT	INTEGER	If the explicit cursor is not OPEN yet, then it is NULL. If it is normally OPEN, then it is 0. It is increased by 1 whenever executing FETCH, and it is NULL after CLOSE.

Example of Using Explicit Cursor Parameter

- Before OPEN the explicit cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT month_char, month_num FROM t_month;
BEGIN
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
END;
/
cur_month%ISOPEN   = FALSE
cur_month%FOUND    =
cur_month%NOTFOUND =
cur_month%ROWCOUNT =
Anonymous PL block executed.
```

- After OPEN the explicit cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT month_char, month_num FROM t_month;
BEGIN
```

```
  OPEN cur_month;

  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
  CLOSE cur_month;
END;
/
cur_month%ISOPEN   = TRUE
cur_month%FOUND    =
cur_month%NOTFOUND =
cur_month%ROWCOUNT = 0
Anonymous PL block executed.
```

- After FETCH the explicit cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT month_char, month_num FROM t_month LIMIT 3;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month;
  DBMS_OUTPUT.PUT_LINE( '[ First Fetch ]' );

  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
  DBMS_OUTPUT.PUT_LINE( '[ Second Fetch ]' );
  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
  DBMS_OUTPUT.PUT_LINE( '[ Last Fetch ]' );

  FETCH cur_month INTO v_month_char, v_month_num;
```

```
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
  DBMS_OUTPUT.PUT_LINE( '[ Over Last Fetch ]' );
  FETCH cur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
  CLOSE cur_month;
END;
/
[ First Fetch ]
cur_month%ISOPEN   = TRUE
cur_month%FOUND    = TRUE
cur_month%NOTFOUND = FALSE
cur_month%ROWCOUNT = 1
[ Second Fetch ]
cur_month%ISOPEN   = TRUE
cur_month%FOUND    = TRUE
cur_month%NOTFOUND = FALSE
cur_month%ROWCOUNT = 2
[ Last Fetch ]
cur_month%ISOPEN   = TRUE
cur_month%FOUND    = TRUE
cur_month%NOTFOUND = FALSE
cur_month%ROWCOUNT = 3
[ Over Last Fetch ]
cur_month%ISOPEN   = TRUE
cur_month%FOUND    = FALSE
cur_month%NOTFOUND = TRUE
cur_month%ROWCOUNT = 3
Anonymous PL block executed.
```

- After CLOSE the explicit cursor

```
gSQL>
DECLARE
  CURSOR cur_month IS SELECT month_char, month_num FROM t_month;
  v_month_char VARCHAR(15);
```

```
  v_month_num  INTEGER;
BEGIN
  OPEN cur_month;

  FETCH cur_month INTO v_month_char, v_month_num;
  CLOSE cur_month;
  DBMS_OUTPUT.PUT_LINE('cur_month%ISOPEN   = ' || cur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('cur_month%FOUND    = ' || cur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%NOTFOUND = ' || cur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('cur_month%ROWCOUNT = ' || cur_month%ROWCOUNT);
END;
/
cur_month%ISOPEN   = FALSE
cur_month%FOUND    =
cur_month%NOTFOUND =
cur_month%ROWCOUNT =
Anonymous PL block executed.
```

24.3 Cursor Variable

Create Cursor Variables

Declare the variable by declaring predefined SYS_REFCURSOR type variable or by defining REF CURSOR TYPE so that the cursor variable is created. For more information, refer to **Cursor Variable Declaration**.

- REF CURSOR types are as follows.
  - Strong REF CURSOR type
    - If return_type is specified when defining REF CURSOR type, then it is the strong REF CURSOR type.
    - The strong REF CURSOR type variable can connect only the query whose query set type is as same as the defined return_type to the query of CURSOR VARIABLE.
    - Assigning the strong REF CURSOR type variable is available when the defined return_types are same.
  - Weak REF CURSOR type
    - If return_type is not specified when defining REF CURSOR type, then it is the weak REF CURSOR type.
    - SYS_REFCURSOR type is the weak REF CURSOR type as well.
    - It is more flexible than the strong REF CURSOR variable.
    - The weak ref cursor type variable can be assigned as the SYS_REFCURSOR type variable, and the SYS_REFCURSOR type variable can be assigned as the weak REF CURSOR type variable.

Example of Create Cursor Variable

- Definition of REF CURSOR type

```
gSQL>
DECLARE
  TYPE strong_refcur IS REF CURSOR RETURN t_month%ROWTYPE;   ❶ strong ref cursor type
  TYPE weak_refcur IS REF CURSOR;                            ❷ weak ref cursor type
BEGIN
  NULL;
END;
/
Anonymous PL block executed.
```

- Declaration of CURSOR VARIABLE

```
gSQL>
DECLARE
  TYPE strong_refcur IS REF CURSOR RETURN t_month%ROWTYPE;   ❶ strong ref cursor type
  TYPE weak_refcur IS REF CURSOR;                           ❷ weak ref cursor type
  v_sys_refcursor     SYS_REFCURSOR;                        ❸ weak ref cursor type variable
  v_strong_refcursor  strong_refcur;                        ❹ strong ref cursor type
variable
  v_weak_refcursor    weak_refcur;                          ❺ weak ref cursor type variable
BEGIN
  NULL;
END;
/
Anonymous PL block executed.
```

Opening and Closing Cursor Variables

- It connects the cursor variable and SELECT statement or DML statement to perform by performing **OPEN FOR Statement** after declaring the cursor variable.
- The cursor query may have the bind variable designating the specified value in using clause of OPEN FOR statement.
- If FOR UPDATE statement exists in cursor query, then it LOCKs the ROW in the result set.
- When REOPENing the cursor variable, then it does not require CLOSE. The connection to the previous query is cut after REOPENing.
- Perform **CLOSE Statement** after finish using the cursor variable.
- It does not allow accessing the query result of CLOSEd cursor variable or referring to the cursor variable attributes.

Example of Cursor Variable's OPEN and CLOSE

```
DECLARE
  v_refcur_month SYS_REFCURSOR;
BEGIN
  OPEN v_refcur_month FOR SELECT * FROM t_month;
  CLOSE v_refcur_month;
END;
/
Anonymous PL block executed.
```

- Cursor variable's OPEN with using clause.

```
gSQL>
DECLARE
  v_refcur_month SYS_REFCURSOR;
  var            INTEGER;
BEGIN
  var := 1;

  OPEN v_refcur_month FOR 'SELECT * FROM t_month WHERE month_num = :v' USING IN var;
END;
/
Anonymous PL block executed.
```

Fetching Data with Cursor Variables

It can bring the row from the result set by executing **FETCH Statement** after OPENing the cursor variable. The result returned by the cursor variable should be compatible with into clause.

Example of FETCHing Cursor Variable

```
gSQL>
DECLARE
  TYPE ref_month IS REF CURSOR RETURN t_month%ROWTYPE;
  v_refcur_month ref_month;

  v_month        t_month%ROWTYPE;
BEGIN
  OPEN v_refcur_month FOR SELECT * FROM t_month;

  LOOP
    FETCH v_refcur_month INTO v_month;

    EXIT WHEN v_refcur_month%NOTFOUND;

    DBMS_OUTPUT.PUT_LINE( 'v_month.month_char : ' || v_month.month_char || ' ,
v_month.month_num : ' || v_month.month_num );
  END LOOP;

  CLOSE v_refcur_month;
END;
```

```
/
v_month.month_char : JANUARY , v_month.month_num : 1
v_month.month_char : MARCH , v_month.month_num : 3
v_month.month_char : MAY , v_month.month_num : 5
v_month.month_char : JULY , v_month.month_num : 7
v_month.month_char : SEPTEMBER , v_month.month_num : 9
v_month.month_char : NOVEMBER , v_month.month_num : 11
Anonymous PL block executed.
```

Assigning Value to Cursor Variables

The cursor variable can assign another cursor variable value or the host variable value. If the source cursor variable is OPEN and assigns the target cursor variable value, then both cursor variables indicate the same SQL. If the source cursor variable is not OPEN and assigns the target cursor variable value, then both curs or variables are not OPEN.

Example of Assigning Cursor Variable

```
gSQL>
DECLARE
  source_refcur_month SYS_REFCURSOR;
  target_refcur_month SYS_REFCURSOR;
  v_month_char   VARCHAR(15);
  v_month_num    INTEGER;
BEGIN
  DBMS_OUTPUT.PUT_LINE( 'OPEN source_refcur_month' );

  OPEN source_refcur_month FOR SELECT * FROM t_month;
  DBMS_OUTPUT.PUT_LINE( 'source_refcur_month%ISOPEN : ' || source_refcur_month%ISOPEN );
  DBMS_OUTPUT.PUT_LINE( 'target_refcur_month%ISOPEN : ' || target_refcur_month%ISOPEN );
  DBMS_OUTPUT.PUT_LINE( 'Assign source_refcur_month to target_refcur_month' );

  target_refcur_month := source_refcur_month;
  DBMS_OUTPUT.PUT_LINE( 'source_refcur_month%ISOPEN : ' || source_refcur_month%ISOPEN );
  DBMS_OUTPUT.PUT_LINE( 'target_refcur_month%ISOPEN : ' || target_refcur_month%ISOPEN );
  DBMS_OUTPUT.PUT_LINE( 'CLOSE source_refcur_month' );
  CLOSE source_refcur_month;
  DBMS_OUTPUT.PUT_LINE( 'source_refcur_month%ISOPEN : ' || source_refcur_month%ISOPEN );
  DBMS_OUTPUT.PUT_LINE( 'target_refcur_month%ISOPEN : ' || target_refcur_month%ISOPEN );
```

```
END;
/
OPEN source_refcur_month
source_refcur_month%ISOPEN : TRUE
target_refcur_month%ISOPEN : FALSE
Assign source_refcur_month to target_refcur_month
source_refcur_month%ISOPEN : TRUE
target_refcur_month%ISOPEN : TRUE
CLOSE source_refcur_month
source_refcur_month%ISOPEN : FALSE
target_refcur_month%ISOPEN : FALSE
Anonymous PL block executed.
```

Cursor Variable Attributes

Cursor variable attributes are as same as explicit cursor attributes, and it describes the status of the cursor variable. It can be used as a cursor variable attribute by adding the attribute after the cursor variable nam e. Attributes except for cursor_variable_name%ISOPEN attribute cause 'cursor is not defined' error befor e OPEN the cursor variable or after CLOSE the cursor variable.

Table 24-3 Cursor variable attributes

Attribute name	Return type	Description
cursor_variable_name %ISOPEN	BOOLEAN	If the cursor variable is OPEN, then it is TRUE. Otherwise, it is FALSE.
cursor_variable_name %FOUND	BOOLEAN	If the data exists after FETCH, then it is TRUE. If the data does not exis t, then it is FALSE.
cursor_variable_name %NOTFOUND	BOOLEAN	It has an opposite value of cursor_variable_name%FOUND after FETC H.
cursor_variable_name %ROWCOUNT	INTEGER	If the cursor variable is OPEN, then it is 0, and it is increased by 1 whe never executing FETCH.

Example of Using Cursor Variable Attributes

- Before OPEN the cursor variable

```
gSQL>
DECLARE
  v_refcur_month SYS_REFCURSOR;
```

```
BEGIN
  DBMS_OUTPUT.PUT_LINE('v_refcur_month%ISOPEN   = ' || v_refcur_month%ISOPEN);
  DBMS_OUTPUT.PUT_LINE('v_refcur_month%FOUND    = ' || v_refcur_month%FOUND);
  DBMS_OUTPUT.PUT_LINE('v_refcur_month%NOTFOUND = ' || v_refcur_month%NOTFOUND);
  DBMS_OUTPUT.PUT_LINE('v_refcur_month%ROWCOUNT = ' || v_refcur_month%ROWCOUNT);
END;
/
v_refcur_month%ISOPEN   = FALSE
ERR-2F000(17036): cursor is not defined :

Cursor Variable as Routine Parameter

Using the cursor variable as routine parameter is useful to transfer the query result. The parameter should be IN or IN OUT type to FETCH or CLOSE the cursor variable in the procedure or the function. The parame ter should be OUT or IN OUT type to OPEN the cursor variable. Declaring the ref cursor type in the packag e is useful to transfer the query result of the cursor variable in each different routine.

Example of Using Cursor Variable as Parameter

- Example of routine parameter

```
gSQL>
CREATE OR REPLACE PROCEDURE p_open( p_refcur_month OUT SYS_REFCURSOR ) AS
BEGIN
  OPEN p_refcur_month FOR SELECT * FROM t_month;
END;
/
Procedure created.
gSQL>
CREATE OR REPLACE PROCEDURE p_fetch( p_refcur_month IN SYS_REFCURSOR ) AS
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  FETCH p_refcur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
END;
/
Procedure created.
gSQL>
DECLARE
  v_refcur_month SYS_REFCURSOR;
BEGIN
  p_open( v_refcur_month );
  DBMS_OUTPUT.PUT_LINE( 'v_refcur_month%ISOPEN : ' || v_refcur_month%ISOPEN );

  p_fetch( v_refcur_month );
```

```
  DBMS_OUTPUT.PUT_LINE( 'v_refcur_month%FOUND : ' || v_refcur_month%FOUND );

  CLOSE v_refcur_month;
  DBMS_OUTPUT.PUT_LINE( 'v_refcur_month%ISOPEN : ' || v_refcur_month%ISOPEN );
END;
/
v_refcur_month%ISOPEN : TRUE
v_month_char : JANUARY , v_month_num : 1
v_refcur_month%FOUND : TRUE
v_refcur_month%ISOPEN : FALSE
Anonymous PL block executed.
```

- Example of using package's ref cursor type

```
gSQL>
CREATE OR REPLACE PACKAGE pkg_refcur AS
  TYPE ref_month IS REF CURSOR RETURN t_month%ROWTYPE;
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;

  PROCEDURE p_open( p_refcur_month OUT ref_month, p_month IN INTEGER );
  PROCEDURE p_fetch( p_refcur_month IN ref_month );
  PROCEDURE p_close( p_refcur_month IN ref_month );
END;
/
Package created.
gSQL>
CREATE OR REPLACE PACKAGE BODY pkg_refcur AS
  PROCEDURE p_open( p_refcur_month OUT ref_month, p_month IN INTEGER ) AS
  BEGIN
    IF p_month = 1 THEN
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 1;
    ELSIF p_month = 3 THEN
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 3;
    ELSIF p_month = 5 THEN
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 5;
    ELSIF p_month = 7 THEN
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 7;
    ELSIF p_month = 9 THEN
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 9;
    ELSIF p_month = 11 THEN
```

```
      OPEN p_refcur_month FOR SELECT * FROM t_month WHERE month_num = 11;
    ELSE
      DBMS_OUTPUT.PUT_LINE( 'NO ODD MONTH' );
    END IF;

    DBMS_OUTPUT.PUT_LINE( 'p_refcur_month%ISOPEN : ' || p_refcur_month%ISOPEN );
  END;

  PROCEDURE p_fetch( p_refcur_month IN ref_month ) AS
  BEGIN
    FETCH p_refcur_month INTO v_month_char, v_month_num;
    DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
  END;

  PROCEDURE p_close( p_refcur_month IN ref_month ) AS
  BEGIN
    CLOSE p_refcur_month;
    DBMS_OUTPUT.PUT_LINE( 'p_refcur_month%ISOPEN : ' || p_refcur_month%ISOPEN );
  END;
END;
/
Package created.

DECLARE
  v_pkg_refcur_month pkg_refcur.ref_month;
BEGIN
  pkg_refcur.p_open( v_pkg_refcur_month, 5 );
  pkg_refcur.p_fetch( v_pkg_refcur_month );
  pkg_refcur.p_close( v_pkg_refcur_month );
END;
/
p_refcur_month%ISOPEN : TRUE
v_month_char : MAY , v_month_num : 5
p_refcur_month%ISOPEN : FALSE
Anonymous PL block executed.
```

Cursor Variable as Host Variable

The cursor variable can be declared as the host variable. The host cursor variable is useful to transfer the query result between the server and the client, and it can share the same query result sets between the se rver and the client.

Declare REF CURSOR type host variable and transfer it to the server to use the cursor variable as the host variable. Calling the cursor variable between the server and the client is not limited. Declare the cursor var iable in the client and fetch it after OPENing in the server, then it can be closed after it is FETCHed in the client.

Example of Host Cursor Variable

```
gSQL>
\var host_refcur_month REFCURSOR
gSQL>
BEGIN
  OPEN :host_refcur_month FOR SELECT * FROM t_month;
END;
/
Anonymous PL block executed.
gSQL>
DECLARE
  v_month_char VARCHAR(15);
  v_month_num  INTEGER;
BEGIN
  FETCH :host_refcur_month INTO v_month_char, v_month_num;
  DBMS_OUTPUT.PUT_LINE( 'v_month_char : ' || v_month_char || ' , v_month_num : ' ||
v_month_num );
END;
/
v_month_char : JANUARY , v_month_num : 1
Anonymous PL block executed.
gSQL>
BEGIN
  CLOSE :host_refcur_month;
END;
/
Anonymous PL block executed.
```

25.

Using PSM Subprograms

25.1 Anonymous PL Block

An anonymous PL block is an SQL statement for a one - time execution of a PSM statement instead of st oring a PSM statement in the database. An anonymous PL block is a one of a regular SQL provided by GO LDILOCKS, so it is used in the same way as other SQL s in ODBC, JDBC and precompiler which are provide d by GOLDILOCKS. A syntax is as same as a syntax of a general basic block
For more information, refer to **Block (BEGIN .. END)**.

```
<<Label>> ❶ (optional)
DECLARE   ❷ (optional)
❸ declare items (variables, cursors, types, ...) (optional)
BEGIN     ❹ (required)
❺ PSM statements to execute (required)
EXCEPTION ❻ Exception Handling Part (optional)
END;
```

Refer to the following instructions when using an anonymous PL block.

Interface	Instructions for use
in common	A bind parameter can be used unlike a schema-level procedure/ function. It also supports a prepare-execute method.
ODBC	It is used completely same as a general SQL.
JDBC	A CallableStatement class should be used if it has a bind parameter with IN-OUT or OUT attribute. (Refer to **CallableStatement**.)
Precompiler (gpec)	N/A
Interactive command tool (gsql)	It should notify the end of the statement by entering '/'<Enter> after inputting a n anonymous PL block.

25.2 Nested Procedure

A nested procedure is a procedure type subprogram declared within a specific PL block. A nested proced ure has a scope which can be referenced only on a declared PL block and its subordinates.
For more information, refer to **Procedure Declaration and Definition**.

```
DECLARE
  PROCEDURE PROC1( A1 INTEGER )  ❶ Define Nested Procedure
    IS
    BEGIN
      DBMS_OUTPUT.PUT_LINE( 'A1 = ' || A1 );
    END;
BEGIN
  PROC1( 100 );  ❷ Call Nested Procedure
END;
/
```

The followings are items available within a nested subprogram.

- An argument variable of a nested subprogram
- A PL block in which a nested subprogram is defined, and variables and various items (type, cursor,...) defined in its superordinate scope.
- A bind parameter when it is an anonymous PL block. (e.g. '?', ':V1')

A nested procedure supports a forward declaration, so it can separately specify a declare statement and a define statement. By using this, a logic of cross call between two nested procedures can be implemented.

```
gSQL> DECLARE
  PROCEDURE PROC1( A1 INTEGER );  ❶ declare proc1
  PROCEDURE PROC2( A1 INTEGER )   ❷ define  proc2
  IS
  BEGIN
    IF A1 > 0 THEN
      DBMS_OUTPUT.PUT_LINE( '(proc2)A1 = ' || A1 );
      PROC1( A1 -1 );  ❸ call proc1
    END IF;
  END;
  PROCEDURE PROC1( A1 INTEGER )   ❹ define  proc1
  IS
  BEGIN
    IF A1 > 0 THEN
```

```
      DBMS_OUTPUT.PUT_LINE( '(proc1)A1 = ' || A1 );
      PROC2( A1 -1 );  ❺ call proc2
    END IF;
  END;
BEGIN
  PROC1(5); ❻ call proc1
END;
/

(proc1)A1 = 5
(proc2)A1 = 4
(proc1)A1 = 3
(proc2)A1 = 2
(proc1)A1 = 1
Anonymous PL block executed.
```

GOLDILOCKS PSM limits the maximum subordinate statement depths to 50 to prevent the infinite cross r eferencing. If it is exceeded, then the following error occurs. (It is also applied same to a nested function, schema-level procedure/ function.)

```
gSQL> DECLARE
  PROCEDURE PROC1( A1 INTEGER );  ❶ declare proc1
  PROCEDURE PROC2( A1 INTEGER )   ❷ define  proc2
  IS
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'A1 = ' || A1 );
    PROC1( A1 -1 );
  END;
  PROCEDURE PROC1( A1 INTEGER )   ❸ define  proc1
  IS
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'A1 = ' || A1 );
    PROC2( A1 -1 );
  END;
BEGIN
  PROC1(100);
END;
/
ERR-42000(16411): maximum number of recursive SQL levels (50) exceeded.
```

25.3 Nested Function

A nested function is as same as a nested procedure, but it is a subprogram in function form.
For more information, refer to **Function Declaration and Definition**.

```
gSQL> DECLARE
  V1 INTEGER := 0;
  FUNCTION FUNC1( A1 INTEGER )
    RETURN INTEGER
    IS
    BEGIN
      RETURN A1 * 10;
    END;
BEGIN
  V1 := FUNC1( 10 );
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
V1 = 100
Anonymous PL block executed.
```

A nested function can be used in all PSM expressions within a visible scope, but is can not be used in an SQL statement.

```
gSQL> DECLARE
  V1 INTEGER := 0;
  FUNCTION FUNC1( A1 INTEGER )
    RETURN INTEGER
    IS
    BEGIN
      RETURN A1 * 10;
    END;
BEGIN
  SELECT FUNC1(10) INTO V1 FROM DUAL;
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
ERR-HY000(17032): PSM compilation error :
(1) at (10:3): ERR-HY000(17079): a nested function not allowed in executing SQL
```

25.4 Schema-level Procedure

A schema-level subprogram is an SQL object which has a name and is stored in a database. A schema-level procedure is a schema-level subprogram in procedure form.

Creating Schema-level Procedure

A schema-level procedure is created as follows. A precision and a scale value should be specified if in need.
For more information, refer to **CREATE PROCEDURE**.

```
CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 INTEGER )
IS
  V1 INTEGER;
BEGIN
  SELECT COUNT(*)
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A2;
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
```

The information about a created schema-level procedure can be found with a INFORMATION_SCHEMA.ROUTINES table.
For more information, refer to **ROUTINES**.

```
gSQL> SELECT SPECIFIC_NAME, ROUTINE_DEFINITION
  FROM  INFORMATION_SCHEMA.ROUTINES
  WHERE SPECIFIC_NAME = 'PROC1';
SPECIFIC_NAME ROUTINE_DEFINITION
------------- ------------------------------------------------------
PROC1         PROCEDURE "PUBLIC"."PROC1" ( A1 INTEGER, A2 INTEGER )
              IS
                V1 INTEGER;
              BEGIN
                SELECT COUNT(*)
                  INTO V1
```

```
                FROM T1
                WHERE T1.I1 >= A1 AND T1.I1 <= A2;
              DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
            END;

1 row selected.
```

The information about an argument can be found with a INFORMATION_SCHEMA.PARAMETERS table. For more information, refer to **PARAMETERS**.

```
gSQL> SELECT P.PARAMETER_NAME, P.ORDINAL_POSITION
  FROM  INFORMATION_SCHEMA.ROUTINES     R,
        INFORMATION_SCHEMA.PARAMETERS   P
  WHERE R.SPECIFIC_NAME = 'PROC1'
    AND R.SPECIFIC_SCHEMA = P.SPECIFIC_SCHEMA
    AND R.SPECIFIC_NAME = P.SPECIFIC_NAME
  ORDER BY P.ORDINAL_POSITION;
PARAMETER_NAME ORDINAL_POSITION
-------------- ----------------
A1                            1
A2                            2
2 rows selected.
```

Using Schema-level Procedure

A schema-level procedure is used by an inner statement of other PSM or by a CALL statement. Other PSM statements call a schema-level procedure in the same form of a nested procedure.

```
gSQL> BEGIN
  PROC1( 2, 4 );  ❶ Call schema-level procedure
END;
/
V1 = 3
Anonymous PL block executed.
```

A CALL statement which is an SQL executing the given PSM is executed as follows.
For more information, refer to **CALL Statement**.

```
gSQL> CALL PROC1( 2, 4 );
V1 = 3
Procedure Call complete.
```

It supports the following syntax for a procedure to support a procedure call escape sequence used in ODB C or JDBC.

```
{ CALL procedure_name( param1, param2, ... ) }
```

A syntax of a procedure call escape sequence is used like as a general SQL.

```
gSQL> { CALL PROC1(2, 4) };
V1 = 3
Procedure Call complete.
```

gsql which is an interactive command tool of GOLDILOCKS does not support performing a procedure thr ough \EXEC which is the tool's own command.

The following options about a privilege of when executing a schema-level procedure can be specified. If a user except for a definer performs an SQL within PSM according to these options, it may refer to a table with the same name in different schemas according to the definition of that user's schema-path. (A nam e of the object used when declaring an item (e.g. T1%ROWTYPE) is always interpreted as a definer.)

- AUTHID DEFINER (default): The user is altered to the user created that procedure, then it is performe d.
- AUTHID CURRENT_USER: The user is not altered, and it is performed by the current user.

```
CREATE OR REPLACE PROCEDURE "PROC1"( A1 INTEGER, A2 INTEGER )
AUTHID CURRENT_USER
IS
  V1 INTEGER;
BEGIN
  SELECT COUNT(*)
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
```

Dropping Schema-level Procedure

A schema-level procedure is dropped by the following DROP PROCEDURE statement.
For more information, refer to **DROP PROCEDURE**.

```
DROP PROCEDURE PROC1;
```

It also supports IF EXISTS statement like as other DROP statements of GOLDILOCKS.

```
DROP PROCEDURE IF EXISTS PROC1;
```

Recompiling Schema-level Procedure

If an object referenced inside of a schema-level subprogram is altered, then it may affects the correspondi ng subprogram and should create the execution plan again.

Referenced Object in a Declarative Part or an Argument

If the used object is altered when defining various items in a declarative part or an argument type, then t he procedure plan is automatically recompiled.

- An object used in %TYPE, %ROWTYPE
- An object used in an explicit cursor definition statement

If the corresponding procedure is performed for the first time after an object is altered, then the plan is a utomatically recreated according to the following order.

1. Bring the plan of the corresponding procedure from a plan cache.
2. Search for objects which were altered during validating an object list of that plan.
3. Discard the current plan, and create a new plan from a procedure definition statement stored in a di ctionary.
4. Register a newly created plan on a plan cache.
5. Execute the plan.

Referenced Object in an SQL of the Body

An SQL plan used in the body is not stored in a procedure plan, and only the SQL text is stored. When ex ecuting a procedure, it creates a plan by compiling the corresponding SQL statement in real time, then ex ecutes it. Therefore, an SQL object used within a body does not affect the procedure plan itself.

However, if an object is altered, the number or type of binds which are the existing interfaces of a proced ure may be altered, or columns may be dropped. Therefore, an error may occur when executing it if the p rocedure is not appropriately altered.

25.5 Schema-level Function

A schema-level function is a schema-level subprogram in function form, which is used within an expressio n.

Creating Schema-level Function

A schema-level function is created as follows. A precision and a scale value of an argument type should b e specified if in need.
For more information, refer to **CREATE FUNCTION**.

```
gSQL> CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
RETURN INTEGER
IS
  V1 INTEGER;
BEGIN
  SELECT COUNT(*)
    INTO V1
    FROM T1
    WHERE T1.I1 >= A1 AND T1.I1 <= A2;
  RETURN V1;
END;
/
Function created.
```

Like as a procedure, a created schema-level function is found throughINFORMATION_SCHEMA.ROUTINE S and INFORMATION_SCHEMA.PARAMETERS table.

Using Schema-level Function

A schema-level function can be used in all expressions in which a general SQL or an SQL object within PS M can be used.

```
gSQL> SELECT FUNC1( 2, 4 ) FROM DUAL;
FUNC1( 2, 4 )
-------------
            3
```

```
1 row selected.
```

It is used as follows within PSM.

```
gSQL> DECLARE
  V1 INTEGER;
BEGIN
  V1 := FUNC1( 2, 4 );
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
V1 = 3
Anonymous PL block executed.
```

It can be performed by using CALL statement as follows.
For more information, refer to **CALL Statement**.

```
gSQL> \var V1 INTEGER
gSQL> CALL FUNC1( 2, 4 ) INTO :V1;
Procedure Call complete.
gSQL> \print V1
V1
--
 3
```

Like as a schema-level procedure, a procedure call escape sequence statement is also supported.

```
{ ? = CALL function_name( param1, param2, ... ) }
```

```
gSQL> { :V1 = CALL FUNC1( 2, 4 ) };
Procedure Call complete.
gSQL> \print V1
V1
--
 3
```

Dropping Schema-level Function

A schema-level function is dropped by the following DROP FUNCTION statement.
For more information, refer to **DROP FUNCTION**.

```
gSQL> DROP FUNCTION FUNC1;
Function dropped.
```

25.6 Built-in Procedures

GOLDILOCKS PSM provides the following built-in procedures to debug or process the exception when m aterializing the procedure and the function.

Table 25-1 Built-in procedures

Procedure	Description
DBMS_OUTPUT.ENABLE(buffer_si ze IN NATIVE_INTEGER := 20000)	It activates a message logging feature to the given buffer size. If the buffer size is not given it is set to 20000 bytes by default. If the feature i s already activatedm then it discards all messages and creates a new buffer.
DBMS_OUTPUT.DISABLE	It deactivates a message logging feature. All messages previously logged are discarded.
DBMS_OUTPUT.SET_LOG(file_pat h IN VARCHAR(4000))	It simultaneously outputs on the file in a given path when logging a message. If the given path is a relative path (its first letter is not /), then it searches for a target file below a directory corresponding to <SYSTEM_LOGGER_DIR> prope rty. Specify the permission as follows. • CALL DBMS_OUTPUT.SET_LOG('a.txt' , 640)
DBMS_OUTPUT.PUT_LINE(item IN VARCHAR(4000))	It stores a message created with a given expression including the new line ch aracter on a buffer.
DBMS_OUTPUT.PUT(item IN VARC HAR(4000))	It stores a message created with a given expression on a buffer.
DBMS_OUTPUT.NEW_LINE	It stores the new line character on a buffer.
DBMS_OUTPUT.GET_LINE(line OU T VARCHAR(4000), status OUT NA TIVE_INTEGER)	It returns the oldest single message line which is not read among messages st ored on a buffer. If there is a message, a status returns 0, if there is not any m essage it returns 1.
DBMS_STANDARD.RAISE_APPLICA TION_ERROR(error_code IN NATIV E_INTEGER, error_message IN VAR CHAR(4000), stack_flag IN BOOLE AN := FALSE)	It generates an arbitrary user exception. and error_code should be the value b etween -20000 and -20999. If it is TRUE, the last stack_flag argument stacks a given error on the existing errors. If it is FALSE, the corresponding error repl aces all errors. (It can be omitted, and the default is FALSE when it is omitted.)
DBMS_LOCK.SLEEP(seconds IN NU MBER)	It pauses the session for the specified time.
DBMS_SQL.RETURN_RESULT(rc IN SYS_REFCURSOR)	It returns the result of the query executed through *ref cursor* to the client app lication.

```
gSQL> DECLARE
V1 VARCHAR(1024);
V2 INTEGER;
BEGIN
```

```
  DBMS_OUTPUT.ENABLE(2000);
  DBMS_OUTPUT.PUT_LINE('TEST MSG');
  DBMS_OUTPUT.GET_LINE( V1, V2);
  DBMS_OUTPUT.PUT_LINE('V1 = ' || v1);
  DBMS_OUTPUT.PUT_LINE('V2 = ' || v2);
END;
/
V1 = TEST MSG
V2 = 0
Anonymous PL block executed.
```

A message logging feature is managed per each section, and gsql (an interactive command tool of GOLD ILOCKS) can turn on or off the message logging feature with a serveroutput option. If any content remai ns in a message buffer after performing PSM, all are automatically output.

```
gSQL> \set serveroutput on
gSQL> \var msg VARCHAR(4000)
gSQL> \var status NATIVE_INTEGER
gSQL> CALL DBMS_OUTPUT.PUT_LINE( 'aaa' );
aaa
Procedure Call complete.
gSQL> CALL DBMS_OUTPUT.PUT_LINE( 'bbb' );
bbb
Procedure Call complete.
gSQL> CALL DBMS_OUTPUT.GET_LINE( :msg, :status );
Procedure Call complete.
gSQL> \print msg
MSG
----
null
gSQL> \print status
STATUS
------
     1
```

26.

Using SQLs in PSM

26.1 Static SQLs

Overview

A static SQL is an extended SQL to use PSM variable supported by GOLDILOCKS. PSM variable is available in every expression which allows the bind parameter in SQL.

- SELECT INTO Statement
  - For more information, refer to **SELECT INTO Statement** in PSM Language Element References.
- Data Manipulation Language(DML)
  - INSERT Statement Extension
    - For more information, refer to **INSERT Statement Extension** in PSM Language Element References.
  - INSERT INTO ... UPDATE Statement Extension
    - For more information, refer to **INSERT INTO ... UPDATE Statement Extension** in PSM Language Element References.
  - UPDATE Statement Extension
    - For more information, refer to **UPDATE Statement Extension** in PSM Language Element References.
  - DELETE Statement Extension
    - For more information, refer to **DELETE Statement Extension** in PSM Language Element References.
- Transaction Control Language
  - COMMIT
    - For more information, refer to **COMMIT** in SQL References.
  - ROLLBACK
    - For more information, refer to **ROLLBACK** in SQL References.
  - SAVEPOINT
    - For more information, refer to **SAVEPOINT savepoint_specifier** in SQL References.
  - LOCK TABLE
    - For more information, refer to **LOCK TABLE** in SQL References.

Examples

- When using the built-in data type PSM variable

```
gSQL>
DECLARE
  v_id      NUMBER;
```

```
  v_name    VARCHAR(50);
BEGIN
  -- SELELECT INTO Statement
  SELECT id , name
    INTO v_id , v_name
    FROM emp
   WHERE id = 201;
   DBMS_OUTPUT.PUT_LINE( '[SELECT INTO] ' || v_id || ' , ' || v_name );
  -- INSERT Statement Extension
  v_id   := 200;
  v_name := 'Jennifer Whalen';
  INSERT INTO emp VALUES( v_id , v_name );

  -- DELETE Statement Extension
  DELETE FROM emp
   WHERE id = v_id
  RETURNING name INTO v_name;
  DBMS_OUTPUT.PUT_LINE( '[DELETE] ' || v_id || ' , ' || v_name );

  -- UPDATE Statement Extension
  UPDATE emp
     SET id = v_id , name = v_name
   WHERE id = 200;
  -- Commit
  COMMIT;
END;
/
[SELECT INTO] 201 , Michael Hartstein
[DELETE] 200 , Jennifer Whalen
Anonymous PL block executed.
```

- When using the ROW type PSM variable

```
gSQL>
DECLARE
  TYPE rec_emp IS RECORD( f_id emp.id%TYPE , f_name emp.name%TYPE );
  v_rec_emp rec_emp;
BEGIN
  -- SELELECT INTO Statement
  SELECT id , name
    INTO v_rec_emp
```

```
    FROM emp
   WHERE id = 201;
   DBMS_OUTPUT.PUT_LINE( '[SELECT INTO] ' || v_rec_emp.f_id ||
                         ' , ' || v_rec_emp.f_name );
  -- INSERT Statement Extension
  v_rec_emp.f_id   := 200;
  v_rec_emp.f_name := 'Jennifer Whalen';
  INSERT INTO emp VALUES( v_rec_emp.f_id , v_rec_emp.f_name );

  -- DELETE Statement Extension
  DELETE FROM emp
   WHERE id = v_rec_emp.f_id
  RETURNING * INTO v_rec_emp;
   DBMS_OUTPUT.PUT_LINE( '[DELETE] ' || v_rec_emp.f_id ||
                         ' , ' || v_rec_emp.f_name );

  -- UPDATE Statement Extension
  UPDATE emp
     SET ROW = v_rec_emp
   WHERE id = 200;
  -- Commit
  COMMIT;
END;
/
[SELECT INTO] 201 , Michael Hartstein
[DELETE] 200 , Jennifer Whalen
Anonymous PL block executed.
```

Processing Query Result Sets

PSM processes result sets by using an implicit cursor or an explicit cursor.

PSM defines the implicit cursor as follows.

- SELECT INTO
- Implicit Cursor FOR LOOP

PSM defines the explicit cursor as follows.

- Explicit Cursor FOR LOOP

- It is an explicit cursor defined by a user, and it is available during executing PSM statement.

Processing Query Result Sets with SELECT INTO Statements

It retrieves the value by executing SELECT INTO statement using an implicit cursor, then stores it in PSM v ariable.
The result set of select into statement is always a single row.

Examples

```
gSQL>
DECLARE
  v_id   emp.id%TYPE;
  v_name emp.name%TYPE;
BEGIN
  SELECT id , name
    INTO v_id , v_name
    FROM emp
   WHERE id = 201;

   DBMS_OUTPUT.PUT_LINE( 'SQL%FOUND = ' || SQL%FOUND );
END;
/
SQL%FOUND = TRUE
Anonymous PL block executed.
```

Processing Query Result Sets with Cursor FOR LOOP Statements

Cursor For LOOP statement executes an implicit cursor and an explicit cursor, then repeatedly returns the row in the result set.

Implicit cursor FOR LOOP statement is cursor FOR LOOP statement which uses SELECT statement. Implicit cursor FOR LOOP statement returns a row in the result set by using an implicit cursor for the select statem ent.

An explicit cursor declared by a user is available in cursor FOR LOOP statement
An explicit cursor declared by a user is also available in another statement in PSM block.

Cursor FOR LOOP statement implicitly creates and uses %ROWTYPE variable for the type returned as a lo op index by a cursor.
A loop index is a variable which is available only during executing cursor FOR LOOP statement.

PSM statement which is operated during the loop can refer to the record and the field by using a loop ind ex.

Cursor FOR LOOP statement is executed by opening the user defined cursor after creating the loop index variable.
It stores the row result in the loop index variable whenever repeating the loop.
If the row is not returned anymore, then the cursor is closed. The cursor is closed even when it throws an exception during the execution.

Examples

- When using SELECT statement in cursor FOR LOOP statement

```
gSQL>
BEGIN
  FOR tmp IN ( SELECT id , name , manager_id FROM emp ) LOOP
    DBMS_OUTPUT.PUT_LINE( 'id = ' || tmp.id ||
                          ' , name = ' || tmp.name ||
                          ' , manager_id = ' || tmp.manager_id );
  END LOOP;
END;
/
id = 200 , name = Jennifer Whalen   , manager_id = 101
id = 201 , name = Michael Hartstein , manager_id = 101
id = 202 , name = Pat Fay           , manager_id = 301
id = 203 , name = Susan Mavris      , manager_id = 201
id = 204 , name = Hermann Baer      , manager_id = 201
id = 205 , name = Shelley Higgins   , manager_id = 301
id = 206 , name = William Gietz     , manager_id = 201
Anonymous PL block executed.
```

- When using an explicit cursor in cursor FOR LOOP statement
  - If the explicit cursor does not have a parameter

```
gSQL>
DECLARE
  CURSOR cur1 IS SELECT id , name , manager_id FROM emp;
BEGIN
  FOR tmp IN cur1 LOOP
    DBMS_OUTPUT.PUT_LINE( 'id = ' || tmp.id ||
                          ' , name = ' || tmp.name ||
                          ' , manager_id = ' || tmp.manager_id );
```

```
  END LOOP;
END;
/
id = 200 , name = Jennifer Whalen   , manager_id = 101
id = 201 , name = Michael Hartstein , manager_id = 101
id = 202 , name = Pat Fay           , manager_id = 301
id = 203 , name = Susan Mavris      , manager_id = 201
id = 204 , name = Hermann Baer      , manager_id = 201
id = 205 , name = Shelley Higgins   , manager_id = 301
id = 206 , name = William Gietz     , manager_id = 201
Anonymous PL block executed.
```

- If the explicit cursor has a parameter

```
gSQL>
DECLARE
  CURSOR cur1( p1 NUMBER ) IS SELECT id , name , manager_id
                               FROM emp
                              WHERE manager_id = p1;
BEGIN
  FOR tmp IN cur1( 201 ) LOOP
    DBMS_OUTPUT.PUT_LINE( 'id = ' || tmp.idgSQL>  ||
                          ' , name = ' || tmp.name ||
                          ' , manager_id = ' || tmp.manager_id );
  END LOOP;
END;
/
id = 203 , name = Susan Mavris      , manager_id = 201
id = 204 , name = Hermann Baer      , manager_id = 201
id = 206 , name = William Gietz     , manager_id = 201
Anonymous PL block executed.
```

Processing Query Result Sets with Explicit Cursors, OPEN, FETCH, and CLOSE

Declare and use an explicit cursor to control the result set as desired.
The user can manage the result set by using OPEN, FETCH, CLOSE statement after declaring the explicit c
ursor.

The query using PL statement may look complicated, but it can flexibly manage the result set as follows.

- It can process result sets in parallel by using multiple explicit cursors.
- It can process multiple rows in the result set in parallel or skip a specific row in a single loop state ment.
- Also, it can use multiple loop statements to process the result sets by dividing them.

For more information, refer to **Explicit Cursor**.

26.2 Dynamic SQL

Unlike a static SQL, the syntax of a dynamic SQL is determined at the time of execution.

In PSM, a dynamic SQL created by a user at run-time can be performed through EXECUTE IMMEDIATE or OPEN FOR statement.

- A dynamic SQL is used in the following cases.
  - When an SQL statement can not be determined when compiling. (e.g. When an SQL statement s hould be altered according to conditions.)
  - When an SQL which is not supported in a static SQL is performed. (e.g. DDL)
- The syntax of a dynamic SQL is unknown until the time of execution, so a run-time error may occur d ue to a syntax error, existence of a target object and validation of a user privilege.

- A dynamic SQL can be used in the following PSM statements.
  - **EXECUTE IMMEDIATE Statement**
  - **OPEN FOR Statement**

EXECUTE IMMEDIATE

Various dynamic SQLs can be performed in EXECUTE IMMEDIATE. However, a statement in a form of an SQL extension provided by PSM can not be used.

The statement is provided in the following form.

```
EXECUTE IMMEDIATE 'dynamic sql' [ USING [IN ¦ OUT ¦ INOUT] variable_list] [INTO variable_list]
[RETURNING INTO variable_list]
```

A value stored in a PSM variable can be applied to a database through USING, INTO, RETURNING INTO st atements which are provided to an EXECUTE IMMEDIATE statement, or a value can be stored from a dat abase to a PSM variable. The differences of using each statement are as follows.

- USING
  - It uses an IN-mode when applying a value of PSM variable to an SQL.
  - It uses an OUT-mode when storing the result of SQL processing in a PSM variable.
    - Therefore, if uses an OUT-mode, it should be described with PSM variables. (An expression is not available.)
  - An IN-mode is applied when a binding type of the variable specified in USING clause is not specifi ed.
  - It is operated as same as using SELECT INTO clause when a target of SELECT is returned as USING OUT.

    - Only a single row can be returned from the database. If two or more results occurs then an error occurs.
    - A PSM variable in a USING IN clause can use only a form of scalar type.
    - A PSM variable in a USING OUT clause can use a record type, but it can not use it by mixing with another type.
- INTO
    - It is used when storing the result of SELECT which is internally processed in a database using an implicit cursor.
    - It can be used only when executing SELECT clause using a dynamic SQL method. (SELECT INTO clause can not be used.)
    - A PSM variable can be a record-type, but it can not be used by mixing with another type.
- RETURING INTO
    - It is used when storing the before/ after of the data processed by INSERT/ UPDATE/ DELETE.
    - It can store only a single row.
    - A PSM variable can be a record-type, but it can not be used by mixing with another type.

The following is an example of outputting the SELECT_INTO statement result by using a dynamic SQL.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> INSERT INTO T1 VALUES ('Seoul', '24');
1 row created.
gSQL> INSERT INTO T1 VALUES ('Pusan', '44');
1 row created.
gSQL> DECLARE
  V1 VARCHAR(20);
  V2 VARCHAR(20);
BEGIN
  EXECUTE IMMEDIATE 'SELECT * INTO ?, ? FROM T1 WHERE C1 = ''Seoul'''
  USING OUT V1, OUT V2;
  DBMS_OUTPUT.PUT_LINE('V1 = ' || V1);
  DBMS_OUTPUT.PUT_LINE('V2 = ' || V2);
END;
/
V1 = Seoul
V2 = 24
Anonymous PL block executed.
```

The following is an example of performing an altering operation and storing the result of when before th e alteration in a variable specified in RETURNING INTO.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> INSERT INTO T1 VALUES ('Seoul', '24');
1 row created.
gSQL> INSERT INTO T1 VALUES ('Pusan', '44');
1 row created.
gSQL> DECLARE
  V1 VARCHAR(20);
  V2 VARCHAR(20);
  V3 VARCHAR(20);
  V4 VARCHAR(20);
BEGIN
  V1 := 'Daegu';
  V2 := '50';
  EXECUTE IMMEDIATE
      'UPDATE T1 SET C1 = ? ,  C2 = ? WHERE C1 = ''Seoul'' RETURNING OLD * INTO ?, ?'
  USING V1, V2 RETURNING INTO V3, V4;
  DBMS_OUTPUT.PUT_LINE('V3 = ' || V3);
  DBMS_OUTPUT.PUT_LINE('V4 = ' || V4);
END;
/
V3 = Seoul
V4 = 24
Anonymous PL block executed.
```

For more information. refer to **EXECUTE IMMEDIATE Statement**.

OPEN FOR, FETCH and CLOSE

When processing a query by using EXECUTE IMMEDIATE, the database can not return one or more result s. If an SQL to be processed is a dynamic SQL, and two or more result sets should be fetched, like as a cur sor, then use OPEN FOR.

The a dynamic SQL in the following form can be used in OPEN FOR statement.

```
OPEN Cursor_variable FOR dynamic_sql [USING variable_list]
```

The following is an example of performing OPEN FOR statement through a dynamic SQL.

```
gSQL> CREATE TABLE T1
(
  C1 VARCHAR(20),
  C2 VARCHAR(20)
);
Table created.
gSQL> INSERT INTO T1 VALUES ('Seoul', '24');
1 row created.
gSQL> INSERT INTO T1 VALUES ('Pusan', '44');
1 row created.
gSQL> DECLARE
  v1 VARCHAR(20);
  v2 VARCHAR(20);
  v3 VARCHAR(20);
  cv1 SYS_REFCURSOR;
  sqlstr VARCHAR(1024);
BEGIN

    sqlstr := 'SELECT * FROM T1 WHERE C1 >= ?';
    v3 := 'AAAA';
    OPEN cv1 FOR sqlstr USING v3;
    FETCH cv1 INTO v1, v2;
    DBMS_OUTPUT.PUT_LINE('V1 = ' || V1 || ' , V2 = ' || V2);
    CLOSE cv1;
END;
/
V1 = Seoul , V2 = 24
Anonymous PL block executed.
```

- USING clause in OPEN FOR statement has the following constraints.
  - Binding mode
    - Only IN mode is available.
  - Available items
    - PSM variable
    - Value expression whose result is returned as a scalar type

For more information, refer to **OPEN FOR Statement**, **FETCH Statement**, **CLOSE Statement**.

27.

PSM Packages

This chapter describes how to modularize common data and PSM codes used in various applications into the package.

27.1 Definition

A package is a schema object which bundles items such as logically-related PSM types, variables, subprograms, cursors and exceptions. A package is stored in the database through the compiling process, so that another program (another package, procedure, external program) may refer, share and execute the items in the package.

Every package has a specification in which referable multiple public items and subprograms are listed.
If a cursor exists among public items or a public subprogram exists, then the package may have a package body. The body includes the following contents.

- SQL statement to be performed by a public cursor, or PSM code which is to be executed by a public subprogram
- Items such as multiple variables and types subprograms which are private and used only internally
- Code for initializing public items (initialization part) which is performed only once when the package is used for the first time (instantiation).

AUTHID statement of the package specification determines whether to perform the package with an invoker privilege or with a definer privilege (Default: definer). It also determines whether to translate the unqualified object in the invoker or in the definer when referring to it.

Only the package owner and the user with EXECUTE PACKAGE privilege can retrieve the definition statement of package specification. However, only the package owner can retrieve the definition statement of package body.

27.2 Features

The following features of package provides an application developer and an operator with high reliability and reusability.

- Modularity
  - It bundles related items and subprograms together, so it is easy to manage the database and understand its structure.

- Easy programming
  - A user can program the related application only by defining a specification even without defining the body.
- Encapsulating
  - It can hide the body contents which is an internal implementation of the package from the packa ge user.
  - It can alter the body (implementation) without recompiling SQL and application which use the pa ckage.
- Performance optimization
  - The entire package is loaded on the memory at once, so that it can quickly call the subprogram in s the memory.
- Easy privilege control
  - It can bundle all separate privileges for using all public items and subprograms into a single privile ge for the entire package.

A package does not support a subprogram overloading, so functions of the same names can not be defin ed in the same block scope.

27.3 Specification

The following public items can be declared in the package specification.

- User-defined type
  - Record or collection (Associative array)
  - A user-defined type declared in a package can be used only in a PSM-family statement.
- Variable
  - It is recommended to define a get/ set subprogram for each variable not to directly refer to the va riable.
- Subprogram
  - Procedure
  - Function
- Explicit cursor
  - It is allowed to define only a name and a returned type in a package specification and define SQL statement performed by a cursor in a body.
  - A cursor variable can not be defined with a public item in a package.
- User-defined exception

Creating Package Specification

Create a package specification by using CREATE PACKAGE statement.

```
CREATE OR REPLACE PACKAGE MY_PKG
IS
  TYPE MY_REC IS RECORD (F1 INTEGER, F2 INTEGER );
END;
/
Package created.
```

Public items in a defined package can be referred from outside of a package by specifying the package na me together as follows.

```
DECLARE
V1 MY_PKG.MY_REC;
BEGIN
    V1.F1 := 10;
    V1.F2 := 20;
    DBMS_OUTPUT.PUT_LINE( 'V1.F1 = ' || V1.F1 || ', V1.F2 = ' || V1.F2 );
END;
/
V1.F1 = 10, V1.F2 = 20
Anonymous PL block executed.
```

Creating Package Body

The body should be declared when a public cursor or subprogram exists in a package, or the initialization code is required. Otherwise, body definition is optional.

The package body has the following constraints.

- The package body should be created in the schema which is as same as that of the package specificat ion.
- The package body should have the name as same as that of the package specification.
- If a cursor in which the SQL statement is not defined exists among open cursors declared in a packag e specification, then the cursor with the same name, record type and argument should be declared b y specifying SQL in the body.
- A subprogram whose name, argument and return type are same as those of an open subprogram de clared in a package specification should be defined in the body.

- The variable, type, exception which are as same as those defined in a package specification can not b e declared in the package body.

Create a package body as follows.

```
CREATE TABLE emp( empno NUMBER, sal NUMBER, comm NUMBER );
Table created.
INSERT INTO emp VALUES( 3548, 6000, 1000 );
1 row created.
INSERT INTO emp VALUES( 9369, 5000, NULL );
1 row created.
INSERT INTO emp VALUES( 7294, 4000, 500 );
1 row created.
COMMIT;
Commit complete.
CREATE OR REPLACE PACKAGE emp_mgmt
IS
  PROCEDURE adjust_sal(v_flag VARCHAR, v_empno NUMBER, v_pct NUMBER);
  FUNCTION get_annual_sal(v_empno NUMBER) RETURN NUMBER;
END;
/
Package created.
CREATE OR REPLACE PACKAGE BODY emp_mgmt
IS
  PROCEDURE adjust_sal(v_flag VARCHAR, v_empno NUMBER, v_pct NUMBER) IS
  BEGIN
    IF v_flag = 'INCREASE' THEN
      UPDATE emp SET sal = sal + (sal * (v_pct / 100)) WHERE empno = v_empno;
    ELSE
      UPDATE emp SET sal = sal - (sal * (v_pct / 100)) WHERE empno = v_empno;
    END IF;
  END;
  FUNCTION get_annual_sal (v_empno NUMBER) RETURN NUMBER
  IS
    v_sal NUMBER;
  BEGIN
    SELECT (sal + NVL(comm,0)) * 12 INTO v_sal FROM emp WHERE empno = v_empno;
    RETURN v_sal;
  END;
END;
/
Package created.
```

Call subprograms of the created package body as follows.

```
call emp_mgmt.adjust_sal('INCREASE',7369, 10);
Procedure Call complete.
SELECT emp_mgmt.get_annual_sal(7294) FROM DUAL;
EMP_MGMT.GET_ANNUAL_SAL(7294)
------------------------------
                        54000
1 row selected.
```

Package State

Packages are classified into a stateful package and a stateless package.

A stateful package includes one or more variables or cursors, and a stateless package is configured with s ubprograms only such as a procedure or a function.

A stateful package creates a package instance in a session when referring to the variable or the cursor of the package for the first time. In this case, it performs the following operations.

- Initialize a package variable
- Execute an initialize section

Generally, a package state is maintained as same as the lifetime of a session. However, a stateful package is invalidated and an instance is initialized in the following cases.

- When the package is recreated by executing REPLACE PACKAGE statement
- When the package is recompiled by executing ALTER PACKAGE statement
- When altering operation (DDL) which affects the package instance form occurs on any object which was referenced by the package.

A stateless package does not have a state, so it is automatically recompiled even when the related object 's form is altered. However, a stateful package drops the existing package instance, then it recreates a pa ckage instance based on the updated package information.

Therefore, be cautious to handle the situational exception when using a package in an application.

28.

PSM Language Element References

28.1 Assignment Statement

Function

Within a PSM block, it stores a value in a variable or in an out-bind parameter.

Syntax

```
<assignment statement> ::=
    <assignment target> := <value expression>
    ;
<assignment target> ::=
      collection_variable ( index )
    ¦ cursor_variable
    ¦ :host_cursor_variable
    ¦ out_parameter
    ¦ :host_variable [ :indicator_variable ]
    ¦ record_variable . field_name
    ¦ scalar_variable
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- collection_variable
  - It is the variable name of COLLECTION type declared in DECLARE section.
- index
  - It is the key value which selects an element among elements of collection_variable.
- cursor_variable
  - It is the cursor name declared in DECLARE section.
- host_variable

    - It is the name of out/ in-out type client-side variable which is transferred from where calling PSM.
- indicator_variable
    - It is the indicator variable name to check the NULL value of host_variable and to find out the actual length of the value.
- record_variable
    - It is the variable name of RECORD type which has already been declared in DECLARE section.
- field_name
    - It is the name of a field among fields included in a RECORD type variable.
- scalar_variable
    - It is the variable name of a general scalar type which has already been declared in DECLARE section.

Description

Targets of assignment statements are classified into an external bind parameter and an internal PSM variable.

- External parameter
    - Host variable
    - Host cursor variable
- Internal variable
    - Out type function argument
    - Internally declared variable
        - Scalar/ record/ multi-set type
        - A specific field of a record type variable
        - A specific element of multi-set type variable

All variables except for a procedure/ function parameter can have a name assigning a scope.

Examples

The following is an example of using an assignment statement.

- Assignment for PSM internal variable

```
gSQL> DECLARE
  V1 INTEGER := 0;
BEGIN
  FOR I IN 1..10 LOOP
```

```
    V1 := V1 + I;
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
END;
/
V1 = 55
Anonymous PL block executed.
```

- Assignment for a host variable

```
gSQL> \var P1 INTEGER
gSQL>
BEGIN
  :P1 := 100;
END;
/
gSQL> \print P1
 P1
---
100
Anonymous PL block executed.
```

Compatibility

The differences between an assignment statement of GOLDILOCKS and that of SQL standard are as follo ws.

- An assignment statement of the SQL standard defines a singleton variable assignment and a multiple variable assignment, but GOLDILOCKS supports only a singleton variable assignment.
- An assignment statement of the SQL standard starts with SET keyword, but GOLDILOCKS does not us e SET keyword.
- An assignment statement of the SQL standard uses an equal operator (=) between a target and a val ue, but GOLDILOCKS uses :=.

Table 28-1 SQL standard compatibility

Feature ID	Description	Compatibility
P002	Computational completeness	X
P006	Multiple assignment	X

For More Information

Refer to the followings.

- **Scalar Variable Declaration**
- **Record Variable Declaration**
- **COLLECTION Variable Declaration**
- **Cursor Variable Declaration**

28.2 Basic LOOP Statement

Function

It repeatedly performs statements within LOOP until the LOOP is terminated by performing GOTO or EXIT.

Syntax

```
<basic loop statement> ::=
    LOOP { <SQL procedure statement> ; }... END LOOP [ loop_name ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- loop_name
  - It is the label name of <basic loop statement>.
  - Its role is only a comment, so it does not matter even when it is different from the real label nam e of <basic loop statement>.

Description

A basic loop statement is repeatedly performs statements within LOOP.
A basic loop statement is a loop-family statement, so it can be a target statement which GOTO, EXIT, and CONTINUE indicates as a label.

Examples

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    V1 := V1 + 1;
    EXIT WHEN V1 > 2;
  END LOOP;
END;
/
V1 = 1
V1 = 2
Anonymous PL block executed.
```

Compatibility

〈basic loop statement〉 statement is as same as 〈loop statement〉 of the SQL standard.

Table 28-2 SQL standard compatibility

Feature ID	Description	Compatibility
P002	Computational completeness	O

For More Information

Refer to the followings.

- **CONTINUE Statement**
- **EXIT Statement**
- **GOTO Statement**

28.3 Block (BEGIN .. END)

Function

It creates a new scope and defines a variable, a cursor, a type and an exception.

Syntax

```
<PSM block> ::=
    [ DECLARE <declare item>... ] BEGIN <SQL procedure statement list> END
    ;
<declare item> ::=
    <variable declaration>
    | <explicit cursor declaration>
    | <explicit cursor definition>
    | <cursor variable declaration>
    | <type definition>
    | <exception declaration>
    | <exception init pragma>
    | <procedure declaration>
    | <procedure definition>
    | <function declaration>
    | <function definition>
<executable statement list> ::=
    [ <label list> ] { <SQL procedure statement> ; }...
<label list> ::=
    { << identifier >>  }...
<SQL procedure statement>
      <PSM Static SQL>
    | <PSM Dynamic SQL>
    | <PSM Control Statement>
```

Invocation and Access Rules

It can be used only within PROCEDURE, FUNCTION or an anonymous block.

Syntax Rules and Parameters

- Variable declaration
  - It declares scalar/ record/ array type variables which are to be used in a block.
- Explicit cursor declaration
  - It declares cursors which are to to be used in a block.
- Explicit cursor definition
  - It defines cursors which are to be used in a block.
- Cursor variable declaration
  - It declares a cursor variable to be used in a block.
- Type definition
  - It defines user-defined types which are to be used when declaring variables in a block.
- Exception declaration
  - It defines exceptions to be used in a block.
- Exception init pragma
  - It sets the error code which is to be processed by a user-defined exception.
- Procedure declaration
  - It declares procedures to be used in a block.
- Procedure definition
  - It defines procedures to be used in a block.
- Function declaration
  - It declares functions to be used in a block.
- Function definition
  - It defines functions to be used in a block.
- Static SQL
  - It indicates Data Manipulation Language (DML) and Data Control Language (DCL) which can be performed in PSM.
- Dynamic SQL
  - It indicates statements related to dynamic query processing supported by GOLDILOCKS PSM.
- PSM Control Statement
  - It indicates various flow control statements supported by GOLDILOCKS PSM.

Description

<psm block> is a basic component of PSM.
A block can have a declaration part and a exception handling part.
A block can be duplicated, and the duplicated block has a new subordinate variable scope. A superordinate block can not refer to a variable in a subordinate block.

Examples

```
gSQL>
<<MAIN>>
DECLARE
  V1 INTEGER := 1;
BEGIN
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
  <<SUB1>>
  DECLARE
    V1 VARCHAR(10) := 'ABC';
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    DBMS_OUTPUT.PUT_LINE( 'SUB1.V1 = ' || SUB1.V1 );
    DBMS_OUTPUT.PUT_LINE( 'MAIN.V1 = ' || MAIN.V1 );
 END;
END;
/
V1 = 1
V1 = ABC
SUB1.V1 = ABC
MAIN.V1 = 1
Anonymous PL block executed.
```

Compatibility

<compound statement> of the SQL standard defines ATOMIC /NOT ATOMIC statement which specifies a new savepoint, but GOLDILOCKS does not support it.

Table 28-3 SQL standard compatibility

Feature ID	Description	Remarks
P002	Computational completeness	It does not support ATOMIC statement.

For More Information

Refer to **Overview of PSM**.

28.4 CASE Statement

Function

It performs a statement list satisfying conditions which returns TRUE among given conditions.

Syntax

```
<case statement> ::=
    <simple case statement>
    | <searched case statement>
    ;
<simple case statement> ::=
    CASE <case operand> <simple case statement when clause>...
    [ <case statement else clase> ]
    END CASE
<searched case statement> ::=
    CASE <searched case statement when clause>...
    [ <case statement else clase> ]
    END CASE
<simple case statement when clause> ::=
    WHEN <when operand>
        THEN <executable statement list>
<searched case statement when clause> ::=
    WHEN <search condition>
        THEN <executable statement list>
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Case operand
  - They are all expressions which can be evaluated with a scalar value.
  - However, it can not include a subquery statement.
- When operand
  - It is an expression to compare whether it is as same as <case operand>.
  - However, it can not include a subquery statement.
- Search condition
  - It is a conditional expression to be performed when the evaluation result of <searched case statement> is TRUE.
  - However, it can not include a subquery statement.
- Executable statement list
  - It is a list of all statements which can be performed within PSM.

Description

It performs statements in WHEN clause returning TRUE by evaluating conditions like as IF statement.
It evaluates conditional expressions in order, and stops evaluating after finding the TRUE conditional clause.
If the case satisfying the condition does not exist and ELSE clause is not specified, then an error occurs.

Examples

Using a Simple CASE

```
gSQL> DECLARE
V1 integer := 0;
BEGIN
  SELECT 2 INTO V1 FROM DUAL;
  CASE V1 WHEN 0 THEN DBMS_OUTPUT.PUT_LINE ('Result = 0');
          WHEN 1 THEN DBMS_OUTPUT.PUT_LINE ('Result = 1');
          WHEN 2 THEN DBMS_OUTPUT.PUT_LINE ('Result = 2');
          ELSE DBMS_OUTPUT.PUT_LINE ('Result = OTHER');
  END CASE;
END;
/
```

```
Result = 2
Anonymous PL block executed.
```

Using a Searched CASE

```
gSQL> DECLARE
V1 integer := 0;
BEGIN
  SELECT 2 INTO V1 FROM DUAL;
  CASE WHEN V1 = 0 THEN DBMS_OUTPUT.PUT_LINE ('Result = 0');
       WHEN V1 = 1 THEN DBMS_OUTPUT.PUT_LINE ('Result = 1');
       WHEN V1 = 2 THEN DBMS_OUTPUT.PUT_LINE ('Result = 2');
       ELSE DBMS_OUTPUT.PUT_LINE ('Result = OTHER');
  END CASE;
END;
/
Result = 2
Anonymous PL block executed.
```

Compatibility

CASE statement of the SQL standard defines the comparison of row type (list type) values, but GOLDILOCKS does not support it.
CASE statement of the SQL standard can define multiple conditions in a list in <when operand> by delimiting them with ',', but GODILOCKS does not support it.

Table 28-4 SQL stantard compatibility

Feature ID	Description	Remarks
P002	Computational completeness	It does not support P004, P008.
P004	Extended CASE statement	-
P008	Comma-separated predicates in simple CASE statement	-

28.5 CLOSE Statement

Function

It closes an open cursor.

Syntax

```
<close statement> ::=
    CLOSE cursor_name
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- cursor_name
  - It is the name of a cursor to be closed.

Description

It closes an open cursor.
A closed cursor can be opened again by using an open statement.

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  CURSOR C1 IS SELECT I1 FROM T1;
  V1 T1%ROWTYPE;
BEGIN
  OPEN C1;
  FETCH C1 INTO V1;
  CLOSE C1;
END;
/
Anonymous PL block executed.
```

Compatibility

The SQL standard does not define it.

For More Information

Refer to the followings.

- **FETCH Statement**
- **OPEN Statement**

28.6 Collection Method Invocation

Function

It provides a method which can explores a collection type variable.

Syntax

```
<collection method> ::=
         variable_name . <method>
    ;
<method> ::=
        first ()
      ¦ last  ()
      ¦ prior ( expression )
      ¦ next  ( expression )
      ¦ count ()
      ¦ exists ( expression )
      ¦ delete ( expression )
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- It can be used only in a variable declared as a collection type.
- FIRST, LAST, COUNT can not have a parameter.
- A parameter should be specified when an object should be specified such as PRIOR, NEXT, EXISTS, D ELETE.
- DELETE is operated as same as PSM statement, and it can not return a different variable as a result. (I t can not be used in an expression.)

Description

Refer to the following table.

Table 28-5 Function

Name	Function	Return value	Whether to require an argument
FIRST	It returns the smallest key.	A key type specified in INDEX OF	X
LAST	It returns the biggest key.	A key type specified in INDEX OF	X
PRIOR	It returns a key smaller than the input key.	A key type specified in INDEX OF	O
NEXT	It returns a key bigger than the input key.	A key type specified in INDEX OF	O
COUNT	It returns the stored count.	INTEGER	X
DELETE	It deletes a value corresponding to a key.	N/A	O
EXISTS	It returns whether a key exists or not.	BOOLEAN	O

Examples

```
DECLARE
TYPE rec IS TABLE OF VARCHAR(20) INDEX BY VARCHAR(20);
v1 rec;
v2 VARCHAR(20);
BEGIN
  DBMS_OUTPUT.PUT_LINE( '-----------------------------------');
  DBMS_OUTPUT.PUT_LINE( 'first = ' || v1.first);
  DBMS_OUTPUT.PUT_LINE( 'last = '  || v1.last);
  DBMS_OUTPUT.PUT_LINE( 'prior = ' || v1.prior('aaa'));
  DBMS_OUTPUT.PUT_LINE( 'next = '  || v1.next('aaa'));
  DBMS_OUTPUT.PUT_LINE( 'count = ' || v1.count());
  FOR I IN 1 .. 9
  LOOP
      v1('a' || to_char(i)) := 'a' || to_char(i);
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( '-----------------------------------');
  DBMS_OUTPUT.PUT_LINE( 'first = ' || v1.first);
  DBMS_OUTPUT.PUT_LINE( 'last = '  || v1.last);
  DBMS_OUTPUT.PUT_LINE( 'count = ' || v1.count());
  DBMS_OUTPUT.PUT_LINE( '-----------------------------------');
```

```
  DBMS_OUTPUT.PUT_LINE( 'Print all from first to last');
  v2 := v1.first;
  WHILE v2 IS NOT NULL
  LOOP
      DBMS_OUTPUT.PUT_LINE('Key= ' || v2 || ',Value=' || v1(v2));
      v2 := v1.next(v2);
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( '-----------------------------------');
  DBMS_OUTPUT.PUT_LINE( 'Print all from last to first');
  v2 := v1.last;
  WHILE v2 IS NOT NULL
  LOOP
      DBMS_OUTPUT.PUT_LINE('Key= ' || v2 || ',Value=' || v1(v2));
      v2 := v1.prior(v2);
  END LOOP;
  v1.delete(v1.first());
  DBMS_OUTPUT.PUT_LINE('count = ' || v1.count() );
  DBMS_OUTPUT.PUT_LINE('first = ' || v1.first() );
END;
/
-----------------------------------
first =
last =
prior =
next =
count = 0
-----------------------------------
first = a1
last = a9
count = 9
-----------------------------------
Print all from first to last
Key= a1,Value=a1
Key= a2,Value=a2
Key= a3,Value=a3
Key= a4,Value=a4
Key= a5,Value=a5
Key= a6,Value=a6
Key= a7,Value=a7
Key= a8,Value=a8
Key= a9,Value=a9
```

```
-----------------------------------
Print all from last to first
Key= a9,Value=a9
Key= a8,Value=a8
Key= a7,Value=a7
Key= a6,Value=a6
Key= a5,Value=a5
Key= a4,Value=a4
Key= a3,Value=a3
Key= a2,Value=a2
Key= a1,Value=a1
count = 8
first = a2
Anonymous PL block executed.
```

For More Information

Refer to **COLLECTION Variable Declaration**.

28.7 COLLECTION Variable Declaration

Function

It declares a collection variable.

Syntax

```
<declare record variable> ::=
    variable_name <collectionType>
    ;

<Collection Type Definition> ::=
    TYPE <Type-Name> IS TABLE OF <Element-Type> INDEX BY <Index-Type>
    ;
<Element-Type> ::=
      Built-in SQL Data Type
    ¦ User-Defined Type
    ¦ %TYPE
    ¦ %ROWTYPE
<Index-Type> ::=
      INTEGER
    ¦ LONG
    ¦ CHAR(n)
    ¦ VARCHAR(n)
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

- Type-name
  - It specifies the name of a collection type to be used by a user.
- Element-type
  - It specifies the type of an element to be stored in a collection variable.
- Index-type
  - It specifies the data type of a key stored in a collection variable.

Description

It declares a collection type.

Examples

```
gSQL> DECLARE
TYPE rec IS TABLE OF VARCHAR(20) INDEX BY VARCHAR(20);
v1 rec;
v2 VARCHAR(20);
BEGIN
  DBMS_OUTPUT.PUT_LINE( 'first = ' || v1.first);
  DBMS_OUTPUT.PUT_LINE( 'last = '  || v1.last);
  DBMS_OUTPUT.PUT_LINE( 'prior = ' || v1.prior('aaa'));
  DBMS_OUTPUT.PUT_LINE( 'next = '  || v1.next('aaa'));
  DBMS_OUTPUT.PUT_LINE( 'count = ' || v1.count());
  FOR I IN 1 .. 10
  LOOP
      v1('a' || i) := 'a' || i;
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( 'first = ' || v1.first);
  DBMS_OUTPUT.PUT_LINE( 'last = '  || v1.last);
  DBMS_OUTPUT.PUT_LINE( 'count = ' || v1.count());
  DBMS_OUTPUT.PUT_LINE( 'Print all from first to last');
  v2 := v1.first;
  WHILE v2 IS NOT NULL
  LOOP
      DBMS_OUTPUT.PUT_LINE('Key= ' || v2 || ',Value=' || v1(v2));
```

```
      v2 := v1.next(v2);
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( 'Print all from last to first');
  v2 := v1.last;
  WHILE v2 IS NOT NULL
  LOOP
      DBMS_OUTPUT.PUT_LINE('Key= ' || v2 || ',Value=' || v1(v2));
      v2 := v1.prior(v2);
  END LOOP;
END;
/
first =
last =
prior =
next =
count = 0
first = a1
last = a9
count = 10
Print all from first to last
Key= a1,Value=a1
Key= a10,Value=a10
Key= a2,Value=a2
Key= a3,Value=a3
Key= a4,Value=a4
Key= a5,Value=a5
Key= a6,Value=a6
Key= a7,Value=a7
Key= a8,Value=a8
Key= a9,Value=a9
Print all from last to first
Key= a9,Value=a9
Key= a8,Value=a8
Key= a7,Value=a7
Key= a6,Value=a6
Key= a5,Value=a5
Key= a4,Value=a4
Key= a3,Value=a3
Key= a2,Value=a2
Key= a10,Value=a10
Key= a1,Value=a1
```

```
Anonymous PL block executed.
```

Compatibility

The SQL standard does not define it.

For More Information

Refer to **Collection Method Invocation**.

28.8 CONTINUE Statement

Function

It stops currently performing statement list, and performs the next iteration of a superordinate loop statement.

Syntax

```
<continue statement> ::=
    CONTINUE [ label_name ] [ WHEN condition ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

A statement with a target label should be one of the following loop family statements.

- basic loop statement
- for loop statement
- while statement
- forall statement

Syntax Rules and Parameters

- Label name
  - It can have an identifier chain form.
- Condition
  - If it is specified, it returns to a loop statement only when the condition is TRUE.

Description

It stops currently performing statement list, and returns to the superordinate loop statement.

If a label is specified, it returns to the superordinate loop statement of the label name.
If a label is not specified, it returns to the nearest superordinate loop statement.
If multiple superordinate loop statements with the same names exist, then the nearest statement is select ed.
It can return to a loop statement (exist in a nested scope) which is visible in the current location.

If a condition is specified, then it returns only when the condition is TRUE.
If a condition is not specified, then it definitely returns.

Examples

```
DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  WHILE V1 <= 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    V1 := V1 + 1;
    IF V1 <= 2 THEN
      DBMS_OUTPUT.PUT_LINE( 'CONTINUE' );
      CONTINUE;
    ELSE
      EXIT;
    END IF;
    DBMS_OUTPUT.PUT_LINE( 'END-OF-WHILE' );
  END LOOP AAA;
END;
/
V1 = 1
CONTINUE
V1 = 2
Anonymous PL block executed.
```

Compatibility

〈continue statement〉 statement is similar to 〈iterate statement〉 of the SQL standard.
However, 〈iterate statement〉 statement does not provide WHEN condition feature.

For More Information

Refer to the followings.

- **EXIT Statement**
- **GOTO Statement**

28.9 Cursor FOR LOOP Statement

Function

It performs loops as many times as the number of rows in the result created by a query or a cursor declare d by a user in PSM.

Syntax

```
<Cursor For Loop statement> ::=
       FOR <Variable_Name> IN <Cursor>
       LOOP
            { <SQL procedure statement> ; }...
       END LOOP [ Label_Name ]
       ;
<Cursor> ::=
       < ( Implicit_Cursor_Query ) >
     ¦ < Explict_Cursor_Name > [ ( [ <actual param> ] ) ]

<Implicit_Cursor_Query> ::=
       SELECT statement
     ¦ SELECT_FOR_UPDATE statement
     ¦ INSERT_RETURNING_QUERY statement
     ¦ UPDATE_RETURNING_QUERY statement
     ¦ DELETE_RETURNING_QUERY statement
<actual param> ::=
      ( expression [ , expression ] .. )
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body of PSM.

Syntax Rules and Parameters

The variable declared within For~Loop is valid only within that loop scope. (The variable can not be refere nced from outside of that Cursor For Loop Block Scope)

When Using Cursor Name

A cursor should already have been declared before performing LOOP by using a cursor name.
For more information about an actual param, refer to **OPEN Statement**.

When Using Cursor Query

It can perform only the query which can be internally processed by using an implicit cursor in GOLDILOCK S such as a select and a returning query.

Description

It performs PSM statements within a loop by turning around loops as many time as the number of results created by a cursor.
If a cursor becomes invalid (e.g. closed) during LOOP, it does not perform the loop and it processes itas a n error.
If an explicit cursor name is specified and the corresponding cursor is already opened, then it is processed as an error.

The variable to which a result of the cursor specified in FOR LOOP clause is returned is automatically creat ed. (It is created as a row type of the result set to be returned by an execution result of a cursor.)
However, if an alias for a select target expression which is not a column of a specific table among results of a user cursor query is not specified, then an error may occur.

Examples

Using Explicit Cursor

```
DECLARE
CURSOR c1 IS SELECT * FROM T1;
BEGIN
```

```
  FOR rec IN C1
  LOOP
    DBMS_OUTPUT.PUT_LINE( 'RowCount=' || c1%rowcount || ',C1=' || rec.c1 || ', C2=' ||
rec.c2);
  END LOOP;
END;
/
RowCount=1,C1=1, C2=1
RowCount=2,C1=2, C2=2
RowCount=3,C1=3, C2=3
RowCount=4,C1=4, C2=4
RowCount=5,C1=5, C2=5
RowCount=6,C1=6, C2=6
RowCount=7,C1=7, C2=7
RowCount=8,C1=8, C2=8
RowCount=9,C1=9, C2=9
RowCount=10,C1=10, C2=10
Anonymous PL block executed.
```

Using Cursor Query

```
BEGIN
  FOR rec IN (select * from t1)
  LOOP
      DBMS_OUTPUT.PUT_LINE( 'RowCount=' || sql%rowcount || ',C1=' || rec.c1 || ', C2=' ||
rec.c2);
  END LOOP;
END;
/
C1=1, C2=1
C1=2, C2=2
C1=3, C2=3
C1=4, C2=4
C1=5, C2=5
C1=6, C2=6
C1=7, C2=7
C1=8, C2=8
C1=9, C2=9
C1=10, C2=10
Anonymous PL block executed.
```

For More Information

Refer to the followings.

- **Explicit Cursor Declaration and Definition**
- **GOTO Statement**
- **EXIT Statement**

28.10 Cursor Variable Declaration

Function

It declares a cursor variable in DECLARE section of PSM.

Syntax

```
<cursor variable declaration> ::=
    variable_name <type>
    ;
<cursor type definition> ::=
      TYPE <type_name> IS REF CURSOR [ RETURN <return type> ]
<return type> ::=
      <table_name ¦ view_name ¦ cursor_name ¦ cursor_variable > % ROWTYPE
    ¦ <record_variable_name> % TYPE
    ¦ <record_type_name>
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of PSM.

Syntax Rules and Parameters

Specifying the initial value of a cursor variable or assigning a cursor variable is allowed only between curs or variables.

Description

A cursor variable is operated like as a pointer indicating a cursor which is not dependent on a specific curs or.

Examples

```
DECLARE
TYPE rec IS RECORD (V1 VARCHAR(20), V2 VARCHAR(20));
TYPE cv IS REF CURSOR RETURN rec;
BEGIN
    NULL;
END;
/
Anonymous PL block executed.
```

For More Information

Refer to the followings.

- **OPEN Statement**
- **FETCH Statement**
- **CLOSE Statement**

28.11 DELETE Statement Extension

Function

It can store the result in RETURNING INTO clause by using a record type variable of PSM.

Syntax

```
<PSM delete statement extension: searched> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        [ <returning into clause> ]
    ;
<delete statement: positioned> ::=
    DELETE [ FROM ] table_name [ [ AS ] alias_name ]
        WHERE CURRENT OF cursor_name
    ;
<result offset clause> ::=
    OFFSET skip_count [ ROW | ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    | <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST | NEXT ] [ row_count ] [ ROW ONLY | ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count | offset_row_count, fetch_row_count | ALL }
<returning into clause> ::=
    { RETURN | RETURNING } { * | { <value expression> [ [AS] alias_name] } [, ...] } INTO
variable_name [, ...]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of PSM.

Syntax Rules and Parameters

If a variable to be returned through RETURNING INTO is a record type, then it can not be used by mixing t ogether with a different variable type.

Description

It can store the result in RETURNING INTO clause by using a record type variable of PSM.

Examples

```
gSQL> CREATE TABLE T1( C1 VARCHAR(20), C2 VARCHAR(20));
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO T1 VALUES ('AAA', 'BBB'), ('BBB', 'CCC'), ('CCC', 'DDD');
3 rows created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  rec t1%ROWTYPE;
BEGIN
  DELETE FROM T1 WHERE C1 = 'AAA' RETURNING * INTO rec;
  DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT=' || SQL%ROWCOUNT);
  DBMS_OUTPUT.PUT_LINE('rec.c1=' || rec.c1 || ', rec.c2=' || rec.c2);
END;
/
SQL%ROWCOUNT=1
rec.c1=AAA, rec.c2=BBB
Anonymous PL block executed.
```

For More Information

Refer to **Deleting Data**.

28.12 EXCEPTION_INIT Pragma

Function

It sets the error code which is to be processed by a user-defined exception.

Syntax

```
< PRAGMA EXCEPTION_INIT > ::=
     PRAGMA EXCEPTION_INIT ( <Exception-Name>, <Internal-ErrorCode> )
     ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of PSM.

Syntax Rules and Parameters

A predefined exception can not be used in an exception name which is used as an argument. (A predefined exception name can not be declared.)
An exception name which is used as an argument in the same PL block DECLARE clause should be declared in advance. (Declaration of an exception name in different BLOCK can not be referenced.)
<Internal-ErrorCode> should be an internal error code existing within DB SYSTEM. (SUCCESS code can not be set.

Description

A user explicitly declares an exception name corresponding to an error code of DB SYSTEM.

Examples

```
gSQL> DECLARE
user_exception_1 EXCEPTION;
PRAGMA EXCEPTION_INIT( user_exception_1, -17001);
BEGIN
  RAISE USER_EXCEPTION_1;
  EXCEPTION WHEN user_exception_1 THEN DBMS_OUTPUT.PUT_LINE('User Exception_1');
END;
/
User Exception_1
Anonymous PL block executed.
```

Compatibility

Error codes are different each other according to a vendor, so it is not compatible each other.

For More Information

Refer to the followings.

- **Exception Declaration**
- **Exception Handler**

28.13 Exception Declaration

Function

It declares an exception name within a PL block.

Syntax

```
< Exception-Declaration Statement > ::=
     <Exception-Name>  EXCEPTION
     ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of PSM.

Syntax Rules and Parameters

It can not declare a predefined exception name.
Duplicated declarations are not allowed in DECLARE clause of the same SCOPE.

Description

A user explicitly declares an exception.

Examples

```
DECLARE
user_exception_1 EXCEPTION;
```

```
user_exception_2 EXCEPTION;
user_exception_3 EXCEPTION;
BEGIN
  RAISE USER_EXCEPTION_2;
  EXCEPTION WHEN user_exception_1 THEN DBMS_OUTPUT.PUT_LINE('User Exception_1');
            WHEN user_exception_2 THEN DBMS_OUTPUT.PUT_LINE('User Exception_2');
            WHEN user_exception_3 THEN DBMS_OUTPUT.PUT_LINE('User Exception_3');
END;
/
User Exception_2
Anonymous PL block executed.
```

Compatibility

An exception declaration of the standard SQL is as follows, but GOLDILOCKS supports the syntax as abov e.

```
<condition declaration> ::=
DECLARE <condition name> CONDITION [ FOR <sqlstate value> ]
```

For More Information

Refer to the followings.

- **Exception Declaration**
- **EXCEPTION_INIT Pragma**

28.14 Exception Handler

Function

It performs an operation defined for an exception which is explicitly occurred by a user or an operation de fined for an implicit error due to a DB SYSTEM error occurred during performing PL/ SQL.

Syntax

```
< Exception Handler Statement > ::=
       EXCEPTION < Exception_When_List >
       ;
< Exception_When_List > ::=
       WHEN < Exception_Name_List > THEN <excutable statement list>  [ WHEN OTHERS THEN
<excutable statement list> ]
< Exception_Name_List > ::=
        <Exception_Name> [ { OR <Exception_Name> }... ]
```

Invocation and Access Rules

It can be used within a PL block.

Syntax Rules and Parameters

OTHERS (predefined exception) can not be specified together with another exception name by using OR. Duplicated specifying of OTHERS (predefined exception) is not allowed in an exception handler, and OTH ERS should be specified at the last.

Description

Exception Types

Type	Definer	Has error	Has name	Raise implicitly	Raise explicitly
Predefined	System	Yes	Yes	Yes	Optionally
User-defined	User	If user assign	If user assign	No	Yes

A predefined exception has an exception name and an error code which are specified in advance in GOL DILOCKS.
Other exceptions are classified into an internally defined exception and a user-defined exception. An inter nally defined exception is that a user sets the internal error code name of GOLDILOCKS differently from a predefined exception name, and a user-defined exception is that only the exception name is declared wit hout specifying a separate error code.

Predefined Exception

Table 28-6 Predefined exception type

Name	Description
CASE_NOT_FOUND	It can not satisfy all conditions of CASE WHEN, or ELSE clause is not defined.
DUP_VAL_ON_INDEX	INDEX duplicated error occurred.
INVALID_CURSOR	A cursor status is incorrect.
INVALID_NUMBER	It can not be converted to a number.
NO_DATA_FOUND	SELECT statement returns zero data.
ROWTYPE_MISMATCH	Field types of two RowType variables are different each other.
TOO_MANY_ROWS	It returns two or more rows.
VALUE_ERROR	It is an error such as type mismatch and invalid casting.
ZERO_DIVIDE	It tries dividing by 0.
OTHERS	It includes errors which are not defined in a predefined.

Examples

```
gSQL> DECLARE
V1 INTEGER := 0;
BEGIN
   DBMS_OUTPUT.PUT_LINE('Step1');
   V1 := 1 / 0;
```

```
   DBMS_OUTPUT.PUT_LINE('Step2');
   EXCEPTION WHEN OTHERS THEN DBMS_OUTPUT.PUT_LINE( 'Exception V1=' || V1);
END;
/
Step1
Exception V1=0
Anonymous PL block executed.
```

Compatibility

It does not support the SQL standard grammar.

For More Information

Refer to the followings.

- **EXCEPTION_INIT Pragma**
- **Exception Declaration**

28.15 EXECUTE IMMEDIATE Statement

Function

It executes a dynamic SQL within PSM.

Syntax

```
<EXECUTE IMMEDIATE statement> ::=
    EXECUTE IMMEDIATE <dynamic-sql> [ <binding-parameters> ]
    ;
<dynamic-sql> ::=
      single_quote_string
    ¦ psm_variable
<binding-parameters> ::=
      <into-clause>
    ¦ <using-clause>
    ¦ <returning-into-clause>
    ¦ <into-clause> <using-clause>
    ¦ <using-clause> <returning-into-clause>
<into-clause> ::=
    INTO psm_variable [ {, psm_variable} ... ]
<using-clause> ::=
    USING [ <Bind-Type> ] <expression> [ {, [ <Bind-Type> ] <expression>} ... ]
<Bind-Type> ::=
     IN
   ¦ OUT
   ¦ IN OUT
<returing-into-clause> ::=
    RETURNING INTO psm_variable [ {, psm_variable} ... ]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

Dynamic SQL

- single_quote_string: It is an SQL statement enclosed with a single quote ('). (double_quote_string is recognized as a variable in PSM.)
- Psm-variable: It is an SQL statement stored in a variable which is used in PSM.

The following is an example of expressing a data by using quote(s) in an SQL statement to be performed.

```
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES ( ''Tom'' ) '; -- Tom
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES ( ''Tom''''House'') '; -- Tom'House
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES ( ''''''Tom'') ';   -- 'Tom
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES ( CHR(39) || ''TOM'' ) '; -- 'Tom
```

A marker (? or :V1) is used in a location where a user input a variable in a dynamic SQL.
An SQL statement specified in a dynamic SQL should be valid.

INTO Clause

The result of performing a dynamic SQL exists, and it is not bound through a marker, but the result of processing an SQL statement is returned. (It is internally a form of an implicit cursor fetch.)
The syntax is as follows.

```
EXECUTE IMMEDIATE 'SELECT ... FROM .. WHERE ...';
EXECUTE IMMEDIATE 'INSERT ... RETURNING ...';
EXECUTE IMMEDIATE 'UPDATE ... RETURNING ...';
EXECUTE IMMEDIATE 'DELETE ... RETURNING ...';
```

USING Clause

It lists a variable or an expression in USING clause (IN can be omitted.) as many as the number of input variables used in a dynamic SQL.
If the result of performing a dynamic SQL exists, then it lists variables as many as the number of result columns in USING OUT clause. (when returning the results to INTO clause)
The result can be returned in the following syntax by using USING OUT.

```
EXECUTE IMMEDIATE 'SELECT x, y, z INTO :v1, :v2, :v3 ...';
EXECUTE IMMEDIATE 'INSERT INTO ...  RETURNING C1, C2 INTO :V1, :V2';
EXECUTE IMMEDIATE 'UPDATE T1 SET .. RETURNING C1, C2 INTO :V1, :V2';
```

```
EXECUTE IMMEDIATE 'DELETE FROM ...  RETURNING C1, C2 INTO :V1, :V2';
```

RETURNING Clause

If INSERT/UPDATE/DELETE RETURNING INTO statement is used as a dynamic SQL, the result is returned b y binding a variable specified in USING clause in OUT-mode in GOLDILOCKS.
The same result can be returned by using RETURNING-INTO clause for the compatibility with other DBMS.

Other Rules

- DDL/ DCL can not use any BIND clause. (INTO, USING, RETURNING clause)
- It is used as OUT in INTO clause and RETURNING INTO clause, so a separate bind type can not be spec ified nor it be simultaneously used together.
- IN BIND type can use only a scalar type variable.
- OUT BIND type can use a record type variable, but a scalar type or a record type can not be listed bein g mixed together.
- A result can not be returned being divided through INTO clause and USING OUT or RETURNING INTO.

Description

- If a dynamic SQL returns the result as a variable specified in INTO clause
  - A query returning two or more results causes TOO_MANY_ROWS exception.
  - If the result is zero, it causes NO_DATA_FOUND exception.
- If a dynamic SQL returns the result as a variable specified in USING or RETURNING clause
  - If two or more variables which are not ARRAY are returned, it causes TOO_MANY_ROWS excepti on.
  - If the result is zero, an error does not occur.
- The followings are results of which DDL/ DCL performs implicit cursor SQL%Attribute variables.
  - SQL%ROWCOUNT = 0
  - SQL%ISOPEN = FALSE
  - SQL%FOUND = FALSE
  - SQL%NOTFOUND = TRUE
- Other dynamic SQLs store SQL%Attribute values corresponding to the processing results of that SQL statement.

Examples

```
gSQL> DECLARE
V1 INTEGER;
V2 VARCHAR(20);
BEGIN
    V1 := 1;
    V2 := 'abcdef';
    DBMS_OUTPUT.PUT_LINE('#INSERT');
    EXECUTE IMMEDIATE 'insert into t1 values (:a1, :a2)' USING v1, v2;
    EXECUTE IMMEDIATE 'select c1, c2 from t1 where c1 = 1' INTO v1, v2;
    DBMS_OUTPUT.PUT_LINE('C1='|| v1 || ', C2=' || v2);
    V1 := 1;
    V2 := 'xyz';
    DBMS_OUTPUT.PUT_LINE('#UPDATE');
    EXECUTE IMMEDIATE 'update t1 set c2 = :a1 where c1 = :a2' USING V2, V1;
    V1 := 1;
    V2 := '';
    DBMS_OUTPUT.PUT_LINE('#SELECT');
    EXECUTE IMMEDIATE 'select c1, c2 from t1 where c1 = :a1' INTO v1, v2 USING v1;
    DBMS_OUTPUT.PUT_LINE('C1='|| v1 || ', C2=' || v2);
    V1 := 1;
    V2 := '';
    DBMS_OUTPUT.PUT_LINE('#DELETE');
    EXECUTE IMMEDIATE 'delete from t1 where c1 = :a1' USING v1;
END;
/
#INSERT
C1=1, C2=abcdef
#UPDATE
#SELECT
C1=1, C2=xyz
#DELETE
Anonymous PL block executed.
```

28.16 EXIT Statement

Function

It exits a loop statement which has the given label among superordinate loop statements, then performs the next statement.

Syntax

```
<exit statement> ::=
    EXIT [ label_name ] [ WHEN condition ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Label name
  - It is a label name of a loop statement to be exited.
  - It can be in an identifier chain form.
- Condition
  - If a condition is specified, then it can exit a loop statement only when that condition is TRUE.

Description

- It stops currently performing statement list and exits a superordinate loop statement.
- A statement with a target label should be one of the following loop family statements.
  - basic loop statement
  - for loop statement

    - while statement
    - forall statement
- If a label is specified, then it exits a superordinate loop statement which has that label name.
- If a label is not specified, then it exits the nearest superordinate loop statement.
- If multiple superordinate loop statements with the same label names exist, then the nearest statemen t is selected.
- It can exit only a loop statement (exist in a nested scope) which is visible in the current location.

- If a condition is specified, then it exits only when the condition is TRUE.
- If a condition is not specified, then it definitely exits.

Examples

```
gSQL> DECLARE
  V1 INTEGER := 1;
BEGIN
  <<AAA>>
  WHILE V1 <= 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    EXIT;
    V1 := V1 + 1;
  END LOOP AAA;
END;
/
V1 = 1
Anonymous PL block executed.
```

Compatibility

It does not exist in the SQL standard.

28.17 Explicit Cursor Attribute

Function

It returns the status value of a cursor defined in PSM.

Syntax

```
〈Explicit cursor attribute〉 ::=
    cursor_name '%' { ISOPEN ¦ FOUND ¦ NOTFOUND ¦ ROWCOUNT }
```

Invocation and Access Rules

It can be used only in the body section of PSM.

Syntax Rules and Parameters

- Cursor_name
  - It is the name of a cursor whose status value is to be obtained.

Description

- It returns the status value of a given cursor.
  - ISOPEN: It is whether the current cursor is OPEN.
  - FOUND: It is whether the data is returned by the recent fetch.
  - NOTFOUND: It is an opposite of FOUND.
  - ROWCOUNT: It is the number of fetched records after the cursor is recently OPEN.
- The following values are returned according to the cursor status.

Table 28-7 Results according to the performing moment

Attribute name	Before OPEN	After OPEN	After FETCH	After CLOSE
ISOPEN	FALSE	TRUE	TRUE	FALSE

Attribute name	Before OPEN	After OPEN	After FETCH	After CLOSE
FOUND	NULL	NULL	TRUE/FALSE	NULL
NOTFOUND	NULL	NULL	TRUE/FALSE	NULL
ROWCOUNT	NULL	NULL	N (the number)	NULL

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  CURSOR C1 IS SELECT * FROM T1;
  V1 INTEGER := 0;
  V2 INTEGER := 0;
  TOTAL INTEGER := 0;
BEGIN
  FOR I IN 1..100 LOOP
    INSERT INTO T1 VALUES( I );
  END LOOP;
  COMMIT;
  IF NOT C1%ISOPEN THEN
    OPEN C1;
  END IF;
  LOOP
    FETCH C1 INTO V1;
    EXIT WHEN C1%NOTFOUND;
    TOTAL := TOTAL + V1;
    V2 := V1;
  END LOOP;
  DBMS_OUTPUT.PUT_LINE( 'COUNT = ' || C1%ROWCOUNT || ' TOTAL = ' || TOTAL );
  CLOSE C1;
END;
/
COUNT = 100 TOTAL = 5050
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.18 Explicit Cursor Declaration and Definition

Function

It declares a cursor in DECLARE section of PSM.

Syntax

```
<cursor declaration> ::=
    CURSOR cursor_name [ <cursor param spec> ] RETURN rowtype
    ;
<cursor param spec> ::=
      ( <cursor param decl> [ , <cursor param decl> ] .. )
<cursor param decl> ::=
      param_name [ IN ] datatype [ { ':=' ¦ DEFAULT } expression ]
<cursor definition> ::=
    CURSOR cursor_name [ <cursor param spec> ] [ RETURN rowtype ]
    IS <cursor query>
    ;
<cursor query> ::==
    select statement
    ¦ select for update_statement
    ¦ insert returning query statement
    ¦ update returning query statement
    ¦ delete returning query statement
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

Cursor Name

It is a cursor name to be declared.
The length of a cursor name should be shorter than 128 bytes.
It should be a unique name in that scope.

RowType

It defines a record type of a cursor.
The number of select targets specified when defining a cursor should be same, and the data type should be compatible.
If a rowtype is not specified, then a rowtype which is appropriate to a SELECT target of select_statement specified when defining a cursor is automatically specified.

Param Name

It is a name which distinguishes parameters within a specific cursor.
It should be a unique name in that cursor.
If the name is as same as a name of another variable which can be referenced within a scope, then a para meter of that cursor is preferentially referenced.

DataType

It specifies the data type of the corresponding parameter.
It can use all built-in types provided by GOLDILOCKS and types defined within PSM.
However, a statement which restricts a scope (precision/ scale) can not be specified in a built-in type, but it is internally specified as the maximum scope of the corresponding data type.

Cursor Query

- The cursor can execute the following queries.
  - Select statement
  - Select For Update statement
  - Insert Returning statement
  - Update Returning statement
  - Delete Returning statement

- SELECT INTO statement is not available.

Description

- <explicit cursor declaration> statement declares or defines a cursor.
  - Cursor declaration: It declares only a name and format of a cursor.
  - Cursor definition: It detailedly defines a name, format of a cursor and SELECT statement to be pe rformed.
- An explicit cursor is used by defining it after declaration. or it can be used by defining it without a dec laration.
- When using an explicit cursor by defining it after declaration, then the cursor name, the parameter sp ecification and the record type definition should exactly match.
- A declaration and a definition of an explicit cursor should exist in the same block.
- An explicit cursor is created when the cursor enters the defined block, and it is automatically CLOSEd and deleted when it exits the block.
- 'MAXIMUM_NAMED_CURSOR_COUNT' property restricts the maximum number of explicit cursors w hich can be created in a specific time.
- The following variables can be used in <cursor query> statement performed by an explicit cursor.
  - Parameter of the cursor
  - All PSM variables which can be referenced in a scope at the time of declaration. (It is not a scope of the time of open.)
  - External bind parameter (in case of an anonymous PL block)
- An explicit cursor performing <cursor query> specified by a user has the following properties.
  - IN_SENSITIVE (Changes by another transaction do not affect it.)
  - NON_SCROLLABLE (It can not fetch the previous record again.)
  - READ_ONLY (Only a read operation is available.)
  - WITH-HOLD (A cursor is not automatically closed even though COMMIT/ ROLLBACK is performe d.)

Examples

```
gSQL> CREATE TABLE t1( c1 INTEGER, c2 VARCHAR( 6 ) );
Table created.
gSQL> COMMIT;
Commit complete.
```

- Insert Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   CURSOR cur1( p1 INTEGER, p2 varchar(6) ) RETURN t1%ROWTYPE
      IS INSERT INTO t1 VALUES ( p1, p2 ) RETURNING *;
BEGIN
   OPEN cur1( 1, 'aaa' );

   FETCH cur1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE cur1;
END;
/
var1.c1 = 1 , var1.c2 = aaa
Anonymous PL block executed.
```

- Select Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   CURSOR cur1( p1 INTEGER, p2 varchar(6) ) RETURN t1%ROWTYPE IS
      SELECT * FROM t1 WHERE c1 = p1 AND c2 = p2;
BEGIN
   OPEN cur1( 1, 'aaa' );
   FETCH cur1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE cur1;
END;
/
var1.c1 = 1 , var1.c2 = aaa
Anonymous PL block executed.
```

- Update Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   CURSOR cur1( p1 INTEGER, p2 varchar(6) ) RETURN t1%ROWTYPE IS
      UPDATE t1 SET c1 = p1, c2 = p2 RETURNING *;
BEGIN
```

```
   OPEN cur1( 3, 'ccc' );

   FETCH cur1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE cur1;
END;
/
var1.c1 = 3 , var1.c2 = ccc
Anonymous PL block executed.
```

- Delete Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   CURSOR cur1( p1 INTEGER, p2 varchar(6) ) RETURN t1%ROWTYPE IS
      DELETE FROM t1 WHERE c1 = p1 AND c2 = p2 RETURNING *;
BEGIN
   OPEN cur1( 3, 'ccc' );

   FETCH cur1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE cur1;
END;
/
var1.c1 = 3 , var1.c2 = ccc
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- **OPEN FOR Statement**
- **FETCH Statement**

- CLOSE Statement

28.19 FETCH Statement

Function

It fetches a single record of OPEN cursor.

Syntax

```
<fetch statement> ::=
    FETCH cursor_name <into clause>
    ;
<into clause> ::=
    INTO { variable [ , variable ] .. ¦ record }
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Cursor name
  - It is a cursor name to be fetched.
- Variable
  - It is a scalar type variable or a bind parameter which stores a column value among the fetch results.
- Record
  - It is a record type variable to store the entire single record of which is the fetch result.

Description

It fetches a record from an open cursor, then copies the value to a variable specified in INTO clause.
If a cursor is declared only but not defined, then an error occurs.
The cursor should be open.

A variable type given to INTO clause should be compatible with a data type of the fetched record result.
The number of variables given to INTO clause should be as same as the number of the cursor's SELECT tar gets.
However, if a variable given in INTO clause is a record type, then only a single variable should be specified.
Also, the number of the record variable fields should be as same as the number of SELECT targets.

If a fetch is called when a record to be fetched does not exist, then the value of target variables in INTO cl ause is not altered.

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  CURSOR C1 IS SELECT * FROM T1;
  V1 INTEGER := 0;
  V2 INTEGER := 0;
  CNT INTEGER := 0;
  TOTAL INTEGER := 0;
BEGIN
  FOR I IN 1..100 LOOP
    INSERT INTO T1 VALUES( I );
  END LOOP;
  COMMIT;
  OPEN C1;
  LOOP
    FETCH C1 INTO V1;
    CNT := CNT + 1;
    TOTAL := TOTAL + V1;
    V2 := V1;
    EXIT WHEN V1 = 100;
```

```
  END LOOP;
  CLOSE C1;
  DBMS_OUTPUT.PUT_LINE( 'CNT = ' || CNT || ' TOTAL = ' || TOTAL );
END;
/
CNT = 100 TOTAL = 5050
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- **OPEN Statement**
- **CLOSE Statement**

28.20 FOR LOOP Statement

Function

As long as an index variable has the given value scope, it performs internal statements by increasing or reversing the index variable by 1.

Syntax

```
<for loop statement> ::=
    FOR index_variable_name IN [ REVERSE ] lower_bound .. upper_bound
    LOOP { <SQL procedure statement> ; }... END LOOP [ loop_name ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Index variable name
  - It is a variable name to be used as an index in FOR statement. Internally, NATIVE_BIGINT type variable is used.
- Lower bound
  - It should be an integer type. If a number with a floating point is used, then the number below decimal point is rounded up while converting the type.
- Upper bound
  - It should be an integer type. If a number with a floating point is used, then the number below decimal point is rounded up while converting the type.

Description

for loop statement performs an internal statement list by increasing or decreasing the index variable value.

- If REVERSE is specified
  - an index variable is decreased by 1 from upper_bound value, and it terminates execution of *for loop* statement when the index variable value becomes smaller than lower_bound.
  - If upper_bound value is smaller than lower_bound then an internal statement list is not performed.
- If REVERSE is not specified
  - an index variable is increased by 1 from lower_bound, and it terminates execution of *for loop* statement when the index variable value becomes bigger than upper_bound.
  - If lower_bound value is bigger than upper_bound, then an internal statement list is not performed.

Examples

```
gSQL> BEGIN
  FOR I IN 0 .. 5 LOOP
    DBMS_OUTPUT.PUT_LINE( 'I = ' || I );
  END LOOP;
END;
/
I = 0
I = 1
I = 2
I = 3
I = 4
I = 5
Anonymous PL block executed.
gSQL> BEGIN
  FOR I IN REVERSE 0 .. 5 LOOP
    DBMS_OUTPUT.PUT_LINE( 'I = ' || I );
  END LOOP;
END;
/
I = 5
I = 4
I = 3
```

```
I = 2
I = 1
I = 0
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- **CONTINUE Statement**
- **EXIT Statement**
- **GOTO Statement**

28.21 Function Declaration and Definition

Function

It declares and defines a function.

Syntax

```
<function declaration> ::=
        FUNCTION <function name> [ ( <parameter list> ) ] <return clause>
        ;

<function definition> ::=
        FUNCTION <function name> [ ( <parameter list> ) ] <return clause>
        { IS ¦ AS }
        <item declaration>
        BEGIN
        <pl statement list>
        END [ <function name> ]
        ;

<parameter list> ::=
      <parameter name> [ <parameter mode> ] <datatype> [ <parameter default> ] [ , ... ]

<parameter mode> ::=
      IN
    ¦ OUT
    ¦ IN OUT

<parameter default> ::=
      { := ¦ DEFAULT } <value expression>

<return clause> ::=
      RETURN <datatype>
    ¦ RETURN TABLE ( <table function column list> )

<table function column list> ::=
```

```
    <column name> <datatype> [ , ... ]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

function name

It is a name of function to be created in a PL block, and it should be a unique name in a PL block.
In other words, PL item and function declared in PL block can not have the same name.
The length of a function name should be shorter than 128 bytes.

parameter name

It defines a parameter name of the function.
The name of each parameter should be unique in a function.
In other words, the function's parameter and PL item can not have the same name.
The length of a parameter name should be shorter than 128 bytes.
The maximum number of parameters available in a single function is limitless.

parameter mode

It sets each parameter mode.
The parameter modes are IN, OUT, and IN OUT.
If the parameter mode is not specified, the default mode is *IN*.

parameter default

It is the default value of the parameter.
The parameter with the specified parameter default can be omitted when executing the function.
If the parameter is not specified but omitted, then the default value is <value expression> specified when defining the parameter.
The datatype of <value expression> should be the datatype of the parameter.
All parameters defined after the parameter having <parameter default> should have <parameter default>.

return clause

It defines the return type of the function.
It is defined as follows in <return clause>.

- RETURN <datatype>
  - It defines the datatype of the return value returned by the function.
- RETURN TABLE (<table function column list>)
  - It defines the table type of the returned result set.

table function column list

It is the column name of the result set returned by the table function.
The length of a column name should be shorter than 128 bytes.
The number of columns are limitless.
Each column name is unique in <table function column list>.
The column name can be as same as the parameter name and the declare item name.
The column defined in <table function column list> can not be referenced in PL block of the function.

Item Declaration

It declares items such as a local variable to be used within a function.
It can declare all items which can be declared in a PL block.

PL Stmt List

It is a body section of a function, and it lists PL statements to be performed.

Description

It declares and defines the function as follows.

- PL block (e.g. anonymous block, procedure and function's block, block statement's block)
  - It is one of PL block's item and it declares and defines the function.
  - The function declared and defined in a PL block is a nested function.
  - Nested function is available only within the PL block range.
- Package specification
  - It declares the public function of the package.
  - The public function of the package is available in the database.

- Package body
  - It defines the public function declared in the package specification.
  - It declares and defines the private function of the package.
  - The private function of the package is available only within the package range.

The usage of the function is as same as that of schema-level function.

Examples

```
gSQL> CREATE TABLE t_score( c_grade INTEGER, c_score INTEGER );

Table created.

gSQL> INSERT INTO t_score VALUES ( 1 , 98 ) , ( 1 , 97 ) , ( 1 , 99 ),
                                 ( 2 , 95 ) , ( 2 , 98 ) , ( 2 , 92 ),
                                 ( 3 , 98 ) , ( 3 , 96 ) , ( 3 , 94 );

9 rows created.

gSQL> COMMIT;

Commit complete.
```

- Nested function

```
gSQL>
DECLARE
  v_max_score INTEGER;

  FUNCTION nestedfunc RETURN INTEGER;

  FUNCTION nestedfunc RETURN INTEGER AS
    v_max INTEGER;
  BEGIN
    SELECT MAX( c_score )
      INTO v_max
      FROM t_score;

    RETURN v_max;
  END;
```

```
BEGIN
  v_max_score := nestedfunc;

  DBMS_OUTPUT.PUT_LINE( 'Max Score : ' || v_max_score );
END;
/
Max Score : 99
Anonymous PL block executed.
```

- Package function

```
gSQL>
CREATE OR REPLACE PACKAGE pkg1 AS
  -- Declare Package Public Function
  FUNCTION func1( p_grade INTEGER, p_option VARCHAR ) RETURN INTEGER;
END;
/

Package created.
gSQL>
CREATE OR REPLACE PACKAGE BODY pkg1 AS
  -- Declare Package Private Function
  FUNCTION func2( p_grade INTEGER, p_option VARCHAR ) RETURN INTEGER;

  -- Define Package Public Function
  FUNCTION func1( p_grade INTEGER, p_option VARCHAR ) RETURN INTEGER AS
    var INTEGER;
  BEGIN
    var := func2( p_grade, p_option );

    RETURN var;
  END;

  -- Define Package Private Function
  FUNCTION func2( p_grade INTEGER, p_option VARCHAR ) RETURN INTEGER AS
    var INTEGER;
  BEGIN
    IF p_option = 'MIN' THEN
      SELECT MIN(c_score) INTO var FROM t_score WHERE c_grade = p_grade;
    ELSIF p_option = 'MAX' THEN
      SELECT MAX(c_score) INTO var FROM t_score WHERE c_grade = p_grade;
```

```
    ELSIF p_option = 'AVG' THEN
      SELECT AVG(c_score) INTO var FROM t_score WHERE c_grade = p_grade;
    ELSE
      var := -1;
    END IF;

    RETURN var;
  END;
END;
/

Package created.

gSQL> SELECT pkg1.func1(  1 , 'MAX' ) FROM DUAL;

PKG1.FUNC1(  1 , 'MAX' )
------------------------
                      99

1 row selected.
```

Compatibility

It is as same as a schema-level function.

For More Information

Refer to **CREATE FUNCTION**.

28.22 GOTO Statement

Function

It tries to jump into the nearest statement which has a given label among statements accessible from the current location.

Syntax

```
<goto statement> ::=
    GOTO label_name
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Label_name
  - It is a label name of a statement in which is to be jumped.
  - It can be in an identifier chain form.

Description

It starts performing by jumping into a statement which has the corresponding label name.
If multiple candidate statements exist, then it jumps into the nearest statement.
It can jump only to a statement (exist in a nested scope) which is visible in the current location.
Both forward jump and backward jump are possible.

Examples

```
gSQL> DECLARE
  V1 INTEGER := 0;
BEGIN
  <<LABEL1>>
  IF V1 > 0 THEN
    GOTO LABEL2;
  END IF;
  V1 := V1 + 1;
  DBMS_OUTPUT.PUT_LINE('a');
  GOTO LABEL1;
  DBMS_OUTPUT.PUT_LINE('b');
  <<LABEL2>>
  DBMS_OUTPUT.PUT_LINE('c');
END;
/
a
c
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- **EXIT Statement**
- **CONTINUE Statement**

28.23 IF Statement

Function

It performs a statement list corresponding to the condition returning TRUE among the given conditions.

Syntax

```
<if statement> ::=
    IF <search condition> <if statement then clause>
    [ <if statement elsif clase> ]
    [ <if statement else clase> ]
    END IF
    ;
<if statement then clause> ::=
    THEN <executable statement list>
<if statement elsif clause> ::=
    ELSIF <search condition> THEN <executable statement list>
<if statement elsif clause> ::=
    ELSE <executable statement list>
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Search condition
  - It is an expression which can be finally evaluated as a boolean type.
- Executable statement list
  - It is a list of all statements supported by GOLDILOCKS PSM.

Description

Like as CASE statement, it performs statement lists of IF, ELSIF clauses returning TRUE by evaluating conditions.
If it can not satisfy any condition and <if statement else clause> exists, then it performs the corresponding statement.
ELSIF clauses evaluates conditional expressions in order, and stops evaluating after finding the TRUE conditional clause.

Examples

```
gSQL> DECLARE
  V1 INTEGER := 10;
BEGIN
  IF V1 > 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'POSITIVE' );
  ELSIF V1 = 0 THEN
    DBMS_OUTPUT.PUT_LINE( 'ZERO' );
  ELSE
    DBMS_OUTPUT.PUT_LINE( 'NEGATIVE' );
  END IF;
END;
/
POSITIVE
Anonymous PL block executed.
```

Compatibility

<if statement> statement is as same as a syntax and an operation of the SQL standard.

Table 28-8 SQL standard compatibility

Feature ID	Description	Compatibility
P002	Computational completeness	O

28.24 Implicit Cursor Attribute

Function

It returns the status value of an implicit cursor defined in PSM.

Syntax

```
<Implicit cursor attribute> ::=
    SQL '%' { ISOPEN ¦ FOUND ¦ NOTFOUND ¦ ROWCOUNT }
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Description

- It stores the result of SQL statement which was executed just before.
  - ISOPEN: It is whether the cursor is OPEN, and it is always set to FALSE.
  - FOUND: It is whether the data is returned by the SQL result of just before.
  - NOTFOUND: It is an opposite of FOUND.
  - ROWCOUNT: It is the number of records affected by the SQL result of just before.

Examples

```
DECLARE
V1 INTEGER;
BEGIN
    SELECT COUNT(*) INTO V1 FROM T1;
    DBMS_OUTPUT.PUT_LINE('COUNT RET    = ' ¦¦ V1);
    DBMS_OUTPUT.PUT_LINE('SQL%ISOPEN   = ' ¦¦ SQL%ISOPEN);
```

```
    DBMS_OUTPUT.PUT_LINE('SQL%FOUND    = ' || SQL%FOUND);
    DBMS_OUTPUT.PUT_LINE('SQL%NOTFOUND = ' || SQL%NOTFOUND);
    DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT = ' || SQL%ROWCOUNT);
END;
/
COUNT RET    = 0
SQL%ISOPEN   = FALSE
SQL%FOUND    = TRUE
SQL%NOTFOUND = FALSE
SQL%ROWCOUNT = 1
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.25 INSERT Statement Extension

Function

It is an extended feature of an insert statement to input data by specifying record type variable supported in PSM in VALUES clause.

Syntax

```
<PSM Insert Statement Extension Statement> ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
           <Insert_source>
           [ <Returning_into_clause> ]
    ;
<Insert_source> ::=
      <value-list>
    ¦ <from_subquery>
    ¦ <from_default>
<from subquery> ::=
    <query_expression>
<from default> ::=
    DEFAULT VALUES
<Value-List> ::=
      VALUES <Value_item> [ , ...]
<value-Item> ::=
     PSM-Record-Type-Variable
     ¦  ( { <value expression> ¦ DEFAULT } [, ...] )
<Returning_into_clause> ::=
      [ RETURN ¦ RETURNING ] { * ¦ { <value_expression> [ [AS] alias_name ] } [, ...] INTO
variable_name [, ...]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

A PSM insert extension statement can not be used in an original SQL statement of EXECUTE IMMEDIATE.

Syntax Rules and Parameters

It is operated as same as the basic syntax of an insert statement. However, a feature specifying PSM recor d type variables are added other than a feature consecutively listing existing value expressions in parenthe ses in value item.

A PSM record type variable should be specified when using a variable without parentheses in Value_Item. When using it in an insert extension statement form, a variable which is not a record type can not be use d being mixed.

Description

It stores a record by using a record type variable of PSM other than a general insert statement, or obtains a result through returning into.
For more information about insert, refer to the following example.

Examples

```
gSQL> DECLARE
  rec t1%ROWTYPE;
BEGIN
    rec.i1 := 'AAA';
    rec.i2 := 'BBB';
    rec.i3 := 'CCC';
    INSERT INTO t1 (i1, i2, i3) VALUES rec ;
END;
/
Anonymous PL block executed.
gSQL> SELECT * FROM t1;
I1  I2  I3
--- --- ---
AAA BBB CCC
```

Compatibility

It is not defined in the SQL standard.

28.26 INSERT INTO ... UPDATE Statement Extension

Function

It is the extended function of *insert into .. update* statement. It creates a new row in a table by specifying the record type variable supported by PSM in a values clause, or updates the row by specifying the variable in a set clause.

Syntax

```
<PSM Upsert Statement Extention Statement > ::=
    INSERT INTO table_name [ ( column_name [, ...] ) ]
        <insert source>
        <duplicate key clause>
        [ <Returning_into_clause> ]
    ;
<insert source> ::=
      <values-list>
    ¦ <from subquery>
    ¦ <from_default>
<Value-List> ::=
      VALUES <Value_item> [ , ...]
<value-Item> ::=
         PSM-Record-Type-Variable
     ¦  ( { <value expression> ¦ DEFAULT } [, ...] )
<from subquery> ::=
    <query expression>
<from default> ::=
    DEFAULT VALUES
<duplicate key clause>
    ON DUPLICATE KEY { DO NOTHING ¦ <do update clause> }
<do update clause> ::=
    [DO] UPDATE <target-list>
<target-List> ::=
        SET <set clause> [, ...]
```

```
      ¦ SET ROW = <psm_variable>
<set clause> ::=
      column_name = { <value expression> ¦ DEFAULT }
    ¦ ( column_name [, ...] ) = ( { <value expression> ¦ DEFAULT } [, ...] )
    ¦ ( column_name [, ...] ) = ( <query expression> )
<returning_into_clause> ::=
      [ RETURN ¦ RETURNING ] { * ¦ { <value_expression> [ [AS] alias_name ] } [, ...] INTO
variable_name [, ...]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. procedure, function, package)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- <values clause>
  - The function specifying PSM record type variable other than consecutively listing existing value ex pressions in parentheses in the value item has been added.
  - PSM record type variable should be specified when using the variable without parentheses in the value item.
  - When describing by extending the value item, then the variable other than the record type variab le is not allowed.
- <target list>
  - <PSM_Variable> used in SET ROW statement should be the variable declared as the record type.
- <returning into clause>
  - <Variable> used in RETURNING INTO statement does not need to be a record type. However, if it is specified as a record type, then it can not be used together with other data type variables nor c an list two or more record type variables.

Description

Returning into statement in an upsert statement stores the inserted result when insert is executed, and it stores the updated result when update is executed.

Examples

- Execute insert.

```
gSQL> CREATE TABLE t1( c1 INTEGER UNIQUE, c2 INTEGER, c3 INTEGER );
Table created.
gSQL> DECLARE
  v_rec t1%ROWTYPE;
BEGIN
  v_rec.c1 := 1;
  v_rec.c2 := 1;
  v_rec.c3 := 1;

  INSERT INTO t1 VALUES v_rec ON DUPLICATE KEY UPDATE SET c1 = c1 + 1;
END;
/
Anonymous PL block executed.
gSQL> SELECT * FROM t1;
C1 C2 C3
-- -- --
 1  1  1
1 row selected.
```

- Execute update.

```
gSQL> CREATE TABLE t1( c1 INTEGER UNIQUE, c2 INTEGER, c3 INTEGER );
Table created.
gSQL> INSERT INTO t1 VALUES ( 1 , 1 , 1 );
1 row created.
gSQL> DECLARE
  v_rec t1%ROWTYPE;
BEGIN
  v_rec.c1 := 2;
  v_rec.c2 := 2;
  v_rec.c3 := 2;
  INSERT INTO t1 VALUES (1, 1, 1) ON DUPLICATE KEY UPDATE SET ROW = v_rec;
END;
/
gSQL> SELECT * FROM t1;
C1 C2 C3
```

```
-- -- --
 2  2  2
1 row selected.
```

- Returning statement of when executing insert

```
gSQL> CREATE TABLE t1( c1 INTEGER UNIQUE, c2 INTEGER, c3 INTEGER );
Table created.
gSQL> DECLARE
  v_rec1 t1%ROWTYPE;
  v_rec2 t1%ROWTYPE;
BEGIN
  v_rec1.c1 := 1;
  v_rec1.c2 := 1;
  v_rec1.c3 := 1;
  INSERT INTO t1 VALUES v_rec1 ON DUPLICATE KEY UPDATE SET c1 = c1 + 1 RETURNING * INTO
v_rec2;
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c1 : ' || v_rec2.c1 );
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c2 : ' || v_rec2.c2 );
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c3 : ' || v_rec2.c3 );
END;
/
v_rec2.c1 : 1
v_rec2.c2 : 1
v_rec2.c3 : 1
Anonymous PL block executed.
gSQL> SELECT * FROM t1;
C1 C2 C3
-- -- --
 1  1  1
1 row selected.
```

- Returning statement of when executing update

```
gSQL> CREATE TABLE t1( c1 INTEGER UNIQUE, c2 INTEGER, c3 INTEGER );
Table created.
gSQL> INSERT INTO t1 VALUES ( 1 , 1 , 1 );
1 row created.
gSQL> DECLARE
  v_rec1 t1%ROWTYPE;
  v_rec2 t1%ROWTYPE;
BEGIN
```

```
  v_rec1.c1 := 2;
  v_rec1.c2 := 2;
  v_rec1.c3 := 2;
  INSERT INTO t1 VALUES (1, 1, 1) ON DUPLICATE KEY UPDATE SET ROW = v_rec1 RETURNING * INTO
v_rec2;
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c1 : ' || v_rec2.c1 );
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c2 : ' || v_rec2.c2 );
  DBMS_OUTPUT.PUT_LINE( 'v_rec2.c3 : ' || v_rec2.c3 );
END;
/
v_rec2.c1 : 2
v_rec2.c2 : 2
v_rec2.c3 : 2
Anonymous PL block executed.
gSQL> SELECT * FROM t1;
C1 C2 C3
-- -- --
 2  2  2
1 row selected.
```

Compatibility

It is not defined in the SQL standard.

28.27 NULL Statement

Function

It is a statement without any feature.

Syntax

```
<null statement> ::=
    NULL
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Description

It is a statement without any feature, and used to set a label of a specific location.

Examples

```
gSQL> BEGIN
  FOR i in 1..10 LOOP
    DBMS_OUTPUT.PUT_LINE( i );
    IF i > 5 THEN
      GOTO label1;
    END IF;
  END LOOP;
  <<label1>>
  NULL;
```

```
END;
/
1
2
3
4
5
6
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.28 OPEN Statement

Function

It executes SELECT statement of a cursor defined in PSM.

Syntax

```
<open statement> ::=
    OPEN cursor_name [ <actual param spec> ]
    ;
<actual param spec> ::=
      ( expression [ , expression ] .. )
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Cursor_name
  - It is the name of a cursor to be opened.

Description

It executes SELECT or SELECT ... FOR UPDATE statement of a defined cursor.
If a cursor is declared only but is not defined, then an error occurs.
Values of actual parameters should be compatible with the data type of those parameters.

The number of actual parameters should be same as the number of parameters of a cursor.
If it is smaller than the number of parameters of a cursor, then the default value should be specified in all

other parameters.

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I2 VARCHAR(10) );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> INSERT INTO T1 VALUES( 1, 'AAA' );
1 row created.
gSQL> INSERT INTO T1 VALUES( 2, 'BBB' );
1 row created.
gSQL> INSERT INTO T1 VALUES( 3, 'CCC' );
1 row created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  CURSOR C1( A1 INTEGER := 1, A2 VARCHAR DEFAULT 'AAA') IS SELECT * FROM T1 WHERE I1 = A1 AND
I2 = A2;
  V1 INTEGER;
  V2 VARCHAR(10);
BEGIN
  OPEN C1( 1 );
  FETCH C1 INTO V1, V2;
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 || ' V2 = ' || V2 );
  CLOSE C1;
END;
/
V1 = 1 V2 = AAA
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- CLOSE Statement
- FETCH Statement

28.29 OPEN FOR Statement

Function

It opens a single cursor by executing SELECT statement through a cursor variable defined in PSM.

Syntax

```
<open statement> ::=
    OPEN cursor_variable_name FOR <cursor_query>
    ;
<cursor_query> ::==
      <static_cursor_query>
    ¦ <dynamic_cursor_query> [ <using_clause> ]
<static_cursor_query> ::==
      select_statement
    ¦ select_for_update_statement
    ¦ insert_returning_query_statement
    ¦ update_returning_query_statement
    ¦ delete_returning_query_statement
<dynamic_cursor_query>
      single_quote_string
    ¦ psm_variable
<using_clause> ::=
    USING [ <bind_type> ] <expression> [ {, [ <bind_type> ] <expression>} ... ]
<bind_type> ::=
     IN
   ¦ OUT
   ¦ IN OUT
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- 〈cursor_variable_name〉
  - It is the name of cursor variable.
- 〈cursor_query〉
  - A cursor query can use both a static cursor query and a dynamic cursor query.
  - The followings are cursor queries.
    - select statement
    - select for update statement
    - insert returning statement
    - update returning statement
    - delete returning statement
  - A dynamic cursor query is used by enclosing sql with a single quoted (') or by storing sql in a psm variable.
  - A using clause is available when writing a dynamic cursor query.
- 〈using_clause〉
  - If a bind variable exists when writing a dynamic cursor query, list variables or expressions in using clause as many as the number of bind variables.
  - The variable in using clause can describe the bind type of IN/ OUT/ IN OUT. The bind type of whe n writing the dynamic cursor query should be same as the bind type of the bind variable.
  - The bind type of the variable in using clause can be omitted. If omitted, the default bind type is I N.

Description

It executes the cursor query of the defined cursor variable.
If the cursor variable is previously open, then that cursor is executed after it is automatically closed and re opened.

Examples

```
gSQL> CREATE TABLE t1( c1 INTEGER, c2 VARCHAR( 6 ) );
Table created.
gSQL> COMMIT;
Commit complete.
```

- Insert Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   curvar1 SYS_REFCURSOR;
BEGIN
   OPEN curvar1 FOR INSERT INTO t1 VALUES ( 1 , 'aaa' ) RETURNING *;
   FETCH curvar1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE curvar1;
END;
/
var1.c1 = 1 , var1.c2 = aaa
Anonymous PL block executed.
```

- Select Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   curvar1 SYS_REFCURSOR;
BEGIN
   OPEN curvar1 FOR SELECT * FROM t1;

   FETCH curvar1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE curvar1;
END;
/
var1.c1 = 1 , var1.c2 = aaa
Anonymous PL block executed.
```

- Update Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   curvar1 SYS_REFCURSOR;
BEGIN
   OPEN curvar1 FOR UPDATE t1 SET c1 = 3, c2 = 'ccc' RETURNING *;

   FETCH curvar1 INTO var1;
```

```
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE curvar1;
END;
/
var1.c1 = 3 , var1.c2 = ccc
Anonymous PL block executed.
```

- Delete Returning Statement

```
gSQL>
DECLARE
   var1 t1%ROWTYPE;
   curvar1 SYS_REFCURSOR;
BEGIN
   OPEN curvar1 FOR DELETE FROM t1 RETURNING *;
   FETCH curvar1 INTO var1;
   DBMS_OUTPUT.PUT_LINE( 'var1.c1 = ' || var1.c1 || ' , var1.c2 = ' || var1.c2 );
   CLOSE curvar1;
END;
/
var1.c1 = 3 , var1.c2 = ccc
Anonymous PL block executed.
```

- Dynamic Cursor Query and Using Clause

```
gSQL> INSERT INTO t1 VALUES( 100 , 'BBB' );
gSQL> COMMIT;
gSQL>
DECLARE
  v_int_in     INTEGER;
  v_varchar_in VARCHAR(6);
  v_out        t1%ROWTYPE;
  v_sql        VARCHAR(1024);
  cv           SYS_REFCURSOR;
BEGIN
  v_sql := 'SELECT * FROM t1 WHERE c1 = ? AND c2 = ?';
  v_int_in := 100;
  v_varchar_in := 'BBB';

  OPEN cv FOR v_sql USING IN v_int_in, v_varchar_in;

  FETCH cv INTO v_out;
```

```
  DBMS_OUTPUT.PUT_LINE( 'c1 : ' || v_out.c1 || ' , v_out.c2 : ' || v_out.c2 );

  CLOSE cv;
END;
/
c1 : 100 , v_out.c2 : BBB
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

For More Information

Refer to the followings.

- **Cursor Variable Declaration**
- **FETCH Statement**
- **CLOSE Statement**

28.30 Procedure Call

Function

It calls a user-defined procedure, a built-in procedure or a nested procedure.

Syntax

```
<Procedure call> ::=
    proc_name [ ( expr { , expr } ... ) ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

- The following privileges for the corresponding procedure are required to call the user-defined procedure.
  - EXECUTE PROCEDURE
  - (EXECUTE PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure belongs
  - EXECUTE ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

- Proc_name
  - It is a name of a procedure to be executed, and it is used in the following format.

Format	Syntax	Description
Single identifier	procedure_name	It calls the procedure of the given name. It is searched in the following order. 1. nested procedure

Format	Syntax	Description
		2. schema-level procedure
identifier chain	label_name.procedure_name	It calls a nested procedure.
	schema_name.procedure_name	It calls a schema-level procedure.
	package_name.procedure_name	It calls a built-in procedure.

If the given the number and type of arguments which were given in the procedure found first are wrong when searching with the given name (proc_name), then it does not search for another procedure but ca uses an error.

Description

It calls a user-defined procedure, a built-in procedure or a nested procedure which was defined an advan ce.
The argument value in which the default value is defined can be omitted when calling.

When using a procedure variable or bind parameter (?, :V1) in an argument which were defines as OUT o r IN-OUT, then the returned value is obtained.

Examples

```
gSQL> DECLARE
  PROCEDURE PROC1( A1 INTEGER )
    IS
    BEGIN
      PUT_LINE( 'A1 = ' || A1 );
    END;
BEGIN
  PROC1( 100 );
END;
/
A1 = 100
Anonymous PL block executed.
```

Compatibility

The SQL standard requires to use ⟨call statement⟩.

28.31 Procedure Declaration and Definition

Function

It declares and defines a procedure.

Syntax

```
<procedure declaration> ::=
      PROCEDURE <procedure name> [ ( <parameter list> ) ]
      ;
<procedure definition> ::=
      PROCEDURE <procedure name> [ ( <parameter list> ) ]
      { IS ¦ AS }
      <item declaration>
      BEGIN
      <pl statement list>
      END [ <procedure name> ]
      ;

<parameter list> ::=
      <parameter name> [ <parameter mode> ] <datatype> [ <parameter default> ] [ , ... ]
<parameter mode> ::=
      IN
    ¦ OUT
    ¦ IN OUT

<parameter default> ::=
      { := ¦ DEFAULT } <value expression>
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

procedure name

It is a name of procedure to be created in a PL block, and it should be a unique name in a PL block.
In other words, PL item and procedure declared in PL block can not have the same name.
The length of a procedure name should be shorter than 128 bytes.

parameter name

It defines a parameter name of the procedure.
The name of each parameter should be unique in a procedure.
In other words, the procedure's parameter and PL item can not have the same name.
The length of a parameter name should be shorter than 128 bytes.
The maximum number of parameters available in a single procedure is limitless.

parameter mode

It sets each parameter mode.
The parameter modes are IN, OUT, and IN OUT.
If the parameter mode is not specified, the default mode is *IN*.

parameter default

It is the default value of the parameter.
The parameter with the specified parameter default can be omitted when executing the procedure.
If the parameter is not specified but omitted, then the default value is <value expression> specified when defining the parameter.
The datatype of <value expression> should be the datatype of the parameter.
All parameters defined after the parameter having <parameter default> should have <parameter default>.

Item Declaration

It declares items such as a local variable to be used within a function.
It can declare all items which can be declared in a PL block.

PL Stmt List

It is a body section of a procedure, and it lists PL statements to be performed.

Description

It declares and defines the procedure as follows.

- PL block (e.g. anonymous block, procedure and function's block, block statement's block)
  - It is one of PL block's item and it declares and defines the procedure.
  - The function declared and defined in a PL block is a nested procedure.
  - Nested procedure is available only within the PL block range.
- Package specification
  - It declares the public procedure of the package.
  - The public procedure of the package is available in the database.
- Package body
  - It defines the public procedure declared in the package specification.
  - It declares and defines the private procedure of the package.
  - The private procedure of the package is available only within the package range.

The usage of the procedure is as same as that of schema-level procedure.

Examples

- Nested procedure

```
gSQL>
DECLARE
  PROCEDURE proc1( p1 INTEGER ) IS
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'p1 = ' || p1 );
  END;
BEGIN
  proc1( 100 );
END;
/
p1 = 100
Anonymous PL block executed.
```

- Package procedure

```
gSQL>
CREATE OR REPLACE PACKAGE pkg1 AS
  -- Declare Package Public Function
  PROCEDURE proc1( p1 INTEGER );
END;
/

Package created.
gSQL>
CREATE OR REPLACE PACKAGE BODY pkg1 AS
  -- Declare Package Private Function
  PROCEDURE proc2( p1 INTEGER );

  -- Define Package Public Function
  PROCEDURE proc1( p1 INTEGER ) AS
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'p1 of proc1 : ' || p1 );

    proc2( p1 * p1 );
  END;

  -- Define Package Private Function
  PROCEDURE proc2( p1 INTEGER ) AS
  BEGIN
    DBMS_OUTPUT.PUT_LINE( 'p1 of proc2 : ' || p1 );
  END;
END;
/
Package created.
gSQL> CALL pkg1.proc1( 10 );
p1 of proc1 : 10
p1 of proc2 : 100
Procedure Call complete.
```

Compatibility

It is as same as a schema-level procedure.

For More Information

Refer to **CREATE PROCEDURE**.

28.32 RAISE Statement

Function

It explicitly generates a user-defined exception.

Syntax

```
〈RAISE Statement〉 ::=
    RAISE  〈Exception-Name〉
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- A name of exception to be raised should be declared in a PL block to which a raise belongs or in DEC LARE clause of a superordinate PL block. However, a predefined exception can be raised without a de claration.
- If a raise statement is used within an exception handler, an exception name can be omitted, in this ca se, the previous exception is spread to the superordinate block.

Description

If it can not be processed in a PL block in which an exception occured, then it is spread to the superordina te PL block.
If an exception to be raised does not exist in a PL block including RAISE statement, nor does exist in all ex ception handlers within a superordinate PL block, then an error occurs.
It is spread from a PL block in which RAISE exception occurred to a superordinate PL block until it is proce

ssed, and it can not be spread to an exception handler of subordinate PL block.

Table 28-9 Propagating user exception

Raise exception	Exception handler SCOPE	Exception handler	Whether to spread it to superordinate
User exception without error code	Same scope	X	It spreads "unhandled exception" err or to a superordinate scope.
User exception with error code	Superordinate scope	X	It spreads a user exception.
User exception with error code	Same scope	X	Itspreads a user defined error code.
User exception with error code	Superordinate scope	X	Itspreads a user defined error code.

Examples

```
gSQL> DECLARE
V1 INTEGER;
exception1   EXCEPTION;
exception100 EXCEPTION;
BEGIN
    DBMS_OUTPUT.PUT_LINE('Step1');
    BEGIN
        RAISE exception1;
        DBMS_OUTPUT.PUT_LINE('Step2');
        EXCEPTION WHEN Exception100 THEN DBMS_OUTPUT.PUT_LINE('in Exception');
    END;
    DBMS_OUTPUT.PUT_LINE('Step3');
    EXCEPTION WHEN Exception1 THEN DBMS_OUTPUT.PUT_LINE('out Exception');
    DBMS_OUTPUT.PUT_LINE('Step4');
END;
/
Step1
out Exception
Step4
Anonymous PL block executed.
```

Compatibility

The SQL standard specifies <handler declaration> and <condition declaration>, but it does not support th e syntax.

For More Information

Refer to the followings.

- **Exception Handler**
- **Exception Declaration**

28.33 Record Variable Declaration

Function

It declares a record type variable in DECLARE section.

Syntax

```
<declare record variable> ::=
    variable_name <recordType>
    ;
<recordType> ::=
     <tableName>%ROWTYPE
   ¦ USER_DEFINED_DATA_TYPE
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

- Variable_name
  - It is a name of variable to be declared.
  - The length of the variable name should be shorter than 128 bytes.
  - It should be a unique name within a scope (PL block body).
  - A variable with the same name can be declared in a PL block body of nested subordinate.
  - It should be used in scope_name.variable_name form to correctly use the variables of duplicated declaration.
  - When using a variable of duplicated declaration without specifying the scope name, then a varia ble of the nearest scope is automatically used.
- Record_type
  - It can use %ROWTYPE and user-defined recordType.
  - For more information about the declaration of recordType, refer to **User Defined Record Type**.

Description

- The declared variable has the following features.
  - It should be a unique name within a scope (PL block body).
  - A variable with the same name can be declared in a PL block body of nested subordinate.
  - It should be used in scope_name.variable_name form to correctly use the variables of duplicated declaration.
  - When using a variable of duplicated declaration without specifying the scope name, then a variable of the nearest scope is automatically used.
- The declared variable is used in that scope and in its subordinate scope, but ':' is not added unlike an embedded SQL.
- The used variable is operated as a bind parameter (INOUT) for that SQL or a PSM control statement.

Examples

```
gSQL> DECLARE
  TYPE MY_REC1 IS RECORD ( F1 INTEGER, F2 VARCHAR(10) );
  V1 MY_REC1;
BEGIN
  V1.F1 := 1;
  V1.F2 := 'AAA';
  INSERT INTO T1 VALUES( V1.F1, V1.F2 );
END;
/
Anonymous PL block executed.
gSQL> COMMIT;
Commit complete.
gSQL> SELECT * FROM T1;
I1 I2
-- ---
 1 AAA
1 row selected.
```

Compatibility

It is not defined in the SQL standard.

28.34 RETURN Statement

Function

It specifies the value of which a function returns, then terminates the function. A procedure does not spe cify the return value, but terminates the procedure.

Syntax

```
<return statement> ::=
    RETURN [ return_value_expr ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.
It can not be used in the PL block of the table function.

Syntax Rules and Parameters

- Return_value_expr
  - It is an expression of a value to be returned, and it can be specified only when it is a function.

Description

It terminates a currently performing procedure/ function.
For a function, if RETURN statement is terminated without being performed, or if RETURN statement doe s not have return_value_expr, then an error occurs.
It can not be used in the table function.

Examples

```
gSQL> CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
  RETURN INTEGER
  IS
    V1 INTEGER;
  BEGIN
    SELECT COUNT(*)
      INTO V1
      FROM T1
      WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    RETURN V1;
  END;
  /
Function created.
```

Compatibility

It is specified in the SQL standard, but conformance rules do not exist.

28.35 RETURN TABLE Statement

Function

It returns the result set of executing the cursor variable's cursor query or the select statement, then termi nates the function.

Syntax

```
<return table statement> ::=
    RETURN TABLE ( { <cursor variable name> ¦ <select statement> } )
    ;
```

Invocation and Access Rules

It can be used only in the table function within PSM.
It can be used only in the body section of a table function block.

Syntax Rules and Parameters

- 〈cursor variable name〉
  - It returns the result set by executing the specified cursor variable's cursor query.
  - The cursor variable should be open.
  - The cursor variable's cursor query should have not been fetched.
  - It allows the cursor variable whose cursor query is the select statement only.
- 〈select statement〉
  - It can use the select statement only.
  - It can not use select for update statement and select into statement.

Description

It returns the result set of executing the cursor variable's cursor query or select statement specified in RET URN TABLE statement.
RETURN TABLE statement is available only in the table function.

Examples

```
gSQL> CREATE TABLE t_score( c_grade INTEGER, c_score INTEGER );

Table created.

gSQL> INSERT INTO t_score VALUES ( 1 , 98 ) , ( 1 , 97 ) , ( 1 , 99 ),
                                 ( 2 , 95 ) , ( 2 , 98 ) , ( 2 , 92 ),
                                 ( 3 , 98 ) , ( 3 , 96 ) , ( 3 , 94 );

9 rows created.

gSQL> COMMIT;

Commit complete.
```

- Example of using the cursor variable

```
gSQL>
CREATE FUNCTION func_cursor_variable( p_option VARCHAR )
  RETURN TABLE( f_class NUMBER, f_score NUMBER )
AS
  s_cur SYS_REFCURSOR;
BEGIN
  IF p_option = 'MIN' THEN
    OPEN s_cur FOR SELECT c_grade, MIN(c_score) FROM t_score GROUP BY c_grade;
  ELSIF p_option = 'MAX' THEN
    OPEN s_cur FOR SELECT c_grade, MAX(c_score) FROM t_score GROUP BY c_grade;
  ELSIF p_option = 'AVG' THEN
    OPEN s_cur FOR SELECT c_grade, AVG(c_score) FROM t_score GROUP BY c_grade;
  ELSE
    OPEN s_cur FOR SELECT NULL, NULL FROM dual;
  END IF;
```

```
  RETURN TABLE( s_cur );
END;
/

Function created.

gSQL> COMMIT;

Commit complete.

-- Calculate the lowest score in each grade.
gSQL> SELECT * FROM TABLE( func_cursor_variable( 'MIN' ) );

F_CLASS F_SCORE
------- -------
      1      97
      2      92
      3      94

3 rows selected.
```

- Example of using the select statement

```
gSQL>
CREATE FUNCTION func_select( p_option VARCHAR )
    RETURN TABLE( f_class NUMBER, f_score NUMBER )
AS
BEGIN
  IF p_option = 'MIN' THEN
    RETURN TABLE ( SELECT c_grade, MIN(c_score) FROM t_score GROUP BY c_grade );
  ELSIF p_option = 'MAX' THEN
    RETURN TABLE ( SELECT c_grade, MAX(c_score) FROM t_score GROUP BY c_grade );
  ELSIF p_option = 'AVG' THEN
    RETURN TABLE ( SELECT c_grade, AVG(c_score) FROM t_score GROUP BY c_grade );
  ELSE
    RETURN TABLE ( SELECT NULL, NULL FROM dual );
  END IF;
END;
/
```

```
Function created.

-- Calculate the average score in each grade.
gSQL> SELECT * FROM TABLE( func_select( 'AVG' ) );

F_CLASS F_SCORE
------- -------
      1      98
      2      95
      3      96

3 rows selected.
```

Compatibility

The SQL standard describes it in <return statement> statement.
However, the SQL standard does not define the cursor variable.

28.36 RETURNING INTO clause

Function

The data processed in an insert/ update/ delete is returned to a PSM variable.

Syntax

```
<Insert, Delete Returning_into_clause> ::=
      [ RETURN ¦ RETURNING ] { * ¦ { <value_expression> [ [AS] alias_name ] } [, ...] INTO
variable_name [, ...]
<Update returning into clause> ::=
    { RETURN ¦ RETURNING } [ NEW ¦ OLD ] { * ¦ { <value expression> [ [AS] alias_name] } [,
...] } INTO Variable [, ...]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

A record type variable can not be used being mixed with other types.

Description

It stores before/ after record of processing an insert/ update/ delete statement through returning into.

Examples

```
gSQL> DECLARE
  rec t1%ROWTYPE;
BEGIN
    INSERT INTO t1 VALUES (1, 2, 3) RETURNING * INTO rec ;
    UPDATE T1 SET ROW = rec RETURNING * INTO rec;
    DELETE FROM T1 RETURNING * INTO rec;
END;
/
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.37 %ROWTYPE Attribute

Function

When declaring a variable, it defines the structure and type as same as those of a specific table, a specific cursor or a result set of a cursor variable.

Syntax

```
<rowtype attribute> ::=
    <identifier chain> % ROWTYPE
```

Invocation and Access Rules

- It can be used only within PSM. (e.g. package, procedure, function)
- It can be used only in the declaration section of a PL block.
- When declaring a variable, it can be used only in <data type> section.
- When declaring a record type field, then it can not be used in <data type> section. (It does not suppo rt complex data type.)

Syntax Rules and Parameters

- Identifier chains are as follows.
  - The name of table, view, synonym to be referenced, or the name of a cursor or a cursor variable

Description

- Search order of the reference targets
  - Cursor or cursor variable
  - Base table, view, or synonym
- Reference scope

- When referring by using a row attribute, only name and type of columns in a result set of a table or a cursor is referenced.
- Therefore, it does not refer to NOT NULL constraint or DEFAULT value settings.

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER NOT NULL, I2 VARCHAR(10) );
Table created.
gSQL> INSERT INTO T1 VALUES( 123, '1234567890' );
1 row created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
  V1 T1%ROWTYPE;
BEGIN
  SELECT * INTO V1.I1, V1.I2 FROM T1;
  DBMS_OUTPUT.PUT_LINE( 'V1.I1 = ' || V1.I1 || ' V1.I2 = ' || V1.I2 );
END;
/
V1.I1 = 123 V1.I2 = 1234567890
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.38 Scalar Variable Declaration

Function

It declares a scalar variable in the declaration section.

Syntax

```
<declare scalar variable> ::=
    variable_name <data type> [ <variable initialize clause> ]
    ;
<variable initialize clause> ::=
      [ NOT NULL ] { DEFAULT | := } <value expression>
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.

Syntax Rules and Parameters

- Variable_name
  - It is a name of variable to be declared.
  - The length of the variable name should be shorter than 128 bytes.
  - It should be a unique name within a scope (PL block body).
  - A variable with the same name can be declared in a PL block body of nested subordinate.
  - It should be used in scope_name.variable_name form to correctly use the variables of duplicated declaration.
  - When using a variable of duplicated declaration without specifying the scope name, then a variable of the nearest scope is automatically used.
- Data_Type
  - It can use all built-in **Data Type** provided in GOLDILOCKS.
- Value_expression
  - It expresses the initial value to specify in the variable.

    - It can use all constants and expressions supported by GOLDILOCKS except for multi-row function s.

Description

- The declared variable has the following features.
    - It should be a unique name within a scope (PL block body).
    - A variable with the same name can be declared in a PL block body of nested subordinate.
    - It should be used in scope_name.variable_name form to correctly use the variables of duplicated declaration.
    - When using a variable of duplicated declaration without specifying the scope name, then a varia ble of the nearest scope is automatically used.
- The declared variable is used in that scope and in its subordinate scope, but ':' is not added unlike an embedded SQL.
- The used variable is operated as a bind parameter (INOUT) for that SQL or a PSM control statement.

Examples

```
gSQL> CREATE TABLE T1 ( I1 INTEGER, I2 VARCHAR(10) );
Table created.
gSQL> COMMIT;
Commit complete.
gSQL> DECLARE
V1 INTEGER := 100;
V2 INTEGER := -100;
V3 VARCHAR(10) := 'ABC';
BEGIN
  IF V1 > 50 THEN
    INSERT INTO T1 VALUES ( V1, V3 );
  ELSE
    INSERT INTO T1 VALUES ( V2, V3 );
  END IF;
END;
/
Anonymous PL block executed.
gSQL> SELECT * FROM T1;
 I1 I2
--- ---
```

```
100 ABC
1 row selected.
```

Compatibility

- The differences between <declare scalar variable> statement of GOLDILOCKS and that of SQL standard are as follows.
  - <SQL variable declaration> of the SQL standard declares a variable in a PL block body (after BEGIN), but GOLDILOCKS declares a variable in a separate declaration section.
  - The SQL standard can declare multiple variables of the same type by using a single DECLARE statement, but GOLDILOCKS can declare only a single variable by using a single statement.
  - The SQL standard uses only DEFAULT syntax when setting the initial value, but GOLDILOCKS can use an assign sign (:=).

28.39 SELECT INTO Statement

Function

A single row is returned through SELECT.

Syntax

```
<select statement: single row> ::=
    SELECT [ <hint clause> ] [ <set quantifier> ] <select list>
        INTO <select target list>
        <table expression>
    ;
<select target list> ::=
    variable_name [, ...]
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

The rules are as same as those of a select statement except the rules for INTO clause.

Description

- SELECT INTO is used to return a single record.
  - If the number of results is zero, "NO_DATA_FOUND" exception occurs.
  - If the number of results are two or more, "TOO_MANY_ROWS" exception occurs.
- The result can be returned through a record type variable of PSM.
  - When using a record type variable, it can not be used being mixed with other type variables

Examples

```
gSQL> CREATE TABLE T1 (c1 VARCHAR(20), c2 VARCHAR(20));
Table created.
gSQL> INSERT INTO T1 VALUES ('AAA', 'BBB'), ('BBB', 'CCC');
2 rows created.
gSQL> DECLARE
  v1 VARCHAR(20);
  v2 VARCHAR(20);
BEGIN
  SELECT * INTO v1, v2 FROM T1 WHERE c1 = 'AAA';
  DBMS_OUTPUT.PUT_LINE('V1=' || v1 || ', v2=' || v2);
END;
/
V1=AAA, v2=BBB
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.40 SQLCODE Function

Function

It returns an error code of a statement which was performed just before in PSM.

Syntax

```
<SQLCODE function> ::= SQLCODE
```

Invocation and Access Rules

It can be used only within PSM.

Syntax Rules and Parameters

It does not have a separate argument.

Description

It returns an error code of a statement performed in PL/ SQL.
A user-defined exception which does not assign an error code returns to 1 at the time when it is processe d by a handler.
When the error is completely processed by an exception handler, it returns to 0.

Examples

```
gSQL> DECLARE
V1 INTEGER;
BEGIN
```

```
    DBMS_OUTPUT.PUT_LINE('SQLCODE=[' || SQLCODE || ']');
    DBMS_OUTPUT.PUT_LINE('SQLERRM=[' || SQLERRM || ']');
END;
/
SQLCODE=[0]
SQLERRM=[[SUNJESOFT][PL/SQL][GOLDILOCKS]successful completion]
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.41 SQLERRM Function

Function

It returns an error message of a statement which was performed just before in PSM.

Syntax

```
<SQLERRM function> ::= SQLERRM
```

Invocation and Access Rules

It can be used only within PSM.

Syntax Rules and Parameters

It does not have a separate argument.

Description

It returns an error message of a statement performed in PL/ SQL.
A user-defined exception which does not assign an error code returns to a user-defined exception at the time when it is processed by a handler.
When the error is completely processed by an exception handler, it outputs successful completion message.

Examples

```
gSQL> DECLARE
V1 INTEGER;
```

```
BEGIN
    DBMS_OUTPUT.PUT_LINE('SQLCODE=[' || SQLCODE || ']');
    DBMS_OUTPUT.PUT_LINE('SQLERRM=[' || SQLERRM || ']');
END;
/
SQLCODE=[0]
SQLERRM=[[SUNJESOFT][PL/SQL][GOLDILOCKS]successful completion]
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.42 %TYPE Attribute

Function

When declaring a variable or defining a specific field of RECORD type, it defines the type as same as the column of a specific table or another variable.

Syntax

```
<type attribute> ::=
    <identifier chain> % TYPE
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the declaration section of a PL block.
It can be used only for <data type> section when declaring a variable or a field of a record type.

Syntax Rules and Parameters

- Identifier_chain
  - It is the name of a table column to be referenced or of the existing declared variable (or a field of the variable).

Description

Reference scope

The reference scope according to the referenced object types are as follows.

- When the referenced object is a column of a table
  - It refers to the data type of the column.

    - It does not refer to a constraint (e.g. NOT NULL) of the column.
    - It does not refer to the default initial value of the column.
- When the referenced object is another variable (or a field of a variable)
    - It refers to the data type of the variable (or a field).
    - It refers to a constraint (NOT NULL) of the variable (or a field).
    - It does not refer to the default initial value of the variable (or a field).
- Search order of the referenced target object is as follows.
  1. The name of a variable (or a field)
  2. The name of a column

NOT NULL Constraints Variables References

It does not refer to the initial value when referring to NOT NULL attribute variable, so a new initial value s hould be specified.
Setting an initial value of a field is not supported when using a type attribute for the field of a current rec ord type variable, so NOT NULL type field can not be referenced.

Examples

```
gSQL> DECLARE
  V1 NUMBER(5,2) := 100.01;
  V2 V1%TYPE;
BEGIN
  DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
  DBMS_OUTPUT.PUT_LINE( 'V2 = ' || V2 );
END;
/
V1 = 100.01
V2 =
Anonymous PL block executed.
```

Compatibility

It is not defined in the SQL standard.

28.43 UPDATE Statement Extension

Function

A feature altering a record by using a record type variable is added other than a feature consecutively listi ng the altering target columns of UNDATE statement in PSM.
It stores the result by using a record type variable in UPDATE (searched) RETURNING INTO clause in PSM.

Syntax

```
<update Extension statement : searched> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        <target-list>
        [ WHERE <search condition> ]
        [ <result offset clause> ]
        [ <fetch limit clause> ]
        [ <returning into clause> ]
    ;
<update statement: positioned> ::=
    UPDATE table_name [ [ AS ] alias_name ]
        <Target-List>
        WHERE CURRENT OF cursor_name
    ;
<result offset clause> ::=
    OFFSET skip_count [ ROW ¦ ROWS ]
<fetch limit clause> ::=
      <fetch first clause>
    ¦ <limit clause>
<fetch first clause> ::=
    FETCH [ FIRST ¦ NEXT ] [ row_count ] [ ROW ONLY ¦ ROWS ONLY ]
<limit clause>
    LIMIT { fetch_row_count ¦ offset_row_count, fetch_row_count ¦ ALL }
<returning into clause> ::=
    { RETURN ¦ RETURNING } [ NEW ¦ OLD ] { * ¦ { <value expression> [ [AS] alias_name] } [,
...] } INTO Variable [, ...]
<target-List> ::=
        SET <set clause> [, ...]
```

```
      ¦ SET ROW = <psm_variable>
<set clause> ::=
      column_name = { <value expression> ¦ DEFAULT }
    ¦ ( column_name [, ...] ) = ( { <value expression> ¦ DEFAULT } [, ...] )
    ¦ ( column_name [, ...] ) = ( <query expression> )
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- <PSM_Variable> to be used in UPDATE SET ROW syntax shoould be a variable declared as a record ty pe.
- <Variable> to be used in UPDATE RETURNING INTO syntax does not need to be a record type.
  - However, if a record type is specified, then it can not be used being mixed with other data type v ariables nor can two or more record type variables be listed.

Description

It alters the record or stores the result of RETURNING INTO through a record type variable in PSM.

Examples

```
gSQL> CREATE TABLE T1 (C1 VARCHAR(20), C2 VARCHAR(20));
Table created.
gSQL> INSERT INTO T1 VALUES ('AAA', 'BBB'), ('BBB', 'CCC'), ('CCC', 'DDD');
3 rows created.
gSQL> DECLARE
    v1 t1%ROWTYPE;
    v2 t1%ROWTYPE;
BEGIN
    v1.c1 := '1';
    v1.c2 := '2';
```

```
    UPDATE T1 SET ROW = v1 WHERE c1 = 'AAA' RETURNING * INTO v2;
    DBMS_OUTPUT.PUT_LINE('SQL%ROWCOUNT=' || SQL%ROWCOUNT );
    DBMS_OUTPUT.PUT_LINE('v2.c1=' || v2.c1 || ', v2.c2=' || v2.c2);
END;
/
SQL%ROWCOUNT=1
v2.c1=1, v2.c2=2
Anonymous PL block executed.
gSQL> SELECT * FROM T1 ORDER BY C1;
C1  C2
--- ---
1   2
BBB CCC
CCC DDD
3 rows selected.
```

Compatibility

It is not defined in the SQL standard.

28.44 WHILE LOOP Statement

Function

It performs internal statements during <search condition> returns TRUE value.

Syntax

```
<while loop statement> ::=
    WHILE <search condition>
    LOOP { <SQL procedure statement> ; }... END LOOP [ loop_name ]
    ;
```

Invocation and Access Rules

It can be used only within PSM. (e.g. package, procedure, function)
It can be used only in the body section of a PL block.

Syntax Rules and Parameters

- Search conditions are as follows.
  - It is a conditional expression which continues to circle a while loop.
  - It should finally return a boolean type.

Description

while loop statement performs an internal statement list as long as the evaluation result of <search condit ion> is TRUE.

Examples

```
gSQL> DECLARE
V1 integer := 0;
BEGIN
  WHILE V1 < 10 LOOP
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
    V1 := V1 + 1;
  END LOOP;
END;
/
V1 = 0
V1 = 1
V1 = 2
V1 = 3
V1 = 4
V1 = 5
V1 = 6
V1 = 7
V1 = 8
V1 = 9
Anonymous PL block executed.
```

Compatibility

<while loop statement> statement is defined as <while statement> in the SQL standard.
<while statement> of the SQL standard performs loop statement as DO ... END WHILE, but GOLDILOCKS performs it as LOOP ... END LOOP.

For More Information

Refer to the followings.

- **CONTINUE Statement**
- **EXIT Statement**
- **GOTO Statement**

29.

PSM SQL References

29.1 ALTER FUNCTION

Function

It recompiles a function.

Syntax

```
<alter function statement> ::=
    ALTER FUNCTION function_name COMPILE
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <alter function statement>.

- The owner of that function
- (ALTER PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the function belo ngs
- ALTER ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

- function Name
  - It is the function name to be compiled.
  - It can define the schema to which the function belongs, such as schema_name.func_name. If sch ema_name is omitted, the default schema name of the user performing the statement is used.

Description

It recompiles a specified schema-level function.

Examples

```
gSQL> ALTER FUNCTION FUNC1 COMPILE;
Function altered.
```

Compatibility

It is a statement altering characteristics specified when performing CREATE in the SQL standard, and asta tement recreating a plan of a function in GOLDILOCKS.

Table 29-1 SQL standard compatibility

Feature ID	Description	Compatibility
F381	Extended schema manipulation	O

For More Information

Refer to the followings.

- CREATE FUNCTION
- DROP FUNCTION

29.2 ALTER PACKAGE

Function

It recompiles a package.

Syntax

```
<alter package statement> ::=
    ALTER PACKAGE package_name <package compile clause>
    ;
<package compile clause> ::=
    COMPILE [PACKAGE¦SPECIFICATION¦BODY]
```

Invocation and Access Rules

One of the following privilege is required to perform <alter package statement>.

- The owner of that package
- (ALTER PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package belong s
- ALTER ANY PACKAGE ON DATABASE

Syntax Rules and Parameters

- Package name
  - It is a name of package to be compiled.
  - It can define the schema to which the package belongs, such as schema_name.package_name. If schema_name is omitted, the default schema name of the user performing the statement is used.

- Package compile clause
  - PACKAGE: It recompiles both the specification and the body. (Default)
  - SPECIFICATION: It recompiles only the specification.
  - BODY: It recompiles only the body.

Description

It recompiles the specified package.
The execution code of the compiled package is stored in the plan cache.

Examples

```
ALTER PACKAGE PKG1 COMPILE;
Package altered.
```

```
ALTER PACKAGE PKG1 COMPILE PACKAGE;
Package altered.
```

```
ALTER PACKAGE PKG1 COMPILE BODY;
Package altered.
```

Compatibility

It is ALTER MODULE statement in the SQL standard.

For More Information

Refer to the followings.

- CREATE PACKAGE
- CREATE PACKAGE BODY
- DROP PACKAGE

29.3 ALTER PROCEDURE

Function

It recompiles a procedure.

Syntax

```
<alter procedure statement> ::=
    ALTER PROCEDURE proc_name COMPILE
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <alter procedure statement>.

- The owner of that procedure
- (ALTER PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure bel ongs
- ALTER ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

- Proc Name
  - It is the procedure name to be compiled.
  - It can define the schema to which the procedure belongs, such as schema_name.proc_name. If s chema_name is omitted, the default schema name of the user performing the statement is used.

Description

It recompiles a specified schema-level procedure.

Examples

```
gSQL> CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER )
IS
BEGIN
  INSERT INTO T1 VALUES( A1 );
END;
/
ERR-01000(16409): Warning: Routine definition has compilation errors
ERR-HY000(17032): PSM compilation error :

I1
--
 2
1 row selected.
```

Compatibility

It is a statement altering characteristics specified when performing CREATE in the SQL standard, and asta tement recreating a plan of a procedure in GOLDILOCKS.

Table 29-2 SQL standard compatibility

Feature ID	Description	Compatibility
F381	Extended schema manipulation	O

For More Information

Refer to the followings.

- CREATE PROCEDURE
- DROP PROCEDURE

29.4 CALL Statement

Function

It performs a schema-level procedure or a function.

Syntax

```
<call statement> ::=
    <sql call statement> ¦ <odbc procedure call escape sequence>
    ;
<sql call statement> ::=
    CALL proc_name [ ( value_expr [ , value_expr ] .. ) ]  [ INTO { '?' ¦ { host_param [
indicator_param ] } } ]
<odbc procedure call escape sequence> ::=
    '{' [ ? = ] CALL proc_name [ ( value_expr [ , value_expr ] .. ) ] '}'
```

Invocation and Access Rules

One of the following privilege is required to perform <call statement>.

- The EXECUTE privilege for that procedure
- (EXECUTE PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure belongs
- EXECUTE ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

- proc_name
  - It is a name of a procedure/ function to be executed.
  - It may includes a schema to whichthe procedure belongs such as Schema_name.Proc_name.
- value_expr
  - It expresses an argument value which were transferred to the procedure. It can use a bind param eter such as '?' or ':V1'.

Description

It executes a schema-level SQL procedure or a function by using specified arguments.

A function of <sql call statement> form returns the result value by using a host variable expression or a dy namic bind parameter (?) after INTO clause.

<odbc procedure call escape sequence> form is a standard statement to call PROCEDURE in ODBC/ JDBC, and GOLDILOCKS supports this statement in a server. (It can also be used in a tool such as gsql.) A functi on returns the result value by using assign expressions (? =) at the front.

Examples

Call Procedure

```
gSQL> CREATE OR REPLACE PROCEDURE PROC1
(
  A1 INTEGER
)
IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('A1=' || A1);
END;
/
Procedure created.
gSQL> \var v1 INTEGER;
gSQL> \exec :v1 := 123;
gSQL> CALL PROC1(:v1);
A1=123
Procedure Call complete.
```

Call Function

```
CREATE OR REPLACE FUNCTION FUNC1
(
  A1 INTEGER
)
RETURN INTEGER
```

```
IS
BEGIN
    return A1;
END;
/
Function created.
gSQL> \var v1 INTEGER;
gSQL> \var v2 INTEGER;
gSQL> \exec :v1 := 123;
gSQL> CALL FUNC1(:v1) INTO :v2;
Procedure Call complete.
gSQL> \print v2;
 V2
---
123
```

Compatibility

The SQL standard allows only the call for a PROCEDURE, so it does not define below [INTO] clause.

29.5 CREATE FUNCTION

Function

It defines a schema-level function.

Syntax

```
<create function statement> ::=
    CREATE [ OR REPLACE ] FUNCTION <function name> [ ( <parameter list> ) ]
       <return clause>
       [ <function characteristics> ]
       { IS ¦ AS }
       <item declaration>
       BEGIN
       <pl statement list>
       END [ <function name> ]
    ;
<parameter list> ::=
      <parameter name> [ <parameter mode> ] <datatype> [ <parameter default> ] [ , ... ]

<parameter mode> ::=
      IN
    ¦ OUT
    ¦ IN OUT

<parameter default> ::=
      { := ¦ DEFAULT } <value expression>

<return clause> ::=
      RETURN <datatype>
    ¦ RETURN TABLE ( <table function column list> )

<table function column list> ::=
      <column name> <datatype> [ , ... ]

<function characteristics> ::=
```

```
    DETERMINISTIC
  ¦ AUTHID CURRENT_USER
  ¦ AUTHID DEFINER
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <create function statement>.

- One of the following privileges is required to create a function.
  - (CREATE PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the functio n belongs
  - CREATE ANY PROCEDURE ON DATABASE
- If a function already exists when using OR REPLACE clause, then one of the following privileges drop ping the existing function is required.
  - The owner of that function
  - (DROP PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the function b elongs
  - DROP ANY PROCEDURE ON DATABASE
- The user who performed the statement becomes the owner of the created function.

Syntax Rules and Parameters

OR REPLACE

It replaces an existing function with a new function when the function already exists.

function name

It is a name of function to be created, and it should be a unique name in a schema.
It can define the schema to which the function belongs, such as schema_name.function_name. If schema _name is omitted, the default schema name of the user performing the statement is used.
The length of a function name should be shorter than 128 bytes.

parameter name

It defines a parameter name of the function.
The name of each parameter should be unique in a function.
In other words, the function's parameter and PL item can not have the same name.

The length of a parameter name should be shorter than 128 bytes.
The maximum number of parameters available in a single function is limitless.

parameter mode

It sets each parameter mode.
The parameter modes are IN, OUT, and IN OUT.
If the parameter mode is not specified, the default mode is *IN*.

parameter default

It is the default value of the parameter.
The parameter with the specified parameter default can be omitted when executing the function.
If the parameter is not specified but omitted, then the default value is <value expression> specified when defining the parameter.
The datatype of <value expression> should be the datatype of the parameter.
All parameters defined after the parameter having <parameter default> should have <parameter default>.

return clause

It defines the return type of the function.
It is defined as follows in <return clause>.

- RETURN <datatype>
  - It defines the datatype of the return value returned by the function.
- RETURN TABLE (<table function column list>)
  - It defines the table type of the returned result set.

table function column list

It is the column name of the result set returned by the table function.
The length of a column name should be shorter than 128 bytes.
The number of columns are limitless.
Each column name is unique in <table function column list>.
The column name can be as same as the parameter name and the declare item name.
The column defined in <table function column list> can not be referenced in PL block of the function.

function characteristics

It defines options to perform a function. It should be specified only once per a single item.

- DETERMINISTIC: The function always returns the same result value when the same argument values a re input.
- AUTHID CURRENT_USER: SQLs which are being performed during performing a function are interpre ted and performed according to an authorization of an invoker.
- AUTHID DEFINER: SQLs which are being performed during performing a function are interpreted and performed according to an authorization of a definer.

Item Declaration

It declares items such as a local variable to be used within a function.
It can declare all items which can be declared in a PL block.

PL Stmt List

It is a body section of a function, and it lists PL statements to be performed.
It can not use a bind parameter such as '?' or ':V1'. within a function.

Description

It defines a schema-level SQL function. The created fucntion can be called from all expressions.

The definition of a function can be viewed in ROUTINES table of INFORMATION_SCHEMA. The definition of a function parameter can be viewed in PARAMETERS table of INFORMATION_SCHEMA.

If a function becomes temporarily unstable due to absences of related objects, then it can try to recreate a plan by using **ALTER FUNCTION** statement.

The created function can be dropped by using **DROP FUNCTION** statement.
The maximum number of functions to be created is not limited. Therefore, they can be created as many a s the storage space is available.

Examples

```
gSQL> CREATE OR REPLACE FUNCTION FUNC1( A1 INTEGER, A2 INTEGER )
  RETURN INTEGER
  IS
    V1 INTEGER;
  BEGIN
    SELECT COUNT(*)
      INTO V1
      FROM T1
      WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    RETURN V1;
  END;
  /
Function created.
```

Compatibility

The SQL standard does not define OR REPLACE clause.

Table 29-3 SQL standard compatibility

For More Information

Refer to the followings.

- DROP FUNCTION
- ALTER FUNCTION

29.6 CREATE PACKAGE

Function

It defines the spec about public items to be used in a package.

Syntax

```
<create package statement> ::=
    CREATE [ OR REPLACE ]
        PACKAGE package_name
        [ <package_characteristics> ]
        { IS ¦ AS }
       <item_declaration>
    END
    ;
<package_characteristics> ::=
    AUTHID CURRENT_USER ¦ AUTHID DEFINER
<item_declaration> ::=    <variable declaration>
                        ¦ <cursor declaration>
                        ¦ <user-defined type declaration>
                        ¦ <function declaration>
                        ¦ <procedure declaration>
                        ¦ <user exception declaration>
                        ¦ <cursor definition>
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <create package statement>.

- One of the following privileges is required to create a package.
  - (CREATE PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package b elongs
  - CREATE ANY PACKAGE ON DATABASE
- If a package already exists when using OR REPLACE clause, then one of the following privileges drop ping the existing package is required.

    - The owner of that package
    - (DROP PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package bel ongs
- The user who performed the statement becomes the owner of the created package.

Syntax Rules and Parameters

OR REPLACE

It replaces an existing package specification when the package already exists.

PACKAGE NAME

It is a name of package to be created, and it should be a unique name in a schema.
It can define the schema to which the package belongs, such as schema_name.package_name. If schema _name is omitted, the default schema name of the user performing the statement is used.
The length of a package name should be shorter than 128 bytes.

Package Characteristics

It defines options to perform a package. It should be specified only once per a single item.

- AUTHID CURRENT_USER: SQLs which are being performed during performing items in a package are interpreted and performed according to an authorization of an invoker.
- AUTHID DEFINER: SQLs which are being performed during performing items in a package are interpr eted and performed according to an authorization of a definer.

Item Declaration

It declares a public variable, a type cursor, a cursor variable, a function spec, and a procedure spec which are accessible from out of the package.
A function and a procedure in the package should be defined through *create package body* statement.
The cursor which was declared in a package without SQL should be defined through *create package bod y* statement.
Also, a function, a procedure, an argument of a cursor and the returning type in a package should be as s ame as those defined in a body statement.

Description

It creates the schema-level package specification.
All public items in the created package can be referred by another procedure/ function/ package/ anony mous block.

The information about package creation can be viewed in MODULES table in DEFINITION_SCHEMA or IN FORMATION_SCHEMA.
The list of each public procedure/ function in the package can be viewed in ROUTINES table in DEFINITIO N_SCHEMA or INFORMATION_SCHEMA.
The definition about parameters of each public procedure/ function in the package can be viewed in PAR AMETERS table in DEFINITION_SCHEMA or INFORMATION_SCHEMA.
Private procedure/ function can be viewed in MODULE_BODY table.
If the information about objects referred by a procedure/ function/ variable in the package are temporaril y unstable, try to recompile it by using <alter package> statement.

Examples

```
CREATE OR REPLACE PACKAGE PKG1
IS
  V1 INTEGER;
  PROCEDURE PROC1;
  FUNCTION FUNC1 RETURN INTEGER;
END;
/
Package created.
```

Compatibility

It is CREATE MODULE statement in the SQL standard.

For More Information

Refer to the followings,

- CREATE PACKAGE BODY

- DROP PACKAGE
- ALTER PACKAGE

29.7 CREATE PACKAGE BODY

Function

It creates the definition about procedure/ function/ cursors to be used in the package.

Syntax

```
<create package body statement> ::=
    CREATE [ OR REPLACE ] PACKAGE BODY package_name
    { IS ¦ AS }
       <item_declaration>
       <cursor_definition>
       <routine_definition>
    [ BEGIN <initialization part> ]
    END
    ;
<item_declaration> ::=    VARIABLE_DECLARATION
                        ¦ CURSOR_DECLARATION
                        ¦ USER_DEFINED_TYPE_DEFINITION
                        ¦ FUNCTION_DECLARATION
                        ¦ PROCEDURE_DECLARATION
                        ¦ USER_EXCEPTION_DECLARATION
<routine_definition> ::= FUNCTION_DEFINITION
                       ¦ PROCEDURE_DEFINITION
<initialization part> ::= <pl_stmt_list>
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <create package body statement>.

- One of the following privileges is required to create a package body.
  - (CREATE PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package b elongs
  - CREATE ANY PACKAGE ON DATABASE
- The package spec should be defined in advance.

- If a package body already exists when using OR REPLACE clause, then one of the following privileges dropping the existing package is required.
  - The owner of that package
  - (DROP PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package bel ongs
  - DROP ANY PACKAGE ON DATABASE
- The user who performed the statement becomes the owner of the created package.

Syntax Rules and Parameters

OR REPLACE

It replaces an existing package body definition when the package body already exists.

PACKAGE NAME

It is a name of package body to be created, and the name as same as the name used in creating a packag e spec should be used. It should be a unique name in a schema.
It can define the schema to which the package belongs, such as schema_name.package_name. If schema _name is omitted, the default schema name of the user performing the statement is used.
The length of a package name should be shorter than 128 bytes.

Item Declaration

It declares PSM identifiers (variable, type, cursor, function spec, procedure spec, exception) to be used in a package body.
Routines declared in a package spec should be defined in a package body.
The cursor which was declared in a package spec without SQL should be defined in a package body.
Also, a function, a procedure, an argument of a cursor and the returning type in a package should be as s ame as those defined in a body statement.

Initialization Part

It describes statements which are performed only once to initialize internal variables while creating a pack age instance.

Description

It creates the schema-level package specification.
All public items in the created package can be referred by another procedure/ function/ package/ anony mous block.

The information about package body creation can be viewed in MODULES_BODY table in DEFINITION_SC HEMA or INFORMATION_SCHEMA.
The list of each private items in a package body can not be viewed in DEFINITION_SCHEMA or INFORMAT ION_SCHEMA.
If the information about objects referred by a procedure/ function/ variable in the package are temporaril y unstable, try to recompile it by using <alter package body> statement.

The created package body can be dropped by using <drop package> or <drop package body> statement.

Examples

```
CREATE OR REPLACE PACKAGE PKG1
IS
  V1 INTEGER;
  PROCEDURE PROC1;
  FUNCTION FUNC1 RETURN INTEGER;
END;
/
Package created.
CREATE OR REPLACE PACKAGE BODY PKG1
IS
  FUNCTION FUNC1 RETURN INTEGER
  IS
  BEGIN
      RETURN V1;
  END;
  PROCEDURE PROC1
  IS
  BEGIN
      IF V1 IS NULL
      THEN
          V1 := 10;
      ELSE
```

```
          V1 := V1 + 10;
      END IF;
  END;
END;
/
Package created.
```

Compatibility

The SQL standard does not define it.

For More Information

Refer to the followings.

- CREATE PACKAGE
- DROP PACKAGE
- ALTER PACKAGE

29.8 CREATE PROCEDURE

Function

It defines a schema-level procedure.

Syntax

```
<create procedure statement> ::=
      CREATE [ OR REPLACE ] PROCEDURE <procedure name> [ ( <parameter list> ) ]
      { IS ¦ AS }
      <item declaration>
      BEGIN
      <pl statement list>
      END [ <procedure name> ]
      ;

<parameter list> ::=
      <parameter name> [ <parameter mode> ] <datatype> [ <parameter default> ] [ , ... ]
<parameter mode> ::=
      IN
    ¦ OUT
    ¦ IN OUT

<parameter default> ::=
      { := ¦ DEFAULT } <value expression>
<procedure characteristics> ::=
      AUTHID CURRENT_USER
    ¦ AUTHID DEFINER
```

Invocation and Access Rules

The user should satisfy the following conditions to perform <create procedure statement>.

- One of the following privileges is required to create a procedure.

    - (CREATE PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure belongs
    - CREATE ANY PROCEDURE ON DATABASE
- If a procedure already exists when using OR REPLACE clause, then one of the following privileges dropping the existing procedure is required.
    - The owner of that procedure
    - (DROP PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure belongs
    - DROP ANY PROCEDURE ON DATABASE
- The user who performed the statement becomes the owner of the created procedure.

Syntax Rules and Parameters

OR REPLACE

It replaces an existing procedure with a new function when the procedure already exists.

procedure name

It is a name of procedure to be created, and it should be a unique name in a schema.
It can define the schema to which the procedure belongs, such as schema_name.procedure_name. If schema_name is omitted, the default schema name of the user performing the statement is used.
The length of a procedure name should be shorter than 128 bytes.

parameter name

It defines a parameter name of the procedure.
The name of each parameter should be unique in a procedure.
In other words, the procedure's parameter and PL item can not have the same name.
The length of a parameter name should be shorter than 128 bytes.
The maximum number of parameters available in a single procedure is limitless.

parameter mode

It sets each parameter mode.
The parameter modes are IN, OUT, and IN OUT.
If the parameter mode is not specified, the default mode is *IN*.

parameter default

It is the default value of the parameter.
The parameter with the specified parameter default can be omitted when executing the procedure.
If the parameter is not specified but omitted, then the default value is <value expression> specified when defining the parameter.
The datatype of <value expression> should be the datatype of the parameter.
All parameters defined after the parameter having <parameter default> should have <parameter default>.

procedure characteristics

It defines options to perform a procedure. It should be specified only once per a single item.

- AUTHID CURRENT_USER: SQLs which are being performed during performing a procedure are interp reted and performed according to an authorization of an invoker.
- AUTHID DEFINER: SQLs which are being performed during performing a procedure are interpreted a nd performed according to an authorization of a definer.

Item Declaration

It declares items such as a local variable to be used within a procedure.
It can declare all items which can be declared in a PL block.

PL Stmt List

It is a body section of a procedure, and it lists PL statements to be performed.
It can not use a bind parameter such as '?' or ':V1'. within a procedure.

Description

It defines a schema-level SQL procedure. The created procedure can be called from CALL statement, anon ymous block, or other procedure/ function.

The definition of a procedure can be viewed in ROUTINES table of INFORMATION_SCHEMA. The definitio n of a procedure parameter can be viewed in PARAMETERS table of INFORMATION_SCHEMA.

If a procedure becomes temporarily unstable due to absences of related objects, then it can try to recreat e a plan by using **ALTER PROCEDURE** statement.

The created procedure can be dropped by using **DROP PROCEDURE** statement.
The maximum number of procedures to be created is not limited. Therefore, they can be created as many as the storage space is available.

Examples

```
gSQL> CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 INTEGER )
  IS
    V1 INTEGER;
  BEGIN
    SELECT COUNT(*)
      INTO V1
      FROM T1
      WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
  END;
  /
Procedure created.
```

Compatibility

The SQL standard does not define the following clauses.

Table 29-4 SQL standard compatibility

For More Information

Refer to the followings.

- DROP PROCEDURE
- ALTER PROCEDURE

29.9 DROP FUNCTION

Function

It drops a function.

Syntax

```
<drop function statement> ::=
    DROP FUNCTION [ IF EXISTS ] func_name
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <drop function statement>.

- The owner of that function
- (DROP PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the function belo ngs
- DROP ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the function does not exist, an error does not occur.

FUNC NAME

It is the function name to be dropped.
It can define the schema to which the function belongs, such as schema_name.func_name. If schema_na me is omitted, the default schema name of the user performing the statement is used.

Description

It drops a specified schema-level function.

Examples

```
gSQL> CREATE OR REPLACE FUNCTION FUNC1
RETURN INTEGER
 IS
    V1 INTEGER;
  BEGIN
    V1 := 10;
    RETURN V1;
  END;
  /
Function created.
COMMIT;
Commit complete.
gSQL> DROP FUNCTION FUNC1;
Function dropped.
```

Compatibility

The SQL standard does not define the following clauses.

Table 29-5 SQL standard compatibility

Feature ID	Description	Compatibility
F032	CASCADE drop behavior	X
S024	Enhanced structured types	X

For More Information

Refer to the followings.

- CREATE FUNCTION

- ALTER FUNCTION

29.10 DROP PACKAGE

Function

It drops a package (of only body or both spec/ body).

Syntax

```
<drop package statement> ::=
    DROP PACKAGE [BODY] [ IF EXISTS ] package_name
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <drop package statement>.

- The owner of that package
- (DROP PACKAGE or CONTROL SCHEMA) ON SCHEMA for the schema to which the package belongs
- DROP ANY PACKAGE ON DATABASE

Syntax Rules and Parameters

BODY

It drops only the body object in the package of the given name. If the keyword *BODY* is not specified it dr ops both the package specification and the body.

IF EXISTS

Even when the package does not exist, an error does not occur.

PACKAGE NAME

It is the package name to be dropped.
It can define the schema to which the package belongs, such as schema_name.package_name. If schema _name is omitted, the default schema name of the user performing the statement is used.

Description

It drops the specified package object.

Examples

```
CREATE PACKAGE PKG1
  IS
    V1 INTEGER;
    FUNCTION FUNC1 (A1 INTEGER) RETURN INTEGER;
  END;
  /
Package created.
DROP PACKAGE IF EXISTS PKG1;
Package dropped.
```

Compatibility

It is DRO MODULE statement in the SQL standard.

For More Information

Refer to the followings.

- CREATE PACKAGE
- CREATE PACKAGE BODY
- ALTER PACKAGE

29.11 DROP PROCEDURE

Function

It drops a procedure.

Syntax

```
<drop procedure statement> ::=
    DROP PROCEDURE [ IF EXISTS ] proc_name
    ;
```

Invocation and Access Rules

One of the following privilege is required to perform <drop procedure statement>.

- The owner of that procedure
- (DROP PROCEDURE or CONTROL SCHEMA) ON SCHEMA for the schema to which the procedure bel ongs
- DROP ANY PROCEDURE ON DATABASE

Syntax Rules and Parameters

IF EXISTS

Even when the procedure does not exist, an error does not occur.

PROC NAME

It is the procedure name to be dropped.
It can define the schema to which the procedure belongs, such as schema_name.proc_name. If schema_ name is omitted, the default schema name of the user performing the statement is used.

Description

It drops a specified schema-level procedure.

Examples

```
gSQL> CREATE OR REPLACE PROCEDURE PROC1( A1 INTEGER, A2 INTEGER )
  IS
    V1 INTEGER;
  BEGIN
    SELECT COUNT(*)
      INTO V1
      FROM T1
      WHERE T1.I1 >= A1 AND T1.I1 <= A2;
    DBMS_OUTPUT.PUT_LINE( 'V1 = ' || V1 );
  END;
  /
Procedure created.
COMMIT;
Commit complete.
gSQL> DROP PROCEDURE PROC1;
Procedure dropped.
```

Compatibility

The SQL standard does not define the following clauses.

Table 29-6 SQL standard compatibility

Feature ID	Description	Compatibility
F032	CASCADE drop behavior	X
S024	Enhanced structured types	X

For More Information

Refer to the followings.

- CREATE PROCEDURE
- ALTER PROCEDURE

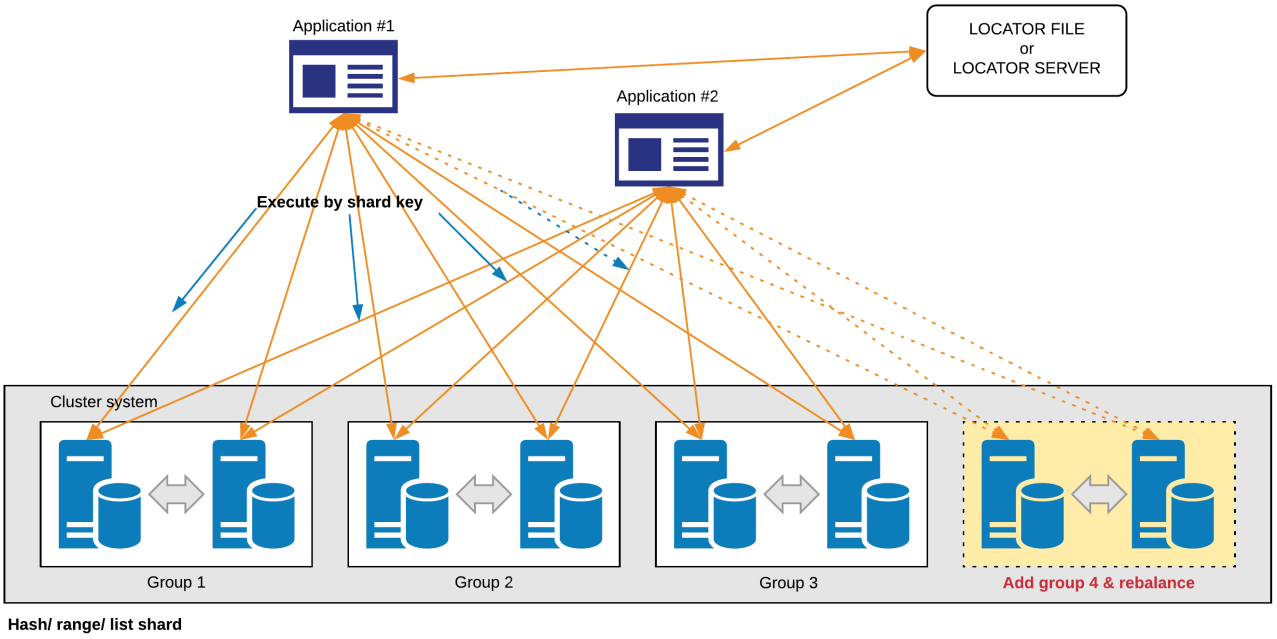
Database Connection

30.1 Features

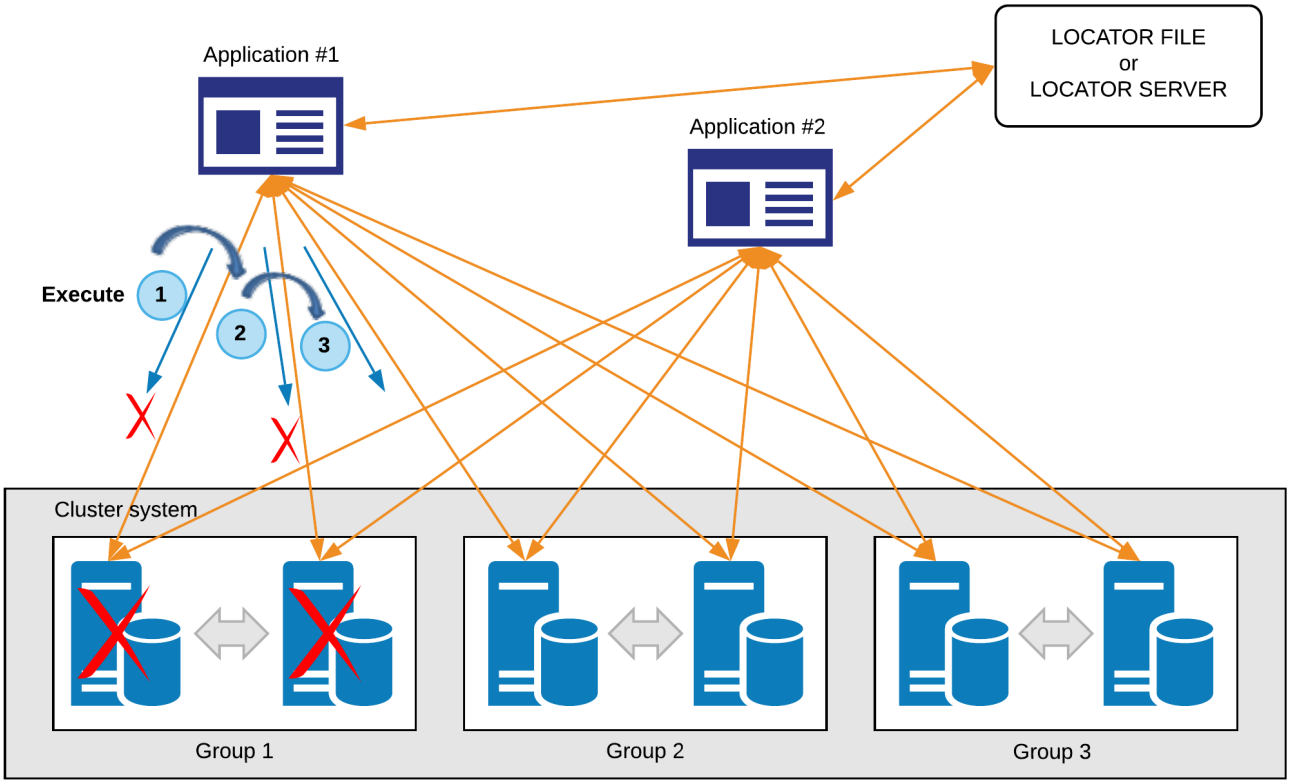
Figure 1 GLOBAL CONNECTION



Global connection feature is a method of optimizing transaction performance in consideration of data loc ality.
A general connection is a connection with a single member, but global connection is a connection with al l members. An application using the global connection makes the member with most data accessed by q ueries perform the query, so the performance is upgraded.
Hash, range, list sharding method can use the global connection, and the application does not need to b e altered at that moment.

When the online scale-out is performed, a user does not need to consider a new node but the the applica tion automatically connects to a new node and operates it.

Figure 2 GLOBAL CONNECTION HA (high availability)



If an error occurs on the selected node when performing SQL, then the SQL is performed through another node in the same group. If errors occur on all nodes in the selected group, then the SQL is performed through another group.

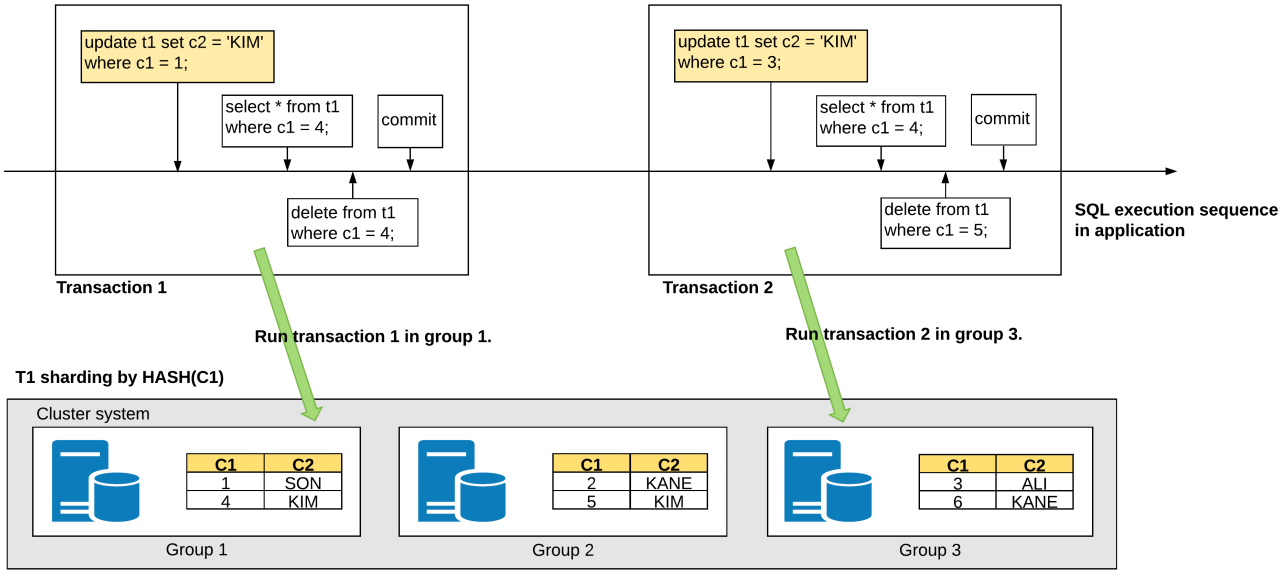
When a node is recovered from an error, the it is automatically connected to the node again online. Moreover, a user can make an application connect again by using the following syntax.

```
ALTER SYSTEM RECONNECT GLOBAL CONNECTION
```

30.2 Selecting Execution Member

An execution member is selected per transaction. When DML query is first performed without a transaction, a group is selected according to the sharding key, and an execution member in the group is selected according to LOCALITY_MEMBER_POLICY property. Then, all queries are processed in the selected member until COMMIT or ROLLBACK. If the first query can not select the appropriate group according to a sharding key, then the group is selected according to LOCALITY_GROUP_POLICY property.

Figure 3 Selecting a member

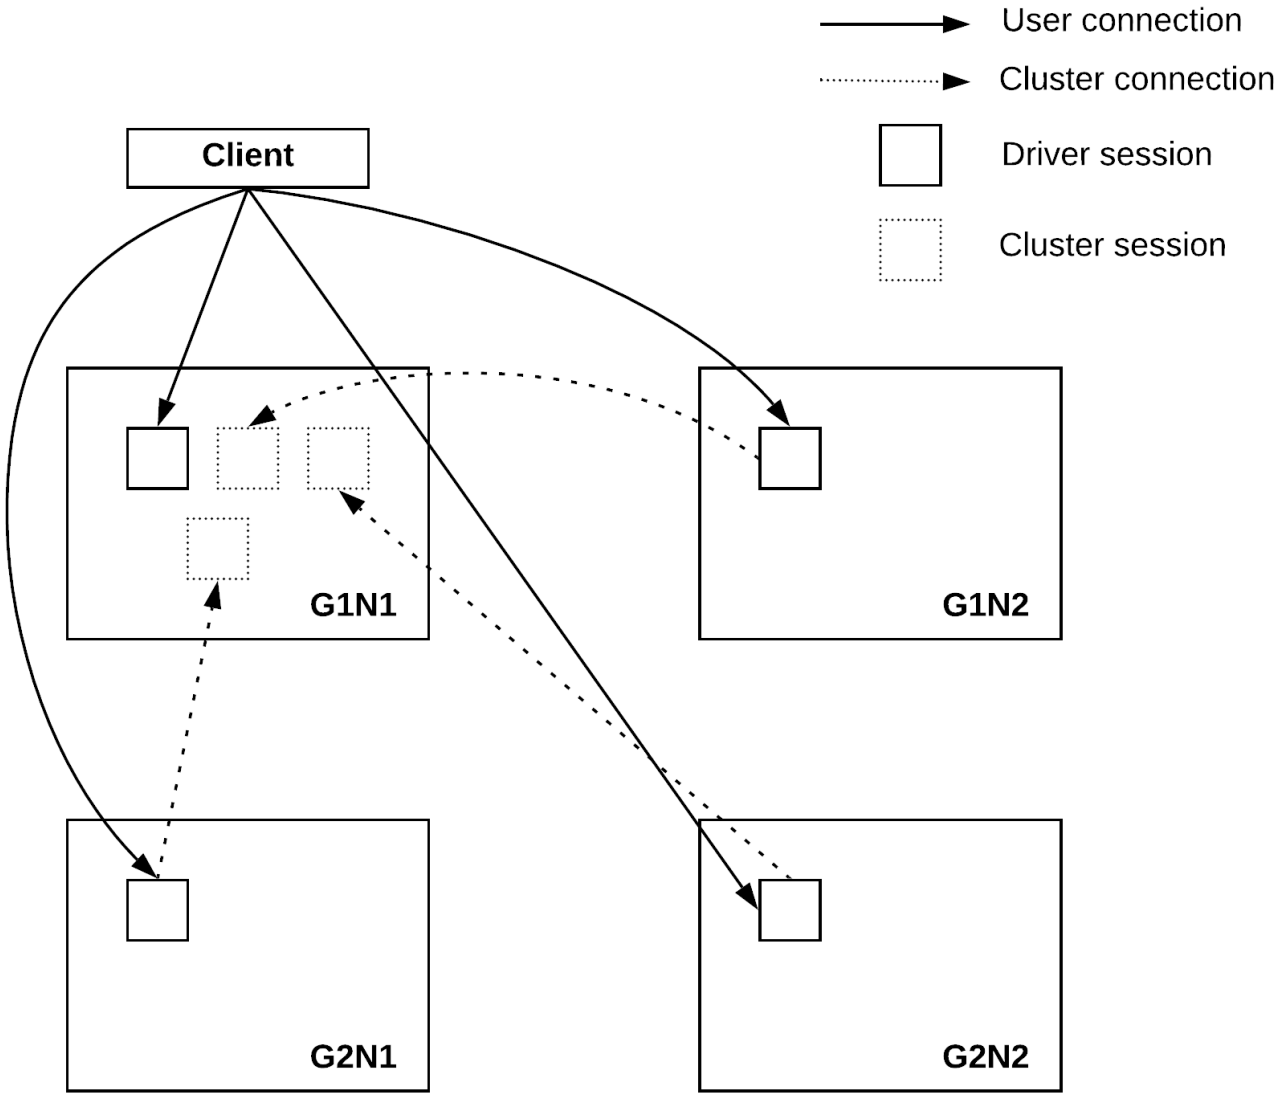


In case of transaction1 in the figure above, UPDATE query is performed in the group1 according to the sharding key, so all queries between COMMITs are performed in group1. In case of transaction2, UPDATE query is performed in group3, and all queries are performed in group3 before COMMIT even when further queries are not appropriate to perform in group3.

The read-only query (SELECT) without a transaction selects an execution member according to a sharding key like as other queries, but further queries are not always performed in the previously selected member.
In other words, all queries included in a transaction is performed only in a single member, but a query irrelevant to a transaction selects a member per a member.

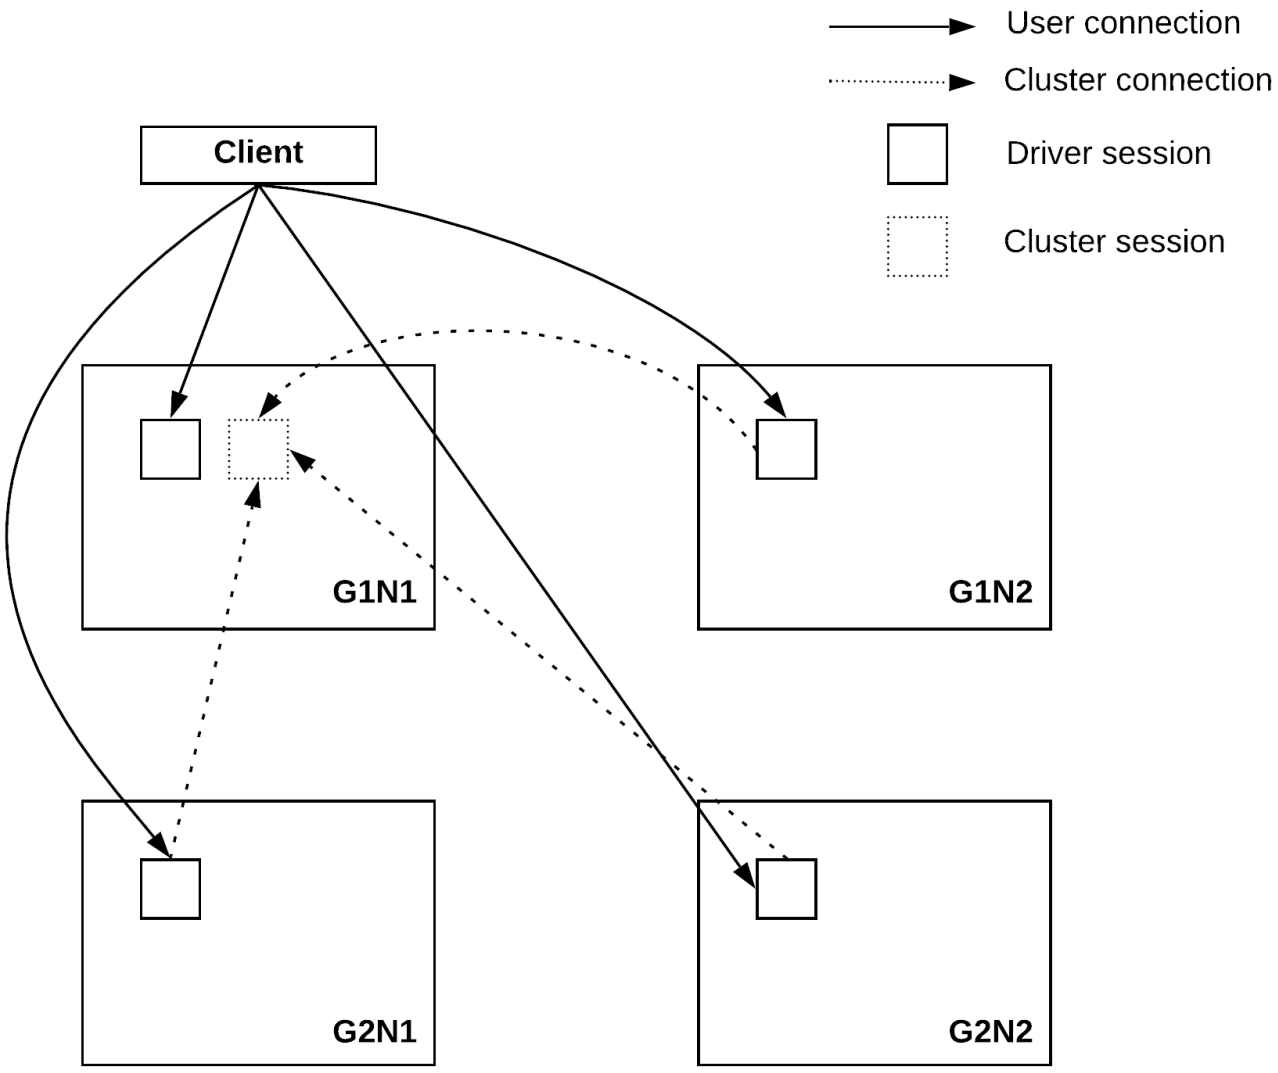
30.3 Global Session

Figure 4 Cluster session derived from global connection



The session directly connected to an application is called as a driver session, and a session from a driver se ssion to another member is called as a cluster session. Global connection creates a driver session in all me mbers, and creates cluster sessions in another member when it is needed. Global connection can make m ultiple cluster sessions in a single member.

Figure 5 Global session



Global session is a feature for a cluster sessions created in the global connection shares a single session to improve the resource efficiency. When the global connection does not use a global session, then the clust er session increases according to increasing groups and members. However, when it uses the global sessi on, then the cluster session does not increase even when groups and members increase.

The global session feature is available only in the global connection, but it is not available in the general c onnection.

30.4 Constraints

When using the global connection, a session dependent object is not available in SQL statement, a sessio n dependent clause nor is a session dependent function available.

Also, if SQLs accessing to multiple cluster nodes exist in a single transaction, then SQLs in the transaction uses the cluster node in common which were selected by the sharding key of the first SQL.

The query in the global connection is performed in consideration of data locality only when it is performe d with prepare execute. However, it is performed in an arbitrary node when it is performed with direct ex ecute.

Session Dependent Object

When using a session dependent object in SQL statement, the global connection is not available.

- Global temporary table

Session Dependent Clause

When using a session dependent clause in SQL statement, the global connection is not available.

- All @domain-related statements

Session Dependent Function and Pseudo Column

When using session dependent information in SQL statement, the global connection is not available.

- CURRVAL(sequence), sequence.CURRVAL
- UUID()
- VERSION()
- SESSION_ID()
- SESSION_SERIAL()
- USER_ID()
- LAST_IDENTITY_VALUE()
- STATEMENT_VIEW_SCN()
- STATEMENT_VIEW_SCN_GCN()
- STATEMENT_VIEW_SCN_DCN()
- STATEMENT_VIEW_SCN_LCN()
- LOCAL_GROUP_ID()
- LOCAL_MEMBER_ID()
- LOCAL_GROUP_NAME()

- LOCAL_MEMBER_NAME()
- CLUSTER_GROUP_ID
- CLUSTER_GROUP_NAME
- CLUSTER_MEMBER_ID
- CLUSTER_MEMBER_NAME
- CLUSTER_SHARD_ID

When Using Global Session

Data Definition Language (DDL) is not available in SQL statement.

30.5 Settings

For more information, refer to the followings.

- **Setting global connection in ODBC**
- **Setting global connection in JDBC**

31.

ODBC

31.1 Overview of GOLDILOCKS ODBC Driver

Concepts of GOLDILOCKS ODBC Driver

Open Database Connectivity (ODBC) is a specifications for a database Application Programming Interface (API). Microsoft ODBC version 3.0 is based on International Standards Organization/ International Electro mechanical Commission (ISO/ IEC) and the recommended specifications of Call Level Interface (CLI) of X/ open. ODBC supports the SQL statements by using C library functions. The application implements the O DBC features by calling these functions.

ODBC architecture has four components which perform the following features.

Component	Description
Application	It calls ODBC function which communicated with an ODBC data source and sends an SQL statement and processes the result set.
Driver manager	It manages the communication between an application and all ODBC drivers which ar e used by the application.
Driver	It processes all ODBC calls from applications, and connects to data source, and submit s the SQL statement to the data source in the application, and returns results to the a pplication. If necessary, the driver converts the ODBC SQL sent form the application to the default SQL which is used in the data source.
Data source	It includes all information which the driver needs to access the data in the DBMS.

The following operations can be executed by using ODBC applications.

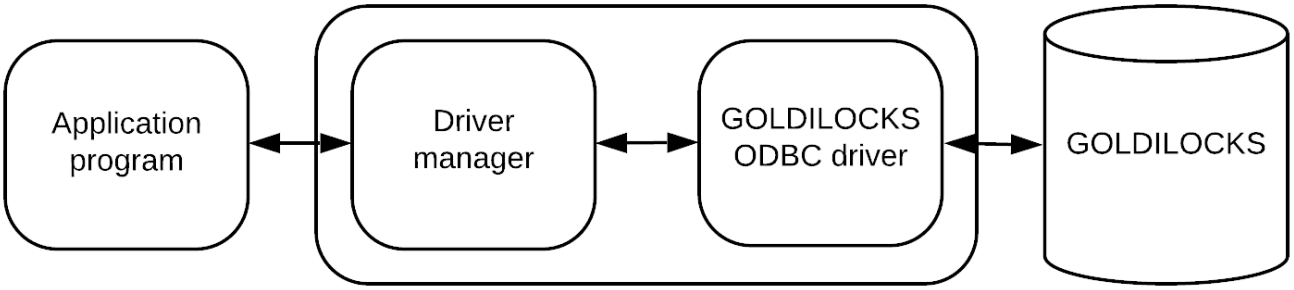
- Connecting to a data source
- Sending SQL statements to the data source
- Processing the results of an SQL statement in the data source
- Handling errors and messages
- Terminating the connection to the data source

Overview of ODBC Components

GOLDILOCKS ODBC Driver Including Driver Manager

The following is a software architecture of when the driver manager is included in the system. In this case, the application should be linked to the driver manager library.

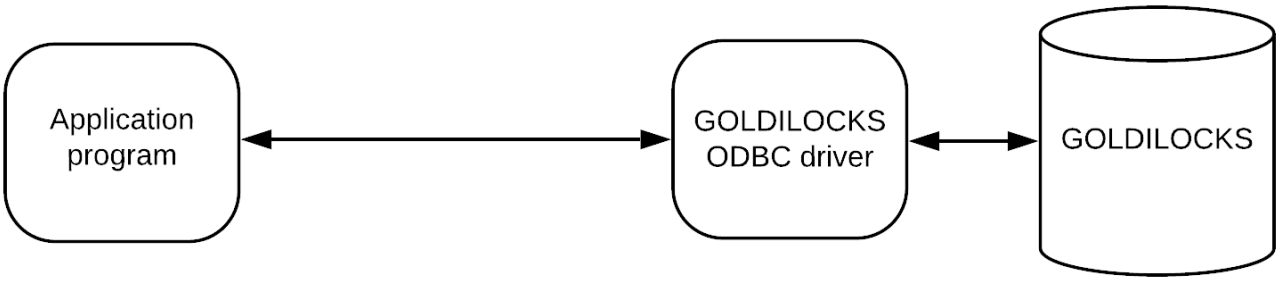
Figure 1 GOLDILOCKS ODBC driver including the driver manager



GOLDILOCKS ODBC Driver Not Including Driver Manager

The following is an architecture of when the application does not include a driver manager and uses GOL DILOCKS ODBC driver. In this case, the application should be linked to GOLDILOCKS ODBC driver library.

Figure 2 GOLDILOCKS ODBC driver not including the driver manager



Using GOLDILOCKS ODBC Driver

Header File

goldilocks.h file installed on $GOLDILOCKS_HOME/include should be included to execute GOLDILOCKS ODBC driver. This file defines constant and type of GOLDILOCKS ODBC driver, and provides a function pr ototype of GOLDILOCKS ODBC driver function.

Library

The application which does not use a driver manager should be linked to a static or shared version of GO LDILOCKS ODBC driver library.

UNIX

Table 31-1 GOLDILOCKS UNIX ODBC driver libraries

File name	Description
libgoldilocks.a	It is a static version of library including DA and CS.
libgoldilocksa.a	It is a static version of DA dedicated library.
libgoldilocksas.so	It is a shared version of DA dedicated library.
libgoldilocksc.a	It is a static version of CS dedicated library.
libgoldilockscs-ul32.so	It is a shared version of 64-bit CS dedicated library recognizing SQLLEN to 4 bytes.
libgoldilockscs-ul64.so	It is a shared version of 64-bit CS dedicated library recognizing SQLLEN to 8 bytes.
libgoldilockscs.so	It is a shared version of 32-bit CS dedicated library.
libgoldilockss.so	It is a shared version of library including DA and CS.

Windows

GOLDILOCKS Windows ODBC driver libraries provide CS libraries only.

Table 31-2 GOLDILOCKS Windows ODBC driver libraries

File name	Description
goldilockscs-ul64.dll	It is a shared version of 64-bit CS dedicated library recognizing SQLLEN to 8 bytes.
goldilockscs.dll	It is a shared version of 32-bit CS dedicated library.
goldilockssetup32.dll	It is a setup library for 32-bit ODBC driver manager.
goldilockssetup64.dll	It is a setup library for 64-bit ODBC driver manager.

31.2 Data Source Configuration

DSN Configuration on UNIX

odbcinst.ini File

odbcinst.ini file is a configuration file for installed ODBC driver.

- unixODBC

```
% odbcinst -j
unixODBC 2.3.2
DRIVERS............: /etc/odbcinst.ini
SYSTEM DATA SOURCES: /etc/odbc.ini
FILE DATA SOURCES..: /etc/ODBCDataSources
USER DATA SOURCES..: /home/goldilocks/.odbc.ini
SQLULEN Size.......: 8
SQLLEN Size........: 8
SQLSETPOSIROW Size.: 8
```

- iODBC

```
% iodbc-config --odbcinstini
/etc/odbcinst.ini
```

ODBC Driver Specification

ODBC driver specification section in odbcinst.ini file specifies the driver property values and list. The regist ered information section is under the driver name in each driver installed.

```
[driver_name]
Description = driver_description
Driver = driver_library_path
Setup = setup_library_path
FileUsage = file_usage
```

The following table describes keywords in the driver specification section.

Keyword	Description
Description	It is a string which describes the driver.

Keyword	Description
Driver	It is a driver library path.
Setup	It is a setup library path.
FileUsage	It is a character which displays how to directly process the file in DSN by the file-based driver.

The following is an example of information of GOLDILOCKS ODBC driver specifications.

```
[GOLDILOCKS ODBC Driver]
Description= GOLDILOCKS ODBC Driver
Driver = /home/goldilocks/home/lib/libgoldilockscs-ul64.so
Setup = /home/goldilocks/home/lib/libgoldilockscs-ul64.so
FileUsage = 0
```

odbc.ini File

odbc.ini file is the configuration file for the DSN connected by the application, and it is divided into a user DSN and system DSN. Typically, a user DSN file is ~ / .odbc.ini file, and a system DSN file is /etc/odbc.ini.

- unixODBC

```
% odbcinst -j
unixODBC 2.3.4
DRIVERS............: /etc/odbcinst.ini
SYSTEM DATA SOURCES: /etc/odbc.ini
FILE DATA SOURCES..: /etc/ODBCDataSources
USER DATA SOURCES..: /home/goldilocks/.odbc.ini
SQLULEN Size.......: 8
SQLLEN Size........: 8
SQLSETPOSIROW Size.: 8
```

- iODBC

```
% iodbc-config --odbcini
/etc/odbc.ini
```

Data Source Specification

Data source specification section of the odbc.ini file describes DSN.

```
[data_source_name]
Driver = driver_name
PROTOCOL = {DA ¦ TCP ¦ IPC}
```

```
CS_MODE = {default ¦ dedicated ¦ shared}
HOST = host_address
PORT = port_no
PREFER_IPV6 = {0 ¦ 1}
CHARSET = {SQL_ASCII ¦ UTF8 ¦ UHC ¦ GB18030}
TCP_NODELAY = {0 ¦ 1}
ALTERNATE_SERVERS = (HOST=ADDRESS1:PORT=PORT1,HOST=ADDRESS2:PORT=PORT2)
CONNECTION_RETRY_COUNT = retry_count
CONNECTION_RETRY_DELAY = retry_delay
FAILOVER_TYPE = {CONNECTION ¦ SESSION}
FAILOVER_GRANULARITY = {0 ¦ 1 ¦ 2}
FAILOVER_ROUTING_POLICY = {0 ¦ 1}
DATE_FORMAT = date_format_string
TIME_FORMAT = time_format_string
TIME_WITH_TIME_ZONE_FORMAT = timetz_format_string
TIMESTAMP_FORMAT = timestamp_format_string
TIMESTAMP_WITH_TIME_ZONE_FORMAT = timestamptz_format_string
CHAR_LENGTH_UNITS = {BYTE ¦ OCTETS ¦ CHAR ¦ CHARACTERS}
ENABLE_SQLDESCRIBEPARAM = {0 ¦ 1}
ENABLE_SQLBINDPARAMETER_CONSISTENCY_CHECK = {0 ¦ 1}
USE_TARGETTYPE = {0 ¦ 1 ¦ 2}
LOCATOR_DSN = locator_dsn_name
LOCATOR_SERVICE = locator_service_name
LOCALITY_AWARE_TRANSACTION = {0 ¦ 1}
LOCALITY_GROUP_POLICY = {0 ¦ 1 ¦ 2}
LOCALITY_GROUP_PATH = group_name1, group_name2, group_name3
LOCALITY_MEMBER_POLICY = {0 ¦ 1 ¦ 2 ¦ 3 ¦ 4}
LOCALITY_MEMBER_PATH = member_name1,member_name2, member_name3
DB_HOME = database_home_path
PACKET_COMPRESSION_THRESHOLD = packet_compression_threshold
USE_GLOBAL_SESSION = {0 ¦ 1}
CONNECTION_TIMEOUT = connection_timeout
LOGIN_TIMEOUT = login_timeout
TRACE = {0 ¦ 1}
TRACEFILE = file_path_name
TRACE_POLICY={DEFAULT ¦ ERROR}
INCLUDE_SYNONYMS = {0 ¦ 1}
DOT_NET_FOR_ODBC = {0 ¦ 1}
[locator_dsn_name]
FILE = location_file_name
HOST = IP address(v4)
```

```
PORT = locator_port
CONNECTION_TIMEOUT = second
ALTERNATE_LOCATORS = (HOST=ADDRESS1:PORT=PORT1,HOST=ADDRESS2:PORT=PORT2)
```

The following table describes keywords in the data source specification section.

Table 31-3 Keywords in the data source specification section

Keyword	Description
data_source_name	It is the data source specified in the data source section.
Driver	It is a driver name installed on odbcinst.ini.
PROTOCOL	It is a connection type with the server. • DA: It directly accesses to the server without communication. • TCP: It communicates with the server through TCP socket. • IPC: It communicates with the server through the shared memory, and it is available only in the same device of the server. It uses TCP connection to transfer IPC information when accessing for the first time, so HOST and PORT should be set. It can access the server only in dedicated mode.
CS_MODE	It sets whether to connect as dedicated mode or shared mode. If it is not set, the default mode is determined depending on the configuration (DEFAULT_CS_MODE) of the listener.
HOST	It is a host IP address or a host name.
PORT	It is a connection port number.
PREFER_IPV6	If the host parameter is the host name, then IPv6 takes precedence over other IP addresses.
TCP_NODELAY	It is a socket TCP_NODELAY option.
UID	It is a user ID.
PWD	It is a user password.
CHARSET	It is a client character set.
ALTERNATE_SERVERS	It is a server list which attempts to connect when the failover occurs. Each servers is separated by a comma (,). To disable the failover feature, set ALTERNATE_SERVERS as a white space.
CONNECTION_RETRY_COUNT	It is the number of times which the driver attempts to connect to the server when the connection fails.
CONNECTION_RETRY_DELAY	It is the server connection retry interval (in seconds) when the connection fails.
FAILOVER_TYPE	• CONNECTION: When the connection fails, it is connected to ALTERNATE_SERVERS. • SESSION: When the connection fails or the connection is disconnected during operating the statement, it is connected to ALTERNATE_SERVERS and the statement is restored. The statement is executed after the failover if the connection is disconnected when a transaction is not in progress.
FAILOVER_GRANULARITY	• 0: The failover proceeds even when an error occurs. • 1: The failover fails when an error except for SQLExecute (), SQLExecDirect ()occ

Keyword	Description
	urs during the failover). • 2: The failover fails when an error occurs.
DATE_FORMAT	It is a DATE type string.
TIME_FORMAT	It is a TIME type string.
TIME_WITH_TIME_ZONE_FORMAT	It is a TIME WITH TIME ZONE type string.
TIMESTAMP_FORMAT	It is a TIMESTAMP type string.
TIMESTAMP_WITH_TIME_ZONE_FORMAT	It is a TIMESTAMP WITH TIME ZONE type string.
CHAR_LENGTH_UNITS	It is the unit of ColumnSize when ParameterType in SQLBindParameter() is SQL_CHAR, SQL_VARCHAR. • BYTE, OCTETS: Byte unit • CHAR, CHARACTERS: Character unit
ENABLE_SQLDESCRIBEPARAM	It determines whether to enable SQLDescribeParam(). • 0: The driver does not support SQLDescribeParam(). • 1: The driver returns SQL_VARCHAR for all parameters.
ENABLE_SQLBINDPARAMETER_CONSISTENCY_CHECK	It determines whether to check ColumnSize and DecimalDigits in SQLBindParameter(). • 0: It does not check ColumnSize and DecimalDigits. • 1: It checks ColumnSize and DecimalDigits.
USE_TARGETTYPE	It sets the type information which is to be received together when receiving a column type through communication. • 0: It receives only the column type. • 1: It receives the column type and column name. • 2: It receives the column type and all information about the column.
LOCATOR_DSN	It is Data Source Name (DSN) which specifies a location information.
LOCATOR_SERVICE	It gets the connection information from a service hint and glocator.
LOCALITY_AWARE_TRANSACTION	It determines whether to use GLOBAL CONNECTION. • 0: It does not use GLOBAL CONNECTION. • 1: It uses GLOBAL CONNECTION.
LOCALITY_GROUP_POLICY	It determines how to select a group if neither of groups are available, or two or more groups are available when using GLOBAL CONNECTION. • 0: It randomly selects the group. • 1: It sequentially selects groups which exist in LOCALITY_GROUP_PATH setting. If neither of groups in LOCALITY_GROUP_PATH are not available, it randomly selects the group. • 2: It sequentially selects groups. It always selects groups in an order of they are connected to the driver.
LOCALITY_GROUP_PATH	It defines the list of selected groups when the available group is not a single one when using GLOBAL CONNECTION. Each group is distinguished with comma (,). e.g. G1,G2,G3
	It determines how to select a member in the selected group when using GLOBAL CO

Keyword	Description
LOCALITY_MEMBER_POLICY	NNECTION. • 0: DML : MASTER / SELECT : MASTER • 1: DML : ANY / SELECT : ANY • 2: DML : MASTER / SELECT : ANY • 3: DML : MASTER / SELECT : SLAVE • 4: It sequentially selects members which exist in LOCALITY_MEMBER_PATH setting. If neither of members in LOCALITY_MEMBER_PATH are not available, it uses the MASTER in the selected group.
LOCALITY_MEMBER_PATH	It defines the list of members to be used in the selected group when using GLOBAL CONNECTION. Each member is distinguished with comma (,). e.g. G1N1,G2N1,G3N1,G1N2,G2N2,G3N2
DB_HOME	It sets the home directory of the database. The default value uses $GOLDILOCKS_HOME environment variable.
PACKET_COMPRESSION_THRESHOLD	It compresses the communication data when the size of the communication data to be sent to the server is bigger than PACKET_COMPRESSION_THRESHOLD. The range of the set value is 32 ~ 2113929216.
USE_GLOBAL_SESSION	It is whether to use GLOBAL SESSION. • 0: It does not use GLOBAL SESSION. • 1: uses GLOBAL SESSION.
CONNECTION_TIMEOUT	It is waiting time (in seconds) for the response after the request.
LOGIN_TIMEOUT	It is waiting time (in seconds) for the login request to be completed.
TRACE	It sets whether to use trace in ODBC API. • 0: It does not use the trace. • 1: It uses the trace.
TRACEFILE	It is the name of the trace file. When the relative path is input, then it is based on the directory in which the program currently runs. The default value is 'odbc_trace.log'.
TRACE_POLICY	It is the trace policy. • DEFAULT: It records both the function parameter and the result. • ERROR: It records the log when the function fails. The default value is DEFAULT.
INCLUDE_SYNONYMS	It sets whether to include the synonym object in SQLGetColumns(). • 0: It does not include the synonym object. • 1: It includes the synonym object.
DOT_NET_FOR_ODBC	It is whether to use ODBC for .NET Framework. • 0: It does not change its usage. • 1: It replaces SQL_DESC_BASE_COLUMN_NAME, SQL_DESC_NAME properties, in SQLGetDescField() and SQLColAttribute() with SQL_DESC_LABEL property.

Table 31-4 Location

Keyword	Description
FILE	Location file name

Keyword	Description
HOST	glocator ip address
PORT	glocator port number
CONNECTION_TIMEOUT	Connection timeout with glocator (second)
ALTERNATE_LOCATORS	If glocator does not respond, it gets the connection information by using ALTERNATE_LOCATORS.

- If properties of FILE, HOST, PORT are all set in LOCATOR_DSN, then the FILE property is prior to others. For more information, refer to **Location File**.

- LOCATOR_SERVICE property enables to connect to a server belonging to LOCATOR_SERVICE. Servers other than the connected server become ALTERNATE_SERVERS.
  If FAILOVER_TYPE is not set, then FAILOVER_TYPE is a session.
  If FAILOVER_GRANULARITY is not set, then FAILOVER_GRANULARITY is 1.
  For more information, refer to **glocator** and **gloctl**.

The following is an example of DSN configuration of GOLDILOCKS.

```
[GOLDILOCKS]
Driver = GOLDILOCKS ODBC Driver
PROTOCOL = TCP
CS_MODE = SHARED
HOST = 192.168.0.10
PORT = 22581
CHARSET = UTF8
TCP_NODELAY = 1
ALTERNATE_SERVERS = (HOST=192.168.0.11:PORT=22581,HOST=192.168.0.12:PORT=22581)
CONNECTION_RETRY_COUNT = 3
CONNECTION_RETRY_DELAY = 1
FAILOVER_TYPE = SESSION
FAILOVER_GRANULARITY = 0
FAILOVER_ROUTING_POLICY = 0
DATE_FORMAT = YYYY-MM-DD
TIME_FORMAT = HH24:MI:SS.FF6
TIME_WITH_TIME_ZONE_FORMAT = HH24:MI:SS.FF6 TZH:TZM
TIMESTAMP_FORMAT = YYYY-MM-DD HH24:MI:SS.FF6
TIMESTAMP_WITH_TIME_ZONE_FORMAT = YYYY-MM-DD HH24:MI:SS.FF6 TZH:TZM
CHAR_LENGTH_UNITS = CHARACTERS
ENABLE_SQLDESCRIBEPARAM = 1
```

```
ENABLE_SQLBINDPARAMETER_CONSISTENCY_CHECK = 1
USE_TARGETTYPE = 0
INCLUDE_SYNONYMS = 0
PACKET_COMPRESSION_THRESHOLD = 2113929216
LOCALITY_AWARE_TRANSACTION = 0
LOCALITY_GROUP_POLICY = 0
LOCALITY_GROUP_PATH = G1,G2,G3
LOCALITY_MEMBER_POLICY = 0
LOCALITY_MEMBER_PATH = G1N1,G2N1,G3N1,G1N2,G2N2,G3N2
USE_GLOBAL_SESSION = 0
CONNECTION_TIMEOUT = 0
LOGIN_TIMEOUT = 0
LOCATOR_DSN = LOCATOR
LOCATOR_SERVICE = S1
TRACE = 1
TRACEFILE = /home/test/log/mytrace.log
TRACE_POLICY = DEFAULT
DOT_NET_FOR_ODBC = 0
[LOCATOR]
FILE = /home/test/.location.ini
HOST = 127.0.0.1
PORT = 42581
ALTERNATE_LOCATORS=(HOST=127.0.0.1:PORT=42582,HOST=127.0.0.1:PORT=42583)
```

DSN Configuration on Windows

ODBC data source manager can add or set up DSN on Windows.

Figure 3 Creating new data source

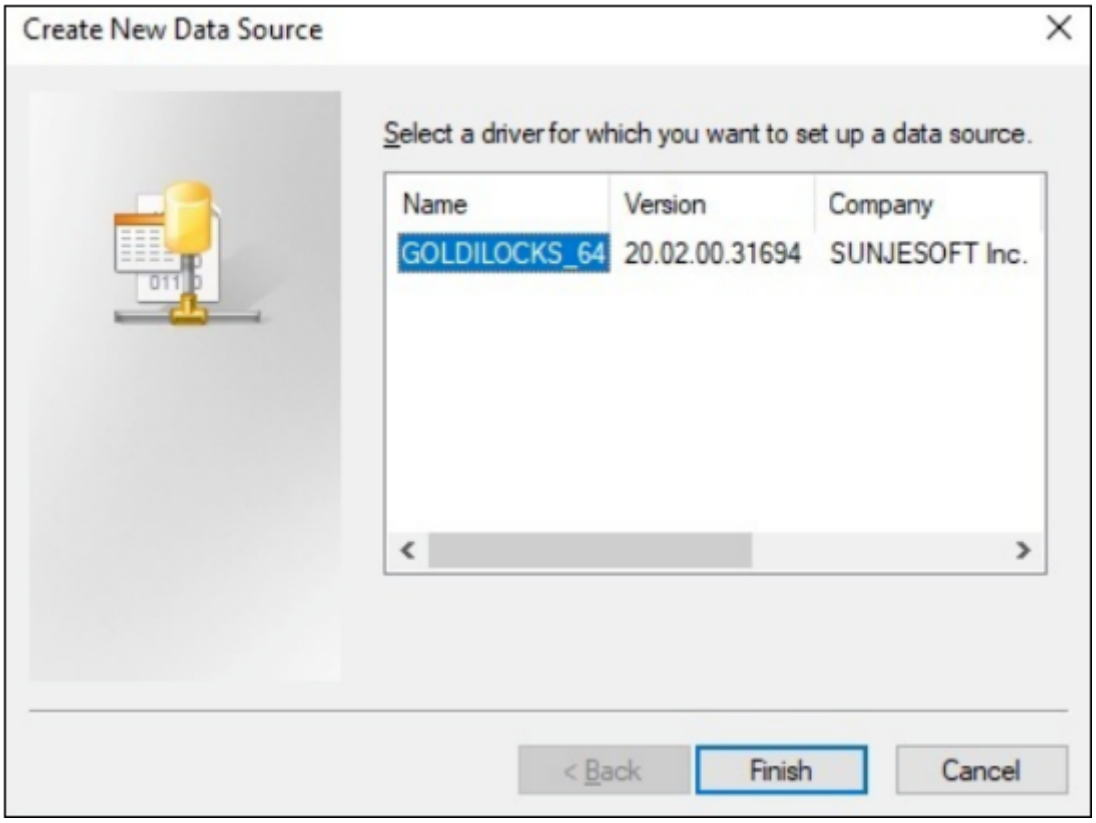


Figure 4 Configuring ODBC driver

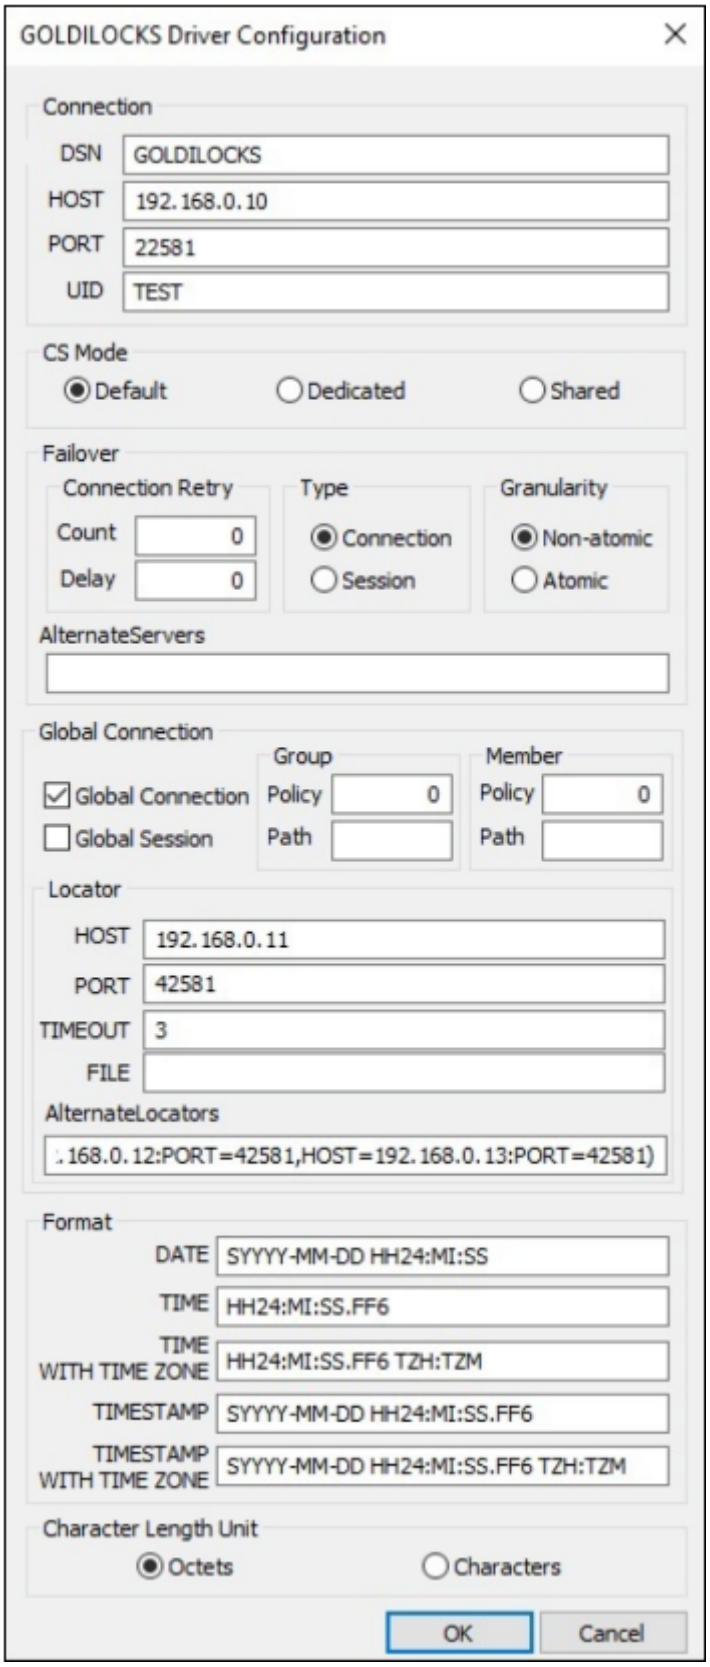


The following table describes keywords for DSN configuration.

Table 31-5 Keywords for DSN configuration

Keyword	Description
DSN	It is a data source name.
HOST	It is a host IP address or a host name.
PORT	It is a connection port number.
UID	It is a user ID.
CS_MODE	It sets whether to connect as dedicated mode or shared mode. If it is not set, the default mode is determined depending on the configuration (DEFAULT_CS_MODE) of the listener.
ALTERNATE_SERVERS	It is a server list which attempts to connect when the failover occurs. Each servers is separated by a comma (,). To disable the failover feature, set ALTERNATE_SERVERS as a white space.
CONNECTION_RETRY_COUNT	It is the number of times which the driver attempts to connect to the server when the connection fails.
CONNECTION_RETRY_DELAY	It is the server connection retry interval (in seconds) when the connection fails.
FAILOVER_TYPE	• CONNECTION: When the connection fails, it is connected to ALTERNATE_SERVERS. • SESSION: When the connection fails or the connection is disconnected during operating the statement, it is connected to ALTERNATE_SERVERS and the statement is restored. The statement is executed after the failover if the connection is disconnected when a transaction is not in progress.
FAILOVER_GRANULARITY	• Non-atomic: The failover proceeds even when an error occurs. • Atomic: The failover fails when an error occurs.
DATE_FORMAT	It is a DATE type string.
TIME_FORMAT	It is a TIME type string.
TIME_WITH_TIME_ZONE_FORMAT	It is a TIME WITH TIME ZONE type string.
TIMESTAMP_FORMAT	It is a TIMESTAMP type string.
TIMESTAMP_WITH_TIME_ZONE_FORMAT	It is a TIMESTAMP WITH TIME ZONE type string.
CHAR_LENGTH_UNITS	It is the unit of ColumnSize when ParameterType in SQLBindParameter() is SQL_CHAR, SQL_VARCHAR. • BYTE, OCTETS: Byte unit • CHAR, CHARACTERS: Character unit
LOCALITY_AWARE_TRANSACTION	It sets whether to use GLOBAL CONNECTION. • It does not use GLOBAL CONNECTION. • It uses GLOBAL CONNECTION.
USE_GLOBAL_SESSION	It sets whether to use GLOBAL SESSION. • It does not use GLOBAL SESSION. • It uses GLOBAL SESSION.
	If an available group does not exist or two or more groups can be selected when using GLOBAL CONNECTION, it sets how to select a group.

Keyword	Description
LOCALITY_GROUP_POLICY	• 0: It arbitrarily selects a group. • 1: It sequentially selects groups existing in LOCALITY_GROUP_PATH settings. If all groups in LOCALITY_GROUP_PATH are not available, then it arbitrarily selects a group. • 2: It sequentially selects groups. It selects a group in a sequence of connected to the driver everytime.
LOCALITY_GROUP_PATH	It specifies a list of selected groups if more than one group can be selected when using GLOBAL CONNECTION. Each group is separated with a comma (,). e.g. G1,G2,G3
LOCALITY_MEMBER_POLICY	It determines how to select a member within a selected group when using GLOBAL CONNECTION. • 0: DML : MASTER / SELECT : MASTER • 1: DML : ANY / SELECT : ANY • 2: DML : MASTER / SELECT : ANY • 3: DML : MASTER / SELECT : SLAVE • 4: It sequentially selects members in LOCALITY_MEMBER_PATH settings. If all members in LOCALITY_MEMBER_PATH are not available, then it arbitrarily selects MASTER in the selected group.
LOCALITY_MEMBER_PATH	It specifies a list of members to be used within a selected group when using GLOBAL CONNECTION. Each member is separated with a comma (,). e.g. G1N1,G2N1,G3N1,G1N2,G2N2,G3N2
LOCATOR_HOST	glocator ip address
LOCATOR_PORT	glocator port number
LOCATOR_CONNECTION_TIMEOUT	Connection timeout with glocator (second)
ALTERNATE_LOCATORS	If glocator does not respond, then it gets the connection information by using ALTERNATE_LOCATORS.
TRACE	It sets whether to use trace in ODBC API. • 0: It does not use the trace. • 1: It uses the trace.
TRACEFILE	It is the name of the trace file. When the relative path is input, then it is based on the directory in which the program currently runs. The default value is 'odbc_trace.log'.
TRACE_POLICY	It is the trace policy. • DEFAULT: It records both the function parameter and the result. • ERROR: It records the log when the function fails. The default value is DEFAULT.
DOT_NET_FOR_ODBC	It is whether to use ODBC for .NET Framework. • 0: It does not change its usage. • 1: It replaces SQL_DESC_BASE_COLUMN_NAME, SQL_DESC_NAME properties, in SQLGetDescField() and SQLColAttribute() with SQL_DESC_LABEL property.

31.3 GLOBAL CONNECTION

GLOBAL CONNECTION of which an application selects and performs an appropriate node for a query pro cessing in cluster environment is supported.

Settings

GLOBAL CONNECTION is available only when PROTOCOL is TCP. In this case, LOCALITY_AWARE_TRANS ACTION property value should be set together with LOCATOR file or LOCATOR server. USE_GLOBAL_SES SION property value should be set to 1 to use the global session feature.

- .odbc.ini of when using DSN

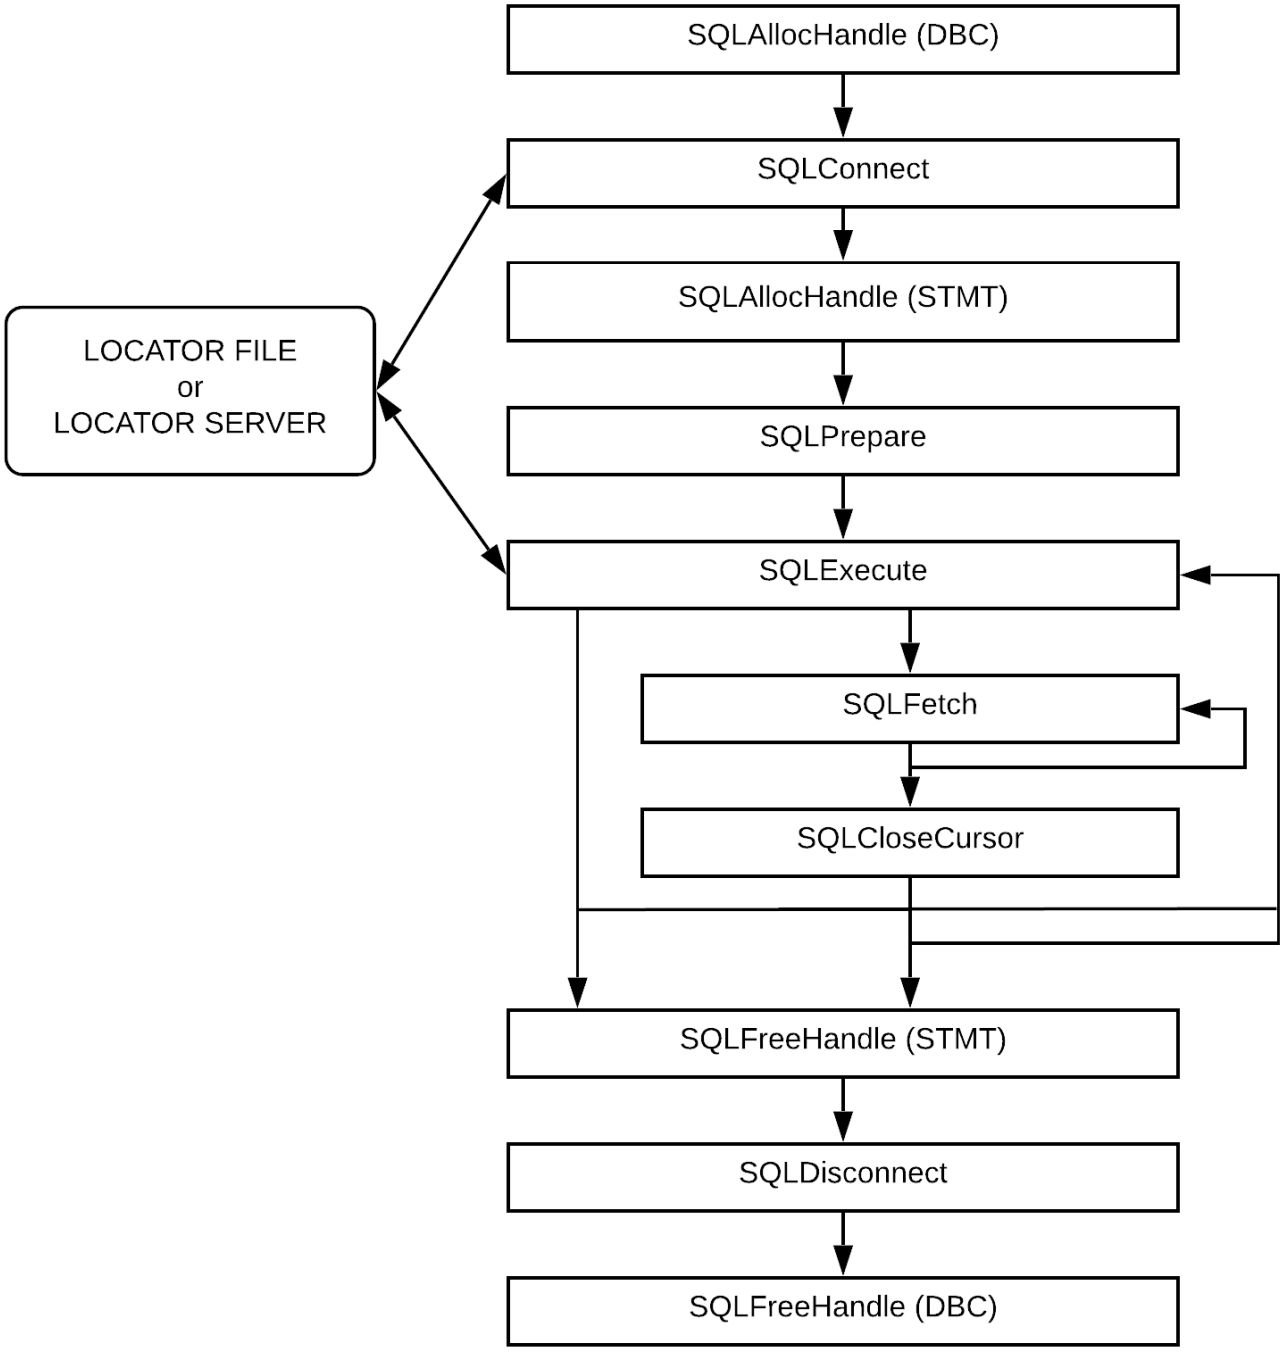
```
[GOLDILOCKS]
PROTOCOL = TCP
HOST = 192.168.0.1
PORT = 22581
UID = TEST
PWD = test
LOCALITY_AWARE_TRANSACTION = 1
LOCATOR_DSN = LOCATOR
[LOCATOR]
FILE = /home/goldilocks/.location.ini
```

- Using connection string

```
SQLDriverConnect( dbc,
                  NULL,
                  (SQLCHAR*)"PROTOCOL=TCP;HOST=192.168.0.1;PORT=22581;UID=TEST;PWD=test;LOCALI
TY_AWARE_TRANSACTION=1;LOCATOR_HOST=192.168.0.2;LOCATOR_PORT=42581",
                  SQL_NTS,
                  NULL,
                  0,
                  NULL,
                  SQL_DRIVER_NOPROMPT );
```

Processing GLOBAL CONNECTION

Figure 5 Basic steps of applying GLOBAL CONNECTION



1. SQLAllocHandle (DBC)
   It allocates a connection handle.

2. SQLConnect
   It connects to a server which was given server information from a user, and obtains the information a bout the cluster system. Then builds the cluster system information through LOCATOR file or LOCAT

OR server, and connects to all nodes of cluster system.

3. SQLAllocHandle(STMT)
   It allocates a statement to each of all connected nodes.

4. SQLPrepare
   It prepares to execute SQL in all connected nodes.

5. SQLExecute
   If the information about the cluster system is not built, an application builds the information about th e cluster system through LOCATOR file or LOCATOR server, then connects to all nodes in the cluster s ystem.
   When connecting to a new node by adding a node to cluster, all statements of other nodes are equal ly created in that node, and prepares to execute SQL.

If the information about a sharding key has already built, an application selects an appropriate node and performs a query by using the sharding key information.
If the information about a sharding key is not built, an application builds the sharding key information of the SQL from an arbitrary server, then selects a node and performs a query.

If an error occurs on the selected node, an appropriate node is selected again, then performs a query.

If the information about a sharding key is altered after SQLExecute, then it deletes the built information about a sharding key
If the information about the cluster system is altered such as adding or deleting a cluster node after SQLE xecute, then it deletes the built cluster system information.

6. SQLFetch
   It brings data from the node on which SQL was executed.

7. SQLCloseCursor
   It closes a cursor from the node on which SQL was executed.

8. SQLFreeHandle(STMT)
   It releases a statement from all connected nodes.

9. SQLDisconnect
   It releases connections with all nodes.

10. SQLFreeHandle(DBC)
    It releases a connection handle.

Handling GLOBAL CONNECTION Exception

When using GLOBAL CONNECTION, if an error occurs on the selected node during the operation, then it is operated as follows according to the transaction occurrence and SELECT progress.

- When a transaction did not occur

If an error occurs on the selected node when a transaction did not occur, then it selects another node wit hin ODBC and executes the query. Though an error occurred on the selected node, the query was normal ly executed on another node, so it does not transfer an error to a user.

- When a transaction occurred or SELECT is in progress

If an error occurs on the selected node when a transaction occurred or SQLFetch() is in progress, then OD BC can not proceeds the current operation any more so it transfers 19068(Retry the transactional operati ons) error. If 19068 error occurs, then a user should perform the transaction or SELECT again.

```
if( !SQL_SUCCEEDED(SQLPrepare( sStmt,
                               (SQLCHAR*)"INSERT INTO T1 VALUES ( ? )",
                               SQL_NTS )) )
{
    goto stmt_error;
}
trans_retry:
if( !SQL_SUCCEEDED(SQLExecute( sStmt )) )
{
    SQLGetDiagRec( SQL_HANDLE_STMT,
                   sStmt,
                   1,
                   sSQLState,
                   &sNativeError,
                   sMessageText,
                   sizeof(sMessageText),
                   &sTextLength );
    if( sNativeError == 19068 )
    {
        goto trans_retry;
    }

    goto stmt_error;
}
```

```
if( !SQL_SUCCEEDED(SQLPrepare( sStmt,
                               (SQLCHAR*)"SELECT * FROM T1 WHERE C1 = ?",
                               SQL_NTS )) )
{
    goto stmt_error;
}
trans_begin:
sReturn = SQLExecute( sStmt );
if( sRetrun == SQL_ERROR )
{
    SQLGetDiagRec( SQL_HANDLE_STMT,
                   sStmt,
                   1,
                   sSQLState,
                   &sNativeError,
                   sMessageText,
                   sizeof(sMessageText),
                   &sTextLength );
    if( sNativeError == 19068 )
    {
        goto trans_retry;
    }

    goto stmt_error;
}
while( 1 )
{
    sReturn = SQLFetch( sStmt );
    if( sReturn == SQL_NO_DATA )
    {
        SQLCloseCursor( sStmt );
        break;
    }
    else if( sReturn == SQL_ERROR )
    {
        SQLGetDiagRec( SQL_HANDLE_STMT,
                       sStmt,
                       1,
                       sSQLState,
                       &sNativeError,
                       sMessageText,
```

```
                        sizeof(sMessageText),
                        &sTextLength );
        if( sNativeError == 19068 )
        {
            goto trans_retry;
        }

        goto stmt_error;
    }
    ...
}
```

- When committing or rolling back a transaction

If an error occurs on the selected node when committing a transaction, then ODBC checks whether the tr ansaction has been committed before the error occurred through another node. Though an error occurre d on the selected node, if the transaction was normally committed, then it does not transfer an error. Als o, if an error occurred on the selected node when a transaction has not been committed, then it transfers 19068(Retry the transactional operations) error. If 19068 error occurs, then a user should perform the tra nsaction again.

If an error occurs on the selected node when rolling back a transaction, then ODBC does not transfer an e rror. It is because the transaction already has been rolled back due to the node error.

```
if( !SQL_SUCCEEDED(SQLSetConnectAttr( sDbc,
                                      SQL_AUTOCOMMIT,
                                      (SQLPOINTER)SQL_AUTOCOMMIT_OFF,
                                      0 ) ))
{
    goto dbc_error;
}
if( !SQL_SUCCEEDED(SQLPrepare( sStmt,
                               (SQLCHAR*)"INSERT INTO T1 VALUES ( ? )",
                               SQL_NTS )) )
{
    goto stmt_error;
}
trans_retry:
if( !SQL_SUCCEEDED(SQLExecute( sStmt )) )
{
    SQLGetDiagRec( SQL_HANDLE_STMT,
                   sStmt,
```

```
                    1,
                    sSQLState,
                    &sNativeError,
                    sMessageText,
                    sizeof(sMessageText),
                    &sTextLength );
    if( sNativeError == 19068 )
    {
        goto trans_retry;
    }

    goto stmt_error;
}
if( !SQL_SUCCEEDED(SQLEndTran( SQL_HANDLE_DBC,
                               sDbc,
                               SQL_COMMIT)) )
{
    SQLGetDiagRec( SQL_HANDLE_DBC,
                    sDbc,
                    1,
                    sSQLState,
                    &sNativeError,
                    sMessageText,
                    sizeof(sMessageText),
                    &sTextLength );
    if( sNativeError == 19068 )
    {
        goto trans_retry;
    }

    goto stmt_error;
}
```

Constraints of GLOBAL CONNECTION

- Use SQLPrepare() and SQLExecute() to select a node appropriate for the query.

Use SQLPrepare() and SQLExecute() to select a node appropriate for the query by using GLOBAL CONNE CTION. SQLExecDirect() does not have an information required to select a node appropriate for the query, so the node is selected according to OCALITY_GROUP_POLICY and LOCALITY_MEMBER_POLICY propert

y.

- Use SQLEndTran() to commit or rollback a transaction.

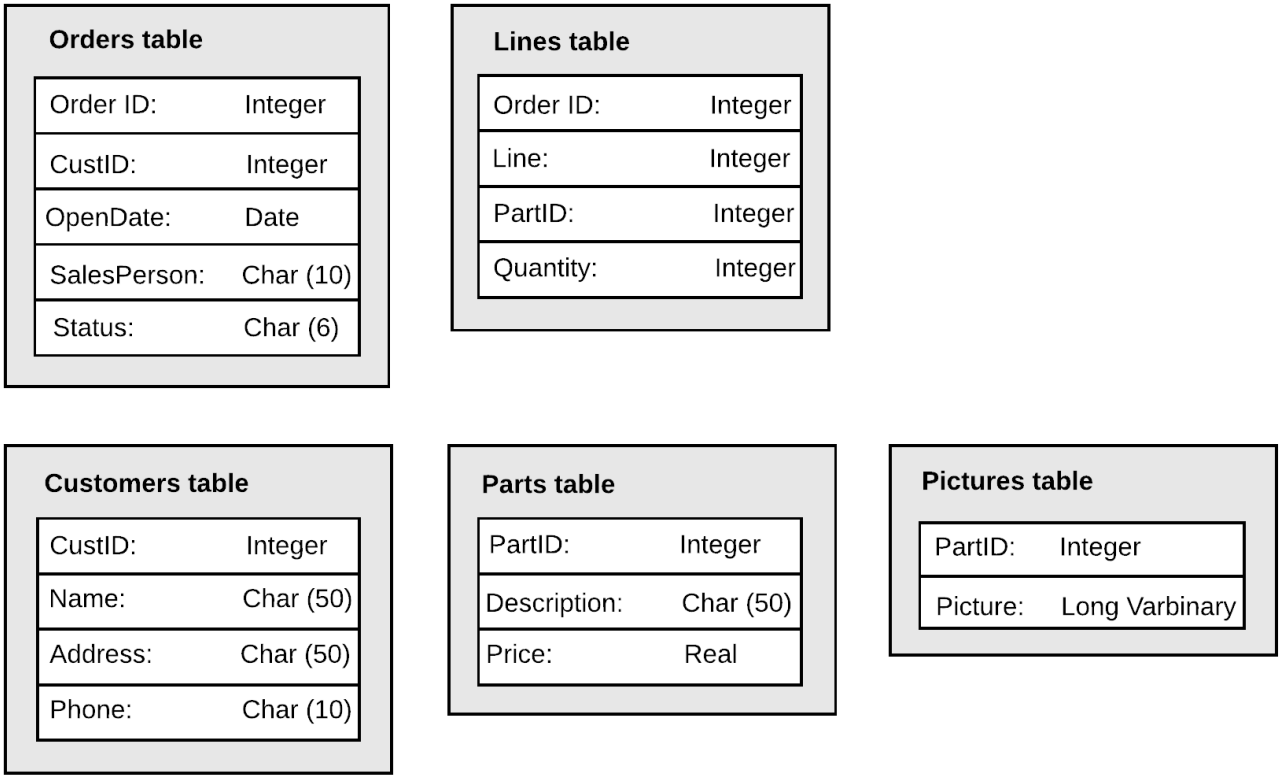
If committing or rolling back with SQL statement when using GLOBAL CONNECTION, then the status cha nge of the transaction is not detected. It is mandatory to use SQLEndTran() to commit or rollback the tran saction.

- Global session feature does not support Data Definition Language (DDL) among SQL statements.

31.4 Catalog Function

All databases have schemas of how to store the data in the database. For example, a simple sales order d atabase will have the schemas shown in the following figure, and the ID columns are used to connect the tables.

Figure 6 Schema of sales orders



The schema is stored in the set of system tables which is called as a database catalog along with other inf ormation such as privileges. This is also known as a data dictionary.

Applications can find this schema by calling the catalog functions. Catalog functions return the informati on to the result set, and typically they are implemented by SELECT statements for the tables in the catalo g.

Using Catalog Data

Applications use catalog data in various ways. The followings are some common usages.

Configuring SQL statements at the time of execution

The vertical applications such as the order input application include the hard-coded SQL statements. The tables and columns used by the application were previously fixed, and the application access these tables. For example, the ordering application typically has one parameterized statement to add a new order to the system.

A general application such as a spreadsheet program using ODBC for collecting the data sometimes configures the SQL statement based on the input from a user at the time of execution. This application may request a user for the format to use tables and columns. However, if the list of tables or columns selected by a user is shown to the application, it will be easier to the user. The application will call catalog functions such as SQLTables and SQLColumns to configure these lists.

Configuring SQL statements during the development

The application development environments allow the developers to create database queries during developing the program. And then the queries are hard-coded and embedded into the application.

These environments can also create a list of what were selected by the developer by using the SQLTables and SQLColumns. The environments find out and display the relationships among the tables automatically selected by using SQLPrimaryKeys and SQLForeignKeys. Then they find out and emphasize the index fields by using SQLStatistics, so the developers can create queries effectively.

Configuring a Cursor

The application, driver, middleware which provides a scroll cursor, find out column(s) which is the only column of identifying a row by using SQLSpecialColumns. The program can configure a keyset including the values of these columns for the collected rows. The application will use these values to collect the latest data for the rows by scrolling backwards.

Catalog Function on ODBC

ODBC includes the following catalog functions.

Function	Description
SQLTables	It returns a list of catalogs, schemas, tables or table types in the data source.
SQLColumns	It returns a list of columns in one or more tables.
SQLStatistics	It returns a list of statistics for a single table. It also returns a list of indexes linked to the table.
SQLSpecialColumns	It returns a list of columns which is the only column of identifying a row in a table. Also,

Function	Description
	it returns a list of columns in the table, and they are automatically updated.
SQLPrimaryKeys	It returns a list of columns which configure the primary key of a table.
SQLForeignKeys	It returns a list of foreign keys in a table or it returns a list of foreign keys in another table referring that table.
SQLTablePrivileges	It returns a list of privileges associated with one or more tables.
SQLColumnPrivileges	It returns a list of privileges associated with one or more columns in a table.
SQLProcedures	It is not supported by the driver.
SQLProcedureColumns	It is not supported by the driver.
SQLGetTypeInfo	It returns a list of SQL data types supported by the data source. These data types are generally used in CREATE TABLE, ALTER TABLE statements.

Data Returning of Catalog Function

Each catalog function returns the data as a result set. The result set is not different from any other result set. It is usually hard-coded into the driver, or it is created by the predefined statement such as the parameterized SELECT statement stored in the procedure of data source.

The result set for each catalog function is described in *For More Information* paragraph of each function in this user manual. The result set can include the columns specified in the driver after the column selected last besides the listed columns. These columns are described in a user manual for the driver.

The applications bind the columns specified in the driver based on the end of result set. They calculate the number of columns specified in the driver as the number of last columns which are smaller than the number of columns after the required column. This saves the trouble of changing the application when a new column is added in future version or ODBC driver. To operate this schema, drives should add the columns specified in the new driver before the columns specified in the old driver to prevent changing the row number based on the end of result set.

Even when they include special characters, they do not quote the identifiers returned in the result set. For example, if the Accounts Payable table's identifier quote character which is specified in the driver and returned by SQL GetInfo is a double quotes ("), and the Accounts Payable table has a Customer Name column, then TABLE_NAME column value in the rows which is returned by SQLColumns is Accounts Payable, but it is not "Accounts Payable", and COLUMN_NAME column value is Customer Name, but it is not "Customer Name".
The application collects the names of customers from the Accounts Payable table as follows.

```
SELECT "Customer Name" FROM "Accounts Payable"
```

Catalog functions are based on SQL-like model in connection based on the user name and password, and their data is returned only to the users with the proper privilege. The file password protection which is ina

ppropriate to this model is defined by the drivers.

Most result set returned by the catalog functions can not be updated, and the application should not exp ect to change the database schema by updating the data in the result set.

Arguments of Catalog Function

Pattern Value Argument

Some arguments in catalog function accept the search pattern, like as TableName argument in SQLTables. The arguments accept the search pattern if SQL_ATTR_METADATA_ID attribute is set to SQL_FALSE. The arguments do not accept the search pattern if SQL_ATTR_METADATA_ID attribute is set to SQL_TRUE.

Search pattern letters have the following features.

- An underscore(_) represents any single character.
- Percent sign (%) represents zero or more characters.
- An escape character is specified in the driver and it is used to include the percent sign, underscore, es cape character as literals. If an escape character is prior to a non-special character, it does not have a ny special meaning. But if an escape character is prior to a special character, it is a special character. F or example, "₩a" is treated as two characters consisting of "₩" and "a", but "₩%" refers to "%".

An escape character is returned by using SQL_SEARCH_PATTERN_ESCAPE option in SQLGetInfo. To inclu de that character as a literal in an argument which accepts search patterns, it should be prior to any unde rscore, percent sign, or escape character.

The following table describes how to use search patterns.

Search pattern	Description
%A%	It is all identifiers which contain A.
ABC_	It is all four letter characters which start with ABC.
ABC₩_	It assumes the escape character a backslash(₩), and the identifier is ABC_.
₩₩%	It assumes the escape character a backslash(₩), and the identifier which start with a backslash(₩) .

⚠ Be cautious when using a escape character in an argument which accepts a search pattern. This is particularly TRUE for the underscore(_) which is generally used as the identifier.
It is a common mistake in the application that the value returned by one catalog function is pass ed to the search pattern argument of another catalog function.
For example, if the application gets MY_TABLE table from the result set of SQLTables and passe s it to SQLColumns to retrieve the column list of MY_TABLE, then, the application will get the c olumns of all tables such as MY_TABLE, MY1TABLE, MY2TABLE instead of getting the columns

of MY_TABLE because they match the search pattern MY_TABLE.

ODBC 2.x driver does not support the search pattern for CatalogName argument of SQL tables. ODBC 3.x driver supports the search pattern within the argument if the environment attribute SQL_ATTR_ODBC_VERSION is set to SQL_OV_ODBC3. The argument does not accept the search pattern if this property is set to SQL_OV_ODBC2.

Passing a NULL pointer to the search pattern argument does not force the argument to search. NULL pointer and the search patterns % (any character) are equivalent. However, a zero-length search pattern is matched with an empty string ("").

31.5 Non-standard Data Type

This chapter describes GOLDILOCKS data types which are not defined in ODBC standard.

C Data Type

Table 31-6 GOLDILOCKS C data type

C type identifier	ODBC C typedef	C type
SQL_C_BOOLEAN	SQLBOOLEAN	unsigned char
SQL_C_LONGVARBINARY	SQL_LONG_VARIABLE_LENGTH_STRUCT	[a]
SQL_C_LONGVARCHAR	SQL_LONG_VARIABLE_LENGTH_STRUCT	[a]
SQL_C_REFCURSOR	SQLHSTMT	void *
SQL_C_TYPE_TIME_WITH_TIMEZONE	SQL_TIME_WITH_TIMEZONE_STRUCT	[b]
SQL_C_TYPE_TIMESTAMP_WITH_TIMEZONE	SQL_TIMESTAMP_WITH_TIMEZONE_STRUCT	[c]
SQL_C_WLONGVARCHAR	SQL_WLONG_VARIABLE_LENGTH_STRUCT	[d]

- [a]

```
typedef struct tagLONG_VARIABLE_LENGTH_STRUCT
{
    SQLBIGINT   len;
    SQLCHAR   * arr;
} LONG_VARIABLE_LENGTH_STRUCT;
```

- [b]

```
typedef struct tagTIME_WITH_TIMEZONE_STRUCT
{
   SQLUSMALLINT hour;
   SQLUSMALLINT minute;
   SQLUSMALLINT second;
   SQLUINTEGER  fraction;
   SQLSMALLINT  timezone_hour;
   SQLSMALLINT  timezone_minute;
```

```
} TIME_WITH_TIMEZONE_STRUCT;
```

- [c]

```
typedef struct tagTIMESTAMP_WITH_TIMEZONE_STRUCT
{
   SQLSMALLINT  year;
   SQLUSMALLINT month;
   SQLUSMALLINT day;
   SQLUSMALLINT hour;
   SQLUSMALLINT minute;
   SQLUSMALLINT second;
   SQLUINTEGER  fraction;
   SQLSMALLINT  timezone_hour;
   SQLSMALLINT  timezone_minute;
} TIMESTAMP_WITH_TIMEZONE_STRUCT;
```

- [d]

```
typedef struct tagWLONG_VARIABLE_LENGTH_STRUCT
{
    SQLBIGINT   len;
    SQLWCHAR  * arr;
} WLONG_VARIABLE_LENGTH_STRUCT;
```

SQL_C_BOOLEAN

It is used to describe boolean value.

- SQL_TRUE
- SQL_FALSE

```
SQLBOOLEAN boolean   = SQL_TRUE;
SQLLEN     indicator = 0;
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_BOOLEAN,
                  SQL_BOOLEAN,
                  0,
                  0,
                  &boolean,
```

```
                0,
                &indicator );
```

SQL_C_LONGVARBINARY

It has SQLCHAR buffer size and SQLCHAR buffer pointer.

SQLCHAR buffer has a binary data.

The actual length of the binary data is transferred through an indicator.

```
SQL_LONG_VARIABLE_LENGTH_STRUCT   longvarbinary;
SQLLEN                            indicator;
SQLCHAR                         * buffer;
buffer = (SQLCHAR*)malloc(128);
longvarbinary.arr = buffer;
longvarbinary.len = 128;
buffer[0] = 0x1;
buffer[1] = 0x2;
buffer[2] = 0x3;
indicator = 3;
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_LONGVARBINARY,
                  SQL_VARBINARY,
                  128,
                  0,
                  &longvarbinary,
                  0,
                  &indicator );
```

SQL_C_LONGVARCHAR

It has SQLCHAR buffer size and SQLCHAR buffer pointer.

SQLCHAR buffer has a string data.

The actual length of the string data is transferred through an indicator.

```
SQL_LONG_VARIABLE_LENGTH_STRUCT   longvarchar;
SQLLEN                            indicator;
SQLCHAR                         * buffer;
```

```
buffer = (SQLCHAR*)malloc(128);
longvarchar.arr = buffer;
longvarchar.len = 128;
buffer[0] = 'A';
buffer[1] = 'B';
buffer[2] = 'C';
indicator = 3;
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_LONGVARCHAR,
                  SQL_VARCHAR,
                  128,
                  0,
                  &longvarchar,
                  0,
                  &indicator );
```

SQL_C_REFCURSOR

It can use REF CURSOR through the allocated SQLHSTMT.

```
SQLHSTMT stmt    = SQL_NULL_HSTMT;
SQLHSTMT refstmt = SQL_NULL_HSTMT;
SQLLEN   refind  = 0;
SQLCHAR  job[10];
SQLLEN   jobind  = 0;
SQLAllocHandle( SQL_HANDLE_STMT,
                dbc,
                &stmt );
SQLAllocHandle( SQL_HANDLE_STMT,
                dbc,
                &refstmt );
SQLPrepare( stmt,
            (SQLCHAR*)"CALL EMP_BY_JOB_REFCURSOR(?, ?)",
            SQL_NTS );
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_CHAR,
                  SQL_VARCHAR,
```

```
                  10,
                  0,
                  job,
                  sizeof(job),
                  &jobind );
SQLBindParameter( stmt,
                  2,
                  SQL_PARAM_OUTPUT,
                  SQL_C_REFCURSOR,
                  SQL_REFCURSOR,
                  0,
                  0,
                  refstmt,
                  0,
                  &refind );
strcpy( (char*)job, "SALESMAN" );
jobind = strlen((char*)job);
SQLExecute( stmt );
SQLFetch( refstmt );
```

SQL_C_TYPE_TIME_WITH_TIMEZONE

It can describe TIME WITH TIMEZONE.

- hour
  - hour
- minute
  - minute
- second
  - second
- fraction
  - 1/1,000,000,000 second
    - It is describable maximum 1/1,000,000 second in GOLDILOCKS.
    - The micro second should be converted to the nano second.
- timezone_hour
  - It is the time of TIMEZONE.
- timezone_minute
  - It is the minute of TIMEZONE.

```
SQL_TIME_WITH_TIMEZONE_STRUCT timetz;
SQLLEN                        indicator = 0;
```

```
timetz.hour            = 10;
timetz.minute          = 20;
timetz.second          = 30;
timetz.fraction        = 123456000;
timetz.timezone_hour   = 9;
timetz.timezone_minute = 0;
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_TYPE_TIME_WITH_TIMEZONE,
                  SQL_TYPE_TIME_WITH_TIMEZONE,
                  0,
                  6,
                  &timetz,
                  0,
                  &indicator );
```

SQL_C_TYPE_TIMESTAMP_WITH_TIMEZONE

It can describe TIMESTAMP WITH TIMEZONE.

- year
  - year
- month
  - month
- day
  - day
- hour
  - hour
- minute
  - minute
- second
  - second
- fraction
  - 1/1,000,000,000 second
    - It is describable maximum 1/1,000,000 second in GOLDILOCKS.
    - The micro second should be converted to the nano second.
- timezone_hour
  - it is the hour of TIMEZONE.
- timezone_minute
  - It is the minute of TIMEZONE.

```
SQL_TIMESTAMP_WITH_TIMEZONE_STRUCT timestamptz;
SQLLEN                             indicator = 0;
timestamptz.year            = 2010;
timestamptz.month           = 9;
timestamptz.day             = 1;
timestamptz.hour            = 10;
timestamptz.minute          = 20;
timestamptz.second          = 30;
timestamptz.fraction        = 123456000;
timestamptz.timezone_hour   = 9;
timestamptz.timezone_minute = 0;
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_TYPE_TIMESTAMP_WITH_TIMEZONE,
                  SQL_TYPE_TIMESTAMP_WITH_TIMEZONE,
                  0,
                  6,
                  &timestamptz,
                  0,
                  &indicator );
```

SQL_C_WLONGVARCHAR

It has SQLWCHAR buffer size and SQLWCHAR buffer pointer.

SQLWCHAR buffer has a unicode string data.

The actual length of the unicode string data is transferred through an indicator.

```
SQL_WLONG_VARIABLE_LENGTH_STRUCT  wlongvarchar;
SQLLEN                            indicator;
SQLWCHAR                         * buffer;
buffer = (SQLWCHAR*)malloc(128 * sizeof(SQLWCHAR));
wlongvarchar.arr = buffer;
wlongvarchar.len = 128;
buffer[0] = 'A';
buffer[1] = 'B';
buffer[2] = 'C';
indicator = 3 * sizeof(SQLWCHAR);
SQLBindParameter( stmt,
                  1,
```

```
                SQL_PARAM_INPUT,
                SQL_C_WLONGVARCHAR,
                SQL_VARCHAR,
                128,
                0,
                &wlongvarchar,
                0,
                &indicator );
```

SQL Data Type

Table 31-7 GOLDILOCKS SQL data type

SQL type identifier	GOLDILOCKS data type	GOLDILOCKS type description
SQL_BOOLEAN	BOOLEAN	It stores TRUE or FALSE.
SQL_REFCURSOR	REF CURSOR	It is the cursor variable of PSM.
SQL_TYPE_TIME_WITH_TIME ZONE	TIME(p) WITH TIME ZO NE	It is TIME WITH TIMEZONE. p of precision stands for the s econds precision.
SQL_TYPE_TIMESTAMP_WIT H_TIMEZONE	TIMESTAMP(p) WITH TI ME ZONE	It is TIMESTAMP WITH TIMEZONE. p of precision stands f or the seconds precision.
SQL_ROWID	ROWID	It is the record identifier.

SQL_BOOLEAN

It is BOOLEAN type of GOLDILOCKS.

SQL_REFCURSOR

It is REF CURSOR type of GOLDILOCKS PSM.

SQL_TYPE_TIME_WITH_TIMEZONE

It is TIME(p) WITH TIME ZONE type of GOLDILOCKS.

The range of fractional seconds precision is 0 ~ 6.

SQL_TYPE_TIMESTAMP_WITH_TIMEZONE

It is TIMESTAMP(p) WITH TIME ZONE type of GOLDILOCKS.

The range of fractional seconds precision is 0 ~ 6.

SQL_ROWID

It is ROWID type of GOLDILOCKS.

```
SQLCHAR  rowid[24];
SQLLEN   indicator = 0;
strcpy( (char*)rowid, "AAAAAAAAYfCAACAAAADiAAA" );
indicator = strlen((char*)rowid);
SQLBindParameter( stmt,
                  1,
                  SQL_PARAM_INPUT,
                  SQL_C_CHAR,
                  SQL_ROWID,
                  0,
                  0,
                  rowid,
                  0,
                  &indicator );
```

31.6 ODBC API References

SQLAllocConnect

Conformance

Introduced version: ODBC 1.0

Overview

SQLAllocConnect function is replaced by SQLAllocHandle function in ODBC 3.x.
For more information, refer to **SQLAllocHandle**.

Syntax

```
SQLRETURN SQLAllocConnect(
    SQLHENV   EnvironmentHandle,
    SQLHDBC * ConnectionHandlePtr);
```

Arguments

EnvironmentHandle

[Input] It is the environment handle.

ConnectionHandlePtr

[Output] It is the pointer of the connection handle to be newly allocated.

SQLAllocEnv

Conformance

Introduced version: ODBC 1.0

Overview

SQLAllocEnv function is replaced by SQLAllocHandle function in ODBC 3.x.
For more information, refer to **SQLAllocHandle**.

Syntax

```
SQLRETURN SQLAllocEnv(
    SQLHENV * EnvironmentHandlePtr);
```

Arguments

EnvironmentHandlePtr

[Output] It is the pointer of the environment handle to be newly allocated.

SQLAllocHandle

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLAllocHandle allocates the environment handle, the connection handle, or the statement handle.

Syntax

```
SQLRETURN SQLAllocHandle(
    SQLSMALLINT   HandleType,
    SQLHANDLE     InputHandle,
    SQLHANDLE *   OutputHandlePtr);
```

Arguments

HandleType

[Input] It is the handle type allocated by SQLAllocHandle and it should be one of SQL_HANDLE_DBC, SQL_HANDLE_ENV, SQL_HANDLE_STMT.

InputHandle

[Input] If HandleType is SQL_HANDLE_ENV, it is SQL_NULL_HANDLE.

If HandleType is SQL_HANDLE_DBC, it should be an environment handle.

If it is SQL_HANDLE_STMT, it should be a connection handle.

OutputHandlePtr

[Output] It is the newly allocated handle pointer.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_INVALID_HANDLE, SQL_ERROR

Diagnosis

SQLSTATE	Error	Description
08003	Connection not open	It is not connected and HandleType is one of SQL_HANDLE_STMT and SQL_HANDLE_DESC.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	OutputHandlePtr argument is a null pointer.
HY010	Function sequence error	HandleType argument is SQL_HANDLE_DBC, and SQLSetEnvAttr is not called for setting SQL_ODBC_VERSION environment attribute.
HY014	Limit on the number of handles exceeded	It limits the number of allocated handles.
HY092	Invalid attribute/option identifier	HandleType argument is not one of SQL_HANDLE_ENV, SQL_HANDLE_DBC, SQL_HANDLE_STMT, SQL_HANDLE_DESC.
IM001	Driver does not support this function	HandleType argument is SQL_HANDLE_DESC.

Description

SQLAllocHandle is used to allocate the handle for environment, connection, statement, descriptor. When using SQLAllocHandle with *OutputHandlePtr, the driver will overwrite the information on the correspoid ning handle. The driver manager can not verify whether the handle in *OutputHandlePtr is already used, and it can not know the previously overwritten information.

Allocating Environment Handle

The environment handle provides the global information such as whether the connection handle is valid or active.

For requesting the environment handle, the application calls SQLAllocHandle whose HandleType is SQL_HANDLE_ENV and whose InputHandle is SQL_NULL_HANDLE. The driver allocates memory for the environment information, and passes an allocated handle to *OutputHandle argument. The application passes the value of *OutputHandle to the call requiring the environment handle argument.

After allocating the environment handle, the application should set the attribute of SQL_ATTR_ODBC_VERSIONby calling SQLSetEnvAttr. If the attribute is not set when calling SQLAllocHandle for allocating the connection handle, SQLSTATE HY010 (Function sequence error) is returned.

Allocating Connection Handle

The connection handle provides the information such as whether the statement is valid, the descriptor ha ndle is connected, or the transaction currently is opened.

For requesting the connection handle, the application calls SQLAllocHandle whose HandleType is SQL_HA NDLE_DBC. InputHandler argument is set to the environment handle returned by calling SQLAllocHandle. The driver allocates memory for the connection information, and passes an allocated handle to *OutputH andle argument. The application passes the value of *OutputHandle to the call requiring a connection ha ndle argument.

If the environment attribute of SQL_ATTR_ODBC_VERSION is not set before the calling SQLAllocHandle which allocates a connection handle, SQLSTATE HY010(Function sequence error) is returned.

Allocating Statement Handle

The statement handle provides the information such as the error message, the cursor name and the SQL s tatement processing status.

For requesting the statement handle, the application connects to the data source and then calls SQLAlloc Handle before sending the SQL statement. In this call, HandleType should be set to SQL_HANDLE_STMT a nd InputHandler should be set to the connection handle returned by calling SQLAllocHandle. The driver al locates memory for the statement information, and passes the allocated handle to *OutputHandle argum ent. The application passes the value of *OutputHandle to the call requiring a statement handle argumen t.

If the statement handle is allocated, the driver automatically allocates four descriptor sets, and these desc riptor handles are allocated to the statement attribute of SQL_ATTR_APP_ROW_DESC, SQL_ATTR_APP_P ARAM_DESC, SQL_ATTR_IMP_ROW_DESC and SQL_ATTR_IMP_PARAM_DESC. This is called as implicit d escriptor allocation.

SQLAllocStmt

Conformance

Introduced version: ODBC 1.0

Overview

SQLAllocStmt function is replaced by SQLAllocHandle function in ODBC 3.x.
For more information, refer to **SQLAllocHandle**.

Syntax

```
SQLRETURN SQLAllocStmt(
    SQLHDBC    ConnectionHandle,
    SQLHSTMT * StatementHandlePtr);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

StatementHandlePtr

[Output] It is the pointer of the statement handle to be newly allocated.

SQLBindCol

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLBindCol binds the application data buffer to the columns in the result set.

Syntax

```
SQLRETURN SQLBindCol(
    SQLHSTMT       StatementHandle,
    SQLUSMALLINT   ColumnNumber,
    SQLSMALLINT    TargetType,
    SQLPOINTER     TargetValuePtr,
    SQLLEN         BufferLength,
    SQLLEN *       StrLen_or_Ind);
```

Arguments

StatementHandle

[Input] It is the statement handle

ColumnNumber

[Input] It is the column number in the result set to be bound. The number is in ascending order starting from 1.

TargetType

[Input] It is the identifier of C data type of *TargetValuePtr buffer. When retrieving data using SQLFetch, SQLFetchScroll, SQLSetPos, the driver converts the data into this type.

If TargetType is the interval data type, the default value is the interval leading precision (2), interval seconds precision (6), and it is set in each field of SQL_DESC_DATETIME_INTERVAL_PRECISION and SQL_DESC_PRECISION of ARD. If TargetType argument is SQL_C_NUMERIC, the default value is precision (38), scale (0), and it is set in each field of SQL_DESC_PRECISION and SQL_DESC_SCALE of ARD. If the default precision and scale are not appropriate, the application must explicitly set the descriptor field by calling SQLSetDescField or SQLSetDescRec.

TargetValuePtr

[Delayed Input/Output] It is the data buffer pointer to bind to the column. SQLFetch and SQLFetch Scroll return data to this buffer.

If TargetValuePtr is the null pointer, the driver releases the data buffer binding for the column. The application may release the binding of all the columns by calling SQLFreeStmt as SQL_BIND option. The application can release the data buffer binding for the column by setting TargetValuePtr argu ment as a null pointer and calling SQLBindCol. But if StrLen_or_IndPtr is valid, the length/indicator buffer for the column is still bound.

BufferLength

[Input] It is the length of *TargetValuePtr buffer in bytes.

The driver uses BufferLength in order to avoid writing beyond the end of *TargetValuePtr buffer w hen returning the variable-length data such as text or binary data. It should be noted that the drive r take into account the null terminator when returning the character data in *TargetValuePtr. So, * TargetValuePtr should include the space for a null terminator, otherwise the drive may drop the da ta. The driver assumes that the buffer is large enough to store data and it ignores BufferLength wh en returning a fixed-length data structure such as an integer or date. It is important that the applic ation allocates the large buffer for the fixed-length data, otherwise the driver can write beyond the end of the buffer.

StrLen_or_IndPtr

[Delayed Input/Output] It is the pointer to the length/indicator buffer to be bound to the column. SQLFetch and SQLFetchScroll return the value to this buffer.

SQLFetch and SQLFetchScroll return the length of data for the length/indicator buffer, SQL_NO_TO TAL and SQL_NULL_DATA. If there are two separate buffers for the length and indicator, the lengt h buffer may return all values, and the indicator buffer may only return only SQL_NULL_DATA. If St rLen_or_IndPtr is the null pointer, the value of length/indicator is not used and an error occurs whe n getting the null data.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_INVALID_HANDLE, SQL_ERROR

Diagnosis

SQLSTATE	Error	Description
07006	Restricted data type attribute vi olation	ColumnNumber argumnet is 0, and TargetType argument is neither S QL_C_BOOKMARK nor is SQL_C_VARBOOKMARK.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY003	Invalid application buffer type	The value of TargetType argument is the invalid data type.

SQLSTATE	Error	Description
HY010	Function sequence error	After calling SQLExecute and SQLExecDirect, then SQL_NEED_DATA is returned, and the function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	The value of BufferLength argument is smaller than 0.
HYC00	Optional feature not implemented	The driver does not support the SQL data type of the column and the value of TargetType argument and the conversion. The value of ColumnNumber argument is 0, and the driver does not support bookmarks.

Description

SQLBindCol is used to bind columns in the result set to the data buffer and the length/indicator buffers in the application. The application calls SQLFetch and SQLFetchScroll to retrieve the data, and the driver returns the bound column data to the specified buffer.
The application does not bind the column, and the data is retrieved by calling SQLGetData.

Binding Column

The application calls SQLBindCol to bind the column, and passes the column number, the type, the address, the data buffer length and the address of length/indicator buffer.

Though the application binds the buffer by calling SQLBindCol, but the driver accesses them when calling SQLFetch and SQLFetchScroll, so these buffers are delayed when it is used. Therefore, the application should make the pointer set in SQLBindCol to be valid until the data is returned. If the application calls after making the pointer invalid, like when releasing the buffer, the result is not correct.

The binding remains until when it is replaced by a new binding, the column binding is released, or the statement is released.

Releasing Bound Column

To release only one bound column, set the column number to be released as ColumnNumber and call SQLBindCol by setting TargetValue to the null pointer in the application. If ColumnNumber is the column number whose binding is released, SQLBindCol continues returning SQL_SUCCESS.

To release all bound columns, call SQLFreeStmt by setting option to SQL_UNBIND in the application. Or, set SQL_DESC_COUNT field of ARD to 0 to release all bound columns.

Rebinding Column

The application can perform one of two operations to change the binding.

- A new binding is specified for an existing bound column by calling SQLBindCol.
- The offset is added to the specified buffer address by calling SQLBindCol. For more information, refer to **Binding Offsets**.

Binding Offsets

Binding offset is the value added to the address before the data and length/indicator buffers (specified in TargetValuePtr and StrLen_or_IndPtr) are dereferenced.

Using binding offset generally has the same effect as rebinding the column by calling SQLBindCol. However, the new address of the data and length/indicator buffer are specified when newly calling SQLBindCol, but binding offset does not change the address, instead it adds only the offsets to the address. The application can specify a new offset anytime, and the offset is always added to the originally bound address. Especially, if the offset is set to 0 or the statement attribute is set to NULL pointer, the driver uses the originally bound address.

The sum of the originally bound address and the offset should be a valid address, but the offset address to be added does not have to be valid.

Binding Array

If the row set size (the value of SQL_ATTR_ROW_ARRAY_SIZE statement attribute) is bigger than 1, the application binds a buffer array instead of a single buffer.

The application can bind an array in two ways as follows.

- Bind an array to each column. Each data structure (array) contains data for a single column, so it is called as **Column-wise Binding**.
- Define as structure containing the entire row data and bind the array of these structures. Each data structure contains data for a single row. so it is called as **Row-wise Binding**.

Each buffer array should have at least as many elements as the row set size.

Column-wise Binding

The application binds the separate data and length/indicator array to each column in column-wise binding.

The application should set SQL_ATTR_ROW_BIND_TYPE statement attribute to SQL_BIND_BY_COLUMN (default value) to use the column-wise binding. Then, the application performs the following processes for the columns to be bound.

1. It allocates the data buffer array.
2. It allocates the array of length/indicator buffer.

If the application directly records to the descriptors when using the column-wise binding, the separate arrays can be used for length and indicator data.

3. It calls SQLBindCol together with the following arguments.

- TargetType is the type of each element of the data buffer array.
- TargetValuePtr is the address of the data buffer array.
- BufferLength is the size of each element of the data buffer array. BufferLength is ignored when the data is fixed length data.
- StrLen_or_IndPtr is the address of the length/indicator array.

Row-wise Binding

The application defines a structure which contains the data and length/indicator buffer of each column to be bound in row-wise binding.

The application performs the following processes to use row-wise binding.

1. It defines a structure which contains a row(including both of data and the length/indicator buffer) and allocates an array of the structures.

If the application directly records to the descriptors when using the row-wise binding, the separate fields can be used for length and indicator data.

2. SQL_ATTR_ROW_BIND_TYPE statement attribute sets the size of structure including a data row or as the buffer instance size for the result columns to be bound. The length should include the space and structure of all bound columns and the padding of the buffer. It should guarantee to point to the starting position in the same column of the next line when the address of the bound column is increased by the specified length. ANSI C guarantees it by using the sizeof operator.

3. It calls SQLBindCol together with the following arguments for each column to be bound.

- TargetType is the type of the data buffer member to be bound to the column.
- TargetValuePtr is the address of the data buffer member in the first array element.
- BufferLength is the size of the data buffer member.
- StrLen_or_IndPtr the address of the length/indicator member to be bound.

Buffer Address

The buffer address is an actual address of the data or the length/indicator buffer. The driver calculates th e buffer address before writing to the buffer (such as the data collect). It is calculated by the following for mula, which uses the address, binding offset, row number specified in TargetValuePtr and StrLen_or_Ind Ptr.

```
Bound Address + Binding Offset + ((Row Number -1) x Element Size )
```

The following table describes the definitions the formula's variables.

Table 31-8 Formula's variable

Variable	Description
Bound address	The address of data buffer is specified in TargetValuePtr argument of SQLBindCol. The address of length/indicator buffer is specified in StrLen_of_IndPtr argument of SQ LBindCol. If the binding address is 0, the data value is not returned, even though the calculated address is not 0.
Binding offset	If row-wise binding is used, this value is stored in the address specified with the SQL_ ATTR_ROW_BIND_OFFSET_PTR statement attribute. If column-wise binding is used or the SQL_ATTR_ROW_BIND_OFFSET_PTR statement attribute is a NULL pointer, then the binding offset is 0.
Row number	It is 1-based number of the row in the row set. When fetching a single row, generally the row number is 1.
Element size	It is the element size of binding array. If column-wise binding is used, it is sizeof (SQLLEN) for the length/indicator buffer. Th e element size of the data buffer of variable length data type is the value of BufferLen gth argument of SQLBindCol, and the element size of the data buffer of fixed length data type is the size of the data type. If row-wise binding is used, the element size of both the data and the length/indicato r buffer are the value of the SQL_ATTR_ROW_BIND_TYPE statement.

Descriptors and SQLBindCol

This chapter describes how SQLBindCol interacts with descriptors.

Calling SQLBindCol for a single statement may affect other statements. It occurs when ARD rela ted to the statement is explicitly allocated and it is related to other statements. The modification s for the descriptor affects all statements related the descriptor because SQLBindCol modifies th e descriptor. If it is not the required behavior, the application should release the relationship bet ween the descriptor and other statements before calling SQLBindCol.

Argument Mapping

Notionally, SQLBindCol performs the following processes in order.

1. It calls SQLGetStmtAttr to obtain ARD handle.

2. It calls SQLGetDescField to obtain the descriptor of SQL_DESC_COUNT field, and if the value in the ColumnNumber argument exceeds the value of SQL_DESC_COUNT, it calls SQLSetDescField to increase the value of SQL_DESC_COUNT to ColumnNumber.

3. It calls SQLSetDescField multiple times to assign values to the following fields of ARD.

- It sets SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE to the value of TargetType.
  - Except when TargetType is one of the concise identifiers of a datetime or interval subtype, it respectively sets SQL_DESC_TYPE to SQL_DATETIME or SQL_INTERVAL. It sets SQL_DESC_CONCISE_TYPE to the concise identifier; and sets SQL_DESC_DATETIME_INTERVAL_CODE to the corresponding datetime or interval subcode.
- It appropriately sets one or more of SQL_DESC_LENGTH, SQL_DESC_PRECISION, SQL_DESC_SCALE, and SQL_DESC_DATETIME_INTERVAL_PRECISION, for TargetType.
- It sets the SQL_DESC_OCTET_LENGTH field to the value of BufferLength.
- It sets the SQL_DESC_DATA_PTR field to the value of TargetValue.
- It sets the SQL_DESC_INDICATOR_PTR field to the value of StrLen_or_Ind.
- It sets the SQL_DESC_OCTET_LENGTH_PTR field to the value of StrLen_or_Ind.

The variable referenced by StrLen_or_Ind argument is used for both indicator and length information. If the value of column when fetching is null, it stores SQL_NULL_DATA in this variable. Otherwise, it stores the data length in this variable.
Entering a null pointer, and the value of column when fetching is null, then the fetch fails because it cannot return SQL_NULL_DATA.

If SQLBindCol fails, the contents of the descriptor fields which will be set in ARD are not defined, and the value of SQL_DESC_COUNT field of ARD is not updated.

Implicit Initialization of COUNT Field

SQLBindCol sets SQL_DESC_COUNT to the value of the ColumnNumber only when ColumnNumber increase the value of SQL_DESC_COUNT. If the value in the TargetValuePtr argument is a null pointer and the value in the ColumnNumber argument is equal to SQL_DESC_COUNT (when releasing the highest bound column), then SQL_DESC_COUNT is set to the number of the highest remaining bound column.

Caution for SQL_DEFAULT

The application should determine the correct length and starting point of the data in the application buffer to successfully retrieve column data. When the application explicitly specifies an TargetType, application errors are easily detected.

However, when the application specifies a TargetType of SQL_DEFAULT, SQLBindCol can be applied to a column of a different data type from the one data type intended by the application, either from changes to the metadata or by applying the code to a different column. In this case, the application may not alway s determine the start or length of the fetched column data. This may lead to unreported data errors or m emory violations.

SQLBindParameter

Conformance

Introduced version: ODBC 2.0
Standards compliance: ODBC

Overview

SQLBindParameter binds the buffer to the parameter marker of SQL statement.

Syntax

```
SQLRETURN SQLBindParameter(
    SQLHSTMT        StatementHandle,
    SQLUSMALLINT    ParameterNumber,
    SQLSMALLINT     InputOutputType,
    SQLSMALLINT     ValueType,
    SQLSMALLINT     ParameterType,
    SQLULEN         ColumnSize,
    SQLSMALLINT     DecimalDigits,
    SQLPOINTER      ParameterValuePtr,
    SQLLEN          BufferLength,
    SQLLEN *        StrLen_or_IndPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ParameterNumber

[Input] It is the parameter number which is increased sequentially from 1.

InputOutputType

[Input] It is the parameter type.

ValueType

[Input] It is the C data type of the parameter.

ParameterType

[Input] It is the SQL data type of the parameter.

ColumnSize

[Input] It is the size of column or expression of the parameter marker.

DecimalDigits

[Input] It is the number of decimal point of column or expression of the parameter marker.

ParameterValuePtr

[Delayed Input] It is the data buffer pointer of the parameter.

BufferLength

[Input/Output] It is the byte length of ParameterValuePtr buffer.

StrLen_or_IndPtr

[Delayed Input] It is the pointer to the length/indicator of the parameter.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

Table 31-9 SQLSTATE values

SQLSTATE	Error	Description
07006	Restricted data type attribute violation	ValueType argument data type can not be converted into ParameterType argument data type.
07009	Invalid descriptor index	The value of ParameterNumber argument is smaller than 1.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY003	Invalid application buffer type	The value of ValueType argument is not a valid C data type.
HY004	Invalid SQL data type	The value of ParameterType argument is not a valid SQL data type.
HY009	Invalid argument value	ParameterValuePtr argument and StrLen_or_IndPtr argument are the NULL pointer, and InputOutputType argument is not SQL_PARAM_OUTPUT. InputOutputType argument is SQL_PARAM_OUTPUT, and ParameterValuePtr argument is the NULL pointer, and C type is a character or binary, and BufferLength is greater than 0.
HY010	Function sequence error	SQL_NEED_DATA is returned after calling SQLExecute, SQLExecDirect, and this function is called before sending all data-at-execution variables.
HY021	Inconsistent descriptor i	Descriptor information is inconsistent when the integrity is checked.

SQLSTATE	Error	Description
	nformation	
HY090	Invalid string or buffer l ength	The value of BufferLength is smaller than 0.
HY104	Invalid precision or scal e value	The value specified in ColumnSize and DecimalDigits is beyond the SQL da ta support range of ParameterType argument.
HY105	Invalid parameter type	The value of InputOutType argument is not valid.
HYC00	Optional feature not im plemented	The driver does not support the conversion of values of ValueType argum entand ParameterType argument. The value of ParameterType argument is valid but the driver does not sup port.

Description

The application calls SQLBindParameter to bind each parameter marker in an SQL statement. Bindings re main valid until the application calls SQLBindParameter again, calls SQLFreeStmt with the SQL_RESET_PA RAMS option, or calls SQLSetDescField to set the SQL_DESC_COUNT header field of the APD to 0.

ParameterNumber Argument

If ParameterNumber is bigger than the value of SQL_DESC_COUNT when calling SQLBindParameter, SQL SetDescField is called to increase the value of SQL_DESC_COUNT to ParameterNumber.

InputOutputType Argument

The InputOutputType argument specifies the type of the parameter. This argument sets the SQL_DESC_P ARAMETER_TYPE field of the IPD.

InputOutputType argument is one of the followings.

- SQL_PARAM_INPUT: The parameter marks a parameter in an SQL statement, not in a procedure nor i n SELECT INTO statement. For example, the parameters in INSERT INTO Employee VALUES (?, ?, ?) ar e input parameters.
  - When the statement is executed, the driver sends data for the parameter, and the *ParameterVal uePtr buffer should contain a valid input value, or the *StrLen_or_IndPtr buffer should contain S QL_NULL_DATA, SQL_DATA_AT_EXEC, or the result of the SQL_LEN_DATA_AT_EXEC macro.
- SQL_PARAM_INPUT_OUTPUT: The parameter marks an input/output parameter in a procedure.
  - When the statement is executed, the driver sends data for the parameter and the *ParameterVal uePtr buffer should contain a valid input value, or the *StrLen_or_IndPtr buffer should contain S QL_NULL_DATA, SQL_DATA_AT_EXEC, or the result of the SQL_LEN_DATA_AT_EXEC macro.
  - After the statement is executed, the driver returns data to the parameter of the application. If the data source does not return a value to an input/output parameter, the driver sets SQL_NULL_DAT A in *StrLen_or_IndPtr buffer.

- SQL_PARAM_OUTPUT: The parameter marks the return value of a procedure, or an output paramete r in a procedure or SELECT INTO statement. For example, the parameter in SELECT ID INTO ? FROM E mployee WHERE NAME = 'Paul' is an output parameter which returns the ID.
  - After the statement is executed, the driver returns data to the parameter, if the ParameterValueP tr and StrLen_or_IndPtr arguments of an application are not null pointers. Otherwise, the driver d iscards the output value.
  - If the data source can not return a value to an output parameter, the driver sets SQL_NULL_DAT A in *StrLen_or_IndPtr buffer.

ValueType Argument

ValueType argument specifies C data type of the parameter. It sets the values of SQL_DESC_TYPE, SQL_D ESC_CONCISE_TYPE, SQL_DESC_DATETIME_INTERVAL_CODE fields of APD.

When the ValueType argument is an interval data type,

- SQL_DESC_TYPE field of APD ParameterNumber record is set to SQL INTERVAL.
- SQL_DESC_CONCISE_TYPE field is set to concise interval data type.
- SQL_DESC_DATETIME_INTERVAL_CODE field is set to subcode of a specific interval data.
- The default value of interval leading precision is (2), and the default value of interval seconds precisio n is (6), and they are respectively set in SQL_DESC_DATETIME_INTERVAL_PRECISION and SQL_DESC _PRECISION fields of APD.
- If the default precision or scale is not appropriate, the application should explicitly set the descriptor fi eld by calling SQLSetDescField or SQLSetDescRec.

When the ValueType argument is a datetime data type,

- SQL_DESC_TYPE field of ParameterNumber record in APD is set to SQL_DATETIME.
- SQL_DESC_CONCISE_TYPE field is set to the concise date C data type.
- SQL_DESC_DATETIME_INTERVAL_CODE field is set to the sub code of the specific datetime data.

When the ValueType argument is an SQL_C_NUMERIC data type,

- The default precision is (38), the default scale is (0), and they are respectively set in SQL_DESC_PRECI SION, SQL_DESC_SCALE fields of APD.
- If the default precision or scale is not appropriate, the application should explicitly set the descriptor fi eld by calling SQLSetDescField or SQLSetDescRec.

ParameterType Argument

ParameterType specifies the SQL data type of the parameter. It sets the values of SQL_DESC_TYPE, SQL_ DESC_CONCISE_TYPE, SQL_DESC_DATETIME_INTERVAL_CODE fields of IPD.

When the ParameterType argument is a datetime data type,

- SQL_DESC_TYPE field of IPD is set to SQL_DATETIME.
- SQL_DESC_CONCISE_TYPE field is set to the concise datetime SQL data type.
- SQL_DESC_DATETIME_INTERVAL_CODE field is set to the sub code of the specific datetime data.

When the ParameterType argument is a interval data type,

- SQL_DESC_TYPE field of IPD is set to SQL_INTERVAL.
- SQL_DESC_CONCISE_TYPE field is set to the concise SQL interval data type.
- SQL_DESC_DATETIME_INTERVAL_CODE field is set to the sub code of the specific interval data.
- The interval leading precision is set in SQL_DESC_DATETIME_INTERVAL_PRECISION field of IPD, and t he interval second precision is set in SQL_DESC_PRECISION field of IPD.
- If the defaults of SQL_DESC_DATETIME_INTERVAL_PRECISION and SQL_DESC_PRECISION are not ap propriate, the application sets it by calling SQLSetDescField.

When the ParameterType argument is an SQL_NUMERIC data type,

- The default precision is (38), the default scale is (0), and they are respectively set in SQL_DESC_PRECI SION and SQL_DESC_SCALE fields of IPD.
- If the default precision or scale is not appropriate, the application should explicitly set the descriptors field by calling SQLSetDescField or SQLSetDescRec.

ColumnSize Argument

ColumnSize argument specifies the size of the column or expression corresponding the parameter marker. It sets different fields of the IPD depending on SQL data type of ParameterType.

- If ParameterType is SQL_CHAR, SQL_VARCHAR, SQL_LONGVARCHAR, SQL_BINARY, SQL_VARBINAR Y, SQL_LONGVARBINARY, concise SQL datetime, or interval data type, it sets the value of ColumnSiz e in SQL_DESC_LENGTH field of IPD.
- If ParameterType is SQL_DECIMAL, SQL_NUMERIC, SQL_FLOAT, SQL_REAL, or SQL_DOUBLE, it sets t he value of ColumnSize in SQL_DESC_PRECISION field of IPD.
- For other data types, ColumnSize argument is ignored.

DecimalDigit Argument

- If ParameterType argument is SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP, SQL_INTERVAL_SECOND, S QL_INTERVAL_DAY_TO_SECOND, SQL_INTERVAL_HOUR_TO_SECOND, or SQL_INTERVAL_MINUTE_ TO_SECOND, it sets the value of DecimalDigits in SQL_DESC_PRECISION field of IPD.
- If ParameterType argument is SQL_NUMERIC or SQL_DECIMAL, it sets the value of DecimalDigits in S QL_DESC_SCALE field of IPD.
- For other data types, DecimalDigits argument is ignored.

ParameterValuePtr Argument

When calling SQLExecute and SQLExecDirect, ParameterValuePtr points to the actual data for the param eter. The data type should be in a form specified by ValueType argument. This argument sets the SQL_DE SC_DATA_PTR field of the APD.

If *StrLen_or_IndPtr is the result of the SQL_LEN_DATA_AT_EXEC (length) macro or SQL_DATA_AT_EXE C, then ParameterValuePtr is an application-defined pointer value which is related to the parameter. It is r eturned to the application through SQLParamData.
For example, ParameterValuePtr might be a non-zero token such as a parameter number, a pointer to da ta, or a pointer to a structure that the application used to bind input parameters.

If InputOutputType argument is SQL_PARAM_INPUT_OUTPUT or SQL_PARAM_OUTPUT, ParameterValue Ptr should be a buffer pointer in which the output value is stored.

If the value in the SQL_ATTR_PARAMSET_SIZE statement attribute is bigger than 1, ParameterValuePtr p oints to an array. A single SQL statement processes the complete array of input values for an input or inp ut/output parameter and returns an array of output values for an input/output or output parameter.

BufferLength Argument

For character and binary C data, the BufferLength argument specifies the length of the *ParameterValue Ptr buffer (if the value in the SQL_ATTR_PARAMSET_SIZE statement attribute is 1), or specifies the length of the element in the *ParameterValuePtr array(if the value in the SQL_ATTR_PARAMSET_SIZE statement attribute is bigger than 1).

Both when input and output, BufferLength is used to determine the position in the array of *ParameterV aluePtr for. It sets SQL_DESC_OCTET_LENGTH field of APD.

For an input/output parameter and an output parameter, BufferLength is used to determine whether or not to truncate the output.

- For character C data, if the number of bytes available to return is equal to or bigger than BufferLengt h, the data in *ParameterValuePtr is truncated to BufferLength minus 1 bytes and it is null-terminate d.
- For binary C data, if the number of bytes available to return is equal to or bigger than BufferLength, t he data in *ParameterValuePtr is truncated to BufferLength bytes.
- For other C data types, the BufferLength argument is ignored.

StrLen_or_IndPtr Argument

The StrLen_or_IndPtr argument contains one of the followings when SQLExecute or SQLExecDirect is call ed. (This argument sets the SQL_DESC_OCTET_LENGTH_PTR and SQL_DESC_INDICATOR_PTR of APD.)

- The length of the parameter value stored in *ParameterValuePtr. This is ignored except for character or binary C data.
- SQL_NTS: The parameter value is a null-terminated string.
- SQL_NULL_DATA: The parameter value is NULL.
- The result of the SQL_LEN_DATA_AT_EXEC(length) macro: The data for the parameter will be sent when performing SQLPutData.
    - If the ParameterType argument is SQL_LONGVARBINARY, SQL_LONGVARCHAR, or a long, and SQL_NEED_LONG_DATA_LEN information of SQLGetInfo returns "Y", then the length is the number of bytes of data to be sent for the parameter
    - If SQL_NEED_LONG_DATA_LEN information of SQLGetInfo is "N", length should be a nonnegative value and is ignored.
    - For example, to specify 10,000 bytes of SQL_LONGVARCAHR parameter data to be sent by calling SQLPutData for multiple times, *StrLen_or_IndPtr should be set to SQL_LEN_DATA_AT_EXEC(10000).
- SQL_DATA_AT_EXEC: The data for the parameter will be sent when performing SQLPutData.

If StrLen_or_IndPtr is a null pointer, the driver assumes that all input parameter values are non-NULL and that character and binary data is null-terminated. If InputOutputType is SQL_PARAM_OUTPUT, and ParameterValuePtr and StrLen_or_IndPtr are both null pointers, the driver discards the output value.

If the InputOutputType argument is SQL_PARAM_INPUT_OUTPUT, SQL_PARAM_OUTPUT, then StrLen_or_IndPtr points to SQL_NULL_DATA, the number of bytes available to return in *ParameterValuePtr (excluding the null-termination byte of character data), or SQL_NO_TOTAL (if the number of bytes available to return cannot be determined).

If the value in the SQL_ATTR_PARAMSET_SIZE statement attribute is greater than 1, StrLen_or_IndPtr points to an array of SQLLEN values.

Passing Parameter Values

An application can pass the value for a parameter by calling the *ParameterValuePtr buffer or multiple SQLPutData. Parameters whose data is passed through SQLPutData are known as data-at-execution parameters. These are typically used to send data for SQL_LONGVARBINARY and SQL_LONGVARCHAR parameters, and can be mixed with other parameters.

The application should perform the following process to pass the parameter values.

1. It calls SQLBindParameter for each parameter to bind buffers for the parameter's value (ParameterValuePtr argument) and length/indicator (StrLen_or_IndPtr argument). For data-at-execution parameters, ParameterValuePtr is an application-defined pointer value such as a parameter number or a pointer to data. The value will be returned later and can be used to identify the parameter.

2. It sets values for an input parameter or an input/output parameter in the *ParameterValuePtr and *StrLen_or_IndPtr buffers.

- For normal parameters, the application inputs the parameter value in the *ParameterValuePtr buffer and the length of that value in the *StrLen_or_IndPtr buffer.
- For data-at-execution parameters, the application inputs the result of the SQL_LEN_DATA_AT_EXEC (length) macro (when calling an ODBC 2.0 driver) in the *StrLen_or_IndPtr buffer.

3. It calls SQLExecute or SQLExecDirect to execute the SQL statement.

- If data-at-execution parameters do not exist, the process is complete.
- If any data-at-execution parameters exist, the function returns SQL_NEED_DATA.

4. It calls SQLParamData to retrieve the application-defined value specified in the ParameterValuePtr argument of SQLBindParameter for the first data-at-execution parameter to be processed. SQLParamData returns SQL_NEED_DATA.

Although data-at-execution parameters resemble data-at-execution columns, the value returned by SQLParamData is different for each.

Data-at-execution parameters are parameters in an SQL statement for which data will be sent toSQLPutData when the statement is executed together with SQLExecDirect or SQLExecute. They are bound with SQLBindParameter.

The value returned by SQLParamData is a pointer value passed to the ParameterValuePtr argument of SQLBindParameter. Data-at-execution columns are columns in a rowset for which data will be sent when a row is updated or added with SQLBulkOperations or updated with SQLSetPos. They are bound with SQLBindCol. The value returned by SQLParamData is the address of the row in the TargetValuePtr* buffer (set by a call to **SQLBindCol) which is to be processed.

5. It calls SQLPutData for one or more times to send data for the parameter. One or more calls are required if the data value is bigger than what is specified in the *ParameterValuePtr buffer of SQLPutData. Multiple SQLPutData calls for the same parameter are allowed only when sending character C data to a column with a character, binary, or data source-specific data type or when sending binary C data to a column with a character, binary, or data source-specific data type.

6. It calls SQLParamData again to signal that all data has been sent for the parameter.

- If one or more data-at-execution parameters exist, SQLParamData returns SQL_NEED_DATA and processes the application-defined value for the next data-at-execution parameter. The application repeats steps 4 and 5.
- If data-at-execution parameter does not exist, the process is complete. If the statement was successfully executed, SQLParamData returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO. If the execution failed, it returns SQL_ERROR. At this point, SQLParamData can be returned by any SQLSTATE. It can also be returned by SQLExecDirect or SQLExecute which is used to execute the statement.
- Output values for any input/output or output parameters are available in the *ParameterValuePtr an

d *StrLen_or_IndPtr buffers after the application retrieves all result sets generated by the statement.

Calling SQLExecute or SQLExecDirect puts the statement in an SQL_NEED_DATA state. At this point, the application can call only SQLCancel, SQLGetDiagField, SQLGetDiagRec, SQLGetFunctions, SQLParamData, or SQLPutData together with the statement or the connection handle related to the statement.

If it calls any other function for the statement or the connection related to the statement, the function returns SQLSTATE HY010(Function sequence error). The statement is released from the SQL_NEED_DATA state when SQLParamData or SQLPutData returns an error, SQLParamData returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, or the statement is canceled.

If the application calls SQLCancel while the driver still needs data for data-at-execution parameters, the driver cancels statement execution. Then the application can call SQLExecute or SQLExecDirect again.

Using Parameter Array

An application prepares a statement together with parameter markers and passes it in an array of parameters in the following two ways.

- One method is for the driver to rely on the array-processing capabilities, in this case the entire statement with the array of parameters is treated as one atomic unit. Oracle is an example of a data source which supports array processing capabilities.
- The other method is for the driver to generate a batch of SQL statements. Each set of parameters in the parameter array is allocated per an SQL statement and is made into a batch, then the batch is executed. Arrays of parameters can not be used in an UPDATE WHERE CURRENT OF statement.

When processing the parameter array, the number of each result sets/ rows are available per each parameter set or the number of each result sets/ rows are available in whole. The SQL_PARAM_ARRAY_ROW_COUNTS option in SQLGetInfo indicates whether the number of rows are available for each set of parameters(SQL_PARC_BATCH) or only a single row is available (SQL_PARC_NO_BATCH).

The SQL_PARAM_ARRAY_SELECTS option in SQLGetInfo indicates whether a result set is available for each set of parameters (SQL_PAS_BATCH) or is available only in one result set(SQL_PAS_NO_BATCH). If the driver does not allow a result set-generating statement to be executed together with an array of parameters, SQL_PARAM_ARRAY_SELECTS returns SQL_PAS_NO_SELECT.
For more information, refer to **SQLGetInfo**.

To support the parameter array, the SQL_ATTR_PARAMSET_SIZE statement attribute is set to specify the number of values for each parameter. If the field is bigger than 1, the SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, and SQL_DESC_OCTET_LENGTH_PTR fields of the APD should point to arrays. The number of elements in each array is equal to the value of SQL_ATTR_PARAMSET_SIZE.

The SQL_DESC_ROWS_PROCESSED_PTR field of the APD points to a buffer which contains the number o f sets of parameters which have been processed, including error sets. As like each processed parameters s et, the driver stores a new value in the buffer. Any number will not be returned if this is a null pointer. When arrays of parameters are used, the value pointed to by the SQL_DESC_ROWS_PROCESSED_PTR fiel d of the APD is generated even when SQL_ERROR is returned by the setting function. If SQL_NEED_DAT A is returned, the value pointed to by the SQL_DESC_ROWS_PROCESSED_PTR field of the APD is set to t he set of parameters which is being processed.

Binding Column-wise Parameter

For column-wise binding, the application binds the separate parameter and length/indicator arrays to eac h parameter.

For column-wise binding, the application firstly sets the SQL_ATTR_PARAM_BIND_TYPE statement attrib ute to SQL_PARAM_BIND_BY_COLUMN. (It is the default value.) The application performs the following processes to use column-wise binding.

1. It allocates the parameter buffer array.

2. It allocates the length/indicator buffer array.

If the application directly records to the descriptors when using the column-wise binding, the se parate arrays can be used for length and indicator data.

3. It calls SQLBindParameter together with the following arguments.

- ValueType is the C type of a single element in the parameter buffer array.
- ParameterType is the SQL type of the parameter.
- ParameterValuePtr is the address of the parameter buffer array.
- BufferLength is the size of a single element in the parameter buffer array. The BufferLength argumen t is ignored when the data is fixed-length data.

Binding Row-wise Parameter

For row-wise binding, the application defines a structure which contains parameter and length/indicator buffers for each parameter to be bound.

The application performs the following processes to use row-wise binding.

1. It defines a structure to hold a single set of parameters (including both parameter and length/indicat or buffers) and allocates an array of these structures.

If the application directly records to the descriptors when using the row-wise binding, the separate fields can be used for length and indicator data.

2. SQL_ATTR_PARAM_BIND_TYPE statement attribute sets the size of the structure which contains a single set of parameters or to the size of an instance of a buffer into which the parameters will be bound. The length should include space for all bound parameters. The length should include space for binding parameter and the structure buffer, or should be buffered to ensure the result to point to the beginning of the next parameter when the address of a bound parameter is incremented to the specified length. ANSI C guarantees it by using the sizeof operator.

3. It calls SQLBindParameter together with the following arguments for each parameter to be bound.

- ValueType is the type of the parameter buffer member to be bound to the column.
- ParameterType is the SQL type of the parameter.
- ParameterValuePtr is the address of the parameter buffer member in the first array element.
- BufferLength is the size of the parameter buffer member.
- StrLen_or_IndPtr is the address of the length/indicator member to be bound.

Error Information

If a driver does not perform parameter arrays as same as batches (the SQL_PARAM_ARRAY_ROW_COUNTS option is as same as SQL_PARC_NO_BATCH), error situations are handled as if one statement were executed.

If the driver performs parameter arrays as batches, an application can use the SQL_DESC_ARRAY_STATUS_PTR header field of the IPD to determine if a parameter of an SQL statement or a parameter in an array of parameters caused SQLExecDirect or SQLExecute to return an error.
This field contains status information for each row of parameter values. If the field represents that an error occurs, fields in the diagnostic data structure will represent the row and parameter number of the failed parameter. The number of columns in the array will be defined by the SQL_DESC_ARRAY_SIZE header field in the APD, and it can be set by the SQL_ATTR_PARAMSET_SIZE statement attribute.

The SQL_DESC_ARRAY_STATUS_PTR header field in the APD is used to ignore parameters. For more information about ignoring parameters, refer to **Ignoring Parameter Set**.

When SQLExecute or SQLExecDirect returns SQL_ERROR, the elements in the array pointed to by the SQL_DESC_ARRAY_STATUS_PTR field in the IPD contain SQL_PARAM_ERROR, SQL_PARAM_SUCCESS, SQL_PARAM_SUCCESS_WITH_INFO, SQL_PARAM_UNUSED, or SQL_PARAM_DIAG_UNAVAILABLE.

For each element in this array, the diagnostic data structure contains one or more status records. The SQL_DIAG_ROW_NUMBER field of the structure represents the row number of the parameter values which c

aused the error. If it is possible to determine the particular parameter in a row of parameters which cause d the error, the parameter number will be entered in the SQL_DIAG_COLUMN_NUMBER field.

SQL_PARAM_UNUSED is set when a parameter is not used due to an error because SQLExecute or SQLEx ecDirect forcibly canceled an earlier parameter. For example, if 50 parameters exist and an error occurred while executing the 40th set of parameters which caused the cancellation by SQLExecute or SQLExecDire ct, then SQL_PARAM_UNUSED is set in the status array for parameters from 41 to 50.

SQL_PARAM_DIAG_UNAVAILABLE is set when the driver treats arrays of parameters as a single unit, so it does not generate individual error information of parameter level.

Some errors in the processing of a single set of parameters cause processing of the subsequent sets of pa rameters in the array to stop. Other errors do not affect the processing of subsequent parameters. The dri ver defines which errors will stop processing. If processing does not stop, all parameters in the array are p rocessed, SQL_SUCCESS_WITH_INFO is returned as a result of the error, and the buffer defined by SQL_A TTR_PARAMS_PROCESSED_PTR is set to the total number of sets of parameters processed which include s error sets.

ODBC behavior when an error occurs in the processing of an array of parameters is different bet ween ODBC 3.x and ODBC 2.x.

In ODBC 2.x, the function returns SQL_ERROR and stops the processing. The buffer pointed to by the pirow argument of SQLParamOptions contained the number of the error row.

In ODBC 3.x, the function returns SQL_SUCCESS_WITH_INFO, and it may stop or continue proc essing. If it continues, the buffer specified by SQL_ATTR_PARAMS_PROCESSED_PTR will be set to the value of all parameters processed, including those which resulted in an error. This change in behavior can cause problems for existing applications.

When SQLExecute or SQLExecDirect returns SQL_ERROR or SQL_NEED_DATA before completing the pro cessing of all parameter sets in a parameter array, the status array contains statuses for those parameters which have already been processed.
The location pointed to by the SQL_DESC_ROWS_PROCESSED_PTR field in the IPD contains the row num ber in the parameter array which caused the SQL_ERROR or SQL_NEED_DATA error code. When an array of parameters is sent to a SELECT statement, the availability of status array values is defined by the driver. They are available after the statement is executed or result sets are fetched.

Ignoring Parameter Set

SQL_DESC_ARRAY_STATUS_PTR field of APD can be used to indicate the binding parameter set which sh ould be ignored in SQL statement. The application should perform the following processes in order that t

he driver directly ignores one or more parameter sets during the execution.

1. It calls SQLSetDescField in order that the header field of SQL_DESC_ARRAY_STATUS_PTR of APD poi nts to an array of SQLUSMALLINT values including the status information. The field also can be set th rough SQL_ATTR_PARAM_OPERATION_PTR of Attribute argument in SQLSetStmtAttr, and it allows to set the field without a descriptor handle which is the application.

2. It sets each element of the array defined by SQL_DESC_ARRAY_STATUS_PTR of APD to one of the f ollowing two values.

- SQL_PARAM_IGNORE: The row is excluded from the execution of the statement.
- SQL_PARAM_PROCEED: The row is included in the execution of the statement.

3. It calls SQLExecDirect or SQLExecute, and executes the prepared statement. It applies the following r ules to the array defined by SQL_DESC_ARRAY_STATUS_PTR of APD.

- The pointer is set to NULL by default.
- If the pointer is NULL, all parameter set are used as if all elements are set to SQL_ROW_PROCEED.
- Setting the element to SQL_PARAM_PROCEED does not guarantee that the operation would use the specific parameter set.
- SQL_PARAM_PROCEED is defines as 0 in the header file.

An application can set SQL_DESC_ARRAY_STATUS_PTR field of APD to refer to the same array as SQL_D ESC_ARRAY_STATUS_PTR field of IRD. It is very useful when binding the parameters to the row data. The parameters may be ignored depending on the status of row data.

Along with SQL_PARAM_IGNORE, the following status codes are to ignore the parameter set in the SQL statement.

- SQL_ROW_DELETED
- SQL_ROW_UPDATED
- SQL_ROW_ERROR

Along with SQL_PARAM_PROCEED, the following status codes are to process the parameter set in the S QL statement.

- SQL_ROW_SUCCESS
- SQL_ROW_SUCCESS_WITH_INFO
- SQL_ROW_ADDED

Rebinding Parameter

The application can include many parameters, but if there is a buffer area for calling SQLExecDirect or SQ LExecute which uses only some parameters, rebinding the parameter is particularly useful. The remaining space of buffer area can be used to set the next parameter by modifying the existing binding through off

set.

The SQL_DESC_BIND_OFFSET_PTR header field of APD points to the binding offset. If the field is not NUL L, the driver dereferences to the pointer. If values of SQL_DESC_DATA_PTR, SQL_INDICATOR_PTR do not exist, and SQL_DESC_OCTET_LENGTH_PTR field is the NULL pointer, then the dereferenced value is adde d to the fields in the descriptor records during the execution time.

Offset is valid after rebinding. The application can directly modify the offset without calling SQLSetDescFi eld or SQLSetDescRec to update the descriptor field because SQL_DESC_BIND_OFFSET_PTR field is the po inter to offset rather than the offset itself. The pointer is NULL by default.

SQL_DESC_BIND_OFFSET_PTR field of ARD can be set by calling SQLSetDescField or through SQL_ATTR_ PARAM_BIND_OFFSET_PTR in Attribute argument of SQLSetStmtAttr. The offset binding always adds the value directly to SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR and SQL_DESC_OCTET_LENGTH_PT R. If offset is changed to another value, the new value is continuously added directly to each descriptor fi eld. The new offset is not added to the previous one.

Descriptor

The way which the parameter is bound is determined by APD and the IPD fields. The arguments in SQLBi ndParameter are used to set the descriptor fields. It is more effective to use the SQLBindParameter becau se the application can call SQLBindParameter without obtaining the descriptor handle, but the fields can also be set by the SQLSetDescField function.

> ⚠ Calling SQLBindParameter for a single statement may affect other statements. It occurs when A RD related to the statement is explicitly allocated and it is related to other statements. The modi fications for the field affects all statements related the descriptor because SQLBindParameter m odifies the fields of ARD. If it is not the required behavior, the application should release the rela tionship between the descriptor and other statements before calling SQLBindParameter.

Notionally, SQLBindParameter should perform the following processes.

1. It calls SQLGetStmtAttr, and obtains the APD handle.

2. It calls SQLGetDescField, and obtains SQL_DESC_COUNT field of APD is obtained. If the value of Col umnNumber exceeds the value of SQL_DESC_COUNT, then it calls SQLSetDescField to increase the v alue of SQL_DESC_COUNT to the value of ColumnNumber.

3. It calls SQLSetDescField multiple times, and sets the values of the following fields of APD.

- It sets SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE to the value of ValueType.
  - It excludes ValueType if ValueType is one of the implied identifiers in datetime or interval sub for mat. It sets SQL_DESC_TYPE to SQL_DATETIME or SQL_INTERVAL, and it sets SQL_DESC_CONCI

SE_TYPE to the implied identifier, and sets SQL_DESC_DATETIME_INTERVAL_CODE to the corres ponding datetime or interval subcode.

- It sets SQL_DESC_OCTET_LENGTH field to the value of BufferLength.
- It sets SQL_DESC_DATA_PTR field to the value of ParameterValue.
- It sets SQL_DESC_OCTET_LENGTH_PTR field to the value of StrLen_or_Ind.
- It also sets SQL_DESC_INDICATOR_PTR field to the value of StrLen_or_Ind.
- StrLen_or_Ind specifies both the indicator information and length of parameter value.

4. It calls SQLGetStmtAttr, and obtains the IPD handle.

5. It calls SQLGetDescField, and obtains SQL_DESC_COUNT field of IPD. If the value of ColumnNumber exceeds the value of SQL_DESC_COUNT, then it calls SQLSetDescField to increase the value of SQL_ DESC_COUNT to the value of ColumnNumber.

6. It calls SQLSetDescField multiple times, and sets the values of following fields of IPD.

- It sets SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE to the value of ParameterType.
  - It excludes ParameterType, if ParameterType is one of the implied identifiers with datetime or int erval sub format. It sets SQL_DESC_TYPE to SQL_DATETIME or SQL_INTERVAL, and it sets SQL_D ESC_CONCISE_TYPE to the implied identifier, and sets SQL_DESC_DATETIME_INTERVAL_CODE t o the corresponding datetime or interval subcode.
- It sets one or more SQL_DESC_LENGTH, SQL_DESC_PRECISION and SQL_DESC_DATETIME_INTERVA L_PRECISION for ParameterType, properly.
- It sets SQL_DESC_SCALE to the value of DecimalDigits.

If it failed to call SQLBindParameter, the contents of the descriptor fields to be set in APD are not defined and SQL_DESC_COUNT field of APD is not changed. Additionally, SQL_DESC_LENGTH, SQL_DESC_PRECI SION, SQL_DESC_SCALE, and SQL_DESC_TYPE fields of the proper record in IPD are not defined and SQL _DESC_COUNT field of IPD is not changed.

SQLBrowseConnect

It is not supported.

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLBrowseConnect finds the attribute and its value which are required to connect to the data source, an d supports a method for the iterative list.

Syntax

```
SQLRETURN SQLBrowseConnect(
    SQLHDBC         ConnectionHandle,
    SQLCHAR *       InConnectionString,
    SQLSMALLINT     StringLength1,
    SQLCHAR *       OutConnectionString,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLength2Ptr);
```

SQLBulkOperations

It is not supported.

Conformance

Introduced version: ODBC 3.0
Standards compliance: ODBC

Overview

SQLBulkOperations performs the massive bookmark operations such as the bulk inserts, and the updates, deletes, fetches through the bookmark.

Syntax

```
SQLRETURN SQLBulkOperations(
    SQLHSTMT       StatementHandle,
    SQLUSMALLINT   Operation);
```

SQLCancel

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLCancel cancels the statement in progress.

Syntax

```
SQLRETURN SQLCancel(
    SQLHSTMT     StatementHandle);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Returns

SQL_SUCCESS, SQL_ERROR or SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle,. This asynchronous function is still being executed even when SQLCancel is called. It failed because the asynchronous operation was being executed in the connection handle related to StatementHandle.
HYT00	Connection timeout expired	The login time limit is expired before connecting to the data source. The time limit can be set via SQL_ATTR_LOGIN_TIMEOUT of SQLSetConnectAttr.

Description

SQLCancel can cancel the following processing in the statement.

- The asynchronously executing function for statement
- The function for the statement requiring the data
- The function whose statement is operated in another thread.

When calling SQLCancel to cancel the asynchronously executing function for statement or the function fo r the statement requiring the data, the diagnosis record is deleted and SQLCancel posts self diagnosis rec ord. However, when calling SQLCancel to cancel the statement operated in another thread, it neither del etes the diagnosis record nor posts self diagnosis record.

When cancelling the statement operating in another thread, it is allowed to make temporary new connec tion to cancel the statement.

SQLCancelHandle

Conformance

Introduced version: ODBC 3.8
Standards compliance: It is not available.

Overview

SQLCancelHandle cancels the statement processing.
For more information, refer to **SQLCancel**.

Syntax

```
SQLRETURN SQLCancelHandle(
    SQLSMALLINT  HandleType,
    SQLHANDLE    Handle);
```

Arguments

HandleType

[Input] It is the handle type. It supports SQL_HANDLE_STMT only.

Handle

[Input] It should be the statement handle.

Returns

SQL_SUCCESS, SQL_ERROR or SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequenc	The asynchronously executing statement-related function is called for the statement handles associated with the handle. This asynchronous function is still being executed even when SQLCancelHandle is called.

SQLSTATE	Error	Description
	e error	It failed because the asynchronous operation was being executed in the related connection handle when the handle is a statement.
HYT00	Connection timeout expired	The login time limit is expired before connecting to the data source. The time limit can be set via SQL_ATTR_LOGIN_TIMEOUT of SQLSetConnectAttr.
IM001	Driver does not support function	It does not support HandleType except for SQL_HANDLE_STMT.

SQLCloseCursor

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLCloseCursor closes an open cursor on the statement and discards the remaining results.

Syntax

```
SQLRETURN SQLCloseCursor(
    SQLHSTMT     StatementHandle);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
24000	Invalid cursor state	Open cursor does not exist on the statement.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	SQL_NEED_DATA is returned after calling SQLExecute, SQLExecDirect, the function is called before sending all data-at-execution parameters.

Description

If open cursor does not exist, SQLCloseCursor returns SQLSTATE 24000(Invalid cursor state). Calling SQLCloseCursor is as same as calling SQLFreeStmt with SQL_CLOSE option. However, when open cursor does not exist, SQLCloseCursor returns SQLSTATE 24000 (Invalid cursor state), but calling SQLFreeStmt does not affect the application.

SQLColAttribute

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLColAttribute returns the descriptor information for the result set column. The descriptor information i s returned as a string or integer value.

Syntax

```
SQLRETURN SQLColAttribute (
    SQLHSTMT        StatementHandle,
    SQLUSMALLINT    ColumnNumber,
    SQLUSMALLINT    FieldIdentifier,
    SQLPOINTER      CharacterAttributePtr,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLengthPtr,
    SQLLEN *        NumericAttributePtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ColumnNumber

[Input] It is the record number to retrieve for a field value in IRD. It starts from 1 and corresponds t o the column number of result data which sequentially increases. The column can be described in r andom order.

The number 0 column can be specified to ColumnNumber, but the undefined value is returned exc ept for SQL_DESC_TYPE and SQL_DESC_OCTET_LENGTH.

FieldIdentifier

[Input] It is the descriptor handle. It defines the field retrieved in IRD. (e.g. SQL_COLUMN_TABLE_ NAME)

CharacterAttributePtr

[Output] It is the buffer pointer returning the field value when the value of FieldIdentifier field of th e ColumnNumber column of IRD is a string. If the field value is not a string, it is not used.

If CharacterAttributePtr is NULL, StringLengthPtr returns the total number of bytes which can be re turned. (Except for null-termination character)

BufferLength

[Input] It is the length of *CharacterAttributePtr when FieldIdentifier is defined in ODBC and Chara cterAttributePtr points to a string or binary buffer. If FieldIdentifier is defined in ODBC and *Charac terAttributePtr is an integer, it is ignored.

StringLengthPtr

[Output] It is the pointer returning the total number of bytes which can be returned in *Character AttributePtr. (Except for null-termination character for the character data)

For the character data, if the number of bytes which can be returned is equal to or bigger than Buf ferLength, the description information of *CharacterAttributePtr is truncated to the length of Buff erLength minus 1, and it is null terminated by the driver.

For other data types, the value of BufferLength is ignored.

NumericAttributePtr

[Output] It is the buffer pointer which returns the field value when the value of FieldIdentifier field of the ColumnNumber column of IRD is a number such as SQL_DESC_COLUMN_LENGTH. If the fie ld value is not a number, it is not used.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	*CharacterAttributePtr buffer is not large enough to return the e ntire string, so the string is truncated. The length of string not tru ncated is returned to *StringLengthPtr. (The function returns SQL _SUCCESS_WITH_INFO.)
07005	Prepared statement not a cursor-specification	The statement does not return the result set, and FieldIdentifier is not SQL_DESC_COUNT. The column to explain does not exist.
07009	Invalid descriptor index	The value of ColumnNumber argument is bigger than the number of columns in the result set.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.

SQLSTATE	Error	Description
HY010	Function sequence error	This function is called before SQLPrepre, SQLExecDirect, the catalog function. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, and this function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	*CharacterAttributePtr is a string, BufferLength is smaller than 0 but it is not SQL_NTS.
HY091	Invalid descriptor field identifier	The value of FieldIdentifier argument is not defined.

Description

SQLColAttribute returns information to *NumericAttributePtr or *CharacterAttributePtr. Integer information is returned as SQLLEN value to *NumericAttributePtr. All other data type information is returned to *CharacterAttributePtr. When information is returned to *NumericAttributePtr, the driver ignores CharacterAttributePtr, BufferLength, StringLengthPtr. When the information is returned to *CharacterAttributePtr, the driver ignores NumericAttributePtr.

SQLColAttribute returns the value in the descriptor field of IRD. The value of FieldIdentifier returned to SQLColAttribute can be obtained by calling SQLGetDescField with appropriate IRD handle.

The following table is the descriptor types returned to SQLColAttribute. The type of NumericAttributePtr is SQLLEN*.

FieldIdentifier	Information return	Description
SQL_DESC_AUTO_UNIQUE_VALUE (ODBC 1.0)	NumericAttributePtr	• SQL_TRUE: It is an auto increment column. • SQL_FALSE: It is neither an auto increment column nor a numeric type.
SQL_DESC_BASE_COLUMN_NAME (ODBC 3.0)	CharacterAttributePtr	It is the default column name for the result set columns. If the default column name does not exist(in case of an expression column), the variable will contain an empty string. This information is returned in the record field of SQL_DESC_BASE_COLUMN_NAME which is the read-only field of IRD.
SQL_DESC_BASE_TABLE_NAME (ODBC 3.0)	CharacterAttributePtr	It is the base table name which contains the column. If the base table name can not be defined or is not applicable the variable contains an empty string. This information is returned in the record field of SQL_DESC_BASE_TABLE_NAME which is the read-only field of IRD.
SQL_DESC_CASE_SENSITIVE (ODBC 1.0)	NumericAttributePtr	• SQL_TRUE: The column is case-sensitive for sorting or comparisons. • SQL_FALSE: The column is neither case-sensitive for sorting or comparison nor is a character.

FieldIdentifier	Information return	Description
SQL_DESC_CATALOG_NAME (ODBC 2.0)	CharacterAttributePtr	It is the catalog of the table containing the column.
SQL_DESC_CONCISE_TYPE (ODBC 1.0)	NumericAttributePtr	It is concise data type. For datetime and interval data, the concise data such as SQL_TYPE_TIME, SQL_INTERVAL_YEAR is returned. This information is returned in the record field of SQL_DESC_CONCISE_TYPE of IRD.
SQL_DESC_COUNT (ODBC 1.0)	NumericAttributePtr	It is the number of columns which can be used in the result set. If column does not exist in the result set, 0 is returned. ColumnNumber argument is ignored. This information is returned in the header field of SQL_DESC_COUNT of IRD.
SQL_DESC_DISPLAY_SIZE (ODBC 1.0)	NumericAttributePtr	It is the maximum number of characters required to display the column.
SQL_DESC_FIXED_PREC_SCALE (ODBC 1.0)	NumericAttributePtr	• SQL_TRUE: The column has the fixed precision and non-zero scale. • SQL_FALSE: The column does not have the fixed precision but it has the non-zero scale.
SQL_DESC_LABEL (ODBC 2.0)	CharacterAttributePtr	It is the column label or title. For example, the column name, EmpName, can be displayed as employee name or alias. If the label doe not exist, the column name is returned. If a label or name is not specified to the column, an empty string is returned.
SQL_DESC_LENGTH (ODBC 3.0)	NumericAttributePtr	It is the maximum or actual length of data of the string or binary data type. A fixed length data type is the maximum character length, and a variable-length data type is the actual character length. This value always excludes the null-termination byte of the string at the end. This information is returned in the record field of SQL_DESC_LENGTH of IRD.
SQL_DESC_LITERAL_PREFIX (ODBC 3.0)	CharacterAttributePtr	This VARCHAR (128) record field contains a character or string which the driver recognizes the prefix of the data type. The data type to which a prefix is not applied contains an empty string.
SQL_DESC_LITERAL_SUFFIX (ODBC 3.0)	CharacterAttributePtr	This VARCHAR (128) record field contains a character or string which the driver recognizes the suffix of the data type. The data type to which a suffix is not applied contains an empty string.
SQL_DESC_LOCAL_TYPE_NAME (ODBC 3.0)	CharacterAttributePtr	The VARCHAR (128) record field contains the localized(native language) name of data type which is different from the regular name of data type. If the localized name does not exist, an empty string is returned. This field is only for display purposes. The character set of string depends on the locale, and the default is usually the character set of the server.
		It is the column alias of when the column alias is applied. If the column alias

FieldIdentifier	Information return	Description
SQL_DESC_NAME (ODBC 3.0)	CharacterAttributePtr	is not applied, the column name is returned. In both cases, SQL_DESC_UNNAMED is set to SQL_NAMED. If column name or alias does not exist, an empty string is returned, and SQL_DESC_UNNAMED is set to SQL_UNNAMED. This information is returned in the record field of SQL_DESC_NAME of IRD.
SQL_DESC_NULLABLE (ODBC 3.0)	NumericAttributePtr	• SQL_NULLABLE: The column can have NULL value. • SQL_NO_NULLS: The column can not have NULL value. • SQL_NULLABLE_UNKNOWN: It is unknown whether NULL value is allowed for the column. This information is returned in the record field of SQL_DESC_NULLABLE of IRD.
SQL_DESC_NUM_PREC_RADIX (ODBC 3.0)	NumericAttributePtr	If the data type of SQL_DESC_TYPE field is the approximate numeric data type, this field contains 2 because SQL_DESC_PRECISION field contains the number of bits. If the data type of SQL_DESC_TYPE field is the exact numeric data type, this field contains 10 because SQL_DESC_PRECISION field contains the number of decimal digits. This field is set to 0 for all non-numeric data types.
SQL_DESC_OCTET_LENGTH (ODBC 3.0)	NumericAttributePtr	It is byte length of string or binary data type. For a fixed-length character or binary data type, it is the actual byte length. For a variable-length character or binary data type, it is the maximum length in bytes. This value does not include null termination. This information is returned in the record field of SQL_DESC_OCTET_LENGTH of IRD.
SQL_DESC_PRECISION (ODBC 3.0)	NumericAttributePtr	It is the precision applicable to the numeric data type. For SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP, all interval data types representing time interval, the value is the applicable fractional seconds precision. This information is returned in the record field of SQL_DESC__PRECISION of IRD.
SQL_DESC_SCALE (ODBC 3.0)	NumericAttributePtr	It is the scale applicable to the numeric data type. For DECIMAL or NUMERIC data type, the scale is defined, and for all other data types, it is not defined. This information is returned in the record field of SQL_DESC_SCALE of IRD.
SQL_DESC_SCHEMA_NAME (ODBC 2.0)	CharacterAttributePtr	It is the schema of a table containing a column.
SQL_DESC_SEAR		• SQL_PRED_NONE: The column can not used in WHERE clause. (It is as same as SQL_UNSEARCHABLE of ODBC 2.x.) • SQL_PRED_CHAR: The column can be used in WHERE clause but only

FieldIdentifier	Information return	Description
CHABLE (ODBC 1.0)	NumericAttributePtr	with the LIKE predicate. (It is as same as SQL_LIKE_ONLY of ODBC 2.x.). • SQL_PRED_BASIC: Any comparison operator except LIKE can be used in WHERE clause. (It is as same as SQL_EXCEPT_LIKE of ODBC 2.x.) • SQL_PRED_SEARCHABLE: The column can be used in WHERE clause together with any comparison operator.
SQL_DESC_TABLE_NAME (ODBC 2.0)	CharacterAttributePtr	It is the name of table including the column. If the tabe name is unknown, an empty string is returned.
SQL_DESC_TYPE (ODBC 3.0)	NumericAttributePtr	It is the numeric value to specify the SQL data type. For datetime or interval data type, the verbose data type such as SQL_DATETIME or SQL_INTERVAL is returned. This information is returned in the record field of SQL_DESC_TYPE of IRD.
SQL_DESC_TYPE_NAME (ODBC 1.0)	CharacterAttributePtr	It is the data type name which is dependent on the data source. (e.g. "CHARACTER", "CHARACTER VARYING", "CHARACTER LONG VARYING")
SQL_DESC_UNNAMED (ODBC 3.0)	NumericAttributePtr	It is SQL_NAMED or SQL_UNNAMED. If the column alias or column name is included in the field of SQL_DESC_NAME of IRD, SQL_NAMED is returned, and if there is not a column name or alias, SQL_UNNAME is returned. This information is returned in the record field of SQL_DESC_UNNAMED of IRD.
SQL_DESC_UNSIGNED (ODBC 1.0)	NumericAttributePtr	• SQL_TRUE: The column is neither an unsigned nor is a number. • SQL_FALSE: The column is a signed.
SQL_DESC_UPDATABLE (ODBC 1.0)	NumericAttributePtr	The column can have the value of SQL_ATTR_READONLY, SQL_ATTR_WRITE, SQL_ATTR_READWRITE_UNKNOWN.

SQLColAttributes

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLColAttributes function in ODBC 2.0 was replaced with SQLColAttribute function in ODBC 3.x. For more information, refer to **SQLColAttribute**.

SQLColumnPrivileges

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLColumnPrivileges returns a list of columns and related privileges for the specified table as a result set.

Syntax

```
SQLRETURN SQLColumnPrivileges(
    SQLHSTMT      StatementHandle,
    SQLCHAR *     CatalogName,
    SQLSMALLINT   NameLength1,
    SQLCHAR *     SchemaName,
    SQLSMALLINT   NameLength2,
    SQLCHAR *     TableName,
    SQLSMALLINT   NameLength3,
    SQLCHAR *     ColumnName,
    SQLSMALLINT   NameLength4);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the catalog name. CatalogName can not include the string search pattern.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, CatalogName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, CatalogName is case-sensitive, and it is an or dinary argument literally processed.

NameLength1

[Input] It is the length of *CatalogName.

SchemaName

[Input] It is the schema name. SchemaName can not include the string search pattern.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, SchemaName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, SchemaName is case-sensitive, and it is an or dinary argument literally processed.

NameLength2

[Input] It is the length of *SchemaName.

TableName

[Input] It is the table name. This argument can not be a null pointer. TableName can not include th e string search pattern.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, TableName is treated as a case-insensitive identifier. If it is set to SQL_FALSE, TableName is case-sensitive, and it is an ordinar y argument literally processed.

NameLength3

[Input] It is the length of *TableName.

ColumnName

[Input] It is the string search pattern for the column name.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, ColumnName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, ColumnName is case-sensitive, and it is a pat ternvalue literally processed.

NameLength4

[Input] It is the length of *ColumnName.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08S01	Communication link failure	Before the function processing is completed, the connection betwee n the driver and the data source is failed.
24000	Invalid cursor state	SQLFetch, SQLFetchScroll are called and a cursor is open.
HY000	General error	It is an error without specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	TableName argument is the null pointer. The attribute value of SQL_ATTR_METADATA_ID is SQL_TRUE state

SQLSTATE	Error	Description
		ment, and SchemaName or ColumnName is the null pointer.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, and the function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	A name length argument value is smaller than 0 but it is not SQL_NTS.
HYT00	Timeout expired	Before downloading the entire result set from the data source, the query timeout expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

SQLColumnPrivileges returns the standard result set aligned as TABLE_CAT, TABLE_SCHEM, TABLE_NAME, COLUMN_NAME, PRIVILEGE.

The following table describes the columns in the result set.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	VARCHAR	It is the catalog identifier.
TABLE_SCHEM (ODBC 1.0)	2	VARCHAR	It is the schema identifier.
TABLE_NAME (ODBC 1.0)	3	VARCHAR not NULL	It is the table identifier.
COLUMN_NAME (ODBC 1.0)	4	VARCHAR not NULL	It is the column name. It returns an empty string for a column which does not have a name.
GRANTOR (ODBC 1.0)	5	VARCHAR	It is the grantor name.
GRANTEE (ODBC 1.0)	6	VARCHAR not NULL	It is the grantee name.
PRIVILEGE (ODBC 1.0)	7	VARCHAR not NULL	It is the column privilege identifier. It can be one of the followings. • SELECT: The grantee is allowed to retrieve the column data. • INSERT: The grantee is allowed to insert the data to the column of the associated table. • UPDATE: The grantee is allowed to update the column data. • REFERENCES: The grantee is allowed to reference the column in the constrains. (e.g. unique, referential, table check constraint)

Column name	Column number	Data type	Description
IS_GRANTABLE (ODBC 1.0)	8	VARCHAR	It checks whether the grantee can grant the privilege to other user, and it is specified as "YES", "NO".

SQLColumns

Conformance

Introduced version: ODBC 1.0
Standards compliance: Open Group

Overview

SQLColumns returns a list of column names in the specified table as a result set.

Syntax

```
SQLRETURN SQLColumns(
    SQLHSTMT       StatementHandle,
    SQLCHAR *      CatalogName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      SchemaName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      TableName,
    SQLSMALLINT    NameLength3,
    SQLCHAR *      ColumnName,
    SQLSMALLINT    NameLength4);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the catalog name. CatalogName can not include the string search pattern.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, CatalogName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, CatalogName is case-sensitive, and it is an or dinary argument literally processed.

NameLength1

[Input] It is the length of *CatalogName

SchemaName

[Input] It is the string search pattern for the schema name.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, SchemaName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, SchemaName is case-sensitive, and it is an or dinary argument literally processed.

NameLength2

[Input] It is the length of *SchemaName.

TableName

[Input] It is the string search pattern for the table name.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, TableName is treated as a case-insensitive identifier. If it is set to SQL_FALSE, TableName is case-sensitive, and it is an ordinar y argument literally processed.

NameLength3

[Input] It is the length of *TableName.

ColumnName

[Input] It is the string search pattern for the column name.

If the SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, ColumnName is treated a s a case-insensitive identifier. If it is set to SQL_FALSE, ColumnName is case-sensitive, and it is a pat tern value literally processed.

NameLength4

[Input] It is the length of *ColumnName.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08S01	Communication l ink failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
24000	Invalid cursor stat e	SQLFetch, SQLFetchScroll are called and a cursor is open.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio n error	It is a memory allocation error.
HY009	Invalid use of null pointer	TableName argument is a null pointer. The attribute value of SQL_ATTR_METADATA_ID statement is SQL_TRUE, S chemaName or ColumnName is a null pointer.
HY010	Function sequenc e error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, and the function is called before sending all data-at-execution variables.

SQLSTATE	Error	Description
HY090	Invalid string or buffer length	A name length argument value is smaller than 0 but it is not SQL_NTS.
HYT00	Timeout expired	Before downloading the entire result set from the data source, the query timeout expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

This function is generally used prior to the execution of statement which retrieves information about the columns of the table or tables in the catalog of the data source. SQLColumns can be used to retrieve all data types returned by SQLTables. By contrast, SQLColAttribute and SQLDescribeCol describe the columns in the result set, and SQLNumResultCols returns the number of columns in the result set.

SQLColumns returns the standard result set sorted as TABLE_CAT, TABLE_SCHEM, TABLE_NAME, ORDINAL_POSITION.

The following table describes the columns in the result set.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	VARCHAR	It is the catalog name.
TABLE_SCHEM (ODBC 1.0)	2	VARCHAR	It is the schema name.
TABLE_NAME (ODBC 1.0)	3	VARCHAR not NULL	It is the table name.
COLUMN_NAME (ODBC 1.0)	4	VARCHAR not NULL	It is the column name. It returns an empty string for a column which does not have a name.
DATA_TYPE (ODBC 1.0)	5	SMALLINT not NULL	It is SQL data type. For datetime and interval data types, the column returns the concise data type like SQL_TYPE_DATE, SQL_INTERVAL_YEAR_TO_MONTH.
TYPE_NAME (ODBC 1.0)	6	VARCHAR not NULL	It is the data type name dependent on the data source. (e.g. "CHARACTER", "CHARACTER VARYING", "CHARACTER LONG VARYING")
COLUMN_SIZE (ODBC 1.	7	INTEGER	If DATA_TYPE is SQL_CHAR or SQL_VARCHAR, the column includes the maximum number of characters up to length of the column. If it is datetime data column, it is the number of characters needed for converting the value to the character. If it is a numeric data type, it is the total

Column name	Column number	Data type	Description
0)			number of digits of the column NUM_PREC_RADIX or the number of b its allowed for the column. If it is an interval data type, it is the number of characters needed to be represented by the interval leading precisio n.
BUFFER_LEN GTH (ODBC 1.0)	8	INTEGER	If SQL_C_DEFAULT is specified, it is the byte length of the data to be tr ansmitted to SQLGetData, SQLFetch, SQLFetchScroll.
DECIMAL_D IGITS (ODBC 1.0)	9	SMALLINT	For a positive number, it is the number of significant digits on the right of the decimal point. For a negative number, it is the number of signific ant digits on the left of the decimal point. For SQL_TYPE_TIME and SQ L_TYPE_TIMESTAMP, this column is the number of digits of fractional s econds. For interval data type that contains the second, it is the numbe r of digits right of the decimal point(fractional seconds). The data type that DECIMAL DIGITS can not be applied, returns NULL.
NUM_PREC _RADIX (OD BC 1.0)	10	SMALLINT	For the numeric data type, it is 2 or 10. For 2, COLUMN_SIZE and DECIMAL_DIGITS are the number of bits allo wed in the column. For 10, COLUMN_SIZE and DECIMAL_DIGITS are th e number of digits allowed in the column. The data type that NUM_PREC_RADIX can not be applied, returns NUL L.
NULLABLE (ODBC 1.0)	11	SMALLINT n ot NULL	• SQL_NO_NULLS: The column can not have NULL value. • SQL_NULLABLE: The column can have NULL value. • SQL_NULLABLE_UNKNOWN: It is unknown whether the column is allowed to have NULL value.
REMARKS (ODBC 1.0)	12	VARCHAR	It is the description on the column.
COLUMN_D EF (ODBC 3. 0)	13	VARCHAR	It is the default value of column. If the value is enclosed by the quote, t he column should be interpreted as a string.
SQL_DATA_ TYPE (ODBC 3.0)	14	SMALLINT n ot NULL	It is the SQL data type of the record field of SQL_DESC_TYPE of IRD. Th e column is the same as DATA TYPE except the datetime and interval d ata types. For datetime and interval data types, the column returns the nonconcise data type like SQL_DATE, SQL_INTERVAL, and the specific data type is determined using SQL_DATETIME_SUB column.
SQL_DATETI ME_SUB (O DBC 3.0)	15	SMALLINT	It is the sub type code of datetime and interval data types. Other data t ypes return NULL.
CHAR_OCTE T_LENGTH (ODBC 3.0)	16	INTEGER	It is the maximum length in bytes of characters or binary data type colu mn. Other data types return NULL.
ORDINAL_P			

Column name	Column number	Data type	Description
OSITION (ODBC 3.0)	17	INTEGER not NULL	It is the column position in the table.
IS_NULLABLE (ODBC 3.0)	18	VARCHAR	• "NO": The column can not contain NULL. • "YES": The column can contain NULL. If it is unknown whether NULL is allowed, It returns a zero-length string.

SQLConnect

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLConnect sets a connection between the driver and the data source. The connection handle refers to a ll information about the connection including status, transaction status and error information.

Syntax

```
SQLRETURN SQLConnect(
    SQLHDBC        ConnectionHandle,
    SQLCHAR *      ServerName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      UserName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      Authentication,
    SQLSMALLINT    NameLength3);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

ServerName

[Input] It is the data source name.

NameLength1

[Input] It is the length of *ServerName.

UserName

[Input] It is the user identifier.

NameLength2

[Input] It is the length of *UserName.

Authentication

[Input] It is the authentication string (typically password).

NameLength3

[Input] It is the length of *Authentication.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE, SQL_STILL_EXECUTING

Diagnosis

SQLSTATE	Error	Description
08001	Client unable to establish connection	The driver can not set a connection with a data source.
08002	Connection name in use	The specified ConnectionHandle is already connected with the data source.
08004	Server rejected the connection	In the state of the setting limits, the data source rejects to establish the connection.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
28000	Invalid authorization specification	The argument value of UserName or Authentication is not correct.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY090	Invalid string or buffer length	The value of NameLength1, NameLength2 or NameLength3 is smaller than 0, but it is not SQL_NTS.
HYT00	Timeout expired	Before connecting to the data source, Login timeout expired. The timeout can be set through SQL_ATTR_LOGIN_TIMEOUT of SQLSetConnectAttr.

Description

The driver searches for the user DSN information in an order of $HOME/.odbc.ini file and /home/.odbc.ini file which are files set in $ODBCINI environment variable. If the DSN which was input in the user DSN does not exist, the driver searches for the DSN information in an order of $ODBCSYSINI/odbc.ini file, /etc/odbc.ini file which is system DSN.

SQLCopyDesc

It is not supported.

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLCopyDesc copies the descriptor information from one descriptor handle to another descriptor handle.

Syntax

```
SQLRETURN SQLCopyDesc(
    SQLHDESC     SourceDescHandle,
    SQLHDESC     TargetDescHandle);
```

SQLDescribeCol

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLDescribeCol returns a column name, type, column size, decimal place, information about null permit i n the result set column. The information can be used in the fields of IRD.

Syntax

```
SQLRETURN SQLDescribeCol(
    SQLHSTMT       StatementHandle,
    SQLUSMALLINT   ColumnNumber,
    SQLCHAR *      ColumnName,
    SQLSMALLINT    BufferLength,
    SQLSMALLINT *  NameLengthPtr,
    SQLSMALLINT *  DataTypePtr,
    SQLULEN *      ColumnSizePtr,
    SQLSMALLINT *  DecimalDigitsPtr,
    SQLSMALLINT *  NullablePtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ColumnNumber

[Input] It is the column number in the result set which is started from 1 and increased sequentially.

ColumnName

[Output] It is the buffer pointer which is terminated by a null and returns the column name. This va lue can be read in SQL_DESC_NAME field of IRD. If the column name does not exist or the column name is unknown, the driver returns an empty string.

If ColumnName is null, NameLengthPtr returns the total number of bytes returnable. (excluding nu ll-termination character)

BufferLength

[Input] It is the length of *ColumnName.

NameLengthPtr

[Output] It is the buffer pointer which returns the total number of bytes returnable to *ColumnName (excluding the null-termination character). If the returnable length is equal to or bigger than BufferLength, *ColumnName is truncated to the length of BufferLength minus null.

DataTypePtr

[Output] It is the buffer pointer which returns the SQL type of a column. The value can be read in SQL_DESC_CONCISE_TYPE of IRD.

ColumnSizePtr

[Output] It is the buffer pointer which returns the column size of the data source.

DecimalDigitsPtr

[Output] It is the buffer pointer which returns the decimal place of the data source.

NullablePtr

[Output] It is the buffer pointer which returns whether the column allows for null. The value can be read in SQL_DESC_NULLABLE field of IRD. It is one of the followings.

- SQL_NO_NULLS: The column does not allow NULL.
- SQL_NULLABLE: The column allows NULL.
- SQL_NULLABLE_UNKNOWN: The driver can not determine whether the column allows NULL.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	*ColumnName is not large enough to return the entire column name, so the column name is truncated. The column length not truncated is returned in *NameLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
07005	Prepared statement not a cursor-specification	The statement does not return a result set, so there is not a column to be explained.
07009	Invalid descriptor index	The value of ColumnNumber argument is bigger than the number of columns in the result set.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.

SQLSTATE	Error	Description
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation failure	It is a memory allocation error.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, the function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	The value of BufferLength argument is smaller than 0.

Description

Generally, the application calls SQLDescibeCol before or after calling SQLExecute related after calling SQL Prepare. Also, the application may call SQLDescribeCol after calling SQLExecDirect.

SQLDescribeParam

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLDescribeParam returns the description of a parameter marker related to a prepared SQL statement. T his information can be used in the fields of the IPD.

Syntax

```
SQLRETURN SQLDescribeParam(
    SQLHSTMT        StatementHandle,
    SQLUSMALLINT    ParameterNumber,
    SQLSMALLINT *   DataTypePtr,
    SQLULEN *       ParameterSizePtr,
    SQLSMALLINT *   DecimalDigitsPtr,
    SQLSMALLINT *   NullablePtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ParameterNumber

[Input] It is the parameter marker number which is started from 1 and increased sequentially.

DataTypePtr

[Output] It is the buffer pointer which returns the SQL type of parameter. The value can be read in the record field of SQL_DESC_CONCISE_TYPE of IPD.

ParameterSizePtr

[Output] It is the buffer pointer which returns the size of column or expression for the parameter marker.

DecimalDigitsPtr

[Output] It is the buffer pointer which returns the decimal places of column or expression for the p arameter marker.

NullablePtr

[Output] It is the buffer pointer which returns whether the parameter allows for null. The value can be read in SQL_DESC_NULLABLE of IPD. The value is one of the followings.

- SQL_NO_NULLS: The parameter does not allow NULL.
- SQL_NULLABLE: The parameter allows NULL.
- SQL_NULLABLE_UNKNOWN: The driver can not determine whether the parameter allows NULL.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
07009	Invalid descriptor index	The value of ParameterNumber argument is smaller than 1. The value of ParameterNumber argument is bigger than the number of parameters of the related SQL statement.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The function is called before SQLPrepare or SQLExecDirect. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, and the function is called before sending all data-at-execution variables.

Description

SQL_VARCHAR should be returned to *DataTypePtr, 4000 should be returned to *ParameterSizePtr, 0 should be returned to *DecimalDigitsPtr, and SQL_NULLABLE should be returned to *NullablePtr because the driver can not provide the exact information of the parameter using the prepared SQL.

SQLDisconnect

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLDisconnect closes the connection related to the specific connection handle.

Syntax

```
SQLRETURN SQLDisconnect(
    SQLHDBC     ConnectionHandle);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE, SQL_STILL_EXECUTING

Diagnosis

SQLSTATE	Error	Description
08003	Connection not open	The connection of ConnectionHandle argument is not open.
25000	Invalid transaction state	The transaction is in progress on the connection of ConnectionHandle argument. The transaction remains active.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.

Description

If the application calls SQLDisconnect to the connection handle with an incomplete transaction, the driver returns SQLSTATE 25000 (Invalid transaction state), the transaction is not changed, and the connection is open. The incomplete transaction is a transaction which is not committed or rolled back by using SQLEnd Tran.

If the application calls SQLDisconnect before disconnecting all statements, the driver is disconnected from the data source, then deletes all statements and the descriptor explicitly assigned to the connection handl e.

SQLDriverConnect

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLDriverConnect can replace SQLConnect, and it supports the data source which requires more information of connection than three arguments of SQLConnect.

SQLDriverConnect establishes the connection by using the connection string which includes other information required by the data source name, one or more users, one or more passwords and the data sources.

When the connection is established, SQLDriverConnect returns the completed connection string. The application can use this string when requesting the next connection.

Syntax

```
SQLRETURN SQLDriverConnect(
    SQLHDBC         ConnectionHandle,
    SQLHWND         WindowHandle,
    SQLCHAR *       InConnectionString,
    SQLSMALLINT     StringLength1,
    SQLCHAR *       OutConnectionString,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLength2Ptr,
    SQLUSMALLINT    DriverCompletion);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

WindowHandle

[Input] It is the window handle. The application passes the superordinate window handle or a null pointer, and for the null pointer, SQLDriverConnect does not display the dialog box.

InConnectionString

[Input] It is the full connection string, partial connection string or empty string.

StringLength1

[Input] It is the length of *InConnectionString.

OutConnectionString

[Output] It is the buffer pointer of the completed connection string. If it is successfully connected to the target data source, the buffer contains the completed connection string. The application should allocate a buffer with at least 1,024 characters.

If OutConnectionString is NULL, the total number of returnable characters are returned in StringLength2Ptr (excluding null termination character).

BufferLength

[Input] It is the length of *OutConnectionString

StringLength2Ptr

[Output] It is the buffer pointer which returns the total number of returnable characters to *OutConnectionString (excluding null termination character). If the returnable length is equal to or bigger than BufferLength, *OutConnectionString is truncated to the length of BufferLength minus a null-termination character.

DriverCompletion

[Input] It is a flag that indicates whether the driver has to request more information. the value is one of SQL_DRIVER_PROMPT, SQL_DRIVER_COMPLETE, SQL_DRIVER_COMPLETE_REQUIRED, SQL_DRIVER_NOPROMPT.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE, SQL_STILL_EXECUTING

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	*OutConnectionString buffer is not large enough to return the entire connection string, so the connection string is truncated. The connection string length not truncated is returned in *StringLength2Ptr. (The function returns SQL_SUCCESS_WITH_INFO.)
08001	Client unable to establish connection	The driver can not establish a connection with the data source.
08002	Connection name in use	The specified ConnectionHandle is already connected with a data source.

SQLSTATE	Error	Description
08004	Server rejected the connection	In the state of the limits of the setting value, the data source rejects to establish the connection.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
28000	Invalid authorization specification	The user identifier and authentication string of the connection string are not correct.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY090	Invalid string or buffer length	The value of StringLength1 argument is smaller than 0, but it is not SQL_NTS. The value of BufferLength argument is smaller than 0.
HY110	Invalid driver completion	The value of DriverCompletion argument is not one of SQL_DRIVER_PROMPT, SQL_DRIVER_COMPLETE, SQL_DRIVER_COMPLETE_REQUIRED, SQL_DRIVER_NOPROMPT.
HYC00	Optional feature not implemented	The driver does not support the ODBC operation which is required by the application.
HYT00	Timeout expired	Before connecting to the data source, login timeout is expired. The timeout can be set through SQL_ATTR_LOGIN_TIMEOUT of SQLSetConnectAttr.

Description

The syntax of connection string is as follows.

```
connection-string ::= empty-string[;] ¦ attribute[;] ¦ attribute; connection-string
empty-string ::=attribute ::= attribute-keyword=attribute-value ¦ DRIVER=[{]attribute-value[}]
attribute-keyword ::= DSN ¦ PROTOCOL ¦ CS_MODE ¦ HOST ¦ PORT ¦ UID ¦ PWD ¦ ALTERNATE_SERVERS ¦
FAILOVER_TYPE ¦ FAILOVER_GRANULARITY ¦ DATE_FORMAT ¦ TIME_FORMAT ¦ TIME_WITH_TIME_ZONE_FORMAT
¦ TIMESTAMP_FORMAT ¦ TIMESTAMP_WITH_TIME_ZONE_FORMAT ¦ CHAR_LENGTH_UNITS ¦ CONN_NAME
attribute-value ::= character-string
```

character-string is zero or more characters. attribute-keyword is case-insensitive, and attribute-value may be case-sensitive. The value of DSN keyword does not consist only of white spaces.

The following table describes attribute-keywords.

Keyword	Description
DSN	It is the data source name.
PROTOCOL	It is the connection type (DA, TCP).
CS_MODE	It sets whether to connect with dedicated mode or shared mode. If the setting is not used, the mode is determined depending on the configuration (DE

Keyword	Description
	FAULT_CS_MODE) of listener.
HOST	It is the host name or the IP address.
PORT	It is the connection port number.
TCP_NODELAY	It is a socket TCP_NODELAY option.
UID	It is the user ID.
PWD	It is the password for user ID. If password does not exist, it is an empty string (PWD=;).
ALTERNATE_SERVERS	It is a server list which attempts a connection when the failover occurs, and each server is separated with comma (,). If failover is not used, ALTERNATE_SERVERS is not set.
FAILOVER_TYPE	• CONNECTION: When the connection fails, it is connected to ALTERNATE_SERVERS. • SESSION: When the connection fails or the connection is disconnected during operating the statement, it is connected to ALTERNATE_SERVERS and the statement is restored. The statement is executed after the failover if the connection is disconnected when a transaction is not in progress.
FAILOVER_GRANULARITY	• 0: Failover proceeds even when an error occurs during the failover. • 1: Failover fails when an error occurs except for SQLExeceute(), SQLExecDirect() during the failover. • 2: Failover fails when an error occurs during the failover.
DATE_FORMAT	It is the DATE type format string.
TIME_FORMAT	It is the TIME type format string.
TIME_WITH_TIME_ZONE_FORMAT	It is the TIME WITH TIME ZONE type format string.
TIMESTAMP_FORMAT	It is the TIMESTAMP type format string.
TIMESTAMP_WITH_TIME_ZONE_FORMAT	It is the TIMESTAMP WITH TIME ZONE type format string.
CHAR_LENGTH_UNITS	If ParameterType is one of SQL_CHAR or SQL_VARCHAR in SQLBindParameter(), it is a unit of ColumnSize. • BYTE, OCTETS: Bytes unit • CHAR, CHARACTERS: Characters unit
CONN_NAME	It is the connection name used in XA. The specified name is valid only in embedded SQL program, and is ignored in other programs.

SQLEndTran

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLEndTran requests a commit or rollback for active transactions of all statements related to the connecti on.

Syntax

```
SQLRETURN SQLEndTran(
    SQLSMALLINT   HandleType,
    SQLHANDLE     Handle,
    SQLSMALLINT   CompletionType);
```

Arguments

HandleType

[Input] It is the handle identifier. If it is an environment handle it is SQL_HANDLE_ENV, and if it is a connection handle it is SQL_HANDLE_DBC.

Handle

[Input] It is the handle of HandleType which indicates the transaction range.

CompletionType

[Input] It is SQL_COMMIT or SQL_ROLLBACK.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE, SQL_STILL_EXECUTING

Diagnosis

SQLSTATE	Error	Description
08003	Connection not o	HandleType is SQL_HANDLE_DBC, and a handle is not connected.

SQLSTATE	Error	Description
	pen	
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned, and the function is called before sending all data-at-execution variables.
HY012	Invalid transaction operation code	The value of CompletionType argument is not one of SQL_COMMIT or SQL_ROLLBACK.
HY092	Invalid attribute/ option identifier	The value of HandleType argument is not one of SQL_HANDLE_ENV or SQL_HANDLE_DBC.

Description

If CompletionType is SQL_COMMIT, then SQLEndTran requests the commit for all active transactions of statements related to the connection. If CompletionType is SQL_ROLLBACK, then SQLEndTran requests the rollback for all active transactions of statements related to the connection. If active transaction does not exist, SQLEndTran returns SQL_SUCCESS without affecting the data source.

If the driver is a manual commit mode(The SQL_ATTR_AUTOCOMMIT attribute is set to SQL_AUTOCOMMIT_OFF by calling SQLSetConnectAttr.) and the SQL statement is executed for the current data source, a new transaction implicitly starts.

SQLEndTran does not affect the open cursor related to the connection when committing. The cursor remains on the row pointed before calling SQLEndTran.

SQLEndTran closes all open cursors on all statements when rolling back. SQLEndTran sets the statement to the ready state, and the application does not call SQLPrepare, but it calls SQLExecute.

If an active transaction does not exist, SQLEndTran returns SQL_SUCCESS.

If the driver is an auto commit mode, SQLEndTran always returns SQL_SUCCESS regardless of CompletionType.

SQLError

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLError returns an error or status information.

SQLExecDirect

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

If SQLExecDirect has the parameter in the statement, it executes the statement by using the current value of parameter marker. SQLExecDirect is the fastest way of when the statement is executed only once.

Syntax

```
SQLRETURN SQLExecDirect(
    SQLHSTMT     StatementHandle,
    SQLCHAR *    StatementText,
    SQLINTEGER   TextLength);
```

Arguments

StatementHandle

[Input] It is the statement handle.

StatementText

[Input] It is the executed SQL statement.

TextLength

[Input] It is the length of *StatementText.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NEED_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_NO_DATA, SQL_INVALID_HANDLE, SQL_PARAM_DATA_AVAILABLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The string or binary data returned to the input/output or output parameters are truncated. The right part of the string is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value changed	It is temporarily replaced with a similar value because the attribute value of t he specified statement is not suitable for executing the operation. (SQLGetS tmtAttr can be called to see which value is temporarily changed.) The replac ed value is valid until the cursor is closed, and it is changed to the previous v alue when the cursor is closed. The statement attributes which can be changed are as follows. SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ ATTR_KEYSET _SIZE, SQL_ATTR_MAX_LENGTH, SQL_ATTR_MAX_ROWS, SQL_ ATTR_QUE RY_TIMEOUT, SQL_ATTR_SIMULATE_CURSOR. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The data value identified by ValueType argument of SQLBindParameter can not be converted to the data type identified by ParameterType argument of SQLBindParameter. The data value returned to the parameter of SQL_PARAM_INPUT_OUTPUT o r SQL_PARAM_OUTPUT can not be converted to the data type identified by ValueType argument of SQLBindParameter. (If one or more rows are successfully returned, the function returns SQL_SU CCESS_WITH_INFO.)
07007	Restricted parameter value violation	The parameter type is SQL_PARAM_INPUT_OUTPUT, and *StrLen_or_IndPtr of SQLBindParameter is not one of SQL_NULL_DATA, SQL_DEFAULT_PARA M, SQL_LEN_DATA_AT_EXEC(len), or SQL_DATA_AT_EXEC.
08S01	Communication link failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
22001	String data, right truncation	The string, or binary data is truncated.
22002	Indicator variable req uired but not supplied	NULL data is bound to the output parameter whose of StrLen_or_IndPtr of S QLBindParameter is the null pointer.
24000	Invalid cursor state	The cursor is positioned in StatementHandle through SQLFetch, SQLFetchScr oll. The cursor is open but it is not positioned in StatementHandle. *StatementText is the positioned update or delete statement, and the cursor

SQLSTATE	Error	Description
		is positioned before the start or after the end of the result set.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	*StatementText is the null pointer.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	The argument value of TextLength is smaller than 0, but it is not SQL_NTS. The parameter value set by SQLBindParameter is the null pointer, and the parameter length is not 0, SQL_NULL_DATA, SQL_DATA_AT_EXEC, SQL_DEFAULT_PARAM, or less than SQL_LEN_DATA_AT_EXEC_OFFSET. The parameter value set by SQLBindParameter is not the null pointer, and C data type is SQL_C_BINARY or SQL_C_CHAR, and the parameter length is smaller than 0, but it is not less than SQL_NTS, SQL_NULL_DATA, SQL_DATA_AT_EXEC, SQL_DEFAULT_PARAM, or equal to or less than SQL_LEN_DATA_AT_EXEC_OFFSET.
HYT00	Timeout expired	Before returning the result set from the data source, the query timeout is expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

The application sends the SQL statement to the data source by calling SQLExecDirect.

The application can include one or more parameter markers in an SQL statement. The application should include a question mark (?) on the appropriate position of SQL statement to include a parameter marker.

If the SQL statement is the SELECT statement and the application connects the cursor with SQLSetCursorName, the driver uses the specified cursor. If the application does not connect the statement and the cursor, then the driver creates a cursor name.

If the data source is the manual commit mode, and the transaction has not yet been started, the driver starts the transaction before sending the SQL statement.

If SQLExecDirect finds the parameter of data-at-execution, it returns SQL_NEED_DATA. The application transmits data by using SQLParamData and SQLPutData.

If SQLExecDirect executes the statement such as searched update, insert, or delete, but rows have not been changed on the data source, then calling SQLExecDirect returns SQL_NO_DATA.

If the attribute value of SQL_ATTR_PARAMSET_SIZE statement is bigger than 1, and the SQL statement in cludes at least one parameter marker character, then SQLExecDirect executes the SQL statement once pe r a parameter set in the array pointed by ParameterValuePtr argument of SQLBindParameter.

SQLExecute

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

If a statement includes a parameter, SQLExecute performs the prepared statement by using the current v alue of the parameter marker.

Syntax

```
SQLRETURN SQLExecute(
    SQLHSTMT     StatementHandle);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NEED_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL _NO_DATA, SQL_INVALID_HANDLE, SQL_PARAM_DATA_AVAILABLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The string or binary data returned to the input/output or output parameters are truncated. The right part of the string is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value	It is temporarily replaced with a similar value because the attribute value of t he specified statement is not suitable for executing the operation. (SQLGetS tmtAttr can be called to see which value is temporarily changed.) The replac ed value is valid until the cursor is closed, and it is changed to the previous v alue when the cursor is closed.

SQLSTATE	Error	Description
	changed	The statement attributes which can be changed are as follows. SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ ATTR_KEYSET _SIZE, SQL_ATTR_MAX_LENGTH, SQL_ATTR_MAX_ROWS, SQL_ ATTR_QUE RY_TIMEOUT, SQL_ATTR_SIMULATE_CURSOR. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The data value identified by ValueType argument of SQLBindParameter can not be converted to the data type identified by ParameterType argument of SQLBindParameter. The data value returned to the parameter of SQL_PARAM_INPUT_OUTPUT o r SQL_PARAM_OUTPUT can not be converted to the data type identified by ValueType argument of SQLBindParameter. (If one or more rows are successfully returned, the function returns SQL_SU CCESS_WITH_INFO.)
07007	Restricted parameter value violation	The parameter type is SQL_PARAM_INPUT_OUTPUT, and *StrLen_or_IndPtr of SQLBindParameter is not one of SQL_NULL_DATA, SQL_DEFAULT_PARA M, SQL_LEN_DATA_AT_EXEC(len), or SQL_DATA_AT_EXEC.
08S01	Communication link failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
22001	String data, right truncation	The string, or binary data is truncated.
22002	Indicator variable req uired but not supplied	NULL data is bound to the output parameter whose of StrLen_or_IndPtr of S QLBindParameter is the null pointer.
24000	Invalid cursor state	The cursor is positioned in StatementHandle through SQLFetch, SQLFetchScr oll. The cursor is open but it is not positioned in StatementHandle. *StatementText is the positioned update or delete statement, and the cursor is positioned before the start or after the end of the result set.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	*StatementText is the null pointer.
HY010	Function sequence er ror	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
		The argument value of TextLength is smaller than 0, but it is not SQL_NTS.

SQLSTATE	Error	Description
HY090	Invalid string or buffer length	The parameter value set by SQLBindParameter is the null pointer, and the parameter length is not 0, SQL_NULL_DATA, SQL_DATA_AT_EXEC, SQL_DEFAULT_PARAM, or less than SQL_LEN_DATA_AT_EXEC_OFFSET. The parameter value set by SQLBindParameter is not the null pointer, and C data type is SQL_C_BINARY or SQL_C_CHAR, and the parameter length is smaller than 0, but it is not less than SQL_NTS, SQL_NULL_DATA, SQL_DATA_AT_EXEC, SQL_DEFAULT_PARAM, or equal to or less than SQL_LEN_DATA_AT_EXEC_OFFSET.
HYT00	Timeout expired	Before returning the result set from the data source, the query timeout is expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

SQLExecute executes the statement prepared by SQLPrepare. The application can call SQLExecute again with the new parameter value after it discards the result of calling SQLExecute.

To execute SELECT statement once or more, the application should call SQLCloseCursor before executing SELECT statement again.

If the data source is a manual commit mode, and the transaction has not yet been started, the driver starts the transaction before sending the SQL statement.

If SQLExecute finds a data-at-execution parameter, it returns SQL_NEED_DATA. The application sends data by using SQLParamData and SQLPutData.

If SQLExecute executes the statement such as searched update, insert, or delete, but rows have not been changed on the data source, calling SQLExecute returns SQL_NO_DATA.

If the attribute value of SQL_ATTR_PARAMSET_SIZE statement is bigger than 1, and the SQL statement includes at least one parameter marker character, then SQLExecute executes the SQL statement once per a parameter set in the array pointed by ParameterValuePtr argument of SQLBindParameter.

SQLExtendedFetch

Conformance

Introduced version: ODBC 1.0.
Compliance: It is not available.

Overview

SQLExtendedFetch fetches the specified data set from the result set, and returns it to all bound columns.

Syntax

```
SQLRETURN SQLExtendedFetch(
    SQLHSTMT         StatementHandle,
    SQLUSMALLINT     FetchOrientation,
    SQLLEN           FetchOffset,
    SQLULEN *        RowCountPtr,
    SQLUSMALLINT *   RowStatusArray);
```

SQLFetch

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLFetch fetches the next row set from the result set, and returns it to all columns bound.

Syntax

```
SQLRETURN SQLFetch(
    SQLHSTMT     StatementHandle);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The string, binary data returned for the columns are truncated. The right part of the string is truncated.
01S07	Fractional truncation	The data returned for the column is truncated. For numeric data types, the decimal place is truncated. For time, timestamp, interval data types which contain the period component, the decimal place of time is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The column data value in the result set can not be converted to the data type specified by TargetType of SQLBindCol.

SQLSTATE	Error	Description
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
22002	Indicator variable required but not supplied	StrLen_or_IndPtr (or SQL_DESC_INDICATOR_PTR set by SQLSetDescField or SQLSetDescRec) of SQLBindCol fetches NULL data to the column which is the null pointer.
22003	Numeric value out of range	The integer part (not the decimal place) of the numerical value returned from one or more columns is truncated.
22007	Invalid datetime format	The string in the result set is not the valid date, time, timestamp format.
22012	Division by zero	The result of the arithmetic expression divided by 0 is returned.
22015	Interval field overflow	When the interval C type is specified in the exact numeric or interval SQL data type, the significant figures in the leading field is lost. The value of SQL type can not be expressed to C interval type.
22018	Invalid character value for cast specification	The character not represented as the character set of C buffer is included in the character column of the result set. The C type is the exact or approximate numeric, datetime, interval data type, and if the SQL type is the character data type, the value of the column bound to the C type is not valid.
24000	Invalid cursor state	StatementHandle is executed but the result set related to StatementHandle does not exist.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The StatementHandle specified is not at the state of running. The function is called without calling SQLExecDirect, SQLExecute, the catalog function. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HYT00	Timeout expired	Before returning the result set from the data source, the query timeout is expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

SQLFetch returns the next data set from the result set. SQLFetch can be called while the result set exists, which is after the result set is created and before the cursor is closed. If the column is bound, the data is returned to the column. If the application specifies the pointer to a row status array or specifies the buffer which returns the number of fetched rows, SQLFetch also returns this information. SQLFetch and SQLFetchScroll can be called being mixed together.

Cursor Position

If the result set is generated, the cursor is positioned before the start of result set. SQLFetch fetches the next row set. It is as same as calling SQLFetchScroll which FetchOrientation is set to SQL_FETCH_NEXT.

The attribute of SQL_ATTR_ROW_ARRAY_SIZE statement specifies the number of rows in the row set. If the row set fetched by SQLFetch overlaps with the end of result set, SQLFetch returns a partial row set. If S is the start row of fetched row set, R is the size of row set, L is the last row of result set, S + R - 1 is bigger than L, then only the first L - S + 1 rows of row set is valid. All remaining rows are empty, and it becomes the SQL_ROW_NOROW state.

After returning SQLFetch, the current row is the first row of row set.

The rules in the following table describes the cursor position according to the conditions in the second table of the session after calling SQLFetch.

Status	The first row of new row set
Before start	1
CurrRowsetStart <= LastResultRow - RowsetSize[1]	CurrRowsetStart + RowsetSize[2]
CurrRowsetStart > LastResultRow - RowsetSize[1]	After end
After end	After end

[1] If the row set size is changed during fetching, the row set size is the row set size used before fetching.
[2] If the row set size is changed during fetching, the row set size is the row set size used in new fetch.

Notation	Description
Before start	The block cursor is positioned before the start of result set. If the first row of new row set is before the start of result set, SQLFetch returns SQL_NO_DATA.
After end	The block cursor is positioned after the end of result set. If the first row of new row set is after the end of result set, SQLFetch returns SQL_NO_DATA.
CurrRowsetStart	It is the first row number of the current row set.
LastResultRow	It is the last row number of result set.
RowsetSize	It is the row set size.

The following is an example of when 100 rows exist in the result set and the row set size is 5, then the following table describes the row set and the return code returned by SQLFetch for the different start position.

Current row set	Return code	New row set	The number of fetched rows
Before start	SQL_SUCCESS	1 to 5	5
1 to 5	SQL_SUCCESS	6 to 10	5
52 to 56	SQL_SUCCESS	57 to 61	5

Current row set	Return code	New row set	The number of fetched rows
91 to 95	SQL_SUCCESS	96 to 100	5
93 to 97	SQL_SUCCESS	98 to 100 4,5 rows of the row status array are set to SQL_ROW_NOROW.	3
96 to 100	SQL_NO_DATA	None	0
99 to 100	SQL_NO_DATA	None	0
After end	SQL_NO_DATA	None	0

Returing the Data in the Bound Column

Like as SQLFetch returns each row, it inserts the data into each bound column in the buffer bound to the column. If the bound column does not exist, SQLFetch does not return any data, but it does not move the cursor forward. Data can be continuously fetched through SQLGetData. If the cursor is a multiple row cur sor (SQL_ATTR_ROW_ARRAY_SIZE is bigger than 1.), SQLGetData can be called when after setting InfoT ype of SQLGetInfo to SQL_FETDATA_EXTENSIONS, or when returning SQL_GD_BLOCK.
For more information, refer to **SQLGetData**.

SQLFetch executes the followings for each bound columns in the row.

1. If data is NULL, the length/indicator buffer is set to SQL_NULL_DATA and the next row is processed. I f the data is NULL and the length/indicator buffer is not bound, SQLFetch returns SQLSTATE 22002 (Indicator variable required but not supplied) for the row and the next row to be processed. For mor e information about how to determine the address of the length/indicator, refer to **Buffer Address** o f SQLBindCol. If the column data is not NULL, SQLFetch executes the process number 2.

2. If the attribute of SQL_ATTR_MAX_LENGTH statement is set to non-zero and the column includes th e character or binary data, the data is truncated to the length of SQL_ATTR_MAX_LENGTH in bytes.

The attribute of SQL_ATTR_MAX_LENGTH statement is intended to reduce network traffic. It is usually implemented by the data source, and the data is truncated before the data is returned fr om the network. Drivers and data sources are not required to support it. Therefore, the applicati on should specify the size to cbValueMax argument of SQLBindCol and creates the buffer to gu arantee that the data is truncated to the specific size.

3. The data is converted to the format specified in TargetType of SQLBindCol.

4. If the data is converted to the variable length data type such as a string or binary, SQLFetch confirms if the data length exceeds the data buffer length. If the character data (including NULL termination c haracter) exceeds the data buffer length, SQLFetch truncates the data to the data buffer length whic h is smaller than NULL termination character length. In this case, the data is terminated by NULL. If t he binary data length exceeds the data buffer length, SQLFetch truncates the data to the data buffer

length. The data buffer length is specified in BufferLength of SQLBindCol. SQLFetch never truncate the data converted to the fixed length data format because the data buffer length is always equal to the data type length.

5. The converted data (truncated data if possible) is put in the data buffer. For more information about how to determine the data buffer address, refer to **Buffer Address** of SQLBindCol.

6. The data length is put in the length/indicator buffer. If both the length pointer and indicator pointer are set in the same buffer (by calling SQLBindCol), the valid data length is recorded in the buffer, and SQL_NULL_DATA is recorded in the buffer if the data is NULL. If the length/indicator buffer is not bound, SQLFetch does not return the length.

- For the character or binary data, it is the data length before truncated after the data is converted because of too small buffer size. If the driver can not determine the length of too long data after conversion, the length is set to SQL_NO_TOTAL. If the data is truncated due to the attribute of SQL_ATTR_MAX_LENGTH statement, this attribute value is put in the length/indicator buffer instead of the actual length. It is because the attribute is designed to truncate the data in the server before conversion. So, the driver can not calculate the actual length.
- For all other data types, it is the data length after conversion.

7. If the data is truncated without any lost of significant digits during conversion(for example, the real number 1.234 is converted into 1 by truncation.), SQLFetch returns SQLSTATE 01S07(Fractional truncation) and SQL_SUCCESS_WITH_INFO. If the data is truncated because the data buffer length is too small (For example the string "abcdef" is put in the buffer of four bytes.), SQLFetch returns SQLSTATE 01004 (Data truncated) and SQL_SUCCESS_WITH_INFO. If the data is truncated because of the attribute of SQL_ATTR_MAX_LENGTH statement, SQLFetch returns SQL_SUCCESS and it does not return SQLSTATE 01S07(Fractional truncation) nor SQLSTATE 01004(Data truncated). If the significant digits of data is truncated while the data is converted (for example, the value of SQL_INTEGER which is bigger than 100,000 is converted into SQL_C_TINYINT.), SQLFetch returns SQLSTATE 22003(Numeric value out of range), SQL_ERROR (If the row set size is 1.) or SQL_SUCCESS_WITH_INFO (If the row set size is bigger than 1.).

If SQLFetch, SQL_SUCCESS of SQLFetchScroll, or SQL_SUCCESS_WITH_INFO is not returned, then the contents of the bound data buffer and the length/indicator buffer are not defined.

Row Status Array

The row status array is used to return the status of each row set. The array address is specified in the attribute of SQL_ATTR_ROW_STATUS_PTR statement. The array should assign the elements as many as specified by the attribute of SQL_ATTR_ROW_ARRAY_SIZE statement in the application. The value is set by SQLFetch, SQLFetchScroll, SQLBulkOperations or SQLSetPos. If the attribute value of SQL_ATTR_ROW_STATUS_PTR statement is the null pointer, the function does not return the row status.

The content of row status buffer is not defined if SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is not returned by SQLFetch, SQLFetchScroll.

The following values are returned to the row status array.

The value of row status array	Description
SQL_ROW_SUCCESS	The row is successfully fetched, and it is not changed after the last fetch from the result set.
SQL_ROW_SUCCESS_WITH_INFO	The row is successfully fetched, and it is not changed after the last fetch from the result set. But the warning about the row is returned.
SQL_ROW_ERROR	An error occurs while the row is fetched.
SQL_ROW_UPDATED	The row is successfully fetched, and it is changed after the last fetch from the result set. If the row is fetched again or it is refreshed by SQLSetPos. Status is changed to the new row status.
SQL_ROW_DELETED	It is deleted after the row is fetched last from the result set.
SQL_ROW_NOROW	The row set is overlapped with the end of result set, and returns that there is not a row.

Row Fetch Buffer

The row fetch buffer is used to return the number of fetched rows. When the data is fetched, the row without data due to an error is also included. It is the number of rows which is not SQL_ROW_NOROW value in the row status array. This buffer address is specified in the arribute of SQL_ATTR_ROWS_FETCHED_PTR statement. The buffer is allocated by the application, and it is set by SQLFetch, SQLFetchScroll. If the attribute value of SQL_ATTR_ROWS_FETCHED_PTR statement is the null pointer, the function does not return the number of fetched rows. The application calls SQLGetStmtAttr as the attribute of SQL_ATTR_ROW_NUMBER to determine the number of current rows in the result set.

The content of row fetch buffer is not defined if SQLFetch, SQLFetchScroll does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO. If SQL_NO_DATA is returned, the value of row fetch buffer is set to 0.

Error Processing

Errors and warnings can be applied to the individual row or the entire function.

Error and Warning for Entire Function

If the error is applied to the entire function, as like SQLSTATE HYT00 (Timeout expired) or SQLSTATE 24000 (Invalid cursor state), SQLFetch returns SQL_ERROR and the corresponding SQLSTATE. The content of row buffer is not defined and the cursor position is not changed.

If the warning is applied to the entire function, SQLFetch returns SQL_SUCCESS_WITH_INFO and the corresponding SQLSTATE. The warning applied to the entire function is returned before the state is recorded to each row.

Error and Warning for Individual Row

The error such as SQLSTATE 22012 (division by zero) or the warning such as SQLSTATE 01004 (data trun cated) is applied to the individual row.

SQLFetch executes the followings.

- It sets the element of row status array to SQL_ROW_ERROR for an error or SQL_ROW_SUCCESS_WIT H_INFO for a warning.
- It adds one or more records which includes SQLSTATE for the error or warnig.
- It sets the row and column number fields in the status record. If SQLFetch can not determine the row or column number, it sets each number to SQL_ROW_NUMBER_UNKNOWN or SQL_COLUMN_NUM BER_UNKNOWN. If the status record is not applied to the specified column, SQLFetch sets the colum n number to SQL_NO_COLUMN_NUMBER.

If an error occurs in all rows of the row set (excluding the row in SQL_ROW_NOROW status), SQLFetch re turns SQL_ERROR. If an error occurs in some rows, it returns SQL_SUCCESS_WITH_INFO. If the row set siz e is 1 and an error occurs in the row, SQLFetch returns SQL_ERROR.

Descriptor and SQLFetch

SQLFetch uses the following descriptor fields.

Descriptor field	Descriptor	Field location	Setting
SQL_DESC_ARRAY_SIZE	ARD	header	SQL_ATTR_ROW_ARRAY_SIZE statement att ribute
SQL_DESC_ARRAY_STATUS_PTR	IRD	header	SQL_ATTR_ROW_STATUS_PTR statement att ribute
SQL_DESC_BIND_OFFSET_PTR	ARD	header	SQL_ATTR_ROW_BIND_OFFSET_PTR statem ent attribute
SQL_DESC_BIND_TYPE	ARD	header	SQL_ATTR_ROW_BIND_TYPE statement attri bute
SQL_DESC_COUNT	ARD	header	ColumnNumber argument of SQLBindCol
SQL_DESC_DATA_PTR	ARD	record	TargetValuePtr argument of SQLBindCol
SQL_DESC_INDICATOR_PTR	ARD	record	StrLen_or_IndPtr argument of SQLBindCol
SQL_DESC_OCTET_LENGTH	ARD	record	BufferLength argument of SQLBindCol
SQL_DESC_OCTET_LENGTH_PTR	ARD	record	StrLen_or_IndPtr argument of SQLBindCol
SQL_DESC_ROWS_PROCESSED_ PTR	IRD	record	SQL_ATTR_ROWS_FETCHED_PTR statement attribute
SQL_DESC_TYPE	ARD	record	TargetType argument of SQLBindCol

All descriptor fields can be set through SQLSetDescField.

Separating Length and Indicator Buffer

The application can bind one or two buffers to store the length and indicator value. If the application call s SQLBindCOl, SQL_DESC_OCTET_LENGTH_PTR and SQL_DESC_INDICATOR_PTR field of ARD is set in th e address passed to StrLen_or_IndPtr argument. The application can set the two fields to another address es by calling SQLSetDescField or SQLSetDescRec.

SQLFetch determines whether the application specifies a separate length and indicator buffer. If the data is not NULL, SQLFetch sets the indicator buffer to 0, and returns the length to the length buffer. If the dat a is NULL, SQLFetch sets the indicator buffer to SQL_NULL_DATA, and it does not modify the length buff er.

SQLFetchScroll

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLFetchScroll fetches the specified data set from the result set, and returns it to all bound columns.

Syntax

```
SQLRETURN SQLFetchScroll(
    SQLHSTMT      StatementHandle,
    SQLSMALLINT   FetchOrientation,
    SQLLEN        FetchOffset);
```

Arguments

StatementHandle

[Input] It is the statement handle.

FetchOrientation

[Input] It is the fetch type: SQL_FETCH_NEXT, SQL_FETCH_PRIOR, SQL_FETCH_FIRST, SQL_FETCH_LAST, SQL_FETCH_ABSOLUTE, SQL_FETCH_RELATIVE, SQL_FETCH_BOOKMARK

FetchOffset

[Input] It is the number of rows to fetch. The interpretation of this argument depends on the value of FetchOrientation argument.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The string, binary data returned for the columns are truncated. The right part of the string is truncated.
01S07	Fractional truncation	The data returned for the column is truncated. For numeric data types, the decimal place is truncated. For time, timestamp, interval data types which contain the period component, the decimal place of time is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The column data value in the result set can not be converted to the data type specified by TargetType of SQLBindCol.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
22002	Indicator variable required but not supplied	StrLen_or_IndPtr (or SQL_DESC_INDICATOR_PTR set by SQLSetDescField or SQLSetDescRec) of SQLBindCol fetches NULL data to the column which is the null pointer.
22003	Numeric value out of range	The integer part (not the decimal place) of the numerical value returned from one or more columns is truncated.
22007	Invalid datetime format	The string in the result set is not the valid date, time, timestamp format.
22012	Division by zero	The result of the arithmetic expression divided by 0 is returned.
22015	Interval field overflow	When the interval C type is specified in the exact numeric or interval SQL data type, the significant figures in the leading field is lost. The value of SQL type can not be expressed to C interval type.
22018	Invalid character value for cast specification	The character not represented as the character set of C buffer is included in the character column of the result set. The C type is the exact or approximate numeric, datetime, interval data type, and if the SQL type is the character data type, the value of the column bound to the C type is not valid.
24000	Invalid cursor state	StatementHandle is executed but the result set related to StatementHandle does not exist.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The StatementHandle specified is not at the state of running. The function is called without calling SQLExecDirect, SQLExecute, the catalog function. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
		The value specified to FetchOrientation argument is not valid.

SQLSTATE	Error	Description
HY106	Fetch type out of range	The attribute value of SQL_ATTR_CURSOR_TYPE statement is SQL_CURSOR_FORWARD_ONLY, and the value of FetchOrientation argument is not SQL_FETCH_NEXT. The attribute value of SQL_ATTR_CURSOR_SCROLLABLE statement is SQL_NONSCROLLABLE, and the value of FetchOrientation argument is not SQL_FETCH_NEXT.
HYT00	Timeout expired	Before returning the result set from the data source, the query timeout is expired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.

Description

SQLFetchScroll returns the specified row set in the result set. The row set is set as the absolute or relative position or the bookmark position. SQLFetchScroll can be called while the result set exists, which is after the result set is created and before the cursor is closed. If the column is bound, the data is returned to the column. If the application specifies the pointer to a row status array or specifies the buffer which returns rows fetched, SQLFetchScroll also returns this information. SQLFetch and SQLFetchScroll can be called being mixed together.

Cursor Position

If the result set is created, the cursor is positioned before the start of result set. SQLFetchScroll positions the block cursor according to FetchOrientation argument and FetchOffset argument as follows. The following rules are used to determine the beginning of new row set.

FetchOrientation	Description
SQL_FETCH_NEXT	It returns the next row set. it is as same as calling SQLFetch. SQLFetchScroll ignores the value of FetchOffset.
SQL_FETCH_PRIOR	It returns the previous row set. SQLFetchScroll ignores the value of FetchOffset.
SQL_FETCH_RELATIVE	It returns the row set of FetchOffset at the beginning of current row set.
SQL_FETCH_ABSOLUTE	It returns the row set starting at FetchOffset.
SQL_FETCH_FIRST	It returns the first row set in the result set. SQLFetchScroll ignores the value of FetchOffset.
SQL_FETCH_LAST	It returns the last complete row set in the result set. SQLFetchScroll ignores the value of FetchOffset.
SQL_FETCH_BOOKMARK	It returns the row set of FetchOffset on the bookmark specified by the attribute of SQL_ATTR_FETCH_BOOKMARK_PTR statement.

The attribute of SQL_ATTR_ROW_ARRAY_SIZE statement specifies the number of rows of the row set. If

the row set fetched by SQLFetchScroll overlaps with the end of result set, SQLFetchScroll returns a partial row set. If S is the start row of fetched row set, R is the row set size, L is the last row of result set, S + R - 1 is bigger than L, and the first L - S + 1 rows of row set is valid. All remaining rows are empty, and it bec omes SQL_ROW_NOROW state.

After returning SQLFetchScroll, the current row is the first row of row set.

Cursor Position Rules

The following chapters describe rules for each FetchOrientation. The following notations are used for the rules.

Notation	Meaning
Before start	The block cursor is positioned before the start of result set. If the first row of the new row set is before the start of the result set, SQLFetchScroll returns SQL_NO_DATA.
After end	The block cursor is positioned after the end of result set. If the first row of the new ro w set is after the end of the result set, SQLFetchScroll returns SQL_NO_DATA.
CurrRowsetStart	It is the first row number of current row set.
LastResultRow	It is the last row number of result set.
RowsetSize	It is the row set size.
FetchOffset	It is the value of FetchOffset argument.
BookmarkRow	It is the row which corresponds to the bookmark specified by the attribute of SQL_AT TR_FETCH_BOOKMARK_PTR statement.

SQL_FETCH_NEXT

The following rule is applied.

State	The first row of the new row set
Before start	1
CurrRowsetStart + RowsetSize[1] <= LastResultRow	CurrRowsetStart + RowsetSize[1]
CurrRowsetStart + RowsetSize[1] > LastResultRow	After end
After end	After end

[1] If the row set size is changed during fetching the row set size is the row set size used before fetching.

SQL_FETCH_PRIOR

The following rule is applied.

State	The first row of the new row set
Before start	Before start
CurrRowsetStart = 1	Before start
1 < CurrRowsetStart <= RowsetSize[1]	1

State	The first row of the new row set
CurrRowsetStart > RowsetSize[1]	CurrRowsetStart - RowsetSize[1]
After end AND LastResultRow < RowsetSize[1]	1
After end AND LastResultRow >= RowsetSize[1]	LastResultRow - RowsetSize + 1[1]

[1] If the row set size is changed during fetching, the row set size is the row set size used in new fetch.

SQL_FETCH_RELATIVE

The following rule is applied.

State	The first row of the new row set
(Before start AND FetchOffset > 0) OR (After end AND FetchOffset < 0)	__ [1]
BeforeStart AND FetchOffset <= 0	Before start
CurrRowsetStart = 1 AND FetchOffset < 0	Before start
CurrRowsetStart > 1 AND CurrRowsetStart + FetchOffset < 1 AND | FetchOffset | > RowsetSize[2]	Before start
CurrRowsetStart > 1 AND CurrRowsetStart + FetchOffset < 1 AND | FetchOffset | <= RowsetSize[2]	1
1 <= CurrRowsetStart + FetchOffset <= LastResultRow	CurrRowsetStart + FetchOffset
CurrRowsetStart + FetchOffset > LastResultRow	After end
After end AND FetchOffset >= 0	After end

[1] SQLFetchScroll returns the row set as same as when FetchOrientation is set to SQL_FETCH_ABSOLUTE and it is called.
[2] If the row set size is changed during fetching, the row set size is the row set size used in new fetch.

SQL_FETCH_ABSOLUTE

The following rule is applied.

State	The first row of the new row set
FetchOffset < 0 AND | FetchOffset | <= LastResultRow	LastResultRow + FetchOffset + 1
FetchOffset < 0 AND | FetchOffset | > LastResultRow AND | FetchOffset | > RowsetSize[1]	Before start
FetchOffset < 0 AND | FetchOffset | > LastResultRow AND | FetchOffset | <= RowsetSize[1]	1
FetchOffset = 0	Before start
1 <= FetchOffset <= LastResultRow	FetchOffset
FetchOffset > LastResultRow	After end

[1] If the row set size is changed during fetching, the row set size is the row set size used in new fetch.

SQL_FETCH_FIRST

The following rule is applied.

State	The first row of the new row set
Any	1

SQL_FETCH_LAST

The following rule is applied.

State	The first row of the new row set
RowsetSize[1]<= LastResultRow	LastResultRow - RowsetSize + 1[1]
RowsetSize[1]> LastResultRow	1

[1]If the row set size is changed during fetching, the row set size is the row set size used in new fetch.

SQL_FETCH_BOOKMARK

The following rule is applied.

State	The first row of the new row set
BookmarkRow + FetchOffset < 1	Before start
1 <= BookmarkRow + FetchOffset <= LastResultRow	BookmarkRow + FetchOffset
BookmarkRow + FetchOffset > LastResultRow	After end

Buffer Address

SQLFetchScroll determines the data address and length/indicator buffer address in the same way as SQLFetch. For more information, refer to **Buffer Address** of SQLBindCol.

Row Status Array

SQLFetchScroll sets the row status array in the same way as SQLFetch. For more information, refer to **Row Status Array** of SQLFetch.

Row Fetch Buffer

SQLFetchScroll returns the number of rows fetched in the same way as SQLFetch. For more information, refer to **Row Fetch Buffer** of SQLFetch.

Error Processing

SQLFetchScroll returns the errors and warning in the same way as SQLFetch. For more information, refer t o **Error Processing** of SQLFetch.

SQLForeignKeys

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLForeignKeys returns the followings.

- The foreign key list of the specified table (the column in the specified table which refers to the the pri mary key of another table)
- The foreign key list of another table which refers to the primary key of the specified table

The driver returns each list as the result set.

Syntax

```
SQLRETURN SQLForeignKeys(
    SQLHSTMT       StatementHandle,
    SQLCHAR *      PKCatalogName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      PKSchemaName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      PKTableName,
    SQLSMALLINT    NameLength3,
    SQLCHAR *      FKCatalogName,
    SQLSMALLINT    NameLength4,
    SQLCHAR *      FKSchemaName,
    SQLSMALLINT    NameLength5,
    SQLCHAR *      FKTableName,
    SQLSMALLINT    NameLength6);
```

Arguments

StatementHandle

[Input] It is the statement handle.

PKCatalogName

[Input] It is the primary key table catalog name. PKCatalogName can not include the string search pattern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, then PKCatalogName i s treated as a case-insensitive identifier. If it is set to SQL_FALSE, then PKCatalogName is case-sensi tive, and it is an ordinary argument literally processed.

NameLength1

[Input] It is the length of *PKCatalogName

PKSchemaName

[Input] It is the primary key table schema name. PKSchemaName can not include the string search pattern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, then PKSchemaName i s treated as a case-insensitive identifier. If it is set to SQL_FALSE, then PKSchemaName is case-sensi tive, and it is an ordinary argument literally processed.

NameLength2

[Input] It is the length of *PKSchemaName

PKTableName

[Input] It is the primary key table name. PKTableName can not include the string search pattern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, then PKTableName is t reated as a case-insensitive identifier. If it is set to SQL_FALSE, then PKTableName is case-sensitive, and it is an ordinary argument literally processed.

NameLength3

[Input] It is the length of *PKTableName

FKCatalogName

[Input] It is the foreign key table catalog name. FKCatalogName can not include the string search p attern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, then FKCatalogName i s treated as a case-insensitive identifier. If it is set to SQL_FALSE, then FKCatalogName is case-sensi tive, and it is an ordinary argument literally processed.

NameLength4

[Input] It is the length of *FKCatalogName

FKSchemaName

[Input] It is the foreign key table schema name. FKSchemaName can not include the string search p attern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, FKSchemaName is trea ted as a case-insensitive identifier. If it is set to SQL_FALSE, FKSchemaName is case-sensitive, and it is an ordinary argument literally processed.

NameLength5

[Input] It is the length of *FKSchemaName

FKTableName

[Input] It is the foreign key table name. FKTableName can not include the string search pattern.

If the attribute of SQL_ATTR_METADATA_ID statement is set to SQL_TRUE, then FKTableName is t reated as a case-insensitive identifier. If it is set to SQL_FALSE, FKTableName is case-sensitive, and i t is an ordinary argument literally processed.

NameLength6

[Input] It is the length of *FKTableName

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08S01	Communication l ink failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
24000	Invalid cursor stat e	SQLFetch, SQLFetchScroll are called and a cursor is open.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio n error	It is a memory allocation error.
HY009	Invalid use of null pointer	The PKTableName argument and FKTableName argument are the null point er. The attribute value of SQL_ATTR_METADATA_ID statement is SQL_TRUE, a nd the arguments of PKSchemaName, FKSchemaName, PKTableame or FKT ableame are the null pointer.
HY010	Function sequenc e error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HY090	Invalid string or b uffer length	A name length argument value is smaller than 0, but it is not SQL_NTS.
HYT00	Timeout expired	Before returning the result set from the data source, the query timeout is ex pired. The timeout can be set through SQL_ATTR_QUERY_TIMEOUT of SQL SetStmtAttr.

Description

If *PKTableName includes the table name, SQLForeignKeys returns a result set which includes the primary key of the specified table and all foreign keys referring it. The foreign key list of another table does not in clude the foreign key pointing to the unique constraint on the specified table.

If *FKTableName includes the table name, SQLForeignKeys returns the result set which contains the forei gn key in the specified table pointing to the primary key of another table, and returns its primary key of a nother table which is referenced by them.

If both *PKTableName and *FKTableName include the table name, SQLForeignKeys returns the foreign k ey of the table specified in *FKTableName which refers to the primary key of the table specified in *PKTa bleName. The key should be one.

SQLForeignKeys returns the standard result set. If the foreign key related to the primary key is requested, the result set is sorted as FKTABLE_CAT, FKTABLE_SCHEM, FKTABLE_NAME, KEY_SEQ. If the primary key related to the foreign key is requested, the result set is sorted as PKTABLE_CAT, PKTABLE_SCHEM, PKTA BLE_NAME, KEY_SEQ.

The following table describes the columns of result set.

Column na me	Column number	Data type	Description
PKTABLE_C AT (ODBC 1 .0)	1	VARCHAR	It is the primary key table catalog name.
PKTABLE_S CHEM (ODB C 1.0)	2	VARCHAR	It is the primary key table schema name.
PKTABLE_N AME (ODBC 1.0)	3	VARCHAR n ot NULL	It is the primary key table name.
PKCOLUMN _NAME (OD BC 1.0)	4	VARCHAR n ot NULL	It is the primary key column name. The driver returns an empty string f or a column which does not have a name.
FKTABLE_C AT (ODBC 1 .0)	5	VARCHAR	It is the foreign key table catalog name.
FKTABLE_SC HEM (ODBC 1.0)	6	VARCHAR	It is the foreign key table schema name.
FKTABLE_N AME (ODBC 1.0)	7	VARCHAR n ot NULL	It is the foreign key table name.
FKCOLUMN		VARCHAR n	It is the foreign key column name. The driver returns an empty string fo

Column name	Column number	Data type	Description
_NAME (ODBC 1.0)	8	ot NULL	r a column which does not have a name.
KEY_SEQ (ODBC 1.0)	9	SMALLINT not NULL	It is the column sequential number of the key starting from 1.
UPDATE_RULE (ODBC 1.0)	10	SMALLINT	It is the operation applied to the foreign key when the SQL operation is UPDATE. (The referenced table has the primary key, and the referring table has the foreign key.) • SQL_CASCADE: If the primary key of referencing table is updated, the foreign key of the referring table is also updated. • SQL_NO_ACTION: If a row in the referring table does not corresponds to the referenced table when updating the primary key of the referenced table, the update is rejected. If the foreign key update of the referring table does not exist as the value of the primary key of the referenced table, the update is rejected. • SQL_SET_NULL: If one or more rows in the referenced table are updated in a way that one or more components of the primary key are changed, the components of the foreign key in the referring table which corresponds to the changed components of the primary key are set to NULL in all matching rows of the referring table. • SQL_SET_DEFAULT: If one or more rows in the referenced table are updated in a way that one or more components of the primary key are changed, the components of the foreign key in the referring table which corresponds to the changed components of the primary key are set to the default value in all matching rows of the referring table.
DELETE_RULE (ODBC 1.0)	11	SMALLINT	It is the operation applied to the foreign key when the SQL operation is DELETE. (The referenced table has the primary key, and the referring table has the foreign key.) • SQL_CASCADE: If the primary key of referenced table is deleted, the foreign key of the referring table is also deleted. • SQL_NO_ACTION: If a row in the referring table does not corresponds to the referenced table when deleting the primary key of the referenced table, the update is rejected. • SQL_SET_NULL: If one or more rows of the referenced table are deleted, each components of the foreign key of the referring table is set to NULL in all matching rows of the referring table. • SQL_SET_DEFAULT: If one or more rows of the referenced table a

Column name	Column number	Data type	Description
			re deleted, each component of the foreign key of the referencing table is set to the applicable default in all matching rows of the referencing table.
FK_NAME (ODBC 2.0)	12	VARCHAR	It is the foreign key name.
PK_NAME (ODBC 2.0)	13	VARCHAR	It is the primary key name.
DEFERRABILITY (ODBC 3.0)	14	SMALLINT	SQL_INITIALLY_DEFERRED, SQL_INITIALLY_IMMEDIATE, SQL_NOT_DEFERRABLE.

SQLFreeConnect

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLFreeConnect function is replaced with SQLFreeHandle function in ODBC 3.x.
For more information, refer to **SQLFreeHandle**.

SQLFreeEnv

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLFreeEnv function is replaced with SQLFreeHandle function in ODBC 3.x.
For more information, refer to **SQLFreeHandle**.

SQLFreeHandle

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLFreeHandle releases the resources related to the specified environment, connection, statement, and d escriptor handles.

Syntax

```
SQLRETURN SQLFreeHandle(
    SQLSMALLINT   HandleType,
    SQLHANDLE     Handle);
```

Arguments

HandleType

[Input] It is the handle type to be released by using SQLFreeHandle. It should be one of SQL_HAND LE_DBC, SQL_HANDLE_DESC, SQL_HANDLE_ENV, SQL_HANDLE_STMT.

If HandleType is not one of the values above, SQLFreeHandle returns SQL_INVALID_HANDLE.

Handle

[Input] It is the handle to be released.

Returns

SQL_SUCCESS, SQL_ERROR, SQL_INVALID_HANDLE.
If SQLFreeHandle returns SQL_ERROR, the handle is still valid.

Diagnosis

SQLSTATE	Error	Description
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio	It is a memory allocation error.

SQLSTATE	Error	Description
	n error	
HY010	Function sequence error	HandleType argument is SQL_HANDLE_ENV, and at least one connection is assigned or connected. Before calling SQLFreeHandle whose HandleType argument is SQL_HANDLE_ENV, SQLDisconnect and SQLFreeHandle argument whose HandleType argument is SQL_HANDLE_DBC should be called. HandleType argument is SQL_HANDLE_DBC, the function is called before SQLDisconnect is called. HandleType argument is SQL_HANDLE_STMT, after calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.

Description

SQLFreeHandle is used to release the environment, connection, statement, descriptor handles.
After the handle is released, the application can not use the released handle.

Releasing the Environment Handle

Before calling SQLFreeHandle whose HandleType is SQL_HANDLE_ENV, the application should call SQLFreeHandle whose HandleType is SQL_HANDLE_DBC for all connection allocated from the environment. Otherwise, SQLFreeHandle returns SQL_ERROR, and the environment and active connection remain valid.

Releasing the Connection Handle

Before calling SQLFreeHandle whose HandleType is SQL_HANDLE_DBC, if the handle is connected, the application should call SQLDisconnect. Otherwise, SQLFreeHandle returns SQL_ERROR, and the connection remains valid.

Releasing the Statement Handle

SQLFreeHandle whose HandleType is SQL_HANDLE_STMT, releases all resources allocated by calling SQLAllocHandle whose HandleType is SQL_HANDLE_STMT. If the application calls SQLFreeHandle with the remaining statement, the remaining result is deleted. When the application releases the statement handle, the driver releases the four auto allocation descriptors related to the statement.

SQLDisconnect automatically deletes all statements and descriptors which are opened for the connection.

SQLFreeStmt

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLFreeStmt stops the processing related to the specified statement, closes an open cursor, removes the remaining result or selectively releases all resources connected to the statement handle.

Syntax

```
SQLRETURN SQLFreeStmt(
    SQLHSTMT       StatementHandle,
    SQLUSMALLINT   Option);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Option

[Input] It is one of the following options.

• SQL_ CLOSE: It closes the cursor related to StatementHandle, and deletes the remaining result. T he applications executes SELECT statement with the same or different parameter values, and it can open cursor again later. If the cursor is not open, this option does not affect the application. SQLCl oseCursor also closes the cursor.

• SQL_DROP: This option is not used any more.

• SQL_UNBIND: It releases all column buffers bound with SQLBindCol for the specified Statement Handle, and sets SQL_DESC_COUNT field of ARD to 0.

• SQL_RESET_PARAMS: It releases all parameter buffers set to SQLBindParameter for the specified StatementHandle, and sets SQL_DESC_COUNT field of APD to 0.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HY092	Option type out of range	The value of option argument is not SQL_CLOSE, SQL_DROP, SQL_UNBIND, SQL_RESET_PARAMS.

Description

Calling SQLFreeStmt with SQL_CLOSE option is as same as calling of SQLCloseCursor. However, if an open cursor does not exist, calling SQLFreeStmt with SQL_CLOSE option does not affect the application. SQLCloseCursor returns SQLSTATE 24000 (Invalid cursor state).

SQLGetConnectAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetConnectAttr returns the current setting of the connection attribute.

Syntax

```
SQLRETURN SQLGetConnectAttr(
    SQLHDBC        ConnectionHandle,
    SQLINTEGER     Attribute,
    SQLPOINTER     ValuePtr,
    SQLINTEGER     BufferLength,
    SQLINTEGER *   StringLengthPtr);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

Attribute

[Input] It is the attribute to be searched

ValuePtr

[Output] It is a memory pointer which returns the current setting value of the attribute specified by Attribute.

If ValuePtr is null, StringLengthPtr returns the total number of bytes returnable (excluding the null-termination character).

BufferLength

[Input] If Attribute is a defined field in ODBC and ValuePtr points to the string or binary buffer, this argument should be the length of *ValuePtr. If Attribute is a defined field in ODBC and *ValuePtr i s an integer, this argument is ignored.

StringLengthPtr

[Output] It is the pointer which returns the total number of bytes returnable in *Value_Ptr (excluding null-termination byte for character data)

For the character data, if the number of returnable bytes is equal to or bigger than BufferLength, *ValuePtr is truncated to length of BufferLength minus 1, and it is null terminated by the driver.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The data truncated to the length of BufferLength minus null-termination character is returned to *ValuePtr. The length of string not truncated is returned to *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
08003	Connection not open	The Attribute value required on the connection status is specified.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY090	Invalid string or buffer length	*ValuePtr is a string, and BufferLength is smaller than 0 but it is not SQL_NTS.
HY092	Invalid attribute/option identifier	The Attribute argument value is not valid.
HYC00	Optional feature not implemented	The Attribute argument value is valid but it is not supported by the driver.

Description

If an attribute specifies the attribute which returns the string, ValuePtr should have the pointer to the string buffer. The maximum length of the returned string including null-termination character is BufferLength in bytes.

Attribute	The description of ValuePtr
SQL_ATTR_ACCESS_MODE (ODBC 1.0)	It is the SQLUINTEGER value. SQL_MODE_READ_ONLY is used as the indicator of the connection which does not request the update. This mode is used for the transaction management, the optimization, and the lock plan of the driver or data source.

Attribute	The description of ValuePtr
	The default value is SQL_MODE_READ_WRITE.
SQL_ATTR_AUTOCOMMIT (ODBC 1.0)	It is SQLUINTEGER value which specifies whether to use auto commit or manual commit. • SQL_AUTOCOMMIT_ON: It is the default value. The driver uses the auto commit mode. Each statement is immediately committed after execution. When SQL_ATTR_AUTOCOMMIT is set to SQL_AUTOCOMMIT_ON, the open transaction is committed to the connection to change from the manual commit mode to the auto commit mode. • SQL_AUTOCOMMIT_OFF: The driver uses the manual commit mode, and the application should explicitly commit or rollback with SQLEndTrans.
SQL_ATTR_CHARACTER_SET	It is the character set string of the driver.
SQL_ATTR_DATABASE_CHARACTER_SET	It is the character set string of the data source.
SQL_ATTR_DATE_FORMAT	It is the DATE format string of the driver.
SQL_ATTR_LOGIN_TIMEOUT (ODBC 1.0)	It is the waiting time (in seconds) for a login request with SQLUINTEGER value. If ValuePtr is 0, timeout is not used, and the connection attempt indefinitely wait.
SQL_ATTR_METADATA_ID (ODBC 3.0)	It is SQLUINTEGER value which determines the string argument of the catalog function. If it is SQL_TRUE, the string argument of catalog function is treated as an identifier, and it is case-insensitive. If the string is not separated by a delimiter, the driver removes all leading or trailing spaces and the string is capitalized. If the string is separated by a delimiter, the driver removes all leading or trailing spaces and the string between delimiters remains literally. If one of the arguments is set to the null pointer, the function returns SQL_ERROR and SQLSTATE HY009 (Invalid use of null pointer). If it is SQL_FALSE, the string argument of catalog function is not treated as an identifier. It may or may not include a search string pattern depending on the string argument. The default value is SQL_FALSE. SQL_ATTR_METADATA_ID can also be set in the statement level.
SQL_ATTR_TIMESTAMP_FORMAT	It is the TIMESTAMP format string of the driver.
SQL_ATTR_TIMESTAMP_WITH_TIMEZONE_FORMAT	It is the TIMESTAMP WITH TIME ZONE format string of the driver.
SQL_ATTR_TIMEZONE	It is the timezone string of the driver.
SQL_ATTR_TIME_FORMAT	It is the TIME format string of the driver.
SQL_ATTR_TIME_WITH_TI	It is the TIME WITH TIME ZONE format string of the driver.

Attribute	The description of ValuePtr
MEZONE_FORMAT	
SQL_ATTR_TXN_ISOLATIO N (ODBC 1.0)	It is 32-bit mask which sets the isolation level for the current connection.

SQLGetConnectOption

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLGetConnectOption function is replaced with SQLGetConnectAttr function in ODBC 3.x.
For more information, refer to **SQLGetConnectAttr**.

SQLGetCursorName

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetCursorName returns the specified statement and related cursor name.

Syntax

```
SQLRETURN SQLGetCursorName(
    SQLHSTMT        StatementHandle,
    SQLCHAR *       CursorName,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   NameLengthPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CursorName

[Output] It is the buffer pointer which returns the cursor name

If CursorName is NULL, NameLengthPtr returns the returnable byte length (excluding the null-termi nation character)

BufferLength

[Input] It is the length of *CursorName.

NameLengthPtr

[Output] It is the memory pointer for the length of bytes returnable to *CursorName (excluding th e null-termination character). If the returnable byte length is equal to or bigger than it, *sCursorNa me is truncated to the length of BufferLength minus 1.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	*CursorName buffer is not large enough to return the entire cursor name, so the cursor name is truncated. The length of cursor name not truncated is returned to *NameLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HY090	Invalid string or buffer length	The value of BufferLength argument is smaller than 0.

Description

The cursor name is used only in positioned update and positioned delete statements. (e.g. UPDATE table-name ...WHERE CURRENT OF cursor-name) If the cursor name is not set with SQLSetCursorName in the application, the driver generates the cursor name starting with SQL_CUR.

SQLGetCursorName can re-set the cursor name, if the statement is the assigned or ready state.

The cursor name which is explicitly or implicitly set is valid until the related statement is deleted by calling SQLFreeHandle whose HandleType is SQL_HANDLE_STMT.

SQLGetData

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetData retrieves a column data in the result set, and it can be called multiple times to retrieve the va riable length data.

Syntax

```
SQLRETURN SQLGetData(
    SQLHSTMT       StatementHandle,
    SQLUSMALLINT   Col_or_Param_Num,
    SQLSMALLINT    TargetType,
    SQLPOINTER     TargetValuePtr,
    SQLLEN         BufferLength,
    SQLLEN *       StrLen_or_IndPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Col_or_Param_Num

[Input] It is the column number for retrieving the column data from the returned data. Result set c olumns are numbered in increasing order, starting from 1.

TargetType

[Input] It is the C data type identifier of *TargetValuePtr buffer.

If TargetType is SQL_ARD_TYPE, the driver uses the type identifier specified in SQL_DESC_CONCISE _TYPE field of ARD.

TargetValuePtr

[Output] It is the buffer pointer to which the data is returned

TargetValuePtr can not be NULL.

BufferLength

[Input] It is the byte length of *TargetValuePtr buffer.

When the driver returns the variable length data such as string or binary data, it uses BufferLength to avoid writing beyond the end of *TargetValuePtr buffer. Be cautious when returning character data to *TargetValuePtr because the driver calculates the null-termination character. Therefore, *TargetValuePtr should include the space for the null-termination character. Otherwise, the driver can truncate the data.

When the driver returns the fixed length data such as integer or date structure, the driver assumes that the buffer is large enough to store the data, and it ignores BufferLength. Therefore, the application should allocate the buffer which is large enough to the fixed length data. If not, the driver can write beyond the end of buffer.

SQLGetData returns SQLSTATE HY090(Invalid string or buffer length), if BufferLength is smaller than 0.

StrLen_or_IndPtr

[Output] It is the buffer pointer which returns the length or indicator value. If the argument is the null pointer, the length and indicator values are not returned, and an error occurs when fetching NULL data.

SQLGetData can return SQL_NO_TOTAL, SQL_NULL_DATA, and the data length which can be returned to the length/indicator buffer.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	All data for the column specified as Col_or_Param_Num can not be retrieved by a single function call. The length of the remaining data in the specified column is returned to *StrLen_or_IndPtr before calling SQL_NO_TOTAL or SQLGetData. (The function returns SQL_SUCCESS_WITH_INFO.)
01S07	Fractional truncation	The data returned for one or more column is truncated. For numeric data types, the decimal place is truncated. For time, timestamp, interval data types which contain the period component, the decimal place of time is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The column data value in the result set can not be converted to the C data type specified by TargetType.
	Invalid descriptor	Col_or_Param_Num argument value is bigger than the number of columns i

SQLSTATE	Error	Description
07009	index	n the result set.
08S01	Communication l ink failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
22002	Indicator variable required but not supplied	StrLen_or_IndPtr is the null pointer, and the returned data is NULL.
22003	Numeric value ou t of range	The integer part (not the decimal place) of the numerical value returned fro m one or more columns is truncated.
22007	Invalid datetime f ormat	The string in the result set is not the valid date, time, timestamp format.
22012	Division by zero	The result of the arithmetic expression divided by 0 is returned.
22015	Interval field over flow	When the interval C type is specified in the exact numeric or interval SQL da ta type, the significant figures in the leading field is lost. The value of SQL type can not be expressed to C interval type.
22018	Invalid character value for cast spe cification	The character not represented as the character set of C buffer is included in the character column of the result set. The C type is the exact or approximate numeric, datetime, interval data type, and if the SQL type is the character data type, the value of the column boun d to the C type is not valid.
24000	Invalid cursor stat e	The function is called without calling SQLFetch or SQLFetchScroll. StatementHandle is executed but result set related to StatementHandle doe s not exist. The cursor is open by calling SQLFetch or SQLFetchScroll, but the cursor is p ointing to before the start or after the end of result set.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio n error	It is a memory allocation error.
HY003	Program type out of range	TargetType argument value is not valid.
HY009	Invalid use of null pointer	TargetValuePtr argument is the null pointer.
HY010	Function sequenc e error	The specified StatementHandle is not in executed state. The function is calle d without calling SQLExecDirect, SQLExecute, the catalog function. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables.
HY090	Invalid string or b uffer length	BufferLength argument value is smaller than 0.

Description

SQLGetData returns the data of the specified column, and it can be called only after one or more rows ar e fetched from the result set of SQLFetch or SQLFetchScroll. When the variable length data is too large to be returned with a single call SQLGetData (because of application restrictions), SQLGetData can partially r etrieve it.

Using SQLGetData

If TargetType argument is the interval data type, the default value is interval leading precision(2), interval seconds precision(6), and it is set to SQL_DESC_DATETIME_INTERVAL_PRECISION field and SQL_DESC_P RECISION field of ARD each. If TargetType argument is the SQL_C_NUMERIC data type, the default value is precision(38), scale(0), and it is set to SQL_DESC_PRECISION field and SQL_DESC_SCALE field of ARD e ach. If the default precision and scale are not appropriate, the application should explicitly set the descrip tor field by calling SQLSetDescField or SQLSetDescRec.

Partial Retrieving of Variable Length Data

SQLGetData can partially retrieve the variable length data whose SQL data type is SQL_CHAR, SQL_VARC HAR, SQL_LONGVARCHAR, SQL_WCHAR, SQL_WVARCHAR, SQL_WLONGVARCHAR, SQL_BINARY, SQL _VARBINARY, SQL_LONGVARBINARY.

The application continuously calls SQLGetData multiple times for the same column to partially retrieve the data of the column. SQLGetData returns the next part of the data at each call. The applications should re assemble the parts, being careful to remove the null-termination character in the middle of the character data. If more data should be returned, SQLGetData returns SQL_SUCCESS_WITH_INFO, SQLSTATE 01004 (Data truncated). If the last part of data is returned, SQL_SUCCESS is returned.

SQLGetData can not be used for returning the part of fixed length data. If SQLGetData is called once or more for a column which contains the fixed-length data, SQL_NO_DATA is returned after the first call.

Retrieving Data Using SQLGetData

SQLGetData performs the following processes to return the data for the specified column.

1. If all data is returned to the column, SQL_NO_DATA is returned.

2. If the data is NULL, *StrLen_or_IndPtr is set to SQL_NULL_DATA. If the data is NULL and *StrLen_or_ IndPtr is the null pointer, SQLGetData returns SQLSTATE 22002 (Indicator variable required but not s upplied).
   If the column data is not NULL, SQLGetData performs the third process.

3. If the attribute of SQL_ATTR_MAX_LENGTH statement is set to non-zero value or the column contai ns the string or binary data or SQLGetData is not called for the column before, then the data is trunc ated to length of SQL_ATTR MAXLENGTH bytes.

The attribute of SQL_ATTR_MAX_LENGTH statement is used to reduce the network traffic. It is generally implemented by the data source, and it truncates the data before returning the data via the network. The driver and the data source are not required to support it. Therefore, the application should allocate a buffer of the proper size, and specify the size of BufferLength argument to guarantee that the data is truncated to the specific size.

4. The data is converted to the data type specified in TargetType. The default precision and scale values for the data type are given to the data. If TargetType is SQL_ARD_TYPE, the data type in SQL_DESC_CONCISE_TYPE field of ARD is used. The data provides the precision and scale of SQL_DESC_DATETIME_INTERVAL_PRECISION field, SQL_DESC_PRECISION field, SQL_DESC_SCALE field of ARD depending on the data type of SQL_DESC_CONCISE_TYPE field. If all default precisions and scales are not appropriate, the application should explicitly set the descriptor field by calling SQLSetDescField or SQLSetDescRec.

5. If the data is converted to the variable length data type such as the string or binary, SQLGetData checks whether the data length exceeds BufferLength (including the null-termination character). If the data length exceeds BufferLength, SQLGetData truncates the data to the length of BufferLength minus the null-termination character. If the binary data length exceeds the data buffer length, SQLGetData truncates it to the length of BufferLength bytes.

   If the null-termination character is not stored in the provided data buffer, SQLGetData returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01004.

   SQLGetData does not truncate the data converted to the fixed length data type. In this case, the length of *TargetValuePtr is always assumed as the size of the data type.

6. It stores the converted data in *TargetValuePtr. Be cautious that SQLGetData can not return data out of line.

7. The data length is stored in *StrLen_or_IndPtr. If StrLen_or_IndPtr is the null pointer, SQLGetData does not return the length.
   - For the string and binary data, it is the length after conversion and before truncated to BufferLength. If the driver can not check the data length after conversion (it can happen when it is a long data type), it returns SQL_SUCCESS_WITH_INFO, and it sets the length to SQL_NO_TOTAL.(The last call of SQLGetData should return the value of data length which is neither 0 nor is SQL_NO_TOTAL) If the data is truncated by the attribute of SQL_ATTR_MAX_LENGTH statement, the attribute value is stored in *StrLen_or_IndPtr. It is because the data is designed to be passed on the server before the attribute is converted, and the driver can not know the actual length. When SQLGetData is continuously called multiple times for the same column, this is the data length available at the beginning of the current call. In other words, the length is reduced due to each subsequent calls.
   - For all other data types, this is the data length after conversion. In other words, it is the size of the type to which data is converted.

8. If the data is truncated without loss of the default value(for example, the real number 1.234 is truncated to an integer 1 when converted), or if it is truncated because BufferLength is too small (e.g. the

string "abcdef" is stored in the buffer of 4-byte length) during data conversion, then SQLGetData returns SQLSTATE 01004 (Data truncated) and SQL_SUCCESS_WITH_INFO. If the data is truncated without loss of the default value due to the attribute of SQL_ATTR_MAX_LENGTH statement, SQLGetData returns SQL_SUCCESS but it does not return SQLSTATE 01004 (Data truncated).

If SQLGetData does not return SQL_SUCCESS nor SQL_SUCCESS_WITH_INFO (When SQLGetData is called for the bound column) the contents of bound data buffer, and the length/indicator buffer are not defined.

If SQLGetData is continuously called, it retrieves the data from the last column requested. The previous offset is not valid.

The following is an example.

```
SQLGetData(icol=n), SQLGetData(icol=m), SQLGetData(icol=n)
```

The second call SQLGetData(icol=n) retrieves the data starting from the column n. All offsets of the data are not valid any more due to the previous SQLGetData call.

SQLGetData and Descriptor

SQLGetData does not directly interact with any descriptor field.

If TargetType is SQL_ARD_TYPE, the data type of SQL_DESC_CONCISE_TYPE field of ARD is used. If TargetType is SQL_ARD_TYPE or SQL_C_DEFAULT, the precisions and scales of SQL_DESC_DATETIME_INTERVAL_PRECISION field, SQL_DESC_PRECISION field, and SQL_DESC_SCALE field of ARD are given according to the data type of SQL_DESC_CONCISE_TYPE field.

SQLGetDescField

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetDescField returns the current setting or value of a single field of descriptor record.

Syntax

```
SQLRETURN SQLGetDescField(
    SQLHDESC        DescriptorHandle,
    SQLSMALLINT     RecNumber,
    SQLSMALLINT     FieldIdentifier,
    SQLPOINTER      ValuePtr,
    SQLINTEGER      BufferLength,
    SQLINTEGER *    StringLengthPtr);
```

Arguments

DescriptorHandle

[Input] It is the descriptor handle.

RecNumber

[Input] It is the descriptor record of information which the application tries to find. If FieldIdentifier argument is the header field, RecNumber is ignored. If RecNumber is equal to or less than SQL_DESC_COUNT, and the row does not include the data for the column or parameter, SQLGetDescField returns the default value of field.

FieldIdentifier

[Input] It is the descriptor field to which the value is returned.

ValuePtr

[Output] It is the buffer pointer which returns the descriptor information. The data type is dependent on the value of FieldIdentifier.

If ValuePtr is the integer type, the application should use SQLULEN buffer initialized to 0.

If ValuePtr is null, StringLengthPtr returns the number of the total returnable bytes (excluding null-

termination character).

BufferLength

[Input] If FieldIdentifier field is defined in ODBC and ValuePtr points to the string or binary buffer, the argument should be the length of *ValuePtr. If FieldIdentifier field is defined in ODBC and *ValuePtr is an integer, the argument is ignored.

StringLengthPtr

[Output] It is the pointer which returns the number of the total returnable bytes from *ValuePtr (excluding null-termination byte for the character data).

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_NO_DATA, SQL_INVALID_HANDLE

If RecNumber is bigger than the number of current descriptor records, SQL_NO_DATA is returned.
If DescriptorHandle is IRD handle and the statement is in the ready state or executing state but associated cursor does not exist, SQL_NO_DATA is returned.

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The buffer length of *ValuePtr is shorter than the value length of descriptor field, so it is truncated. The remaining length of descriptor field is returned in *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
07009	Invalid descriptor index	RecNumber argument is set to 0, and the status attribute of SQL_ATTR_USE_BOOKMARKS is set to SQL_UB_OFF, and DescriptorHandle argument is a IRD handle. FieldIdentifier argument is the record field, RecNumber argument is 0, and DescriptorHandle argument is a IPD handle. RecNumber argument is smaller than 0.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY007	Associated statement is not prepared	DescriptorHandle is related to a IRD handle, and the related handle is not in the preparation state or executing state.
		It is the DescriptorHandle related to StatementHandle for the asynchronous performance function which is still being executed while it is called.

SQLSTATE	Error	Description
HY010	Function sequence error	It is the DescriptorHandle related to StatementHandle which SQLExecute, SQLExecDirect, SQLBulkOperations, SQLSetPos are called and SQL_NEED_DATA is returned. The asynchronously executing function is called for the connection handle related to DescriptorHandle, and it is still being executed even when SQLGetDescField is called.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0, or it can not access the memory.
HY021	Inconsistent descriptor information	SQL_DESC_TYPE and SQL_DESC_DATETIME_INTERVAL_CODE field are not the valid format for ODBC SQL type, SQL type of the specific driver (for IPD) or ODBC C type (for APD or ARD).
HY090	Invalid string or buffer length	*Valueptr is the string, and BufferLength is smaller than 0.
HY091	Invalid descriptor field Identifier	FieldIdentifier is not the field defined in ODBC, and it is not the implemented value. FieldIdentifier is not defined for DescriptorHandle.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The time limit can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver related to DescriptorHandle does not support the function.

Description

The application can call SQLGetDescField to return a single field value of the descriptor record. Calling SQLGetDescField returns the settings for all fields of all descriptor types including the header field, record fields, and bookmarks field. The application can obtain the multiple field settings in an arbitrary order in the same or another descriptor by repeatedly calling SQLGetDescField. SQLGetDescField can be called to return the driver definition descriptor field.

For the performance reason, the application should not call SQLGetDescField for IRD before executing the statement.

Multiple field settings for the size of name, data type, column or parameter data can be retrieved by calling SQLGetDescRec once. SQLGetStmtAttr can be called to return a single field settings in the descriptor he

ader which is the statement attribute. SQLColAttribute, SQLDescribeCol, SQLDescribeParam return the re cords or book mark fields.

When the application calls SQLGetDescField to retrieve the undefined field value for a particular descripto r type, the function returns SQL_SUCCESS but the returned field value is not defined. For example, calling SQLGetDescField for SQL_DESC_NAME field of APD/ ARD or calling SQLGetDescField for SQL_DESC_NUL LABLE field returns SQL_SUCCESS, but the field value is not defined.

When the application calls SQLGetDescField to retrieve the field value whose particular descriptor is defin ed but any settings such as default value are not defined, then the function returns SQL_SUCCESS but th e returned field value is not defined.

Header Field

Each descriptor consists of the following fields.

SQL_DESC_ALLOC_TYPE[All]

It is the header field which is read-only SQLSMALLINT. It specifies whether the descriptor is automa tically assigned by the driver or it is explicitly assigned by the application. The application can read t he field but can not modify it. When the descriptor is automatically allocated by the driver, the field is set to SQL_DESC_ALLOC_AUTO by the driver.

SQL_DESC_ARRAY_SIZE[Application descriptors]

It is the header field which is SQLULEN in ARD. It specifies the number of rows in the row set. This i s the number of rows returned by the operation caused by calling SQLFetch, SQLFetchScroll, SQLB ulkOperations or SQLSetPos.

It is the header field which is SQLULEN in APD. It specifies the number of values of each parameter.

The default value of the field is 1. If SQL_DESC_ARRAY_SIZE is bigger than 1, SQL_DESC_DATA_PT R, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR of APD or ARD points to the arra y. The constant of each array is equal to the field value.

This field in ARD can be set by calling SQLSetStmtAttr together with SQL_ATTR_ROW_ARRAY_SIZE attribute. The field in APD can also be set by calling SQLSetStmtAttr together with SQL_ATTR_PAR AMSET_SIZE.

SQL_DESC_ARRAY_STATUS_PTR[All]

For each descriptor type, the header field which is SQLUSMALLINT* points to the array of SQLUSM ALLINT value. The arrays are named as row status array (IRD), parameter status array (IPD), row op eration array (ARD), parameter operation array (APD).

This header field in IRD points to the row status array which contains the status value after calling S QLBulkOperations, SQLFetch, SQLFetchScroll, or SQLSetPos. The application allocates SQLUSMALLI NT array, and this field should point to the array. The field is generally the NULL pointer. The driver will create an array unless SQL_DESC_ARRAY_STATUS_PTR is set to the NULL pointer.

If the application sets the elements of row status array pointed by SQL_DESC_ARRAY_STATUS_PTR field of IRD, then the operation of driver is not defined.

The array is initialized and created by calling SQLBulkOperations, SQLFetch, SQLFetchScroll or SQLSetPos. If this call does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, then the content of array pointed by the field is not defined.

Elements in the array can contain the following values.

- SQL_ROW_SUCCESS: The row is successfully retrieved, and it is not updated since the last retrieving.
- SQL_ROW_SUCCESS_WITH_INFO: The row is successfully retrieved, and it is not updated since the last return. However, the warning for the row is returned.
- SQL_ROW_ERROR: An error occurs during retrieving the row.
- SQL_ROW_UPDATED: The row is successfully retrieved, and it is updated since the last retrieving. If the row is retrieved again, the state is SQL_ROW_SUCCESS.
- SQL_ROW_DELETED: The row is deleted since the last retrieving.
- SQL_ROW_ADDED: The row is entered by SQLBulkOperations. If the row is retrieved again, the state is SQL_ROW_SUCCESS.
- SQL_ROW_NOROW: The row set and the last of result set are overlapped. And a row is not returned corresponding to the elements of row status array.

This field of IRD can be set by calling SQLSetStmtAttr together with SQL_ATTR_ROW_STATUS_PTR attribute.

SQL_DESC_ARRAY_STATUS_PTR field of IRD is valid only after SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is returned. If the return code is not one of these, the thing pointed by SQL_DESC_ROWS_PROCESSED_PTR is not defined.

This header field in IPD calls SQLExecute or SQLExecDirect and then points to the parameter status array which includes each parameter status information. If SQLExecute or SQLExecDirect is called and SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is not returned, then the content of array pointed by this field is not defined. The application allocates SQLUSMALLINT array, and this field should point the array. The driver will create an array if SQL_DESC_ARRAY_STATUS_PTR field is not set to the NULL pointer.

Elements in the array can contain the following values.

- SQL_PARAM_SUCCESS: SQL statement was successfully executed for this parameter set.
- SQL_PARAM_SUCCESS_WITH_INFO: SQL statement was successfully executed for this parameter set, but there is a warning information available to the diagnostic data structure.
- SQL_PARAM_ERROR: An error occurred when processing the parameter set. Additional error information is in the diagnostic data structure.
- SQL_PARAM_UNUSED: An error occurred while processing some previous parameters, or it is not used because SQL_PARAM_IGNORE is set in the parameter set of the array pointed by SQL_DESC_ARRA

Y_STATUS_PTR field of APD.
- SQL_PARAM_DIAG_UNAVAILABLE: The diagnostic information can not be used. For example, the dri ver treats the array of the parameter as one and does not generate the level of the error information.

This field in IPD can be set by calling SQLSetStmtAttr together with SQL_ATTR_PARAM_STATUS_PTR attri bute.

In ARD, the corresponding field points to the row operation array for the values set by the application to determine whether or not to ignore the row in SQLSetPos operation.

Elements in the array can contain the following values.

- SQL_ROW_PROCEED: The row is included in the bulk operation which uses SQLSetPos. (This setting does not guarantee that the operation occurs on the row. If the row has SQL_ROW_ERROR state of t he row status array of IRD, the driver can not implement the operation for the row.)
- SQL_ROW_IGNORE: The row is excluded from the bulk operation which uses SQLSetPos.

If elements of the array is not set, all rows are included in the bulk operation. If the value of SQL_DESC_A RRAY_STATUS_PTR field of ARD is the NULL pointer, all rows are included in the bulk operation. It is tran slated as same as when the pointer points to a valid array and all elements of the array are SQL_ROW_PR OCEED. When all elements in the array are set to SQL_ROW_IGNORE, the values in the row status array f or the ignored rows are not updated.

This field in ARD can also be set by calling SQLSetStmtAttr together with SQL_ATTR_ROW_OPERATION_P TR attribute.

When SQLExecute or SQLExecDirect is called, this header field in ARD points to the parameter operation array of the values set by the application to indicate whether or not to ignore the parameter set.

Elements in the array can contain the following values.

- SQL_PARAM_PROCEED: The parameter set is included in calling SQLExecute or SQLExecDirect.
- SQL_PARAM_IGNORE: The parameter set is not included in calling SQLExecute or SQLExecDirect.

If elements of the array are not set, all parameter sets of the array are used to call SQLExecute or SQLExec Direct. If the value of SQL_DESC_ARRAY_STATUS_PTR field of APD is the NULL pointer, all parameter set are used. It is read as same as when the pointer points to the valid array, or the array whose all elements are SQL_PARAM_PROCEED.

This field in APD can also be set by calling SQLSetStmtAttr together with SQL_ATTR_PARAM_OPERATION _PTR attribute.

SQL_DESC_BIND_OFFSET_PTR[Application descriptors]

This header field is SQLLEN* and it points to the binding offset. It is set to the NULL pointer by defa ult. If this field is not the NULL pointer, the driver dereferences the pointer and each value of the d

eferred field which has non-NULL value of the descriptor record (SQL_DESC_DATA_PTR_, SQL_DES C_INDICATOR_PTR and SQL_DESC_OCTET_LENGTH_PTR) at fetching time, and uses a new pointer value when binding.

The binding offset is always directly added to SQL_DESC_DATA_PTR field, SQL_DESC_INDICATOR_ PTR field and SQL_DESC_OCTET_LENGTH_PTR field. If the offset value is changed to another value, the new value is directly and continuously added as each descriptor field value. The new offset is n ot added to the previous offset value of the field.

It is the deferred field. This field is not used at the time of setting, but it is used by the driver when the data buffer address is checked.

This field in ARD can be set by calling SQLSsetStmtAttr together with SQL_ATTR_ROW_BIND_OFFS ET_PTR attribute.

For more information, refer to **SQLFetchScroll** or **SQLBindParameter**.

SQL_DESC_BIND_TYPE[Application descriptors]

This header field is SQLUINTEGER and is used to set the binding direction.

This field in ARD specifies the binding direction when SQLFetchScroll or SQLFetch is called on the r elated statement handle.

This field can be set to SQL_BIND_BY_COLUMN(default) to select the column-wise binding for the columns.

The field in ARD can be set by calling SQLSetStmtAttr together with SQL_ATTR_ROW_BIND_TYPE attribute.

The field specifies the binding direction used in the dynamic parameter.

This field may be set to SQL_BIND_BY_COLUMN(default) to select the column-wise binding for the parameter.

This field can be set by calling SQLSetStmtAttr together with SQL_ATTR_PARAM_BIND_TYPE attrib ute.

SQL_DESC_COUNT[All]

This header field is SQLSMALLINT and specifies the 1-based index of the top-level record which incl udes the data. When the driver sets the data structure to the descriptor, SQL_DESC_COUNT should be set to display the number of important records. It is not required to specify how many space to r eserve for the record when the application allocates instances of data structure. Like as the applicat ion specifies the contents of the records, the driver performs the requested operation for the descri ptor handle to guarantee displaying the sufficient size of the data structure.

It is not the number of all data column or all parameters which SQL_DESC_COUNT is bound to, but it is the number of top-level records. If the binding of the top-level column or parameter is released, SQL_DESC_COUNT is changed to the number of next top-level columns or parameters. If the bindi ng of the top-level column, the column which is smaller than the parameter, or parameters is relea sed (if TargetValuePtr argument is set to the NULL pointer, and SQLBindCol is called, or if Paramete

rValuePtr argument is set to the NULL pointer and SQLBindParameter is called), SQL_DESC_COUNT is not changed. If the added column or parameter is bound with bigger number than the number of top level records which includes the data, the driver automatically increases the value of SQL_DESC_COUNT field. If the binding for all columns is released by calling SQLFreeStmt with the SQL_UNBIND option, SQL_DESC_COUNT in ARD and IRD is set to 0. If SQLFreeStmt is called with the SQL_RESET_PARAMS option, SQL_DESC_COUNT fields in APD and IPD is set to 0.

The value of SQL_DESC_COUNT is explicitly set by calling SQLSetDescField in the application. If the value of SQL_DESC_COUNT is explicitly decreased, the records which have the value bigger than the new value of SQL_DESC_COUNT are effectively removed. If the value of SQL_DESC_COUNT field of ARD is set to 0, all buffers are released except for the bound bookmark column. The number of records of the field Of ARD does not include the bound bookmark column. The only way to release the binding of book mark column is to set SQL_DESC_DATA_PTR to NULL pointer.

SQL_DESC_ROWS_PROCESSED_PTR[Implementation descriptors]

This header field is SQLULEN* of IRD, and points to the buffer. The buffer includes the number of rows returned after calling SQLFetch or SQLFetchScroll, and the number of rows or number of errors affected by calling SQLBulkOperations or SQLSetPos and executing the bulk operation.

This header field is SQLUINTEGER* of IPD and points to the buffer which includes the processed parameter set or the number of errors. If it is NULL pointer, the number is not returned.

SQL_DESC_ROWS_PROCESSED_PTR is valid only after calling SQLFetch or SQLFetchScroll(IRD) or after SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is returned by calling SQLExecute, SQLExecDirect or SQLParamData(IPD). If the functions above do not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, then the buffer contents are not defined and the buffer value is set to 0 until SQL_NO_DATA is returned.

The field in ARD can be set by calling SQLSetStmtAttr together with SQL_ATTR_ROWS_FETCHED_PTR attribute. ARD can be set by calling SQL_ATTR_PARAMS_PROCESSED_PTR.

The buffer pointed by this field is allocated by the application. It is the deferred output buffer defined by the driver. NULL pointer is set by default.

Record Field

Each descriptor includes one or more records consisting of the fields which define the column data or dynamic parameter depending on the descriptor type. Each record is a complete specification of a single column or parameter.

SQL_DESC_AUTO_UNIQUE_VALUE[IRDs]

This record field is read-only SQLINTEGER. It is SQL_TRUE if the column is automatically increased. Otherwise, it is SQL_FALSE. The auto-increment column does not need to be read-only.

SQL_DESC_BASE_COLUMN_NAME[IRDs]

This record field is read-only SQLCHAR*. It includs the default column name of the result set column. If the default column name does not exist, the field should include an empty string.

SQL_DESC_TABLE_NAME[IRDs]

This record field is read-only SQLCHAR*. It includes the base table name of the result set column. If the base table name is not defined or used, the field should include an empty string.

SQL_DESC_CASE_SENSITIVE[Implementation descriptors]

This record field is read-only SQLINTEGER. It includes SQL_TRUE if the column or parameter is case-sensitive when sorting or comparing columns or parameters, but it includes SQL_FALSE if the colu mn or parameter is case-insensitive or non-character column.

SQL_DESC_CATALOG_NAME[IRDs]

This record field that is read-only SQLCHAR*. It includes the catalog of the base table which includ es the column. If the column is an expression or a part of a view, the return value is dependent on the driver. If the data source does not support the catalog nor does it check the catalog, the field s hould include an empty string.

SQL_DESC_CONCISE_TYPE[All]

This header field is SQLSMALLINT. It speifies the simple format for the data types which includes da tetime and interval data types.

The value of SQL_DESC_CONCISE_TYPE field, SQL_DESC_TYPE field and SQL_DESC_DATETIME_IN TERVAL_CODE field are interdependent. If time is set in one of the fields, it should be set on other fields as well. SQL_DESC_CONCISE_TYPE can be set by calling SQLBindCol, SQLBindParameter or S QLSetDescField. SQL_DESC_TYPE is set by calling SQLSetDescField or SQLSetDescRec.

If SQL_DESC_CONCISE_TYPE is set as the simple data types except for the interval or datetime data type, then SQL_DESC_TYPE field is set to the same value, and SQL_DESC_DATETIME_INTERVAL_C ODE field is set to 0.

If SQL_DESC_CONCISE_TYPE is set as the simple datetime or interval data type, then SQL_DESC_T YPE field is set to the detailed type(SQL_DATETIME or SQL_INTERVAL), and SQL_DESC_DATETIME _INTERVAL_CODE field is set to the proper subcode.

SQL_DESC_DATETIME_INTERVAL_CODE[All]

This record field is SQLSMALLINT. It includes the subcode which specifies the datetime or interval d ata type when SQL_DESC_TYPE field is SQL_DATETIME or SQL_INTERVAL. It is the same for both S QL and C support it, the code includes the data type name such as "TYPE" or "C_TYPE" for datetim e type, "CODE" replaced from "INTERVAL" or "C_INTERVAL" for interval types.

If SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE of the application descriptor are set to SQL_C_ DEFAULT and the descriptor is not related to the statement handle, then the content of SQL_DESC _DATETIME_INTERVAL_CODE is not defined.

This field can set the datetime data types listed in the following table.

Datetime type	DATETIME_INTERVAL_CODE
SQL_TYPE_DATE SQL_C_TYPE_DATE	SQL_CODE_DATE

Datetime type	DATETIME_INTERVAL_CODE
SQL_TYPE_TIME SQL_C_TYPE_TIME	SQL_CODE_TIME
SQL_TYPE_TIMESTAMP SQL_C_TYPE_TIMESTAMP	SQL_CODE_TIMESTAMP

This field can set the interval data types listed in the following table.

Interval type	DATETIME_INTERVAL_CODE
SQL_INTERVAL_DAY SQL_C_INTERVAL_DAY	SQL_CODE_DAY
SQL_INTERVAL_DAY_TO_HOUR SQL_C_INTERVAL_DAY_TO_HOUR	SQL_CODE_DAY_TO_HOUR
SQL_INTERVAL_DAY_TO_MINUTE SQL_C_INTERVAL_DAY_TO_MINUTE	SQL_CODE_DAY_TO_MINUTE
SQL_INTERVAL_DAY_TO_SECOND SQL_C_INTERVAL_DAY_TO_SECOND	SQL_CODE_DAY_TO_SECOND
SQL_INTERVAL_HOUR SQL_C_INTERVAL_HOUR	SQL_CODE_HOUR
SQL_INTERVAL_HOUR_TO_MINUTE SQL_C_INTERVAL_HOUR_TO_MINUTE	SQL_CODE_HOUR_TO_MINUTE
SQL_INTERVAL_HOUR_TO_SECOND SQL_C_INTERVAL_HOUR_TO_SECOND	SQL_CODE_HOUR_TO_SECOND
SQL_INTERVAL_MINUTE SQL_C_INTERVAL_MINUTE	SQL_CODE_MINUTE
SQL_INTERVAL_MINUTE_TO_SECOND SQL_C_INTERVAL_MINUTE_TO_SECOND	SQL_CODE_MONUTE_TO_SECOND
SQL_INTERVAL_MONTH SQL_C_INTERVAL_MONTH	SQL_CODE_MONTH
SQL_INTERVAL_SECOND SQL_C_INTERVAL_SECOND	SQL_CODE_SECOND
SQL_INTERVAL_YEAR SQL_C_INTERVAL_YEAR	SQL_CODE_YEAR
SQL_INTERVAL_YEAR_TO_MONTH SQL_C_INTERVAL_YEAR_TO_MONTH	SQL_CODE_YEAR_TO_MONTH

SQL_DESC_DATETIME_INTERVAL_PRECISION[All]

This SQLINTEGER record field includes the interval leading precision if SQL_DESC_TYPE field is SQL_INTERVAL. When SQL_DESC_DATETIME_INTERVAL_CODE field is set to the interval data type, the field sets the default interval leading precision.

SQL_DESC_DISPLAY_SIZE[IRDs]

This read-only SQLINTEGER record field contains the maximum number of characters required to s how the data from the column.

SQL_DESC_FIXED_PREC_SCALE[Implementation descriptors]

This read-only SQLSMALLINT record field sets SQL_TRUE if the column is the exact numeric column and it has non-zero scale and the fixed precision. Otherwise, it sets SQL_FALSE.

SQL_DESC_INDICATOR_PTR[Application descriptors]

This SQLLEN* record field in ARD represents the indicator variable. The variable includes SQL_NULL _DATE if the column value is NULL. For APD, the indicator variable is set to SQL_NULL_DATA to sp ecify a dynamic factor as NULL, otherwise the variable is zero.

If SQL_DESC_INDICATOR_PTR field of ARD is NULL pointer, the driver prevents the information ret urned for whether the column is NULL. If the column is NULL and SQL_DESC_INDICATOR_PTR is N ULL pointer, SQLSTATE 22002(Indicator variable required but not supplied) is returned when the d river creates the buffer after calling SQLFetch or SQLFetchScroll. If calling SQLFetch or SQLFetchScr oll does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is not defined.

SQL_DESC_INDICATOR_PTR field determines whether to set the field represented by SQL_DESC_O CTET_LENGTH_PTR. If the column value is NULL, the driver sets the indicator variable to SQL_NULL _DATA. The field represented by SQL_DESC_OCTET_LENGTH_PTR is not set at that moment. If NU LL is not returned while retrieving the data, the buffer represented by SQL_DESC_INDICATOR_PTR is set to 0, and the buffer represented by SQL_DESC_OCTET_LENGTH_PTR sets the data length.

If SQL_DESC_INDICATOR_PTR field of APD is NULL pointer, the application can not use the descrip tor record to specify the argument as NULL.

This field is the deferred field. It is not used when the driver is set, but it is used when the driver dis plays NULL possibility (ARD) or determines the NULL possibility (APD).

SQL_DESC_LABEL[IRDs]

This read-only SQLCHAR* record field includes the label or mark of a column. If the column does n ot have label, then the variable contains the column name. If the column is not named or it can not use the label, then the variable includes an empty string.

SQL_DESC_LENGTH[All]

This SQLULEN record field is the maximum length or actual length of the string or binary data in by tes. It is the maximum length of fixed length data type data or the actual length of variable length data type data. The value always excludes NULL termination character at the end of string. If its dat a type is SQL_TYPE_DATE, SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP or SQL interval data type, the field has the string length of when datetime or interval value is rewritten to string.

The field value is different from the value of "length" defined in ODBC 2.x.

SQL_DESC_LITERAL_PREFIX[IRDs]

This read-only SQLCHAR* record field includes the characters recognized as a suffix by the charact er or the driver. The variable contains the empty string for the data type whose character suffix can

not be converted.

SQL_DESC_LOCAL_TYPE_NAME[Implementation descriptors]

This read-only SQLCHAR* record field includes the localized name in the data type, and it could be different from the regular name in the data type. If the localized name does not exist, an empty stri ng is returned. The field is only for the purpose of displaying.

SQL_DESC_NAME[Implementation descriptor]

This SQLCHAR* record field includes the field alias in the row descriptor. If the column alias is not a pplied, the column name is returned. In some cases, the driver sets SQL DESC_UNNAMED field to S QL_NAMED when setting SQL_DESC_NAME field. If neither column name nor column alias existm the driver returns the empty string of SQL_DESC_NAME field, and sets SQL_DESC_UNNAME field t o SQL_UNNAMED.

The application can set SQL_DESC_NAME field of IPD for an alias to specify the parameter name or stored named procedure parameter. SQL_DESC_NAME field of IRD is the read-only field. If the app lication tries to set this field, SQLSTATE HY091 (invalid descriptor field identifier) will be returned.

For IPD, if the driver does not support the named parameter, the field is not defined. If the driver s upports the named parameter and specifies the parameter, the name of the parameter is returned to this field.

SQL_DESC_NULLABLE[Implementation descriptors]

For IRD, this read-only SQLSMALLINT record field is SQL_NULLABLE if the column have NULL, other wise it is SQL_NO_NULLS. If it is unknown whether the column allows NULL, it is SQL_NULLABLE_U NKNOWN. The field exists particularly for the column in the result set.

For IPD, The field is always set to SQL_NULLABLE because the dynamic parameter can always be N ULL and it can not set by the application.

SQL_DESC_NUM_PREC_RADIX[All]

This SQLINTEGER field has the value of 2 when SQL_DESC_TYPE field is the approximate numeric data type. It is because SQL_DESC_PRECISION field includes the number of bits. The field has the v alue of 10 when SQL_DESC_TYPE field is the exact numeric data type and SQL_DESC_PRECISION c ontains the number of decimal places. The field sets 0 for a non-numeric data types.

SQL_DESC_OCTET_LENGTH[All]

This SQLLEN record field includes the length in bytes of a string or binary data type. For the fixed le ngth character or binary data, it is the actual length in bytes. For the variable length character or bi nary data, it is the maximum length in bytes. The value does not include the empty string of NULL t ermination character for the implement descriptor, and it includes the empty string of NULL termin ation character for the application descriptor. For the application data, the field contains the buffer size. For APD, the field is defined only for the output or input/output parameters.

SQL_DESC_OCTET_LENGTH_PTR[Application descriptors]

The SQLLEN* record field points to the variable including the total length in bytes of the dynamic a rgument(parameter descriptor) or the binding column values (row descriptor).

This value is ignored for all arguments excluding the string or binary data in APD. If the field is SQL_NTS, the dynamic argument should be terminated with NULL. The application sets the variable including the macro result of SQL_DATA_AT_EXEC or SQL_LEN_DATA_AT_EXEC in this record field of APD to indicate that the bound parameter is to be a data parameter at the run-time. If one or more fields exist, SQL_DESC_DATA_PTR can be set as the value which identifies the parameter required by the application, and which is helpful to determine the parameter.

If OCTET_LENGTH_PTR field of ARD is NULL pointer, the driver does not return the column length. If SQL_DESC_OCTET_LENGTH_PTR of APD is NULL pointer, the driver assumes that the string and binary values are terminated by NULL. (Binary values should not be terminated by NULL, but the length should be given to avoid data interruption.)

If SQLFetch or SQLFetchScroll which fills the buffer pointed by the field does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is not defined. It is the deferred field. The field is not immediately used, but it is used later when the driver displays or determines the data length in octet.

SQL_DESC_PARAMETER_TYPE[IRDs]

This SQLSMALLINT record field sets the input parameter to SQL_PARAM_INPUT, the input/output parameter to SQL_PARAM_INPUT_OUTPUT, the output parameter to SQL_PARAM_OUTPUT, the stream input/output parameter to SQL_PARAM_INPUT_OUTPUT_STREAM or the stream output parameter to SQL_PARAM_OUTPUT_STREAM. It is set to SQL_PARAM_INPUT by default.

SQL_DESC_PRECISION[All]

This SQLSMALLINT record field includes the number of valid integers for the exact numeric data types, and it includes the number of bits in mantissa (the binary precision) for the approximate numeric data types. Or, it contains the number of valid integer of the fractional seconds parts of the SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP, or SQL_INTERVAL_SECOND data type. The field is not defined for all other data types.

The field value is different from the "precision" value defined in ODBC 2.x.

SQL_DESC_ROWVER[Implementation descriptors]

This SQLSMALLINT record field indicates whether the column is automatically updated by DBMS when the row is updated(for example, "timestamp" in SQL Server). The record field value is set to SQL_TRUE for the row versioning column, otherwise it is set to SQL_FALSE. The column attribute is similar to setting and calling SQL_ROWVER in IdentifierType argument of SQLSpecialColumn to determine whether to automatically update column.

SQL_DESC_SCALE[All]

This SQLSMALLINT record field includes the number of decimal places defined in the decimal and numeric data types. The field is not defined for all other data types.

The field value is different from the "scale" value defined in ODBC 2.x.

SQL_DESC_SCHEMA_NAME[IRDs]

This read-only SQLCHAR* record field includes the schema name of the base table that includes the column. If the column is an expression or a part of the view, the return value is dependent on the

driver. If the data source does not support the schema or can not identify the schema name, then t his variable contains an empty string.

SQL_DESC_SEARCHABLE[IRDs]

This read-only SQLSMAINT record field sets one of the following values.

• If the column can not be used in WHERE clause, it is SQL_PRED_NONE. (It is as same as SQL_UN SEARCHABLE in ODBC 2.X.)

• If the column can only be used with LIKE predicate in WHERE clause, it is SQL_PRED_CHAR.

• If the column can be used with all comparison operators except for LIKE in WHERE clause, it is S QL_PRED_BASIC. (It is as same as the value of SQL_EXCEPT_LIKE in ODBC 2.x.)

• If the column can be used with any comparison operator in WHERE clause, it is SQL_PRED_SEAR CHABLE.

SQL_DESC_TABLE_NAME[IRDs]

This read-only SQLCHAR* record field includes the base table name which includes column. The re turn value is dependent on the driver if the column is an expression or a part of the view.

SQL_DESC_TYPE[All]

This SQLSMALLINT record field includes an abbreviated SQL data types or C data types for all data t ypes except for the interval and datetime data types. The field specifies SQL_DATETIME or SQL_INT ERVAL for datetime and interval data types.

Whenever this field includes SQL_DATETIME or SQL_INTERVAL, SQL_DESC_DATETIME_INTERVAL_ CODE field should include the appropriate subcode in the implied format. For datetime data types, SQL_DESC_TYPE includes SQL_DATETIME, and SQL_DESC_DATETIME_INTERVAL_CODE field inclu des the subcode that specifies the datetime data type. For interval data types, SQL_DESC_TYPE incl udes SQL_INTERVAL, and SQL_DESC_DATETIME_INTERVAL_CODE field includes the subcode that specifies the interval data type.

The values of SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE field are interdependent. When on e of the fields is set, the other field should also be set. SQL_DESC_TYPE can be set by calling SQLSe tDescField or SQLSetDescRec. SQL_DESC_CONCISE_TYPE can be set by calling SQLBindCol, SQLBin dParameter or SQLSetDescField.

If SQL_DESC_TYPE is set to the implied data type other than the interval or datetime data type, SQ L_DESC_CONCISE_TYPE field is set to the same value and SQL_DESC_DATETIME_INTERVAL_CODE is set to 0.

If SQL_DESC_TYPE is set to the long data type of datetime or interval data type (SQL_DATETIME or SQL_INTERVAL), SQL_DESC_DATETIME_INTERVAL_CODE field is set to the approprieate subcode, SQL_DESC_CONCISE_TYPE may be set to a value corresponding to the implied data type. If SQL_D ESC_TYPE is set to one of the implied datetime or interval data type, SQLSTATE HY021 (Inconsiste nt descriptor information) is returned.

When SQL_DESC_TYPE is set by calling SQLBindCol, SQLBindParameter or SQLSetDescField, the ne xt fields are set to the default values in the following table. The values of remaining fields in the sa

me record are not defined.

SQL_DESC_TYPE value	Setting other fields implicitly
SQL_CHAR, SQL_VARCHAR, SQL_C_CHAR, SQL_C_VARCHAR	SQL_DESC_LENGTH is set to 1. SQL_DESC_PRECISION is set to 0.
SQL_DATETIME	If SQL_DESC_DATETIME_INTERVAL_CODE is set to SQL_CODE_DATE or SQL_CODE_TIME, SQL_DESC_PRECISION is set to 0. If SQL_DESC_TIMESTAMP is set, SQL_DESC_PRECISION is set to 6.
SQL_DECIMAL, SQL_NUMERIC, SQL_C_NUMERIC	SQL_DESC_SCALE is set to 0. SQL_DESC_PRECISION is set to the implemented precision of each data type.
SQL_FLOAT, SQL_C_FLOAT	SQL_DESC_PRECISION is set to the default precision implemented in SQL_FLOAT.
SQL_INTERVAL	When SQL_DESC_DATETIME_INTERVAL_CODE is set to the interval data type, SQL_DESC_DATETIME_INTERVAL_PRECISION is set to 2 (default interval leading precision). When the interval has the part of seconds, SQL DESC PRECISION is set to 6 (the default interval seconds precision).

When the application sets the descriptor field by calling not SQLSetDescRec but SQLSetDescField, the application should define the data type firstly. Therefore other fields in the previous table are implicitly set. If it is not allowed to implicitly set any value, the application explicitly sets the value by calling SQLSetDescField or SQLSetDescRec.

SQL_DESC_TYPE_NAME[Implementation descriptors]

This read-only SQLCHAR* record field includes the data source dependent type name ("CHAR", "VARCHAR", etc.). If the data type name is unknown, the variable includes an empty string.

SQL_DESC_UNNAMED[Implementation descriptors]

If SQL_DESC_NAME field is set, the SQLSMALLINT record field in the row descriptor is set to one of SQL_NAME or SQL_UNNAMED by the driver. If SQL_DESC_NAME field does not include the column alias or if the column alias does not apply, the driver sets SQL_DESC_UNNAMED field to SQL_NAMED. If the application sets SQL_DESC_NAME field of IPD to the parameter name or alias, the driver sets SQL_DESC_UNNAMED field of IPD to SQL_NAMED. If neither column name nor does alias exist, the driver sets SQL_DESC_UNNAMED field of IPD to SQL_UNNAMED.

The application sets SQL_DESC_UNNAMED field of IPD to SQL_UNNAMED. If the application tries to set SQL_DESC_UNANMED field of IPD to SQL_NAMED, the driver returns SQLSTATE HY091 (Invalid descriptor field identifier). SQLSTATE HY091 (Invalid descriptor field identifier) is returned if the read-only application tries to set SQL_DESC_UNNAMED field of IRD.

SQL_DESC_UNSIGNED[Implemetation descriptors]

This read-only SQLSMALLINT record field is set to SQL_TRUE, if the column type is the unsigned or non-numeric data type. It is set to SQL_FALSE, if the column type is the signed data type.

SQL_DESC_UPDATABLE[IRDs]

The read-only SQLSMALLINT record field is set to one of the following values.

• If the result set column is read-only, it is SQL_ATTR_READ_ONLY.

• If the result set column is read and write, it is SQL_ATTR_WRITE.

• If the updatability for the result set column is unknown, it is SQL_ATTR_READWRITE_UNKNOWN.

SQL_DESC_UPDATABLE explains the updatability of the result set column (the column is not in the base table). The updatabilty of the column in the primary table which is a base of the result set columns may be different from the value in this field. The updatability is based on the data type, the user privileges and the result set definition. If it is not sure that the column can be updated, SQL_ATTR_READWITE_UNKNOWN should be returned.

SQL_DESC_CHAR_LENGTH_UNITS[Alls]

This SQLSMALLINT record field indicates the length units of the column whose SQL types are SQL_CHAR, SQL_VARCHAR and SQL_LONGVARCHAR.

• SQL_CLU_CHARACTERS: The length unit is CHARACTER. For example, the length of data "문자열" is 3 if the encoding method is UHC(Unified Hangul Code).

• SQL_CLU_OCTETS: The length unit is OCTETS. For example, the length of data "문자열" is 6 if the encoding method is UHC(Unified Hangul Code).

• SQL_CLU_NONE: The length unit is undefined. It is the value which is returned for the SQL types excluding the SQL types listed above.

SQLGetDescRec

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetDescRec returns the current value or setting for the multiple fields of the descriptor record. The returned field describes the name, the data type, the column size or the argument data.

Syntax

```
SQLRETURN SQLGetDescRec(
    SQLHDESC        DescriptorHandle,
    SQLSMALLINT     RecNumber,
    SQLCHAR *       Name,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLengthPtr,
    SQLSMALLINT *   TypePtr,
    SQLSMALLINT *   SubTypePtr,
    SQLLEN *        LengthPtr,
    SQLSMALLINT *   PrecisionPtr,
    SQLSMALLINT *   ScalePtr,
    SQLSMALLINT *   NullablePtr);
```

Arguments

DescriptorHandle

[Input] It is the descriptor handle.

RecNumber

[Input] It is the descriptor record of the information which the application wants to retrieve. The record number 0 is set as the bookmark record and the descriptor record starts from 1. If RecNumber is equal to or smaller than SQL_DESC_COUNT, but the data for the column or parameter is not included in the row, SQLGetDescField returns the default value of the field.

Name

[Output] It is the buffer pointer which returns SQL_DESC_NAME for the descriptor record. If Name is NULL, StringLengthPtr returns the buffer length of Name (including null-termination character).

BufferLength

[Input] It is the length of name buffer.

StringLengthPtr

[Output] It is the pointer which returns the number of characters returnable in *Name buffer excluding null-termination character. If the number of characters are equal to or bigger than BufferLength, the data of *Name is truncated to BufferLength minus the length of a null-termination character, and is null-terminated.

TypePtr

[Output] It is the buffer pointer which returns the value of SQL_DESC_TYPE for the descriptor field.

SubTypePtr

[Output] It is the buffer pointer which returns the value of SQL_DESC_DATETIME_INTERVAL_CODE field for the record of SQL_DATETIME or SQL_INTERAVL type.

LengthPtr

[Output] It is the buffer pointer which returns the value of SQL_DESC_OCTET_LENGTH field for the descriptor field.

PrecisionPtr

[Output] It is the pointer which returns the value of SQL_DESC_PRECISION field for the descriptor record.

ScalePtr

[Output] It is the pointer which returns the value of SQL_DESC_SCALE field for the descriptor record.

NullablePtr

[Output] It is the pointer which returns the value of SQL_DESC_NULLABLE field for the descriptor record.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_NO_DATA, SQL_INVALID_HANDLE

If RecNumber is bigger than the number of current descriptor records, SQL_NO_DATA is returned. If DescriptorHandle is the IRD handle and the statement is on the preparation or execution state but related cursor does not exist, then SQL_NO_DATA is returned.

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is a specific information message of the driver. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The length of *ValuePtr buffer is shorter than the length of the descriptor field value, so the length is truncated. The remaining length of the descriptor field is returned to *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
07009	Invalid descriptor index	The fieldIdentifier argument is the record field, and the value of RecNumber argument is set to 0, and DescriptorHandle argument is the IPD handle. RecNumber argument is set to 0, and SQL_ATTR_USE_BOOKMARKS attribute is set to SQL_UB_OFF, and DescriptorHandle argument is the IRD handle. RecNumber argument is smaller than 0.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY007	Associated statement is not prepared	DescriptorHandle is related to the IRD handle, and the related statement handle is not on the preparation or execution state.
HY010	Function sequence error	StatementHandle related to DescriptorHandle asynchronously executes the function and it is still executung the function when called. After calling SQLExecute, SQLExecDirect, then SQL_NEED_DATA is returned and the function is called before sending all data-at-execution variables. The function for the connetion handle related to DescriptorHandle is called, and it is still executing when SQLGetDescRec is called.
HY013	Memory management error	The buffer size used as the argument is smaller than 0, or it can not access the memory.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran** function.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver related to DescriptorHandle does not support the function.

Description

The application can call SQLGetDescRec to retrieve the following descriptor field value for a column or pa rameter.

- SQL_DESC_NAME
- SQL_DESC_TYPE
- SQL_DESC_DATETIME_INTERVAL_CODE
- SQL_DESC_OCTET_LENGTH
- SQL_DESC_PRECISION
- SQL_DESC_SCALE
- SQL_DESC_NULLABLE

SQLGetDescRec does not retrieve the header field value.

The application can set the argument corresponding to the null pointer field so that it prevents the return for the field setting.

When the application retrieves the value of the undefined field for the specific descriptor type by calling S QLGetDescRec, the function returns SQL_SUCCESS, but the return value for the field is not defined. For e xample, if SQLGetDescRec is called for SQL_DESC_NAME field or SQL_DESC_NULLABLE field of APD or A RD, then SQL_SUCCESS is returned but the field value is not defined.

When the application calls SQLGetDescRec to retrieve the value of the field which is defined as the specifi c descriptor type but is not set as the default, the function returns SQL_SUCCESS, but the field value is no t defined. For more information, refer to **Initializing Descriptor Field** of SQLSetDescField.

Each field value can be retrieved separately by calling SQLGetDescField. For more information about the d escriptor header or the fields in the record, refer to **SQLSetDescField**.

SQLGetDiagField

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetDiagField returns the current value of the record fields in the diagnostic data structure which cont ains an error, warning, and status information.

Syntax

```
SQLRETURN SQLGetDiagField(
    SQLSMALLINT     HandleType,
    SQLHANDLE       Handle,
    SQLSMALLINT     RecNumber,
    SQLSMALLINT     DiagIdentifier,
    SQLPOINTER      DiagInfoPtr,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLengthPtr);
```

Arguments

HandleType

[Input] It is the handle type identifier which requires diagnostics. The identifier should be one of th e followings.

- SQL_HANDLE_DBC
- SQL_HANDLE_DESC
- SQL_HANDLE_ENV
- SQL_HANDLE_STMT

Handle

[Input] It is the handle for the diagnostic data structure, of the type pointed by HandleType. If Han dleType is SQL_HANDLE_ENV, the Handle can be the shared or non-shared environment handle.

RecNumber

[Input] It indicates the state record of the information found by the application. The status record s tarts from 1. If DiagIdentifier points any field of the diagnostic header, RecNumber is ignored. Othe rwise, RecNumber should be bigger than 0.

DiagIdentifier

[Input] It refers to the diagnostic field whose value is returned. For more information, refer to **DiagI dentifier Argument** in the Description section.

DiagInfoPtr

[Output] It is the buffer pointer to which return the diagnostic information. The data type depnend s on the value of DiagIdentifier. If DiagInfoPtr is an integer type, the application should use the SQL ULEN buffer and initialize it to 0 before calling the function because some drivers record only the lo wer 32-bits or 16-bits of the buffer and leave the upper bits intact. If DiagInfoPtr is NULL, StringLen gthPtr returns the total number of returnable bytes excluding null-termination character in the buff er pointed by DiagInfoPtr.

BufferLength

[Input] If DiagIdentifier is the ODBC defined diagnosis, and DiagInfoPtr points to the string or binar y buffer, the argument should be the length of DiagInfoPtr. If DiagIdentifier is the ODBC defined di agnosis field, and DiagInfoPtr is a number, BufferLength is ignored. If the value of DiagInfoPtr is th e Unicode string (When calling SQLGetDiagFieldW), BufferLength should be an even number. If Di agIdentifier is a driver defined field, the application refers to the field characteristic to the driver ma nager by setting BufferLength argument. BufferLength can have the following values.

- If DiagInfoPtr is a string buffer pointer, BufferLength is the string length or SQL_NTS.
- If DiagInfoPtr is a binary buffer pointer, the application stores the macro result of SQL_LENG_BI NARY_ATTR(length) in BufferLength. A negative number is stored in BufferLength.
- If DiagInfoPtr is not a string or binary buffer pointer, BufferLength should have the value of SQL _IS_POINTER.
- If DiagInfoPtr is the fixed length data type, BufferLength is one of SQL_IS_INTEGER, SQL_IS_UIN TEGER, SQL_IS_SMALLINT, or SQL_IS_USMALLINT.

StringLengthPtr

[Output] It is the buffer pointer which returns the total length of bytes excluding the null-terminati on character which is returned to *DiagInfoPtr for the character data. If the returnable length in by tes is equal to or bigger than BufferLength, the text in *DiagInfoPtr is truncated to the length of Bu fferLength minus null-termination character.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE, SQL_NO_DATA

Diagnosis

SQLGetDiagField does not post the diagnostic record. The result of the return value is used as follows.

- SQL_SUCCESS: The function successfully returns the diagnosis information.
- SQL_SUCCESS_WITH_INFO: The data in the diagnostic field is truncated because *DiagInfoPtr is too s mall to store the requested diagnosis field. The application should compare BufferLength to the actu al byte number stored in *StringLengthPtr to check whether the truncation occurred.
- SQL_INVALID_HANDLE: The handle is not valid for a type indicating HandleType.
- SQL_ERROR: One of the followings occurs.
  - DiagIdentifier argument does not have the valid value.
  - DiagIdentifier argument is one of SQL_DIAG_CURSOR_ROW_COUNT, SQL_DIAG_DYNAMIC_FU NCTION, SQL_DIAG_DYNAMIC_FUNCTION_CODE, SQL_DIAG_ROW_COUNT , and Handle is not the statement handle.
  - When DiagIdentifier refers to the diagnosis record field, RecNumber is a negative number or 0. R ecNumber is ignored for the header field.
  - The requested value is a string, and BufferLength is smaller than 0.
  - If an asynchronous notification is used, the asynchronous execution of handle is not completed.
- SQL_NO_DATA: RecNumber is bigger than the number of diagnosis records for the handle specified i n Handle. If the diagnosis record for handle does not exist, then the function returns SQL_NO_DATA for RecNumber of any positive number.

Description

The application generally calls SQLGetDiagField for one of the three purposes.

- To obtain specific error or warning information when a function returns SQL_ERROR or SQL_SUCCES S_WITH_INFO (SQLBrowseConnect function returns SQL_NEED_DATA.)
- To obtain the number of rows in the data source when insert, delete, or update operations were perf ormed with a call to SQLExecute, SQLExecDirect, SQLBulkOperations or SQLSetPos. Or, to obtain the number of rows which exist in the current open cursor, if the driver can provide this information.
- To obtain the information of which function is executed by a calling SQLExecDirect or SQLExecute

Whenever the function is called, all ODBC functions can post 0 or more diagnosis records. Therefore, the application can call SQLGetDiagField after calling all functions. There is no limitation on the number of di agnosis records which can be stored at a time. SQLGetDiagField retrieves the diagnosis data structure spe cified in Handle and the most recent related diagnosis information. If the application calls another ODBC function instead of SQLGetDiagField or SQLGetDiagRec, diagnostic information obtained by the previous call of the same handle can be lost.

As long as SQLGetDiagField returns SQL_SUCCESS, the application can read the diagnosis record by incre asing RecNumber. The number of state records is displayed on the header field of SQL_DIAG_NUMBER. C alling SQLGetDiagField does not affect the header and record field. As long as a function except for the d

iagnostic function is not called, the application can retrieve a record field by calling SQLGetDiagField agai n using the same handle.

The application can call SQLGetDiagField anytime to return any diagnostic fields. If Handle is not the state ment handle, SQL_DIAG_CURSOR_ROW_COUNT or SQL_DIAG_ROW_COUNT is excluded because it retu rns SQL_ERROR. If any diagnosis field is not defined, calling SQLGetDiagField returns SQL_SUCCESS and t he undefined value.

API call other than the function executed asynchronously causes HY010 (Function sequence error). Howe ver, the error code is not retrieved before the asynchronous processing is completed.

HandleType Argument

Each handle type has the related diagnosis information, and HandleType argument refers to the handle ty pe.

Some headers and record fields are not returned for the environment, connection, statement, descriptor handles. The handles which are not applicable are described in the following Header Fields and Record Fi elds tables.

If HandleType is SQL_HANDLE_ENV, the handle can be the shared or non-shared environment handle.
A specific header diagnosis field of the driver is not related to the environment handle.
The diagnosis header defined for the descriptor handle is only SQL_DIAG_NUMBER and SQL_DIAG_RETU RNCODE.

DiagIdentifier Argument

The argument is the field identifier required in the diagnosis data structure. If RecNumber is equal to or bi gger than 1, the data in the field is the diagnostic information returned by the function. If RecNumber is 0, the field is in the header of the diagnostic data structure, and it has the data related to the function cal l returning the diagnostic information, not the specific information.

The driver may define a driver-specific header and record fields in the diagnosis data structure.

ODBC 3.x application which uses ODBC 2.x driver can call SQLGetDiagField when DiagIdentifier argumen t is SQL_DIAG_CLASS_ORIGIN, SQL_DIAG_CLASS_SUBCLASS_ORIGIN, SQL_DIAG_CONNECTION_NAME, SQL_DIAG_MESSAGE_TEXT, SQL_DIAG_NATIVE, SQL_DIAG_NUMBER, SQL_DIAG_RETURNCODE, SQL_ DIAG_SERVER_NAME, SQL_DIAG_SQLSTATE, and it returns SQL_ERROR for other diagnostic fields.

Header Field

DiagIdentifier	Return type	Returns
		This field contains the number of rows in the cursor. Its meaning depends o n the information type of SQLGetInfo. The information type is SQL_DYNAMI

DiagIdentifier	Return type	Returns
SQL_DIAG_CURSOR_ROW_COUNT	SQLLEN	C_CURSOR_ATTRIBUTES2, SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES2, SQL_KEYSET_CURSOR_ATTRIBUTES2, SQL_STATIC_CURSOR_ATTRIBUTES2, and it refers to the number of rows which can be used in each cursor type. (It is in SQL_CA2_CRC_EXACT and SQL_CA2_CRC_APPROXIMATE bits.) This field content is defined after calling the statement handle, SQLExecute, SQLExecDirect, or SQLMoreResults. SQLGetDiagField returns SQL_ERROR if DiagIdentifier is the statement handle except for SQL_DIAG_CURSOR_ROW_COUNT.
SQL_DIAG_DYNAMIC_FUNCTION	SQLCHAR *	It is a string which describes the SQL statements executing the basic function. The field content is defined after calling SQLExecute, SQLExecDirect, or SQLMoreResults. Calling SQLGetDiagField returns SQL_ERROR if DiagIdentifier is the statement handle except for SQL_DIAG_DYNAMIC_FUNCTION.
SQL_DIAG_DYNAMIC_FUNCTION_CODE	SQLINTEGER	It is the numeric code which describes the SQL statement executing the basic function. The field content is defined after calling SQLExecute, SQLExecDirect, or SQLMoreResults. Calling SQLGetDiagField returns SQL_ERROR if DiagIdentifier is the statement handle except for SQL_DIAG_DYNAMIC_FUNCTION_CODE.
SQL_DIAG_NUMBER	SQLINTEGER	It is the number of records which are in the usable state of the specified handles.
SQL_DIAG_RETURNCODE	SQLRETURN	It is the code returned by the function. The driver does not need to implement SQL_DIAG_RETURNCODE, and it is implemented by the driver manager. If the handle is not called by any function, SQL_SUCCESS is returned for SQL_DIAG_RETURNCODE.
SQL_DIAG_ROW_COUNT	SQLLEN	It is the number of rows which are affected by the INSERT, DELETE, UPDATE statement executed by SQLExecute, SQLExecDirect, SQLBulkOperations, or SQLSetPos. It is defined by the driver after cursor specification is executed. The field content is defined only for the statement handle. Calling SQLGetDiagField returns SQL_ERROR if DiagIdentifier is the statement handle except for SQL_DIAG_ROW_COUNT. The field data is also returned to RowCountPtr of SQLRowCount. The row count returned to SQLRowCount among data of this field remains the same until statement is set back to the prepared or allocated state, but it is set again after calling the non-diagnostic function.

Record Field

DiagIdentifier	Return type	Returns
SQL_DIAG_CLASS_ORIGIN	SQLCHAR *	It is a string representing the document which defines the class of SQLSTATE value in this record. This value is ISO 9075 for all SQLSTATE defined by the Open Group and the ISO call level interface. This value is ODBC 3.0 for the s

DiagIdentifier	Return type	Returns
		pecified ODBC SQLSTATE (for All SQLSTATE classes having IM).
SQL_DIAG_COLUMN_NUMBER	SQLINTEGER	If SQL_DIAG_ROW_NUMBER is the valid row number in the row set or parameter set, this field is a value representing the column number of result set or parameter number of parameter sets. The result set column number always starts from 1. If the state record is related to the bookmark column, the field can be 0. The parameter number starts from 1. If the state record is not related to the column number or to the parameter number, the value can be SQL_NO_COLUMN_NUMBER. If the driver can not determine the column number or parameter number related to the record, the field value is SQL_COLUMN_NUMBER_UNKNOWN. The field content is defined only for the statement handle.
SQL_DIAG_CONNECTION_NAME	SQLCHAR *	It is the string representing the connection name related to the diagnostic record. The field is the driver definition. The field is a zero-length string for the diagnosis which is not related to any server and the environment handle related to the diagnostic data structure.
SQL_DIAG_MESSAGE_TEXT	SQLCHAR *	It is an information message about the error or warning.
SQL_DIAG_NATIVE	SQLINTEGER	It is the driver/ data source-specific native error code. If native error code does not exist, the driver returns 0.
SQL_DIAG_ROW_NUMBER	SQLLEN	This field contains the row number in the row set or the parameter number in the parameter set which is related to the state record. The row number and parameter number start from 1. If the state record is not related to the row number or parameter number, the field value is SQL_NO_ROW_NUMBER. If the driver can not determine the row number or parameter number related to the record, the field value is SQL_ROW_NUMBER_UNKNOWN. The field content is defined only for the statement handle.
SQL_DIAG_SERVER_NAME	SQLCHAR *	It is the string representing the server name related to the diagnostic record. It is as same as the value returned by calling SQLGetInfo with SQL_DATA_SOURCE_NAME option. The field is a zero-length string for the diagnosis which is not related to any server and the environment handle related to the diagnostic data structure.
SQL_DIAG_SQLSTATE	SQLCHAR *	It is SQLSTATE diagnostic code of the five characters.
SQL_DIAG_SUBCLASS_ORIGIN	SQLCHAR *	It is the string of the same format and valid value with SQL_DIAG_CLASS_ORIGIN which is defines the subclass part of the SQLSTATE code. The specific ODBC SQLSTATE codes in ODBC 3.0 are as follows. 01S00, 01S01, 01S02, 01S06, 01S07, 07S01, 08S01, 21S01, 21S02, 25S01, 25S02, 25S03, 42S01, 42S02, 42S11, 42S12, 42S21, 42S22, HY095, HY097, HY098, HY099, HY100, HY101, HY105, HY107, HY109, HY110, HY111,

DiagIdentifier	Return type	Returns
		HYT00, HYT01, IM001, IM002, IM003, IM004, IM005, IM006, IM007, IM008, IM010, IM011, IM012.

Sequence of Status Record

The state record is sequentially located according to the row number and diagnostic type. The driver man ager determines the final step of returning the created state record.

If the diagnostic record is posted by the driver manager and the driver, the driver manager is responsible f or determining the order of the diagnostic records.

If two or more state records exist, the order of the record is determined first by the row number. The follo wing rules are applied to determine the order of the diagnostic record by the row.

- The record not corresponding to any row because SQL_NO_ROW_NUMBER is defined as -1, is positio ned in front of the record corresponding to the particular row.
- The record which does not know the row number because SQL_ROW_NUMBER_UNKNOWN is defin ed as -2 is positioned in front of all the other records.
- For all record which are related to a particular row, the records are sorted by the value of SQL_DIAG ROW_NUMBER. All errors and warnings for the first row are listed, and then all the errors and warnin gs for the next row are sequentially listed.

If SQLSTATE 01S01 is returned by the ODBC 2.x driver, or SQLSTATE 01S01 is returned by the O DBC 3.x driver when calling SQLExtendedFetch or when calling SQLSetPos for the cursor in SQL ExtendedFetch, then the ODBC 3.x driver manager does not require the state record in a diagno sis queue.

Within each row, or for all rows which do not correspond to the row or which do not know the row num ber or which have the row number as same as SQL_NO_ROW_NUMBER, the first record listed is determin ed by using the set of ordering rules. After the first record, the order of other records which affect the ro w is not defined. The application can not assume that an error precedes a warning after the first record. T he application should check the complete diagnostic data structure to get the complete information abou t the failed function call.

The following rules are used to determine the first record in the row. The highest grade record is the first record. The record source (driver manager, driver, gateway, etc.) does not affect the determination of the record ranks.

- Errors state record describing the error has the highest grade. The following rules are applied to align the errors.
  - The record which refers to the transaction failure or possible transaction failure has a higher grad e than any other record.
  - If two or more records describe the same error condition, SQLSTATE defined in the Open Group CLI specifications(Class 03 ~ HZ) has a higher grade than SQLSTATE defined in ODBC and the dri ver.

- Implementation-defined No Data Values state record which describes No Data values (class 02) defin ed by the driver has the second highest rank.
- Warnings state record(class 01) describing the warning has the lowest grade. If two or more records describe the same error condition, SQLSTATE defined in the Open Group CLI specifications has a high er grade than SQLSTATE defined in ODBC and the driver.

SQLGetDiagRec

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetDiagRec returns the current value of the record field of the diagnostic data source (related to the specified handle) which contains an error, warning, state information.

Syntax

```
SQLRETURN SQLGetDiagRec(
    SQLSMALLINT     HandleType,
    SQLHANDLE       Handle,
    SQLSMALLINT     RecNumber,
    SQLCHAR *       SQLState,
    SQLINTEGER *    NativeErrorPtr,
    SQLCHAR *       MessageText,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   TextLengthPtr);
```

Arguments

HandleType

[Input] It is the handle type identifier of which diagnosis is required. The identifier should be one of the followings.

- SQL_HANDLE_DBC
- SQL_HANDLE_DESC
- SQL_HANDLE_ENV
- SQL_HANDLE_STMT

Handle

[Input] It is the handle for the diagnosis data structure of the type pointed by HandleType. If HandleType is SQL_HANDLE_ENV, the handle can be the shared or non-shared environment handle.

RecNumber

[Input] It indicates the state record of the information found by the application. The number of the state record starts from 1.

SQLState

[Output] It is the buffer pointer which returns five character SQLSTATE code for the diagnostic rec ord RecNumber. The first two characters indicate a class and the next three characters indicate a su bclass. The information is in the SQL_DIAG_SQLSTATE diagnostic field.

NativeErrorPtr

[Output] It is the buffer pointer which returns the specific native error code to the data source. The information is in the diagnostic field SQL_DIAG_NATIVE.

MessageText

[Output] It is the buffer point which returns the diagnostic message text string. The information is i n the SQL_DIAG_MESSAGE_TEXT diagnostic field.

If MessageText is NULL, TextLegnthPtr returns the total number of returnable characters (excluding null-termination character) to the buffer pointed by MessageText.

BufferLength

[Input] It is the length of characters within *MessageText buffer. Diagnostic message text does not have the maximum length.

TextLegnthPtr

[Output] It is the buffer pointer to which the total number of characters returnable to *MessageTe xt is returned (excluding null-termination character). If the number of returnable characters is bigg er than BufferLength, the diagnostic message text of *MessageText is truncated to the length of B ufferLength minus null-termination character.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLGetDiagRec does not post the diagnostic record. It uses the result of the return value as follows.

- SQL_SUCCESS: The function successfully returns the diagnosis information.
- SQL_SUCCESS_WITH_INFO: *MessageText buffer is too small to store the requested diagnosis messa ge. The diagnostic record is not generated. The application should compare BufferLength to the actu al byte number stored in *StringLengthPtr to check whether the truncation occurred.
- SQL_INVALID_HANDLE: The handle is not valid for a type indicating HandleType.
- SQL_ERROR: One of the followings occurs.
  - RecNumber argument is the negative number or 0.

    - BufferLength is smaller than 0.
    - If an asynchronous notification is used, the asynchronous execution of handle is not completed.
- SQL_NO_DATA: RecNumber is bigger than the number of diagnosis records for the handle specified i n Handle. If the diagnosis record for handle does not exist, then the function returns SQL_NO_DATA for RecNumber of any positive number.

Description

When the ODBC function returns SQL_ERROR or SQL_SUCCESS_WITH_INFO, generally the application ca lls SQLGetDiagRec. However, the application can call the SQLGetDiagRec after any function is called beca use any ODBC function can post zero or more diagnostic records. The application can call SQLGetDiagRec several times to return some or all records in the diagnostic data structure. ODBC does not have limit on t he number of diagnostic records which can be stored at a time.

SQLGetDiagRec can not be used to return the header field of the diagnostic data structure.(RecNumber s hould be bigger than 0.) The application should call SQLGetDiagField instead of SQLGetDiagRec.

SQLGetDiagRec retrieves only the handle specified to Handle and the latest related diagnostic informatio n. If the application calls any other ODBC function (excluding SQLGetDiagRec, SQLGetDiagField, SQLErro r), diagnostic information from the previous call of the same handle is lost.

The application can repeatedly retrieve the diagnostic record by increasing RecNumber as long as SQLGet DiagRec returns SQL_SUCCESS. SQLGetDiagRec call do not affect the header and record fields. If interven tion of other function does not exist except for SQLGetDiagRec, SQLGetDiagField, SQLError, then the ap plicatin can call SQLGetDiagRec again to retrieve the field in the record. The application can retrieve the t otal number of diagnostic records available by calling SQLGetDiagField to retrieve the value of the SQL_DI AG_NUMBER field, and calling SQLGetDiagRec several times.

HandleType Argument

Each handle type has the related diagnosis information, and HandleType argument refers to the Handle t ype.

Some header and record fields are not returned for the environment, connection, statement, descriptor h andles. In the header field and record field table of **SQLGetDiagField**, the inappropriate handles in the fiel d are described.

If HandleType is SQL_HANDLE_SENV which indicates the shared environment handle, then calling SQLGe tDiagRec returns SQL_INVALID_HANLDE. If HandleType is SQL_HANDLE_ENV, then the handle can be the shared or non-shared environment handle.

SQLGetEnvAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetEnvAttr returns the current settings of the environment attributes.

Syntax

```
SQLRETURN SQLGetEnvAttr(
    SQLHENV        EnvironmentHandle,
    SQLINTEGER     Attribute,
    SQLPOINTER     ValuePtr,
    SQLINTEGER     BufferLength,
    SQLINTEGER *   StringLengthPtr);
```

Arguments

EnvironmentHandle

[Input] It is the environment handle.

Attribute

[Input] It is the attribute to be retrieved.

ValuePtr

[Output] It is the buffer pointer in which to return the current attribute value specified by Attribute. If ValuePtr is NULL, StringLengthPtr returns the total number of bytes returnable to the buffer pointed by ValuePtr (excluding null-termination character).

BufferLength

[Input] If ValuePtr points to a string, the argument should be the length of *ValuePtr. If ValuePtr is an integer, BufferLength is ignored. If *ValuePtr(when SQLGetEnvAttrW is called) is a unicode string, BufferLength should be an even number. If the attribute value is not a string, BufferLength is not used.

StringLengthPtr

[Output] It is the buffer pointer to which the total number of bytes to be returned to *ValuePtr (excluding null-termination character) is returned. If ValuePtr is the null pointer, the length is not returned. If the attribute value is a string and the number of bytes returnable is equal to or bigger than BufferLength, *ValuePtr is truncated to the length of BufferLength minus the length of a null-termination character and is a null-terminated by the driver.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The data returned to *ValuePtr is truncated to the length of BufferLength minus null-termination character. The remaining length of string is returned to *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	SQL_ATTR_ODBC_VERSION is not set through SQLSetEnvAttr. If SQLAllocHandleStd is used, then SQL_ATTR_ODBC_VERSION does not need to be explicitly set.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0 or it can not access the memory.
HY092	Invalid attribute/option identifier	The value specified in attribute argument is not valid for ODBC version supported by the driver.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The value specified in attribute argument is valid for ODBC environment of ODBC version supported by the driver, but it is not supported by the driver.
IM001	Driver does not support this function	The driver related to DescriptorHandle does not support the function.

Description

The driver-specific environment attributes does not exist. If Attribute specifies the attribute which returns a string, ValuePtr should be the buffer pointer whose string is returned. The maximum string length including the null-termination character is the BufferLength in bytes.

SQLGetEnvAttr can be called at any point between the allocation and release of the environment handle. All environment attributes successfully allocated by the application for the environment are maintained until SQLFreeHandle is called with Handletype of SQL_HANDLE_ENV in EnvrionmentHandle. It is recommended to use only one environment handle.

SQL_ATTR_OUTPUT_NTS environment attributes are supported by the application which complies with standards. If SQLGetEnvAttr is called, ODBC 3.x driver manager always returns SQL_TRUE for the attribute. SQL_ATTR_OUTPUT_NTS is set to SQL_TRUE only by calling SQLSetEnvAttr.

The following table describes attribute list which can be queried through SQLGetEnvAttr.

Attribute	ValuePtr Content
SQL_ATTR_CONNECTION_POOLING (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_CP_MATCH (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_ODBC_VERSION (ODBC 3.0)	It is 32-bit integer which indicates whether a particular feature is operated as ODBC 2.x or ODBC 3.x. The following values are used to set the attribute. SQL_OV_ODBC3_80 = The driver manager or driver performs the following ODBC 3.8 behaviors. • The driver expects and returns ODBC 3.x code values for DATE, TIME, TIMESTAMP. • The driver returns ODBC 3.x SQLSTATE codes when SQLError, SQLGetDiagField or SQLGetDiagRec is called. • CatalogName argument of SQLTables allows the pattern matching. SQL_OV_ODBC3 = The driver manager or driver performs the following ODBC 3.x behaviors. • The driver expects and returns ODBC 3.x code values for DATE, TIME, TIMESTAMP. • The driver returns ODBC 3.x SQLSTATE codes when SQLError, SQLGetDiagField or SQLGetDiagRec is called. • CatalogName argument of SQLTables allows the pattern matching. • The driver manager does not support C data type extensibility.

Attribute	ValuePtr Content
	SQL_OV_ODBC2 = The driver manager or driver performs the following ODBC 2.x behaviors. It is very helpful when ODBC 2.x applications operate in the ODBC 3.x driver. • The driver expects and returns ODBC 2.x code values for DATE, TIME, TIMESTAMP. • The driver returns ODBC 2.x SQLSTATE codes when SQLError, SQLGetDiagField or SQLGetDiagRec is called. • CatalogName argument of SQLTables does not allow the pattern matching. • The driver manager does not support C data type extensibility. An application should set this environment attribute before it calls any function which has an SQLHENV argument or a function which returns SQLSTATE HY010 (Function sequence error). The driver should specify whether the additional operations for the environmental flag exists.
SQL_ATTR_OUTPUT_NTS (ODBC 3.0)	It is not supported by the driver.

SQLGetFunctions

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetFunctions returns information whether the driver supports the given ODBC function. The function is implemented by the driver manager or the driver. If the driver implements SQLGetFunctions, the driver manager will call the function in the driver.

Syntax

```
SQLRETURN SQLGetFunctions(
    SQLHDBC           ConnectionHandle,
    SQLUSMALLINT      FunctionId,
    SQLUSMALLINT *    SupportedPtr);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

FunctionId

[Input] It is the #define value which identifies the ODBC function related to SQL_API_ODBC3_ALL_FUNCTIONS or SQL_API_ALL_FUNCTIONS. SQL_API_ODBC3_ALL_FUNCTIONS is used in ODBC 3.x application to determine to support the function in ODBC 3.x and in earlier version. SQL_API_ALL_FUNCTIONS is used in ODBC 2.x to determine whether to support the function in ODBC 2.x and in earlier version.

For more information about the value list of #define which identifies the ODBC function, refer to t he table in the description section.

SupportedPtr

[Output] If FunctionId identifies the single ODBC, SupportedPtr points to the single SQLUSMALLIN T value. If the specified function is supported by the driver, it is SQL_TRUE. Otherwise, it is SQL_FA LSE.

If FunctionId is SQL_API_ODBC3_ALL_FUNCTIONS, SupprtedPtr points to the SQLSMALLINT array

which has the number of elements equal to SQL_API_ODBC3_ALL_FUNCTIONS_SIZE. The array is managed by the driver manager as 4000-bit bitmap which can be used to determine to support th e function in ODBC 3.x or in earlier version. SQL_FUNC_EXISTS macro is called to check whether th e function is supported. ODBC 3.x application can call SQLGetFunctions by using SQL_API_ODBC3 _ALL_FUNCTIONS in preparation for ODBC 2.x or ODBC 3.x.

If FunctionId is SQL_API_ALL_FUNCTIONS, SupportedPtr points to the array with 100 elements. Th e array is indexed by #define value used by the FunctionId to identify each ODBC function, and sev eral elements are reserved without being used. If the function in ODBC 2.x or earlier version is supp orted by the driver, the element is SQL_TRUE. If the ODBC function is not supported by the driver o r it is not the ODBC function, the element is SQL_FALSE.

The array that is returned to *SupportedPtr uses the 0-based indexing.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL_SUC CESS_WITH_INFO.)
08S01	Communication link f ailure	Before the function processing is completed, the connection between the driv er and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation er ror	It is a memory allocation error.
HY010	Function sequence er ror	SQLGetFunctions is called before SQLConnect, SQLBrowseConnect, SQLDriver Connect. SQLBrowseConnect is called for ConnectionHandle, and SQL_NEED_DATA is r eturned. SQLGetfunction is called before SQLBrowseConnect returns SQL_SUCCESS_ WITH_INFO or SQL_SUCCESS. SQLExecute, SQLExecDirect, SQLMoreResults is called for ConnectionHandle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called, befor e the data retrieves all streamed parameters.
HY013	Memory manageme nt error	The size of buffer used as an argument is smaller than 0, or it can not access t he memory.
HY095	Function type out of range	FunctionId value is not valid.

SQLSTATE	Error	Description
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source response to the request. The connection timeout interval can be set to SQL_ATTR_CONNECTION_TIMEOUT through SQLSetConnectAttr.
IM001	Driver does not support this function	The driver related to DescriptorHandle does not support the function.

Description

SQLGetFunctions returns the supported SQLGetFunctions, SQLDataSources, SQLDrivers. This is because the function is implemented in the driver manager. If an unicode function exist, the driver manager maps the ANSI function corresponding to the Unicode function. If an ANSI function exist, the driver manager maps the unicode function corresponding to the ANSI function.

The following is the list of valid values for FunctionId for the functions which comply with ISO 92 standards compliance level.

- SQL_API_SQLALLOCHANDLE
- SQL_API_SQLBINDCOL
- SQL_API_SQLCANCEL
- SQL_API_SQLCLOSECURSOR
- SQL_API_SQLCOLATTRIBUTE
- SQL_API_SQLCONNECT
- SQL_API_SQLCOPYDESC
- SQL_API_SQLDATASOURCES
- SQL_API_SQLDESCRIBECOL
- SQL_API_SQLDISCONNECT
- SQL_API_SQLDRIVERS
- SQL_API_SQLENDTRAN
- SQL_API_SQLEXECDIRECT
- SQL_API_SQLEXECUTE
- SQL_API_SQLFETCH
- SQL_API_SQLFETCHSCROLL
- SQL_API_SQLFREEHANDLE
- SQL_API_SQLFREESTMT

- SQL_API_SQLGETCONNECTATTR
- SQL_API_SQLGETCURSORNAME
- SQL_API_SQLGETDATA
- SQL_API_SQLGETDESCFIELD
- SQL_API_SQLGETDESCREC
- SQL_API_SQLGETDIAGFIELD
- SQL_API_SQLGETDIAGREC
- SQL_API_SQLGETENVATTR
- SQL_API_SQLGETFUNCTIONS
- SQL_API_SQLGETINFO
- SQL_API_SQLGETSTMTATTR
- SQL_API_SQLGETTYPEINFO
- SQL_API_SQLNUMRESULTCOLS
- SQL_API_SQLPARAMDATA
- SQL_API_SQLPREPARE
- SQL_API_SQLPUTDATA
- SQL_API_SQLROWCOUNT
- SQL_API_SQLSETCONNECTATTR
- SQL_API_SQLSETCURSORNAME
- SQL_API_SQLSETDESCFIELD
- SQL_API_SQLSETDESCREC
- SQL_API_SQLSETENVATTR
- SQL_API_SQLSETSTMTATTR

The following is the list of valid values for FunctionId for the functions which comply with open group sta ndard compliance level.

- SQL_API_SQLCOLUMNS
- SQL_API_SQLSPECIALCOLUMNS
- SQL_API_SQLSTATISTICS
- SQL_API_SQLTABLES

The following is the list of valid values for FunctionId for the functions which comply with ODBC standard s compliance level.

- SQL_API_SQLBINDPARAMETER
- SQL_API_SQLBROWSECONNECT
- SQL_API_SQLBULKOPERATIONS[1]
- SQL_API_SQLCOLUMNPRIVILEGES
- SQL_API_SQLDESCRIBEPARAM
- SQL_API_SQLDRIVERCONNECT
- SQL_API_SQLFOREIGNKEYS

- SQL_API_SQLMORERESULTS
- SQL_API_SQLNATIVESQL
- SQL_API_SQLNUMPARAMS
- SQL_API_SQLPRIMARYKEYS
- SQL_API_SQLPROCEDURECOLUMNS
- SQL_API_SQLPROCEDURES
- SQL_API_SQLSETPOS
- SQL_API_SQLTABLEPRIVILEGES

[1] When operating with ODBC 2.x driver, SQLBulkOperations is supported and returned only when the both of the followings are true. ODBC 2.x driver supports SQLSetPos, and the SQL_POS_OPERATIONS information type returns SQL_POS_ADD bit as set.

The valid value of FunctionId for the functions introduced after ODBC 3.8 is SQL_API_SQLCANCELHANDLE. [2]

[2]SQLCancelHandle is returned only when the driver supports both of SQLCancel and SQLCancelHandle. If SQLCancel is supported but SQLCancelHandle is not suported, the application can still call SQLCancelHandle for the statement handle, because it is mapped to SQLCancel.

SQL_FUNC_EXISTS Macro

SQL_FUNC_EXISTS (SupportedPtr, FunctionID) macro is used to call SQLGetFunctions to SQL_API_ODBC3_ALL_FUNCTIONS by using FunctionId argument and to check the function supported in ODBC 3.x or in the earlier version. The application uses SQL_FUNC_EXISTS by setting SupportedPtr transferred from SQLGetFuncions to SupportedPtr argument and by setting the FunctionID argument to the #define for the function. If the function is supported, SQL_FUNC_EXIST returns SQL_TRUE. Otherwise, it returns SQL_FALSE.

When operating with ODBC 2.x driver, ODBC 3.x driver manager returns SQL_TRUE for SQLAllocHandle and SQLFreeHandle. It is because SQLAllocHandle is mapped to SQLAllocEnv, SQLAllocConnect orSQLAllocStmt, and SQLFreeHandle is mapped to SQLFreeEnv, SQLFreeConnect or SQLFreeStmt. However, although SQLFreeHandle returns SQL_TRUE, SQLFreeHandle whose SQL_HANDLE_DESC is used as HandleType argument is not supported. It is because function mapped to ODBC 2.x function for this case does not exist.

SQLGetGroupCount

Conformance

Standards compliance: It is not available.

Overview

SQLGetGroupCount returns the number of cluster groups.

Syntax

```
SQLRETURN SQLGetGroupCount(
    SQLHDBC      ConnectionHandle,
    SQLINTEGER * GroupCountPtr );
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

GroupCountPtr

[Output] It is the number of cluster groups.

Returns

SQL_SUCCESS, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08003	Connection not open	ConnectionHandle is not in a connected state.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY010	Function sequence error	This function should be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.

Description

SQLGetGroupCount can be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.

SQLGetGroupIDs

Conformance

Standards compliance: It is not available.

Overview

SQLGetGroupIDs returns IDs of cluster groups.

Syntax

```
SQLRETURN SQLGetGroupIDs(
    SQLHDBC      ConnectionHandle,
    SQLINTEGER * GroupIDArray );
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

GroupIDArray

[output] It is the array of cluster group IDs.

Returns

SQL_SUCCESS, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08003	Connection not open	ConnectionHandle is not in a connected state.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY010	Function sequence error	This function should be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.

Description

SQLGetGroupID can be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.
The number of elements of GroupIDArray should be as same as the number of cluster groups which are returned by SQLGetGroupCount.

SQLGetGroupName

Conformance

Standards compliance: It is not available.

Overview

SQLGetGroupName returns the name of the cluster group which corresponds to GroupID.

Syntax

```
SQLRETURN SQLGetGroupName(
    SQLHDBC       ConnectionHandle,
    SQLINTEGER    GroupID,
    SQLCHAR     * GroupName,
    SQLSMALLINT   BufferLength,
    SQLSMALLINT * NameLengthPtr );
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

GroupID

[Input] It is the cluster group ID.

GroupName

[output] It is the buffer pointer which returns the name of the cluster group which is terminated with null.

BufferLength

[Input] It is the length of *GroupName.

NameLengthPtr

[Output] It is the buffer pointer which returns the total number of bytes returnable to *ColumnName (excluding the null-termination character). If the returnable length is equal to or bigger than BufferLength, *ColumnName is truncated to the length of BufferLength minus null.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01004	String data, right truncated	The size of *GroupName is not large enough to return the name of the cluster group, so the name of the cluster group is truncated. The length of the cluster name which is not truncated is returned in *NameLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
08003	Connection not open	ConnectionHandle is not in a connected state.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY010	Function sequence error	This function should be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.

Description

SQLGetGroupIDs can be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set.

SQLGetInfo

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetInfo returns the general information on the connection associated with the driver and the data source.

Syntax

```
SQLRETURN SQLGetInfo(
    SQLHDBC         ConnectionHandle,
    SQLUSMALLINT    InfoType,
    SQLPOINTER      InfoValuePtr,
    SQLSMALLINT     BufferLength,
    SQLSMALLINT *   StringLengthPtr);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

InfoType

[Input] It is the information type.

InfoValuePtr

[Output] It is the buffer pointer whose information is returned. According to InfoType requested, one of the following information will be returned. Null termination character, SQLUSMALLINT value, SQLUINTEGER bit mask, SQLUINTEGER flag, SQLUINTEGER binary value, or SQLULEN value.

If InfoType argument is SQL_DRIVER_HDESC or SQL_DRIVER_HSTMT, InfoValuePtr argument is input and output.

If InfoValuePtr is NULL, StringLengthPtr returns the total number of returnable bytes to the buffer pointed by InfoValuePtr (null termination character is excluded).

BufferLength

[Input] It is the length of *InfoValuePtr buffer. If *InfoValuePtr is not a string or InfoValuePtr is the null pointer, BufferLength argument is ignored. The driver assumes the size of *InfoValuePtr as SQLUSMALLINT or SQLUINTEGER according to InfoType. (When SQLGetInfoW is called) if InfoValuePtr is a unicode string, BufferLength must be an even number. Otherwise SQLSTATE HY090 is returned.

StringLengthPtr

[Output] It is the buffer pointer which returns the total number of bytes returnable to *InfoValuePtr (excluding null-termination character for the character data).

If the number of bytes returnable for the character is equal to or bigger than BufferLength, the information in *InfoValuePtr is truncated to the length of BufferLength in byte (excluding null-termination character) and is null terminated by the driver.

BufferLength is ignored for the data of the other data types, and the driver assumes the size of *InfoValuePtr as SQLUSMALLINT or SQLUINTEGER according to InfoType.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, or SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The buffer length of *InfoValuePtr is not large enough to return all required information, so the information is truncated. The length of untruncated information is returned to *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
08003	Connection not open	The connection should be open for the type of information requested in InfoType. SQL_ODBC_VER which is the reserved information in ODBC can be returned without open connection.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	SQLExecute, SQLExecDirect, or SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called, before the data retrieves all streamed parameters.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0, or it can not access the memory.

SQLSTATE	Error	Description
HY024	Invalid attribute valu e	The InfoType argument is SQL_DRIVER_HSTMT, and the value pointed by InfoValuePtr is an invalid statetment handle. The InfoType argument is SQL_DRIVER_HDESC, the value pointed by Info ValuePtr is an invalid descriptor handle.
HY090	Invalid string or buff er length	The value for BufferLength argument is smaller than 0. The value for BufferLength argument is an odd number, and *InfoValueP tr is the unicode data type.
HY096	Information type ou t of range	The value specified in InfoType argument is not valid for ODBC version w hich is supported by the driver.
HY117	Connection is suspe nded due to unkno wn transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional field not i mplemented	The value specified in InfoType is the specific driver value which is not sup ported by the driver.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSet StmtAttr.
IM001	Driver does not sup port this function	The driver which is related to DescriptorHandle does not support the func tion.

Description

The currently defined information types will be described in the following sections. The range of informati on types is reserved by ODBC. The driver developer should reserve the values for the driver-specific use of their own from Open Group. SQLGetInfo does not perform unicode conversion or thunking for InfoTypes defined by the driver. The information type returned to *InfoValuePtr is determined according to InfoTyp es requested.

SQLGetInfo returns one of the following five types.

- Null-termination string
- SQLUSMALLINT value
- SQLUINTEGER bit mask
- SQLUINTEGER value
- SQLUINTEGER binary value

The application should cast according to the value returned in *InfoValuePtr.

The driver should return a value for each information type defined in the following table. If the informatio n type is not applied to the driver or the data source, the driver has to return one of the following values.

Character string ("Y" or "N")

"N"

Character string (not "Y" or "N")

Empty string

SQLUSMALLINT

0

SQLUINTEGER bit mask or SQLUINTEGER binary value

0L

For example, if the data source does not support the procedure, SQLGetInfo returns the following value f or the value of InfoType related to the procedure.

SQL_PROCEDURES

"N"

SQL_ACCESSIBLE_PROCEDURES

"N"

SQL_MAX_PROCEDURE_NAME_LEN

0

SQL_PROCEDURE_TERM

Empty string

SQLGetInfo returns SQLSTATE HY096 for the value of InfoType which is in the range of information type reserved for use by ODBD but which is not defined by the ODBC version supported by the driver. The driv er compiles and calls SQLGetInfo as the SQL_DRIVER_ODBC_VER information type of an application to de termine the ODBC version. SQLGetInfo returns SQLSTATE HYC00 for the value of InfoType which is in the range of reserved information type for the separate use of the driver but which is not supported by the dr iver.

Calling all SQLGetInfo should be open for connection, except for InfoType which returns the driver mana ger version is SQL_ODBC_VER.

Driver Information

The following values of InfoType argument return ODBC information such as an active statement, data so urce name, interface standards compliance level.

- SQL_ACTIVE_ENVIRONMENTS
- SQL_ASYNC_DBC_FUNCTIONS
- SQL_ASYNC_MODE
- SQL_ASYNC_NOTIFICATION
- SQL_BATCH_ROW_COUNT
- SQL_BATCH_SUPPORT
- SQL_DATA_SOURCE_NAME
- SQL_DRIVER_AWARE_POOLING_SUPPORTED
- SQL_DRIVER_HDBC
- SQL_DRIVER_HDESC
- SQL_DRIVER_HENV
- SQL_DRIVER_HLIB
- SQL_DRIVER_HSTMT
- SQL_DRIVER_NAME
- SQL_DRIVER_ODBC_VER
- SQL_DRIVER_VER
- SQL_DYNAMIC_CURSOR_ATTRIBUTES1
- SQL_DYNAMIC_CURSOR_ATTRIBUTES2
- SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES1
- SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES2
- SQL_FILE_USAGE
- SQL_GETDATA_EXTENSIONS
- SQL_INFO_SCHEMA_VIEWS
- SQL_KEYSET_CURSOR_ATTRIBUTES1
- SQL_KEYSET_CURSOR_ATTRIBUTES2
- SQL_MAX_ASYNC_CONCURRENT_STATEMENTS
- SQL_MAX_CONCURRENT_ACTIVITIES
- SQL_MAX_DRIVER_CONNECTIONS
- SQL_ODBC_INTERFACE_CONFORMANCE
- SQL_ODBC_STANDARD_CLI_CONFORMANCE
- SQL_ODBC_VER
- SQL_PARAM_ARRAY_ROW_COUNTS
- SQL_PARAM_ARRAY_SELECTS
- SQL_ROW_UPDATES
- SQL_SEARCH_PATTERN_ESCAPE
- SQL_SERVER_NAME
- SQL_STATIC_CURSOR_ATTRIBUTES1
- SQL_STATIC_CURSOR_ATTRIBUTES2

When performing SQLGetInfo, the driver can improve the performance by minimizing the number of requests or of the number of transmitting information from the server.

DBMS Product Information

The following values of InfoType argument return information on the DBMS product such as DBMS name and information.

- SQL_DATABASE_NAME
- SQL_DBMS_NAME
- SQL_DBMS_VER

Data Source Information

The following values of InfoType argument return information on the data source such as cursor characteristics and transaction features.

- SQL_ACCESSIBLE_PROCEDURES
- SQL_ACCESSIBLE_TABLES
- SQL_BOOKMARK_PERSISTENCE
- SQL_CATALOG_TERM
- SQL_COLLATION_SEQ
- SQL_CONCAT_NULL_BEHAVIOR
- SQL_CURSOR_COMMIT_BEHAVIOR
- SQL_CURSOR_ROLLBACK_BEHAVIOR
- SQL_CURSOR_SENSITIVITY
- SQL_DATA_SOURCE_READ_ONLY
- SQL_DEFAULT_TXN_ISOLATION
- SQL_DESCRIBE_PARAMETER
- SQL_MULT_RESULT_SETS
- SQL_MULTIPLE_ACTIVE_TXN
- SQL_NEED_LONG_DATA_LEN
- SQL_NULL_COLLATION
- SQL_PROCEDURE_TERM
- SQL_SCHEMA_TERM
- SQL_SCROLL_OPTIONS
- SQL_TABLE_TERM
- SQL_TXN_CAPABLE
- SQL_TXN_ISOLATION_OPTION
- SQL_USER_NAME

Supported SQL

The following values of InfoType argument return Information on the SQL statements supported by the d ata source.

- SQL_AGGREGATE_FUNCTIONS
- SQL_ALTER_DOMAIN
- SQL_ALTER_SCHEMA
- SQL_ALTER_TABLE
- SQL_ANSI_SQL_DATETIME_LITERALS
- SQL_CATALOG_LOCATION
- SQL_CATALOG_NAME
- SQL_CATALOG_NAME_SEPARATOR
- SQL_CATALOG_USAGE
- SQL_COLUMN_ALIAS
- SQL_CORRELATION_NAME
- SQL_CREATE_ASSERTION
- SQL_CREATE_CHARACTER_SET
- SQL_CREATE_COLLATION
- SQL_CREATE_DOMAIN
- SQL_CREATE_SCHEMA
- SQL_CREATE_TABLE
- SQL_CREATE_TRANSLATION
- SQL_DDL_INDEX
- SQL_DROP_ASSERTION
- SQL_DROP_CHARACTER_SET
- SQL_DROP_COLLATION
- SQL_DROP_DOMAIN
- SQL_DROP_SCHEMA
- SQL_DROP_TABLE
- SQL_DROP_TRANSLATION
- SQL_DROP_VIEW
- SQL_EXPRESSIONS_IN_ORDERBY
- SQL_GROUP_BY
- SQL_IDENTIFIER_CASE
- SQL_IDENTIFIER_QUOTE_CHAR
- SQL_INDEX_KEYWORDS
- SQL_INSERT_STATEMENT
- SQL_INTEGRITY
- SQL_KEYWORDS
- SQL_LIKE_ESCAPE_CLAUSE
- SQL_NON_NULLABLE_COLUMNS

- SQL_SQL_CONFORMANCE
- SQL_OJ_CAPABILITIES
- SQL_ORDER_BY_COLUMNS_IN_SELECT
- SQL_OUTER_JOINS
- SQL_PROCEDURES
- SQL_QUOTED_IDENTIFIER_CASE
- SQL_SCHEMA_USAGE
- SQL_SPECIAL_CHARACTERS
- SQL_SUBQUERIES
- SQL_UNION

SQL Restrictions

The following values of the InfoType argument return restrictions applied to identifiers and clauses in SQL statements, such as the maximum lengths of identifiers and the maximum number of columns in a select list. Restriction can be imposed by the driver or data source.

- SQL_MAX_BINARY_LITERAL_LEN
- SQL_MAX_CATALOG_NAME_LEN
- SQL_MAX_CHAR_LITERAL_LEN
- SQL_MAX_COLUMN_NAME_LEN
- SQL_MAX_COLUMNS_IN_GROUP_BY
- SQL_MAX_COLUMNS_IN_INDEX
- SQL_MAX_COLUMNS_IN_ORDER_BY
- SQL_MAX_COLUMNS_IN_SELECT
- SQL_MAX_COLUMNS_IN_TABLE
- SQL_MAX_CURSOR_NAME_LEN
- SQL_MAX_IDENTIFIER_LEN
- SQL_MAX_INDEX_SIZE
- SQL_MAX_PROCEDURE_NAME_LEN
- SQL_MAX_ROW_SIZE
- SQL_MAX_ROW_SIZE_INCLUDES_LONG
- SQL_MAX_SCHEMA_NAME_LEN
- SQL_MAX_STATEMENT_LEN
- SQL_MAX_TABLE_NAME_LEN
- SQL_MAX_TABLES_IN_SELECT
- SQL_MAX_USER_NAME_LEN

Scalar Funtion Information

The following values of InfoType argument return information on the scalar functions supported by the d ata source or driver.

- SQL_CONVERT_FUNCTIONS
- SQL_NUMERIC_FUNCTIONS
- SQL_STRING_FUNCTIONS
- SQL_SYSTEM_FUNCTIONS
- SQL_TIMEDATE_ADD_INTERVALS
- SQL_TIMEDATE_DIFF_INTERVALS
- SQL_TIMEDATE_FUNCTIONS

Conversion Information

The following values of InfoType argument return the list of SQL data types of which the data source can be converted to the specified SQL data type with CONVERT scalar function.

- SQL_CONVERT_BIGINT
- SQL_CONVERT_BINARY
- SQL_CONVERT_BIT
- SQL_CONVERT_CHAR
- SQL_CONVERT_DATE
- SQL_CONVERT_DECIMAL
- SQL_CONVERT_DOUBLE
- SQL_CONVERT_FLOAT
- SQL_CONVERT_INTEGER
- SQL_CONVERT_INTERVAL_YEAR_MONTH
- SQL_CONVERT_INTERVAL_DAY_TIME
- SQL_CONVERT_LONGVARBINARY
- SQL_CONVERT_LONGVARCHAR
- SQL_CONVERT_NUMERIC
- SQL_CONVERT_REAL
- SQL_CONVERT_SMALLINT
- SQL_CONVERT_TIME
- SQL_CONVERT_TIMESTAMP
- SQL_CONVERT_TINYINT
- SQL_CONVERT_VARBINARY
- SQL_CONVERT_VARCHAR

Added Information Type in ODBC 3.x

The following values of InfoType argument are added to ODBC 3.x.

- SQL_ACTIVE_ENVIRONMENTS
- SQL_AGGREGATE_FUNCTIONS
- SQL_ALTER_DOMAIN

- SQL_ALTER_SCHEMA
- SQL_ANSI_SQL_DATETIME_LITERALS
- SQL_ASYNC_DBC_FUNCTIONS
- SQL_ASYNC_MODE
- SQL_ASYNC_NOTIFICATION
- SQL_BATCH_ROW_COUNT
- SQL_BATCH_SUPPORT
- SQL_CATALOG_NAME
- SQL_COLLATION_SEQ
- SQL_CONVERT_INTERVAL_YEAR_MONTH
- SQL_CONVERT_INTERVAL_DAY_TIME
- SQL_CREATE_ASSERTION
- SQL_CREATE_CHARACTER_SET
- SQL_CREATE_COLLATION
- SQL_CREATE_DOMAIN
- SQL_CREATE_SCHEMA
- SQL_CREATE_TABLE
- SQL_CREATE_TRANSLATION
- SQL_CURSOR_SENSITIVITY
- SQL_DDL_INDEX
- SQL_DESCRIBE_PARAMETER
- SQL_DM_VER
- SQL_DRIVER_AWARE_POOLING_SUPPORTED
- SQL_DRIVER_HDESC
- SQL_DROP_ASSERTION
- SQL_DROP_CHARACTER_SET
- SQL_DROP_COLLATION
- SQL_DROP_DOMAIN
- SQL_DROP_SCHEMA
- SQL_DROP_TABLE
- SQL_DROP_TRANSLATION
- SQL_DROP_VIEW
- SQL_DYNAMIC_CURSOR_ATTRIBUTES1
- SQL_DYNAMIC_CURSOR_ATTRIBUTES2
- SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES1
- SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES2
- SQL_INFO_SCHEMA_VIEWS
- SQL_INSERT_STATEMENT
- SQL_KEYSET_CURSOR_ATTRIBUTES1
- SQL_KEYSET_CURSOR_ATTRIBUTES2
- SQL_MAX_ASYNC_CONCURRENT_STATEMENTS

- SQL_MAX_IDENTIFIER_LEN
- SQL_PARAM_ARRAY_ROW_COUNTS
- SQL_PARAM_ARRAY_SELECTS
- SQL_STATIC_CURSOR_ATTRIBUTES1
- SQL_STATIC_CURSOR_ATTRIBUTES2
- SQL_XOPEN_CLI_YEAR

Renamed Information Type in ODBC 3.x

The following values of InfoType argument are renamed for ODBC 3.x.

- SQL_ACTIVE_CONNECTIONS: SQL_MAX_DRIVER_CONNECTIONS
- SQL_ACTIVE_STATEMENTS: SQL_MAX_CONCURRENT_ACTIVITIES
- SQL_MAX_OWNER_NAME_LEN: SQL_MAX_SCHEMA_NAME_LEN
- SQL_MAX_QUALIFIER_NAME_LEN: SQL_MAX_CATALOG_NAME_LEN
- SQL_ODBC_SQL_OPT_IEF: SQL_INTEGRITY
- SQL_OWNER_TERM: SQL_SCHEMA_TERM
- SQL_OWNER_USAGE: SQL_SCHEMA_USAGE
- SQL_QUALIFIER_LOCATION: SQL_CATALOG_LOCATION
- SQL_QUALIFIER_NAME_SEPARATOR: SQL_CATALOG_NAME_SEPARATOR
- SQL_QUALIFIER_TERM: SQL_CATALOG_TERM
- SQL_QUALIFIER_USAGE: SQL_CATALOG_USAGE

Deprecated Information Type in ODBC 3.x

The following InfoType argument values are information types which are deprecated in ODBC 3.x driver b ut are still supported for compatibility with ODBC 2.x applications.

- SQL_FETCH_DIRECTION
- SQL_LOCK_TYPES
- SQL_ODBC_API_CONFORMANCE
- SQL_ODBC_SQL_CONFORMANCE
- SQL_POS_OPERATIONS
- SQL_POSITIONED_STATEMENTS
- SQL_SCROLL_CONCURRENCY
- SQL_STATIC_SENSITIVITY

SQLGetStmtAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLGetStmtAttr returns the current setting of the statement attribute.

Syntax

```
SQLRETURN SQLGetStmtAttr(
    SQLHSTMT        StatementHandle,
    SQLINTEGER      Attribute,
    SQLPOINTER      ValuePtr,
    SQLINTEGER      BufferLength,
    SQLINTEGER *    StringLengthPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Attribute

[Input] It is the attribute to be retrieved.

ValuePtr

[Output] It is the buffer pointer in which to return the attribute value specified in Attribute. If ValuePtr is NULL, StringLengthPtr returns the total number of bytes returnable to the buffer pointed by ValuePtr (excluding null-termination character).

BufferLength

[Input] If Attribute is the attribute defined in ODBC and ValuePtr points to a string or binary buffer, the argument is the length of *ValuePtr. If Attribute is the attribute defined in ODBC and *ValuePtr is an integer, BufferLength is ignored. If *ValuePtr (when SQLGetStmtAttrW is called) is a unicode string, BufferLength should be an even number.

If Attribute is the driver defined attribute, the application displays the attribute characteristic to the driver manager by setting BufferLength argument. BufferLength has one of the following values.

• If *ValuePtr is a string pointer, BufferLength is the string length or SQL_NTS.

• If *ValuePtr is a binary buffer pointer, the application stores SQL_LEN_BINARY_ATTR (length) macro result in BufferLength. It stores an negative number in BufferLength.

• If *ValuePtr is a pointer of the value other than a string or a binary string, BufferLength has the value of SQL_IS_POINTER.

• If *ValuePtr has the fixed length data type, BufferLength has SQL_IS_INTEGER or SQL_IS_UINTEGER.

StringLengthPtr

[Output] It is the buffer pointer which returns the total number of bytes returnable to *ValuePtr (excluding null-termination character). If ValuePtr is null, the length is not returned. If the attribute value is a string and the bytes returnable is equal to or bigger than BufferLength, the data in *ValuePtr is truncated to the length of BufferLength minus the null-termination character, and it is null-terminated by the driver).

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The data returned to *ValuePtr is truncated to the length of BufferLength minus null-termination character. The untruncated string value is returned in *StringLengthPtr. (The function returns SQL_SUCCESS_WITH_INFO.)
24000	Invalid cursor state	Attribute argument is SQL_ATTR_ROW_NUMBER, and the cursor is not open or the cursor is positioned before or after the result set.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLGetStmtAttr is called. The asynchronously executing function is called for StatementHandle, and is still being executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This functio

SQLSTATE	Error	Description
		n is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0, or it can not access the memory.
HY090	Invalid string or buffer length	*ValuePtr is a string, and BufferLength is smaller than 0 but it is not equal to SQL_NTS.
HY092	Invalid attribute/ option identifier	The specified value of Attribute argument is not valid for ODBC version supported by the driver.
HY109	Invalid cursor position	Attribute argument is SQL_ATTR_ROW_NUMBER, and the row is deleted or can not be retrieved.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional field not implemented	The value specified in attribute argument is valid ODBC statement attribute in ODBC version supported by the driver, but it is not supported by the driver.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to DescriptorHandle does not support the function.

Description

SQLGetStmtAttr returns the statement attribute value specified in Attribute to *ValuePtr. The value returned can be the SQLULEN value or null-termination string. If the value is SQLULEN, some drivers write the lower 32 bits or 16 bits of the buffer and keep the upper bits as they are. Therefore, the application should use the buffer of SQLULEN and initialize it to 0 before the function is called. Also BufferLength and StringLengthPtr are not used. If the value is the null termination string, the application specifies the maximum string length of BufferLength argument, and the driver returns the string length to *StringLengthPtr buffer.

If an application which is operated with ODBC 2.x driver wants to call SQLGetStmtAttr, SQLGetStmtAttr should be mapped to the SQLGetStmtOption of the driver manager.

The following statement can be retrieved by SQLGetStmtAttr but it can not set by SQLSetStmtAttr because the attributes are read-only.

- SQL_ATTR_IMP_PARAM_DESC

- SQL_ATTR_IMP_ROW_DESC
- SQL_ATTR_ROW_NUMBER

Statement Attributes

The following table describes currently defined attributes and its introduced ODBC version.

Attribute	ValuePtr contents
SQL_ATTR_APP_PARAM_DESC (ODBC 3.0)	It is the APD handle for the time after calling SQLExecute and SQLExecDirect on the statement handle. The initial value of this attribute is the descriptor implicitly allocated when the statement is initially allocated. If the value of this attribute is set to the descriptor which is originally allocated by SQL_NULL_DESC or the handle, an explicitly allocated APD handle which is previously related to the statement handle is detached from it and the statement handle is returned to the implicitly allocated APD handle. This attribute can not be set to a descriptor handle which is implicitly allocated for another statement, nor set to another descriptor handle which is implicitly allocated for the same statement. The implicitly allocated descriptor handles cannot be related to a statement or a descriptor handle.
SQL_ATTR_APP_ROW_DESC (ODBC 3.0)	It is the ARD handle for the next fetches of the statement handle. The initial value of the attribute is the descriptor implicitly allocated when the statement is initially allocated. If the attribute is set to SQL_NULL_DESC or to the descriptor allocated by the handle, ARD handle which is explicitly allocated and related to the previous statement is detached and the statement handle is returned to ARD handle implicitly allocated. The attribute can not be set to a descriptor handle which is implicitly allocated for another statement, nor set to another descriptor handle which is implicitly set on the same statement. The implicitly allocated descriptor handle can not be related to a statement or descriptor handle.
SQL_ATTR_ASYNC_ENABLE (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_EVENT (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_PCALLBACK (ODBC3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_PCONTEXT (ODBC 3.8)	It is not supported by the driver.
	• SQLULEN: It is the value which specifies the concurrency of cursor. • SQL_CONCUR_READ_ONLY: The cursor is read-only, and the update is not allowed.

Attribute	ValuePtr contents
SQL_ATTR_CONCURRENCY (ODBC 2.0)	• SQL_CONCUR_LOCK: The cursor uses the locking of the minimum level which is enough to complete update the row. • SQL_CONCUR_POWVER: The cursor uses the concurrency which controls and compares the row version such as SQLBase ROWID or Sybase TIMESTAMP. • SQL_CONCUR_VALUES: The cursor uses the concurrency which controls and compares the value. The default value of SQL_ATTR_CONCURRENCY is SQL_CONCUR_READ_ONLY. If the Attribute of SQL_ATTR_CURSOR_TYPE is changed to the value not supported by SQL_ATTR_CONCURRENCY, then the value of SQL_ATTR_CONCURRENCY is changed at the execution time, and the warning will be issued when SQLExecDirect or SQLPrepare is called. If SQL_ATTR_CONCURRENCY is changed to SQL_CONCUR_READ_ONLY, while the driver supports and executes SELECT FOR UPDATE statement, then an error is returned. If SQL_ATTR_CONCURRENCY value is changed to SQL_ATTR_CURSOR_TYPE value supported by the driver or the value not supported, SQL_ATTR_CURSOR_TYPE value is changed at the execution time, SQLSTATE 01S02 (Option value changed) is issued when SQLExecDirect or SQLPrepare is executed. If the specified concurrency is not supported in the data source, the driver replaces it with another concurrency and returns SQLSTATE 01S02 (Option value changed). The driver replaces SQL_CONCUR_VALUES with SQL_CONCUR_ROWVER, or vice versa. Also SQL_CONCUR_LOCK is replaced with SQL_CONCUR_ROWVER, SQL_CONCUR_VALUES in order. The validity of the replaced value is not confirmed until the execution time.
SQL_ATTTR_CURSOR_SCROLLABLE (ODBC 3.0)	• SQL_NONSCROLLABLE: It is the default value. The scroll cursor is not required in the statement handle. If the application calls SQLFetchScroll on the handle, the only valid value of FetchOrientation is SQL_FETCH_NEXT. • SQLULEN: It is the value which specifies the required support level of the application. Setting the attribute affects the following SQLExecDirect and SQLExecute. • SQL_SCROLLABLE: The scroll cursor is required in the statement handle. When SQLFetchScroll is called, the application positions the cursor in a mode except sequential mode and specify a valid value of FetchOrientation.
iSQL_ATTR_CURSOR_SENSITIVITY	• SQL_UNSPECIFIED: It is the default value. It is unspecified what the cursor type is and whether cursors on the statement handle can view the changes made to a result set by another cursor. The cursor of the statement handle probably view is none, some, or all. • SQLULEN: It is the value which determines whether the cursor of the statement handle can view a change in the result set generated by another cursor. Setting

Attribute	ValuePtr contents
(ODBC 3.0)	the attribute affects the following SQLExecDirect and SQLExecute. The application can read the attribute again to obtain the initial state or state most recently set by the application. • SQL_INSENSITIVE: All cursors of the statement handle can not view the reflection of any changes made by another cursor and they can view only the results. The insensitive cursor is read-only. It corresponds to a static cursor with a read-only concurrency. • SQL_SENSITIVE: All cursors of the statement handle can view all changes in the result set.
SQL_ATTR_CURSOR_TYPE (ODBC 2.0)	• SQLULEN: It is the value which specifies the cursor type. • SQL_CURSOR_FORWARD_ONLY: The cursor can only move forward. • SQL_CURSOR_KEYSET_DRIVEN: The driver stores and uses keys as many as the number of rows specified in SQL_ATTR_KEYSET_SIZE which is the statement attribute. • SQL_CURSOR_DYNAMIC: The driver stores and uses the key for the row in the row set. The default value is SQL_CURSOR_FORWARD_ONLY. The attribute can not be specified in the prepared SQL statement. If the specified cursor type is not supported by the data source, then the driver replaces it with other type and returns SQLSTATE 01S02 (Option value changed). The driver replaces a mixed or dynamic cursor with a key set-driven or static cursor. The driver replaces a key set-driven cursor with a static cursor.
SQL_ATTR_ENABLE_AUTO_IPD (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_FETCH_BOOKMARK_PTR (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_IMP_PARAM_DESC (ODBC 3.0)	It is the handle of IPD. This attribute value is the descriptor allocated when the statement is initially allocated. The application can not set the attribute. The attribute can be retrieved by calling SQLGetStmtAttr, but it can not be set via SQLSetStmtAttr.
SQL_ATTR_IMP_ROW_DESC (ODBC 3.0)	It is the handle of IRD. This attribute value is the descriptor allocated when the statement is initially allocated. The application can not set the attribute. The attribute can be retrieved by calling SQLGetStmtAttr, but it can not be set via SQLSetStmtAttr.
SQL_ATTR_KEYSET_SIZE	

Attribute	ValuePtr contents
(ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_MAX_LENGTH (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_MAX_ROWS (ODBC 1.0)	• SQLULEN: It is the value which corresponds to the maximum number of rows which are returned from SELECT statement. If *ValuePtr is equal to 0, the driver returns all rows. The attribute is intended to reduce the network traffic. Notionally it is applied when the result set is generated, it limits the result set of the first ValuePtr row. If the number of rows in the result set are bigger than ValuePtr, then the result set is reduced. SQL_ATTR_MAX_ROWS includes those which are applied to all result set of the statement and returned by the catalog function. SQL_ATTR_MAX_ROWS sets the maximum number of the cursor rows. If SQL_ATTR_MAX_ROWS can not be guaranteed to be correctly implemented (if the result set size limit can not be implemented in the data source), then the driver should not imitate SQL_ATTR_MAX_ROWS operation for SQLFetch or SQLFetchScroll. The driver defines whether to apply SQL_ATTR_MAX_ROWS to the statements except for SELECT statement(such as the catalog functions). The attribute can be set in the open cursor. However, it does not immediately bring the effect. In this case, the driver returns SQLSTATE 01S02 (Option value changed) and sets the attribute to its original value.
SQL_ATTR_METADATA_ID (ODBC 3.0)	• SQLULEN: It is the value which determines how to treat the string arguments of the catalog functions. If it is SQL_TRUE, the catalog functions treat the string arguments as the identifiers. In this case, it is not case sensitive. The driver removes the trailing spaces and converts to uppercase for the string whose scope is not defined. The driver removes the leading and trailing spaces and literally takes the string between the delimiters for the string whose scope is defined. If one of the arguments is set to NULL pointer, the function returns SQL_ERROR and SQLSTATE HY009 (Invalid use of null pointer). If it is SQL_FALSE, the catalog functions do not treat the string arguments as the identifiers. In this case, it is case sensitive. The arguments may or may not include a string search pattern depending on the argument. The default value is SQL_FALSE. The list of values of TableType argument of SQLTables is not affected by the attribute. SQL_ATTR_METADATA_ID can be set on the connection level.(SQL_ATTR_METADAT

Attribute	ValuePtr contents
	A_ID and SQL_ATTR_ASYNC_ENABLE are unique and they are the statement attributes and connection attributes.) For more information, refer to **Arguments of Catalog Function**.
SQL_ATTR_NOSCAN (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_PARAM_BIND_OFFSET_PTR (ODBC 3.0)	• SQLULEN*: It is the value which points to the offset to add a pointer to change the dynamic parameter binding. If the field is not NULL, the driver dereferences the pointer, and additionally it dereferences each value of the deferred fields in the descriptor record(SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR) and it uses the new pointer values when bound. It is set to NULL by default. The bind offset is always directly added to SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR fields. If the offset is changed to another value, the new value is directly added to the descriptor field value. The new offset will not be added to any previous offset value in the field. SQL_DESC_BIND TYPE field in APD header is set by setting this statement attribute.
SQL_ATTR_PARAM_BIND_TYPE (ODBC 3.0)	• SQLULEN: It is the value which refers to the binding direction used in the dynamic parameter. This field is set to SQL_PARAM_BIND_BY_COLUMN which selects the column-wise binding. (default value) The field is set to the instance of the buffer to be bound to the structure length or dynamic parameter set to select the row-wise binding. This length should include the space for all bound parameters and the structure padding, or the address of the binding parameter is increased to the specified length, then the result should be buffered to point to the beginning of the next parameter. The sizeof operation of ANSI C guarantees this behavior. SQL_DESC_BIND_TYPE field in APD header is set by setting this statement attribute.
SQL_ATTR_PARAM_OPERATION_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value which points to the array of SQLSMALLINT values used to ignore the parameter while executing the SQL statement. Each value is SQL_PARAM_PROCEED(to execute the parameter) or SQL_PARAM_IGNORE(to ignore the parameter). The parameter set can be ignored during processing by setting the status value of the array pointed by SQL_DESC_ARRAY_STATUS_PTR in APD. The parameter set is processed when the status value is SQL_PARAM_PROCEED or the array elements are not set. The statement attribute can be set to a NULL pointer and the driver does not return the status value of the parameter. The attribute can be set at any time but the new valu

Attribute	ValuePtr contents
	e is not used until SQLExecDirect or SQLExecute is called. The attribute is ignored if bound parameter does not exist. SQL_DESC_ARRAY_STATUS_PTR field in APD header is set by setting this statement a ttribute.
SQL_ATTR_PARAM_STATUS_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value points to SQLUSMALLINT array which includes t he status information value of each row parameter value after calling SQLExecut e or SQLExecDirect. The field is required only when PARAMSET_SIZE is bigger th an 1. The status value can include other values. • SQL_PARAM_SUCCESS: SQL statement is successfully executed for the paramete r set • SQL_PARAM_SUCCESS_WITH_INFO: SQL statement is successfully executed for t he parameter set but the warning information exists in the diagnostic data struct ure. • SQL_PARAM_ERROR: An error occurs when processing the parameter set. The a dditional error information is in the diagnostic data structure. • SQL_PARAM_UNUSED: The parameter set is not used because some previous pa rameter set caused an error which interrupts the processing, or the parameter se t of the array specified by SQL_ATTR_PARAM_OPERATION_PTR is set to SQL_PA RAM_IGNORE. • SQL_PARAM_DIAG_UNAVAILABLE: The driver treats the parameter array as a un iform unit because the error information level is not generated. The statement attribute can be set to a NULL pointer and the driver does not return th e status value of the parameter. The attribute can always be set. But the new value is not used until SQLExecDirect or SQLExecute is called. The attribute may affect the ope ration that the parameter outputs in the driver. SQL_DESC_ARRAY_STATUS_PTR field of IPD header is set by setting this statement at tribute.
SQL_ATTR_PARAMS_PROCESSED PTR (ODBC 3.0)	• SQLULEN*: It is the record field pointing to the buffer in which to return the nu mber of parameter sets processed and it includes the error set. If it is a NULL poi nter, any number will not be returned. SQL_DESC_ROWS_PROCESSED_PTR field of IPD is set by setting this statement attrib ute. If SQLExecDirect or SQLExecute which will fill the buffer specified in this attribute doe s not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is not de fined.

Attribute	ValuePtr contents
SQL_ATTR_PARAMSET_SIZE (ODBC 3.0)	• SQLULEN: It is the value which specifies the number of each parameter values. If SQL_ATTR_PARAMSET_SIZE is bigger than 1, then SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR of APD points to the array. Each array constant is equal to the field value. If binding parameter does not exist, this attribute is ignored. SQL_DESC_ARRAY_SIZE field of APD header is set by setting the statement attribute.
SQL_ATTR_QUERY_TIMEOUT (ODBC 1.0)	• SQLULEN: It is the value which value in seconds which wait for the SQL statement to execute before returing to the application. If ValuePtr is 0(default value), the timeout does not occur. If the specified timeout value exceeds the maximum value of the data source or it is smaller than the minimum value, then SQLSetStmtAttr replaces the value and returns SQLSTATE 01S02 (Option value changed). Even if SELECT statement is timed out, SQLCloseCursor does not need to be called when reuse the statement. It is valid to set the query timeout of the statement attribute for both synchronous and asynchronous mode.
SQL_ATTR_RETRIEVE_DATA (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_ROW_ARRAY_SIZE (ODBC 3.0)	• SQLULEN: It is the value which points to the number of rows returned by calling each SQLFetch or SQLFetchScroll. It is also the number of rows of the bookmark array used in a bulk bookmark operation in SQLBulkOperations. The default value is 1. If the specified row set size exceeds the row set size supported by the data source, the driver replaces the value and returns SQLSTATE 01S02 (option value changed). SQL_DESC_ARRAY_SIZE field of ARD header is set by setting this statement attribute.
SQL_ATTR_ROW_BIND_OFFSET_PTR (ODBC 3.0)	• SQLULEN: It is the value which points to the offset added to pointers to change binding of the column data. If the field is not NULL, the driver dereferences the pointer and adds the value dereferenced to each field of the descriptor record (SQL_DESC_DATA_PTR, SSQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR), and it uses the new pointer value when binding occurs. The default value is NULL. SQL_DESC_BIND_OFFSET_PTR field of ARD header is set by setting the statement attribute.
	• SQLULEN: It is the value which sets the binding direction when SQLFetch or SQL

Attribute	ValuePtr contents
SQL_ATTR_ROW_BIND_TYPE (ODBC 1.0)	FetchScroll is called in the related statement. If SQL_BIND_BY_COLUMN is set, the column-wise binding is selected. If the structure or result column sets the length for an instance of the buffer bound, then the row-wise binding is selected. If the length is specified and the address of the all columns and bound columns are increased to the specified length, then all columns should include enough space for the strucure or the buffer padding. The behavior is guaranteed when sizeof operator is used with the structure or union in ANSI C. The column-wise binding is the default bindng direction of SQLFetch and SQLFetchScroll. SQL_DESC_BIND_TYPE field of ARD header is set by setting this statement attribute.
SQL_ATTR_ROW_NUMBER (ODBC 2.0)	• SQLULEN: It is the current row order in the entire result set. If the number of the current rows can not be determined or the the current row does not exist, then the driver returns 0. The attribute can be retrieved by calling SQLGetStmtAttr. It can not be set by callingSQLSetStmtAttr.
SQL_ATTR_ROW_OPERATION_PTR (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_ROW_STATUS_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value which points to SQLUSMALLINT array containing the status values after calling SQLFetch or SQLFetchScroll. The array has the elements as many as the number of rows in the row set. The statement attribute can be set to a NULL pointer, and in this case the driver does not return the row status value. The attribute can be set at any time but the new value is not used until the next SQLBulkOperations, SQLFetch, SQLFetchScroll or SQLSetPos is called. SQL_DESC_ARRAY_STATUS_PTR field of IRD header is set by setting the statement attribute. The attribute is mapped to rgbRowStatus array of SQLExtendedFetch in ODBC 2.x driver.
SQL_ATTR_ROWS_FETCHED_PTR (ODBC 3.0)	• SQLULEN*: It points to the buffer which returns the number of collected rows after calling SQLFetch or SQLFetchScroll. The number of rows are determined by calling SQLSetPos by setting SQL_REFRESH in operation argument, or determined by processing the bulk operation via SQLBulkOperations. The number of rows include the error rows. SQL_DESC_ROWS_PROCESSED_PTR field of IRD header is set by setting the statemen

Attribute	ValuePtr contents
	t attribute. If calling SQLFetch or SQLFetchScroll which fills in the buffer pointed by the attribute does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is no t defined.
SQL_ATTR_SIMULATE_CU RSOR (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_USE_BOOKMA RKS (ODBC 2.0)	It is not supported by the driver.

SQLGetStmtOption

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

In ODBC 3.x, SQLGetStmtOption function is replaced with SQLGetStmtAttr function.
For more information, refer to **SQLGetStmtAttr**.

SQLGetSuitableGroupID

Conformance

Standards compliance: It is not available.

Overview

SQLGetSuitableGroupID returns the ID of the cluster group which is the most suitable for the prepared st atement to perform in cluster system.

Syntax

```
SQLRETURN SQLGetSuitableGroupID(
    SQLHSTMT     StatementHandle,
    SQLINTEGER * GroupIDPtr );
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

GroupIDPtr

[Output] It is the ID of the cluster group.

Returns

SQL_SUCCESS, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
08S01	Communication l ink failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
HY010	Function sequenc e error	This function is called before SQLPrepare. This function should be called only when the connection property SQL_ATT R_LOCALITY_AWARE_TRANSACTION is set.

Description

SQLGetSuitableGroupID can be called only when the connection property SQL_ATTR_LOCALITY_AWARE_TRANSACTION is set and the statement is prepared.
SQLGetSuitableGroupID returns the ID of the cluster group which is the most suitable for the preparedstatement to perform in cluster system by using the current value of the parameter marker when the parameter exists in the statement. If the cluster group which is the most suitable for the prepared statement to perform can not be determined, then it returns SQL_INVALID_GROUP_ID(-1).

SQLGetTypeInfo

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLGetTypeInfo returns the information of data type supported by the data source. The driver returns inf ormation in the form of SQL result set. Data types are used for Data Definition Language (DDL).

Syntax

```
SQLRETURN SQLGetTypeInfo(
    SQLHSTMT      StatementHandle,
    SQLSMALLINT   DataType);
```

Arguments

StatementHandle

[Input] It is the statement handle for the result set.

DataType

[Input] It is the SQL data type. It is data type or the specified driver SQL data type. SQL_ALL_TYPES specifies that the information about all data types should be returned.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL _SUCCESS_WITH_INFO.)
		It is temporarily replaced with the similar value because the specified sta tement attribute is invalid due to implementation working condition. Th

SQLSTATE	Error	Description
01S02	Option value changed	e replaced value is valid for StatementHandle until the cursor is closed. The updatable statement attributes are as follows. SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ATTR_KEYSET_SIZE, SQL_ATTR_MAX_LENGTH, SQL_ATTR_MAX_ROWS, SQL_ATTR_QUERY_TIMEOUT, SQL_ATTR_SIMULATE_CURSOR. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between t he driver and the data source is failed.
24000	Invalid cursor state	The cursor is open in StatementHandle, and SQLFetch or SQLFetchScroll is called. If SQLFetch or SQLFetchScroll returns SQL_NO_DATA, the driver returns this error. If SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, the driver manager returns this error. The result set is open in StatementHandle, but SQLFetch or SQLFetchScr oll is not called.
40001	Serailization failure	The transaction is rolled back due to a resource deadlock of other trans actions.
40003	Statement completion unk nown	The related connection fails during the function execution and the statu s of the transaction is not able to be checked.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY004	Invalid SQL data type	The value which is specified in DataType argument is neither ODBC SQL data type identifier supported by the driver nor the driver-specific data t ype identifier.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCan cel or SQLCancelHandle is called on StatementHandle before the functi on is called and completed. Then this function is called again on Statem entHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from oth er thread in the multithreaded application before the function is called and completed.
HY010	Function sequence error	The asynchronously executing function is called for the connection han dle related to StatementHandle, but it is still being asynchronously exec uted when SQLGetStmtAttr is called. The asynchronously executing function is called for the StatementHandl e, it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called f

SQLSTATE	Error	Description
		or StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0, or it can not access the memory.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional field not implemented	The combination for the current setting of SQL_ATTR_CONCURRENCY and SQL_ATTR_CURSOR_TYPE statement attributes is not supported by the driver or by the data source. SQL_ATTR_USE_BOOKMARKS statement attribute is not set in SQL_UB_VARIABLE, and SQL_ATTR_CURSOR_TYPE statement attribute is set to the cursor type for the bookmarkwhich is not supported by the driver.
HYT00	Timeout expired	Before the data source returns the result set, the query timeout period is expired. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to DescriptorHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
Im018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SQLGetTypeInfo returns the same result as the standard result set, and it is sorted to be closely mapped to the data types corresponding to the DATA_TYPE, ODBC SQL data type. The data types defined by the data source takes precedence over user defined data types. Therefore, the sorting order can be generalized in the ascending order and whose first order is DATA TYPE and then TYPE_NAME though the order is not always consistent.

For example, if the data source defines an INTEGER and COUNTER data types and COUNTER is automatically increased, and the user defined data type WHOLENUM is defined, then INTEGER, WHOLENUM and C

OUNTER will be returned in order. The result is because WHOLENUM is closely mapped to SQL_INTEGER and ODBC SQL data type. On the other hand, even though the automatic increasing data types are suppo rted by the data source, they are not mapped closely with ODBC SQL data types.

If DataType argument is valid for ODBC version supported by the driver but the driver does not support it, then an empty result set is returned.

The following column names are changed in ODBC 3.x. The column name change does not affect the co mpatibility with the previous version because the application is bound by the column number.

ODBC 2.0 column	ODBC 3.x column
PRECISION	COLUMN_SIZE
MONEY	FIXED_PREC_SCALE
AUTO_INCREMENT	AUTO_UNIQUE_VALUE

In ODBC 3.x, the following columns are added to the result set returned by SQLGetTypeInfo.

- SQL_DATA_TYPE
- INTERVAL_PRECISION
- SQL_DATETIME_SUB
- NUM_PREC_RADIX

The following table lists the columns in the result set. The additional row after column 19 (INTERVAL_PRE CISION) is defined by the driver. The applications should get access to a specific driver column by perform ing the countdown from the end of the result set instead of specifying an explicit ordinal position.

SQLGetTypeInfo may not return for all data types. For example, the driver may not return the us er defined data type. The application can use the valid data types regardless of returning SQLGe tTypeInfo. Data types returned by SQLGetTypeInfo are supported by the data source. They are in tended to be used in Data Definition Language (DDL). The driver can return the data types used in the result set other than the data types that returned by SQLGetTypeInfo. The driver may use the data types which are not supported by the data source in generating the result set for the c atalog function.

Column name	Column number	Data type	Comment
TYPE_NAM E (ODBC 2.0)	1	Varchar not NULL	It is data source-dependent data type name. For example, it is "CHAR()" , "VARCHAR()", "MONEY", "LONG VARBINARY", or "CHAR ( ) FOR BIT DATA". The application should use this name in CREATE TABLE and AL TER TABLE statements.
DATA_TYPE	2	Smallint not	It is SQL data type. It can be the ODBC SQL data type or driver specific SQL data. For DATETIME or INTERVAL data type, the column returns th

Column name	Column number	Data type	Comment
(ODBC 2.0)		NULL	e simple data type (such as SQL_TYPE_TIME or SQL_INTERVAL_YEAR_TO_MOUNT).
COLUMN_SIZE (ODBC 2.0)	3	Integer	It is the maximum column size for the data type supported by the server. For numeric data, it is the maximum precision. For string data, it returns a length of characters. For datetime data types, it returns a length of represented characters. For interval data, it returns the length of characters in the character representation of the interval literal. NULL is returned for data types whose column size is not applicable.
LITERAL_PREFIX (ODBC 2.0)	4	Varchar	A character or string is used as a prefix. For example, a single quote (') is for a character, 0x, or binary data type. NULL is returned for a data type which can not be used as a prefix.
LITERAL_SUFFIX (ODBC 2.0)	5	Varchar	A character or string is used as the termination character. For example, a single mark (') is for the character data type. NULL is returned for data types that can not be used as a suffix.
CREATE_PARAMS (ODBC 2.0)	6	Varchar	It is a keyword list corresponding to each parameter (separated by commas) which is specified by the application in parentheses when the name which is returned to TYPE_NAME is used. Keywords in the list can be length, precision, or scale. They are listed as the order in which the grammar uses keywords. For example, CREATE PARAMS for DECIMAL can be "precision, scale"". CRATE_PARAMS for VARCHAR can be the same "length". If parameter does not exist for defining data type, NULL is returned (e.g. INTERGER). The driver provides CREATE_PARAMS text in the language of the country/region.
NULLABLE (ODBC 2.0)	7	Smallint not NULL	It is whether the data type accepts NULL. SQL_NO_NULLS does not accept NULL as a data type. SQL_NULLABLE does accept NULL as a data type. SQL_NULLABLE_UNKNOWN do not know whether the column accepts NULL.
CASE_SENSITIVE (ODBC 2.0)	8	Smallint not NULL	It is whether the character data type is case-sensitive in sorting and comparison. It is SQL_TRUE if the data type is a character data type and it is case-sensitive. It is SQL_FALSE if the data type is not a character data type or it is case-insensitive.
SEARCHABLE (ODBC 2.0)	9	Smallint not NULL	It is how the data type is used in a WHERE clause. If a column can not be used in WHERE clause, it is SQL_PRED_NONE. (It is as same as the value of SQL_UNSEARCHABLE in ODBC 2.x.) If a column can be used only with LIKE condition in WHERE clause, it is SQL_PRED_CHAR. (It is as same as the value of SQL_LIKE_ONLY in ODBC 2.x.) If a column can be used with all comparison operators except LIKE condition in WHERE clause, it is SQL_PRED_BASIC. (It is as same as the val

Column name	Column number	Data type	Comment
			ue of SQL_ALL_EXCEPT_LIKE in ODBC 2.x.) If a column can be used with all comparison operators in WHERE claus e, it is SQL_SEARCHABLE.
UNSIGNED_ ATTRIBUTE (ODBC 2.0)	10	Smallint	It is whether the data type is signed. If a data type is unsigned, it is SQL_TRUE. If a data type is signed, it is SQL_FALSE. If the attribute can not be used in data type or it is not a numeric data t ype NULL is returned.
FIXED_PREC _SCALE (OD BC 2.0)	11	Smallint not NULL	It is whether the data type (specific data source) has a predefined fixed precision and scale. If the data type has a predefined fixed precision and scale, it is SQL_TR UE. If the data type does not have predefined fixed precision and scale, it is SQL_FALSE.
AUTO_UNIQ UE_VALUE (ODBC 2.0)	12	Smallint	It is whether data type is automatically increased. If the data type is automatically increased, it is SQL_TRUE. If the data type is not automatically increased, it is SQL_FALSE If the attribute can not be used in data type or it is not a numeric data t ype, NULL is returned. The application can insert the value in the column having this attribute, but can not typically update the value of the column. When insertion o ccurs in the automatically increased column, a unique value is inserted i n the column. The increment is not defined but is data source-specific. The application should not assume that the auto-increment column sta rts at a specific point or it is increased by a certain value.
LOCAL_TYP E_NAME (O DBC 2.0)	13	Varchar	It is a localized version of the data type name dependent on the data s ource. If the localized name is not supported by the data source, NULL i s returned. The name is used for display only, like as a dialog box.
MINIMUM_ SCALE (ODB C 2.0)	14	Smallint	It is the minimum scale of the data type on the data source. If the data type is a fixed Scale, MINIMUM_SCALE and MAXIMUM_SCALE column s have this value. For example, SQL_TYPE_TIMESTAMP column has the fixed scale for fractional seconds. NULL is returned if scale can not be u sed.
MAXIMUM_ SCALE (ODB C 2.0)	15	Smallint	It is the maximum scale of the data type on the data source. If scale ca n not be used, NULL is returned. If the maximum scale is not separately defined on the data source, but it is defined as same as the maximum precision, then the column has the same value as COLUMN_SIZE.
SQL_DATA_ TYPE (ODBC 3.0)	16	Smallint NO T NULL	It is the value of SQL data type which appears in SQL_DESC_TYPE field of the descriptor. The column is as same as DATA_TYPE column except for INTERVAL and DATETIME data types. SQL_DATE_TYPE field in the r esult set returns SQL_INTERVAL or SQL_DATETIME for INTERVAL and D ATETIME data types, and SQL_DATETIME_SUB field returns the sub-co

Column name	Column number	Data type	Comment
			de for INTERVAL or DATETIME data types.
SQL_DATETIME_SUB (ODBC 3.0)	17	Smallint	If a value of SQL_DATE_TYPE is SQL_DATETIME or SQL_INTERVAL, this column has the sub code of DATETIME/ INTERVAL. For other data types, the field is NULL. For INTERVAL or DATETIME data types, SQL_DATE_TYPE of the result set returns SQL_INTERVAL or SQL_DATETIME, SQL_DATETIME_SUB field returns the sub code for INTERVAL or DATETIME data type.
NUM_PREC_RADIX (ODBC 3.0)	18	Integer	If the data type is an approximate numeric type, the column has the value 2 to indicate that the COLUMN_SIZE specifies the number of bits. For the exact numeric type, the column has the value 10 to indicate that COLUMN_SIZE specifies decimal values. Otherwise, this column is NULL.
INTERVAL_PRECISION (ODBC 3.0)	19	Smallint	For INTERVAL data type, the column has the value of "INTERVAL leading precision". Otherwise, the column has NULL.

Attribute information can be applied to a particular column in the result set or the data type. SQLGetTypeInfo returns information about the attributes related to a data type. SQLColAttribute returns information about the attributes related to a column in the result set.

SQLMoreResults

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLMoreResults checks that more results are available in the statements including SELECT, UPDATE, INSERT, or DELETE statement, and if so, the processing for the results is initialized.

Syntax

```
SQLRETURN SQLMoreResults(
    SQLHSTMT     StatementHandle);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_NO_DATA, SQL_ERROR, SQL_INVALID_HANDLE, SQL_PARAM_DATA_AVAILABLE

Diagnosis

SQLSTATE	Error	Description
01000	General Warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value changed	The value of the statement attribute is changed while the batch is being processed. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
40001	Serailization failure	The transaction is rolled back due to a resource deadlock of other transactions.

SQLSTATE	Error	Description
40003	Statement completion unknown	The related connection is failed during the function execution, and the status of transaction can not be checked.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before the function is called and completed.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, but it is still being asynchronously executed when SQLMoreResultsr is called. The asynchronously executing function is called for the StatementHandle, it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The size of buffer used as an argument is smaller than 0, or it can not access the memory.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to DescriptorHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
Im018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SELECT statement returns the result set. UPDATE, INSERT, and DELETE statements return the number of r ows affected.

If one of these statements are batched or an array of parameters are passed or in progress, then multiple result sets or the number of rows can be returned.

The batch is processed, and the application is positioned in the first result set. The application can call SQ LBindCol, SQLBulkOperations, SQLFetch, SQLGetData, SQLFetchScroll, SQLSetPos and all the meta data f unctions as if a single result set exists for the first or subsequent result sets. When SQLMoreResults is exec uted as the first result set, the application calls SQLMoreResults to move to the next result set. If another r esult set or its number is available, SQLMoreResults returns SQL_SUCCESS and initializes the result set or performs the aggregate for the additional operations. If any count row generation statement appears bet ween the result set generation statements, the row generation statement can be sent to SQLMoreResults call. If SQLMoreResults is called for UPDATE, INSERT, or DELETE statement, the application can call SQLR owCount.

If a current result set with unfetched rows exists, SQLMoreResults discards the result set and generates th e next result set or aggregates it. If all result sets are processed, SQLMoreResults returns SQL_NO_DATA. For some drivers, the output parameter and the return value can not be used until all result sets and row aggregation are processed. In this case, the output parameter and return value can be used after SQLMor eResults returned SQL_NO_DATA.

All bindings made for the previous result set still remains valid. If the column structure is different from th e result set, then calling SQLFetch or SQLFetchScroll can cause an error or truncation. To prevent it, the a pplication should call SQLBindCol for the explicit rebinding. The application can call SQLFreeStmt with SQ L_UNBIND option to release the binding for all column buffers.

The statement attribute values such as the cursor type, cursor concurrency, key set size, or maximum leng th can be changed while the application calls SQLMoreResults and performs the batch processing. SQLM oreResults can return SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value has changed).

If SQLCloseCursor or SQLFreeStmt is called with an SQL_CLOSE option, then the number of available row s such as all the result set and batch processing result is discarded. The statement handle returns one of t he assigned state and prepared state. When the batch is processed and the statement handle is executed, then SQLCancel is called to cancel the asynchronously executing function. If SQLCancel is executed succe ssfully, all asynchronous status results which are generated by the batch processing, and the number of r ows can be discarded. The statement handle returns one of the assigned state and prepared state.

If the batch or procedure of the statement mixes SELECT, UPDATE, INSERT, DELETE statements with othe r SQL statements, these statements does not affect SQLMoreReuslt.

If a searched update, insert or delete statement in batch statements does not affect to any row of the dat a source, SQLMoreResults returns SQL_SUCCESS. It is different from the case of when SQLExecDirect, SQ LExecute, or SQLParamData returns SQL_NO_DATA. If the application calls SQLRowCount to retrieve the number of rows after SQLMoreResults does not affect any row, then SQLRowCount may return SQL_NO_ DATA.

Availability of the Number of Rows

If the batch processing includes the statement for consecutive multiple row aggregate generation, the ro w aggregation can be rolled up to a single row. For example, if a batch includes five INSERT statements, t he particular data source can return the five individual rows. Some other data sources return a single row that represents the sum of the total five individual rows.

If a batch processing includes the combination of the result set generation and row aggregate generation statement, then the number of rows may not be available.

The driver operation for the availability of the number of rows is listed in SQL_BATCH_ROW_COUNT infor mation type used via SQLGetInfo call. For example, if the batch processing includes two INSERT statemen ts and SELECT statement followed by the other SELECT statement, then the following cases are available.

- The number of rows corresponding to the two INSERT statements can not be used. The first call of S QLMoreResults is located in the result set of the second SELECT statement.
- The number of rows corresponding to the two INSERT statements can be individually used.(SQLGetIn fo does not return SQL_BRC_ROLLED_UP bit for SQL_BATCH_ROW_COUNT information type.) The fi rst call of SQLMoreResults is located in the number of rows of the first INSERT statement, and the sec ond call is positioned in the number of rows of the second INSERT statement. The third call may be lo cated in result set of the second SELECT statement.
- The number of rows corresponding to the two INSERT statements is rolled up to a single available ro w.(Calling SQLGetInfo returns SQL_BRC_ROLLED_UP bit for SQL_BATCH_ROW_COUNT information t ype.) The first SQLMoreResults may be located overlapping with the number of rows, and the second SQLMoreResults may be located in the result set of the second SELECT statement.

A specific driver makes the number of rows available only for the explicit batch processing.

SQLNativeSql

It is not supported.

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLNativeSql returns the SQL string modified by the driver. SQLNativeSql does not executeSQL statement.

Syntax

```
SQLRETURN SQLNativeSql(
    SQLHDBC        ConnectionHandle,
    SQLCHAR *      InStatementText,
    SQLINTEGER     TextLength1,
    SQLCHAR *      OutStatementText,
    SQLINTEGER     BufferLength,
    SQLINTEGER *   TextLength2Ptr);
```

SQLNumParams

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLNumParams returns the number of parameters in the SQL statement.

Syntax

```
SQLRETURN SQLNumParams(
    SQLHSTMT        StatementHandle,
    SQLSMALLINT *   ParameterCountPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ParameterCountPtr

[Output] It is the buffer pointer to which the number of parameters of the statement is to be returned.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.

SQLSTATE	Error	Description
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before the function is called and completed.
HY010	Function sequence error	The function is called in StatementHandle before calling SQLPrepare or SQLExecDirect. The asynchronously executing function is called for the connection handle related to StatementHandle, but it is still being asynchronously executed when SQLNumParams is called. The asynchronously executing function is called for the StatementHandle, it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The internal memory can not be accessed or the available memory size is small.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SQLNumParams can be called only after SQLPrepare is called.

If the statement related to StatementHandle does not have any parameter, then SQLNumParams sets*Par ameterCountPtr to 0.

The number of parameters which are returned by SQLNumParams is as same as the value of SQL_DESC_ COUNT field of IPD.

SQLNumResultCols

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLNumResultCols returns the number of columns in the result set.

Syntax

```
SQLRETURN SQLNumResultCols(
    SQLHSTMT        StatementHandle,
    SQLSMALLINT *   ColumnCountPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

ColumnCountPtr

[Output] It is the buffer pointer to which the number of columns in the result set is to be returned. The number does not include the bookmark column.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
	Memory allocation err	

SQLSTATE	Error	Description
HY001	or	It is a memory allocation error.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before the function is called and completed.
HY010	Function sequence error	The function is called in StatementHandle, before SQLPrepare or SQLExecDirect is called. The asynchronously executing function is called for the connection handle related to StatementHandle, but it is still being asynchronously executed when SQLNumResultsCols is called. The asynchronously executing function is called for the StatementHandle, it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The internal memory can not be accessed or the available memory size is small.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to DescriptorHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync has not been called to complete the previous asynchronous operati	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

SQLSTATE	Error	Description
	on on this handle.	

Description

SQLNumResultCols is successfully called only when the statement is in the prepared, executed, positioned state.

If the statement related to StatementHandle does not return the column, then SQLNumResultCols sets*ColumnCountPtr to 0.

The number of rows returned by SQLNumResultCols is as same as the value of SQL_DESC_COUNT field of IRD.

SQLParamData

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLParamData is used together with SQLPutData to provide the parameters at the statement execution ti me.

Syntax

```
SQLRETURN SQLParamData(
    SQLHSTMT       StatementHandle,
    SQLPOINTER *   ValuePtrPtr);
```

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NEED_DATA, SQL_NO_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE, SQL_PARAM_DATA_AVAILABLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SU CCESS_WITH_INFO.)
08S01	Communication l ink failure	Before the function processing is completed, the connection between the dr iver and the data source is failed.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio n error	It is a memory allocation error.
HY010	Function sequenc e error	The previous function is not SQLExecute nor is SQLExecDirect which returns SQL_NEED_DATA. The previous function is SQLParamData.
HY013	Memory manage ment error	The internal memory can not be accessed or the available memory size is sm all.

SQLSTATE	Error	Description
HYT01	Connection time out expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.

If SQLParamData is called to transfer the data for a parameter, then it can return SQLSTATE of SQLExecute or SQLExecDirect.

Description

The driver returns SQL_NEED_DATA when the application calls SQLExecute or SQLExecDirect which requires data-at-execution. The application calls SQLParamData to determine the data to be transferred. If the driver needs the parameter data, then the value of *ValuePtr entered by the application is returned. The application can use the value to determine the parameter data requested by the driver.

The application calls SQLPutData as many times as necessary to transfer data-at-execution parameter. The application calls SQLParamData again after all parameter data is transferred. When SQLParamData returns SQL_NEED_DATA again, the application should call SQLPutData to transfer the other parameter data again. If all parameter data are transferred, then SQLParamData returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO and the value of *ValuePtr is not defined and the SQL statement can be executed.

SQLParamOptions

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLParamOptions function in ODBC 2.0 is replace with **SQLSetStmtAttr** in ODBC 3.x.

SQLPrepare

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLPrepare prepares the SQL string for execution.

Syntax

```
SQLRETURN SQLPrepare(
    SQLHSTMT      StatementHandle,
    SQLCHAR *     StatementText,
    SQLINTEGER    TextLength);
```

Arguments

StatementHandle

[Input] It is the statement handle.

StatementText

[Input] It is the SQL text string.

TextLength

[Input] It is the length of *StatementText in characters.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
		It is temporarily replaced with the similar value because the specified statem

SQLSTATE	Error	Description
01S02	Option value changed	ent attribute is invalid due to implementation working condition. (SQLGetStmtAttr can be called to see which value is temporarily changed.) The replaced value is valid for StatementHandle until the cursor is closed, and it is changed to the previous value when the cursor is closed. The updatable statement attributes are as follows. SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ATTR_KEYSET_SIZE, SQL_ATTR_MAX_LENGTH, SQL_ATTR_MAX_ROWS, SQL_ATTR_QUERY_TIMEOUT, SQL_ATTR_SIMULATE_CURSOR. (The function returns SQL_SUCCESS_WITH_INFO.)
21S01	Insert value list does not match column list	INSERT statement is in *StatementText, and the number of values to be inserted do not match the derived table.
21S02	Degree of derived table does not match column list	CREATE view statement is in *StatementText, and the number of specified names are not as same as the derived table defined by the query specifications.
22018	Invalid charcter value for cast specification	The SQL statement which includes a string or parameter is in *StatementText, and the value is not compatible with the data type of related table column.
22019	Invalid escape character	StatementText argument includes LIKE predicate such as ESCAPE in WHERE clause, and a control character length of ESCAPE is not 1.
22025	Invalid escape sequence	StatementText argument includes "LIKE pattern value ESCAPE escape character" in WHERE clause, and the pattern value control character is neither "%" nor is "-".
24000	Invalid cursor state	The cursor is open in StatementHandle, and SQLFetch or SQLFetchScroll is called.
34000	Invalid cursor name	*StatementText includes the positioned DELETE or positioned UPDATE, and the cursor referenced by the prepared statement is not open.
3D000	Invalid catalog name	The catalog name specified in StatementText is not valid.
3F000	Invalid schema name	The schema name specified in StatementText is not valid.
42000	Syntax error or access violation	*StatementText includes an SQL statement which is not preparable or it includes a syntax error. *StatementText includes a user without required privileges in a statement.
42S01	Base table or view already exists	*StatementText includes CREATE TABLE or CREATE VIEW statement, and the specified table name or the view name already exists.
		*StatementText includes DROP TABLE or DROP VIEW statement, and the specified table name or view name does not exists. *StatementText includes ALTER TABLE statement, and the specified table name does not exist.

SQLSTATE	Error	Description
42S02	Base table or view not found	*StatementText includes CREATE VIEW statement, and the table name or view name defined does not exist in the query specifications. *StatementText includes CREATE INDEX statement, and the specified table name does not exist. *StatementText includes GRANT or REVOKE statement, and the specified table name or view name does not exist. *StatementText includes SELECT statement, and the table or view name specified does not exist. *StatementText includes DELETE, INSERT or UPDATE statement, and the specified table name does not exist. *StatementText includes CREATE TABLE statement, and the table (refers to other tables) whose constraint is specified does not exist.
42S11	Index already exists	CREATE INDEX statement is in *StatementText, and the specified INDEX name already exists.
42S12	Index not found	DROP INDEX statement is in *StatementText, and the specified INDEX name does not exist.
42S21	Column already exist	ALTER TABLE statement is in *StatementText, and the specified column in ADD clause is not unique or it identifies the existing column in the base table.
42S22	Column not found	CREATE INDEX statement is in *StatementText, and one or more column names do not exist in the specified column list. GRANT or REVOKE statement is in *StatementText, and the specified column name does not exist. SELECT, DELETE or UPDATE statement is in *StatementText, and the specified column name does not exist. CREATE TABLE statement is in *StatementText, the column whose constraint is specified does not exist.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then, this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from another

SQLSTATE	Error	Description
		thread in the multithreaded application before the function is called and co mpleted.
HY009	Invalid use of null pointer	StatementText is a NULL pointer.
HY010	Function sequenc e error	The function is called in StatementHandle before calling SQLPrepare or SQL ExecDirect. The asynchronously executing function is called for the connection handle r elated to StatementHandle, but it is still being asynchronously executed whe n SQLPrepare is called. The asynchronously executing function is called for the StatementHandle, it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for St atementHandle, and SQL_NEED_DATA is returned. This function is called be fore data is sent for all data-at-execution parameters or columns.
HY013	Memory manage ment error	The internal memory can not be accessed or the available memory size is sm all.
HY090	Invalid string or b uffer length	TextLength is equal to or smaller than 0, or it is not as same as SQL_NTS.
HY117	Connection is sus pended due to u nknown transacti on state. Only dis connect and read -only functions ar e allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The concurrency set is not valid for the defined cursor type. SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIAB LE, and SQL_ATTR_CURSOR_TYPE statement attribute is set to the cursor ty pe for the bookmark that is not supported by the driver.
HYT00	Timeout expired	The query timeout is expired before getting the result set from the data sour ce. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmt Attr.
HYT01	Connection time out expired	The connection is expired before the data source responds to the request. T he timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStm tAttr
IM001	Driver does not s upport this functi on	The driver which is related to StatementHandle does not support the functio n.
	Polling is disable d in asynchronou	

SQLSTATE	Error	Description
IM017	s notification mo de	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsy nc has not been called to complet e the previous as ynchronous oper ation on this han dle.	If the previous function call for the handle returns SQL_STILL_EXECUTING a nd if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

The application calls SQLPrepare to send the SQL statements to the data source for preparation. The appli cation can include one or more parameter markers in the SQL statement. The application describes the q uestion mark (?) at an appropriate position in the SQL string to include the parameter marker.

If the application uses SQLPrepare to prepare, or uses SQLExecute to submit COMMIT or ROLLB ACK statement, then it is impossible to interoperate between DBMS products.

The driver can update the statement to use the SQL types used by the data source, and pass it to the data source for the preparation. Especially, the driver updates the extended bit string which is used to define t he SQL statement for a particular function. In the driver, the statement handle is similar to the statement i dentifier in the embedded SQL code. If the data source supports statement identifiers, the driver can send a statement identifier and parameter values to the data source.

After the statement is prepared, the application uses the statement handle to refer to the statement in th e later function calls. The prepared statement related to the statement handle can be executed again wit h calling SQLExecute until the application releases the statement by calling SQLFreeStmt with SQL_DROP option or the statement handle uses one of SQLPrepare, SQLExecDirect or catalog function(SQLColumns, SQLTables, etc.). Once the application prepares the statement, information about the format of the result set may be requested. For some implementations, after SQLPrepare, calling of SQLDescribeCol or SQLDes cribeParam is not as effective as calling after SQLExecute or SQLExecDirec.

The driver can not return an syntax error or access violation when the application calls SQLPrepare. The dr iver can handle all syntax errors and access violations, or it can handle only syntax errors, or it can not han dle all syntax errors nor does return access violations. The application should be able to handle these con ditions when calling a subsequent related functions (the subsequent functions such as SQLNumResultCol s, SQLDescribeCol, SQLColAttribute, SQLExecute).

According to the features of the driver and data source, parameter information (such as the data type) ca n be checked when the statement is prepared (when all parameters are bound) or is executed (when all p arameters are not bound).
The application should release the binding of all parameters previously applied to the SQL statement befo re preparing the new SQL statement in the same statement. It can prevent an error whose previous para meter information is applied to the new statement.

Committing a transaction by explicitly calling SQLEndTran or by working in autocommit mode, c an cause the data source to delete the access plans for all statements on a connection. For more information, refer to SQL_CURSOR_COMMIT_BEHAVIOR and SQL_CURSOR_ROLLBACK_BEHA VIOR information types in **SQLGetInfo**.

SQLPrimaryKeys

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLPrimaryKeys returns the column name consists of the primary key of a table. The driver returns information as a result set. The function does not support returning the primary key from the multiple tables in a single call.

Syntax

```
SQLRETURN SQLPrimaryKeys(
    SQLHSTMT       StatementHandle,
    SQLCHAR *      CatalogName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      SchemaName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      TableName,
    SQLSMALLINT    NameLength3);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the catalog name. If the driver supports the catalog only for a few tables, an empty string ("") indicates the table with no catalog. CatalogName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, CatalogName is treated as an ordinary argument literal, and it is case sensitive.

NameLength1

[Input] It is the length of *CatalogName in characters.

SchemaName

[Input] It is the schema name. If the driver supports the schema only for a few tables, an empty string ("") indicates the table with no schema. SchemaName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, SchemaName is treated as a pattern value string, and it is not case sensitive.

NameLength2

[Input] It is the length of *SchemaName in characters.

TableName

[Input] It is the table name. The argument can not be a null pointer. TableName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, TableName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, TableName is treated as an ordinary literal, and it is not case sensitive.

NameLength3

[Input] It is the length of *TableName in characters.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	SQLFetch or SQLFetchScroll is called, and the cursor is open. SQLFetch or SQLFetchScroll is not called, but the cursor is open.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other transactions.
40003	Statement completion unknown	The related connection fails during the function execution and the status of the transaction is not able to be checked.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
		Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called a

SQLSTATE	Error	Description
HY008	Operation canceled	nd completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from another t hread in the multithreaded application before this function is called and com pleted.
HY009	Invalid use of null poi nter	TableName argument is a null pointer. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and Catal ogName argument is a null pointer. SQLGetInfo with the SQL_CATALOG_NAME information type returns that cat alog names are supported. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and Sche maName argument is a null pointer.
HY010	Function sequence er ror	The asynchronously executing function is called for the connection handle rel ated to StatementHandle, and this function is still being executed when SQLP rimaryKeys is called. SQLExecute, SQLExecDirect, or SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. This function is called befor e the data is checked for all connected parameters. The asynchronously executing function is called for StatementHandle, and is s till being executed when this function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for Stat ementHandle, and SQL_NEED_DATA is returned. This function is called befor e data is sent for all data-at-execution parameters or columns.
HY013	Memory manageme nt error	The internal memory can not be accessed or the available memory size is smal l.
HY090	Invalid string or buffe r length	A name length argument value is smaller than 0 but it is not as same as SQL_ NTS. The name argument is not a null pointer. A name length argument value is bigger than the maximum length correspon ding to the name.
HY117	Connection is suspen ded due to unknown transaction state. Onl y disconnect and rea d-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
		The catalog is specified, but the driver or the data source does not support th e catalog.

SQLSTATE	Error	Description
HYC00	Optional feature not implemented	The schema is specified, but the driver or the data source does not support th e schema. The combination of current setting of SQL_ATTR_CONCURRENCY and SQL_A TTR_CURSOR_TYPE statement attributes is not supported by the driver or dat a source. SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABL E, and SQL_ATTR_CURSOR_TYPE statement attribute is set to the cursor type for the bookmark that is not supported by the driver.
HYT00	Timeout expired	The query timeout is expired before getting the result set from the data sourc e. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAtt r.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. Th e timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtA ttr.
IM001	Driver does not supp ort this function	The driver which is related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notific ation mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync h as not been called to complete the previou s asynchronous oper ation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING an d if the notification mode is activated, then SQLCompleteAsync should be call ed for the handle to do post processing and complete the operation.

Description

SQLPrimaryKeys returns the result as the standard result set sorted by TABLE_CAT, TABLE_SCHEM, TABLE _NAME, and KEY_SEQ. For more information about how to use this information, refer to **Using Catalog Data**.

The names in the following columns are changed in ODBC 3.x. The column name change does not affect compatibility with the previous version because the application binds by the column number.

ODBC 2.0 column	ODBC 3.x column
TABLE_QUALIFIER	TABLE_CAT
TABLE_OWNER	TABLE_SCHEM

SQLGetInfo is called together with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME_LEN,

SQL_MAX_TABLE_NAME_LEN, and SQL_MAX_COLUMN_NAME_LEN options to determine the actual col umn length of TABLE_CAT, TABLE_SCHEM, TABLE_NAME, and COLUMN_NAME.

For more information about general use, arguments, and the returned data of the ODBC catalo g functions, refer to **Catalog Function**.

The following table is a column list in the result set. An additional column after the column 6 can be defin ed by the driver. The application should access the related column by counting down from the end in the result set rather than by explicitly specifying the position. For more information, refer to **Data Returning o f Catalog Function**.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	Varchar	It is the primary key table catalog name. If it can not be used in the dat a source, it is NULL. If the driver supports the catalog only for some tabl es, such as when the drive retrieves the data from another DBMS, it ret urns an empty string ("") for the table which does not have a catalog.
TABLE_SCH EM (ODBC 1 .0)	2	Varchar	It is the primary key table schema name. If it can not be used in the dat a source, it is NULL. If the driver supports the schema only for some tab le, such as when the drive retrieves the data from another DBMS, it ret urns an empty string ("") for the table which does not have a schema.
TABLE_NA ME (ODBC 1 .0)	3	Varchar not NULL	It is the primary key table name.
COLUMN_N AME (ODBC 1.0)	4	Varchar not NULL	It is the primary key column name. The driver returns an empty string f or a column which does not have a name.
KEY_SEQ (ODBC 1.0)	5	Smallint not NULL	It is the column sequence number of the key (starting from 1).
PK_NAME (ODBC 2.0)	6	Varchar	It is the primary key name. If it can not be applied to the data source, it is NULL.

SQLProcedureColumns

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLProcedureColumns returns the list of input output parameters and the columns which configure the r esult set of the specified procedure. The driver returns information as the result set for the specified state ment.

Syntax

```
SQLRETURN SQLProcedureColumns(
    SQLHSTMT      StatementHandle,
    SQLCHAR *     CatalogName,
    SQLSMALLINT   NameLength1,
    SQLCHAR *     SchemaName,
    SQLSMALLINT   NameLength2,
    SQLCHAR *     ProcName,
    SQLSMALLINT   NameLength3,
    SQLCHAR *     ColumnName,
    SQLSMALLINT   NameLength4);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the name of the procedure catalog. If the driver does not support the catalog, it returns an empty string ("") and the procedure does not include catalog. CatalogName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, CatalogName is treated as an ordinary argument literal, and it is case sensitive. For more information, refer to Arguments of Catalog Function.

NameLength1

[Input] It is the length of *CatalogName in characters.

SchemaName

[Input] It is the name of procedure schema. It is the string search pattern for the schema name. If t he driver does not support the schema, it returns an empty string ("") and the procedure does not i nclude the schema. SchemaName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, SchemaName is treated as a pattern value string argum ent, and it is case sensitive.

NameLength2

[Input] It is the length of *SchemaName in characters.

ProcName

[Input] It is the procedure name. This argument can not be a null pointer. ProcName can not includ e the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, ProcName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, ProcName is treated as an ordinary literal, and it is not case sensitive.

NameLength3

[Input] It is the length of *ProcName in characters.

ColumnName

[Input] It is the column name. This argument can not be a null pointer. ColumnName can not inclu de the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, ColumnName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, ColumnName is treated as an ordinary literal, and it is n ot case sensitive.

NameLength4

[Input] It is the length of *ColumnName in characters.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUC CESS_WITH_INFO.)

SQLSTATE	Error	Description
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	The cursor is open in StatementHandle, and SQLFetch or SQLFetchScroll is called. If SQLFetch or SQLFetchScroll returns SQL_NO_DATA, the driver returns this error. If SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, the driver manager returns this error. The result set is open in StatementHandle, but SQLFetch or SQLFetchScroll is not called.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other transactions.
40003	Statement completion unknown	The related connection fails during the function execution and the status of the transaction is not able to be checked.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	TableName argument is a null pointer. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and CatalogName argument is a null pointer. SQLGetInfo with the SQL_CATALOG_NAME information type returns that catalog names are supported. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and SchemaName, ProcName or ColumnName argument is a null pointer.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still executing when SQLProcedureColumns is called. SQLExecute, SQLExecDirect, or SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. This function is called before the data is checked for all connected parameters. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns. The asynchronously executing function is called for StatementHandle, and is still being executed when this function is called.
HY090	Invalid string or buffe	A name length argument value is smaller than 0 but it is not as same as SQL_NTS.

SQLSTATE	Error	Description
	r length	A name length argument value is bigger than the maximum length correspon ding to the name.
HY117	Connection is suspen ded due to unknown transaction state. Onl y disconnect and rea d-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The catalog is specified, but the driver or the data source does not support th e catalog. The schema is specified, but the driver or the data source does not support th e schema. The combination of current setting of SQL_ATTR_CONCURRENCY and SQL_A TTR_CURSOR_TYPE statement attributes is not supported by the driver or dat a source. SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABL E, and SQL_ATTR_CURSOR_TYPE statement attribute is set to the cursor type for the bookmark that is not supported by the driver.
HYT00	Timeout expired	The query timeout is expired before getting the result set from the data sourc e. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAtt r.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. Th e timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtA ttr.
IM001	Driver does not supp ort this function	The driver which is related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notific ation mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync h as not been called to complete the previou s asynchronous oper ation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING an d if the notification mode is activated, then SQLCompleteAsync should be call ed for the handle to do post processing and complete the operation.

Description

SQLProcedureColumns returns the list of input output parameters and the columns which configure the r esult set of the specified procedure. The driver returns information as the result set for the specified state ment.

SQLProcedureColumns returns the results as a standard result set, sorted in an order of PROCEDURE_CAT, PROCEDURE_SCHEM, PROCEDURE_NAME, COLUMN TYPE. Column names are returned in an order of e ach parameter name (in call order) and the name of each column in the result set returned by the proced ure.

SQLGetInfo is called together with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME, SQL_ MAX_PROCEDURE_NAME_LEN options in an application to determine the actual column length of PROC EDURE_CAT, PROCEDURE_SCHEM, PROCEDURE_NAME, COLUMN_NAME.

The names in the following columns are changed in ODBC 3.x. The column name change does not affect compatibility with the previous version because the application binds by the column number.

ODBC 2.0 column	ODBC 3.x column
PROCEDURE_QUALIFIER	PROCEDURE_CAT
PROCEDURE_OWNER	PROCEDURE_SCHEM
PRECISION	COLUMN_SIZE
LENGTH	BUFFER_LENGTH
SACLE	DECIMAL_DIGITS
RADIX	NUM_PREC_RADIX

In ODBC 3.x, the following columns are added to the result set returned by SQLProcedureColumns.

- COLUMN_DEF
- DATETIME_CODE
- CHAR_OCTET_LENGTH
- ORDINAL_POSITION
- IS_NULLABLE

The following table lists the columns in the result set. The additional row after column 19 (IS_NULLABLE) is defined by the driver. The applications should get access to a specific driver column by performing the c ountdown from the end of the result set instead of specifying an explicit ordinal position.

Column name	Column number	Data type	Description
PROCEDUR E_CAT (ODB	1	Varchar	It is the procedure catalog name. If it can not be used in the data sourc e, it is NULL. If the driver supports the catalog only for some tables, suc

Column name	Column number	Data type	Description
C 2.0)			h as when the drive retrieves the data from another DBMS, it returns a n empty string ("") for the table which does not have a catalog.
PROCEDURE_SCHEM (ODBC 2.0)	2	Varchar	It is the procedure schema name. If it can not be used in the data sourc e, it is NULL. If the driver supports the schema only for some table, suc h as when the drive retrieves the data from another DBMS, it returns a n empty string ("") for the table which does not have a schema.
PROCEDURE_NAME (ODBC 2.0)	3	Varchar not NULL	It is the procedure name. If the procedure does not have a name, then i t returns an empty string.
COLUMN_NAME (ODBC 2.0)	4	Varchar not NULL	It is the procedure column name. If the procedure does not have a nam e, then the driver returns an empty string.
COLUMN_TYPE (ODBC 2.0)	5	Smallint not NULL	It defines the procedure types. • SQL_PARAM_TYPE_UNKNOWN: The procedure column type is no t known. (ODBC 1.0) • SQL_PARAM_INPUT: The procedure column is an input parameter. (ODBC 1.0) • SQL_PARAM_INPUT_OUTPUT: The procedure column is an input/ output parameter. (ODBC 1.0) • SQL_PARAM_OUTPUT: The procedure column is an output param eter. (ODBC 2.0) • SQL_RETURN_VALUES: The procedure column is a return value of the procedure. (ODBC 2.0) • SQL_RESULT_COL: The procedure column is a column of result set. (ODBC 1.0)
DATA_TYPE (ODBC 1.0)	6	Smallint not NULL	It is SQL data type. For datetime and interval data type, this column ret urns a concise data type such as SQL_TYPE_DATE, SQL_INTERVAL_YEA R_TO_MONTH.
TYPE_NAME (ODBC 2.0)	7	Varchar not NULL	It is the name of a data source dependent data type. For example, it is CHAR(), VARCHAR(), MONEY, LONG VARBINARY or CHAR ( ) FOR BIT DATA. An application should use this name in CREATE TABLE and ALT ER TABLE statement.
COLUMN_SIZE (ODBC 2. 0)	8	Integer	It is the maximum column size of the data type supported by the server. The maximum precision is returned for the numeric data type, string da ta type returns return the character length, DATATIME data type return s the length of expressed character, INTERVAL data type returns the ch aracter length of literal INTERVAL character, and the datatype to which the column size is not applicable returns NULL.
BUFFER_LENGTH (ODBC 1.0)	9	Integer	It is the byte length transferred from SQLGetData or SQLFetch operatio n when SQL_C_DEFAULT is specified. The size of numeric data can be different from that of the data stored in the data source. For a string or a binary data, this value is as same as COLUMN_SIZE column.

Column name	Column number	Data type	Description
DECIMAL_DIGITS (ODBC 1.0)	10	Smallint	It is the practional digit in a column of the data source. If the decimal place of the data type can not be applicable, it returns NULL.
NUM_PREC_RADIX (ODBC 2.0)	11	Smallint	It is 2 or 10 for a numeric data type. If it is 2, COLUMN_SIZE and DECIMAL_DIGITS are number of bits allowed for a column. If it is 10, COLUMN_SIZE and DECIMAL_DIGITS are number of digits allowed for a column. The data type to which NUM_PREC_RADIX can not be applicable returns NULL.
NULLABLE (ODBC 2.0)	12	Smallint not NULL	It is whether the data type allows NULL value. If it is SQL_NULLABLE, the data type allows NULL value. If it is SQL_NO_NULLS, the data type does not allow NULL value. If it is SQL_NULLABLE_UNKNOWN, it is unknown if the column allows NULL value.
REMAKRS (ODBC 2.0)	13	Varchar	It is a description about the procedure column.
COLUMN_DEF (ODBC 3.0)	14	Varchar	It is the default value of a column. If this value is enclosed in double quotes, then this column should be interpreted as a string.
SQL_DATA_TYPE (ODBC 3.0)	15	Smallint not NULL	It is the SQL data type value appears in the SQL_DESC_TYPE field of a descriptor. This column is as same as DATA_TYPE column, except for INTERVAL and DATETIME data type. For INTERVAL and DATETIME data types, SQL_DATE_TYPE field in the result set returns SQL_INTERVAL or SQL_DATETIME, and SQL_DATETIME_SUB field returns the subcode for INTERVAL or DATETIME data type.
SQL_DATETIME_SUB (ODBC 3.0)	16	Smallint	It is the subtype code ofdatetime and interval data types. It returns NULL for other data types.
CHAR_OCTET_LENGTH (ODBC 3.0)	17	Integer	It is the maximum length in byte of character or binary data type column. It returns NULL for other data types.
ORDINAL_POSITION (ODBC 3.0	18	Integer not NULL	It is the column location in a table.
IS_NULLABLE (ODBC 3.0)	19	Varchar	• "YES": A column can include NULL. • "NO": A column can not include NULL. • It returns a string whose length is 0 when it is unknown whether to allow NULL.

SQLProcedures

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLProcedures returns the list of procedure names stored in the specified data source. Procedure is a general term used to describe a named object which can be called by using the executable object or input and output parameter.

Syntax

```
SQLRETURN SQLProcedures(
    SQLHSTMT       StatementHandle,
    SQLCHAR *      CatalogName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      SchemaName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      ProcName,
    SQLSMALLINT    NameLength3);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the name of the procedure catalog. If the driver does not support the catalog, it returns an empty string ("") and the procedure does not include catalog. CatalogName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, CatalogName is treated as an ordinary argument literal, and it is case sensitive. For more information, refer to **Arguments of Catalog Function**.

NameLength1

[Input] It is the length of *CatalogName in characters.

SchemaName

[Input] It is the name of procedure schema. The string search pattern for the schema name. If the d river does not support the schema, it returns an empty string ("") and the procedure does not inclu de the schema. SchemaName can not include the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, SchemaName is treated as a pattern value string argum ent, and it is case sensitive.

NameLength2

[Input] It is the length of *SchemaName in characters.

ProcName

[Input] It is the procedure name. This argument can not be a null pointer. ProcName can not includ e the string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, ProcName is treated as an identifier, and it is not case sensitive. If it is set to SQL_FALSE, ProcName is treated as a pattern value string argument, an d it is case sensitive.

NameLength3

[Input] It is the length of *ProcName in characters

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDL E.

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUC CESS_WITH_INFO.)
08S01	Communication link f ailure	Before the function processing is completed, the connection between the driv er and the data source is failed.
24000	Invalid cursor state	The cursor is open in StatementHandle, and SQLFetch or SQLFetchScroll is call ed. If SQLFetch or SQLFetchScroll returns SQL_NO_DATA, the driver returns this e rror. If SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, the driver manager returns this error. The result set is open in StatementHandle, but SQLFetch or SQLFetchScroll is not called.
		The transaction is rolled back due to a resource deadlock of other transaction

SQLSTATE	Error	Description
40001	Serialization failure	s.
40003	Statement completio n unknown	The related connection fails during the function execution and the status of t he transaction is not able to be checked.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation er ror	It is a memory allocation error.
HY009	Invalid use of null poi nter	TableName argument is a null pointer. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and Catal ogName argument is a null pointer. SQLGetInfo with the SQL_CATALOG_NAME information type returns that cat alog names are supported. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and Sche maName, ProcName or ColumnName argument is a null pointer.
HY010	Function sequence er ror	The asynchronously executing function is called for the connection handle rel ated to StatementHandle, and this function is still being executed when SQLP rocedureColumns is called. SQLExecute, SQLExecDirect, or SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. This function is called befor e the data is checked for all connected parameters. The asynchronously executing function is called for StatementHandle, and is s till being executed when this function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for Stat ementHandle, and SQL_NEED_DATA is returned. This function is called befor e data is sent for all data-at-execution parameters or columns.
HY013	Memory manageme nt error	The internal memory can not be accessed or the available memory size is smal l.
HY090	Invalid string or buffe r length	A name length argument value is smaller than 0 but it is not as same as SQL_ NTS. A name length argument value is bigger than the maximum length correspon ding to the name.
HY117	Connection is suspen ded due to unknown transaction state. Onl y disconnect and rea d-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
		The catalog is specified, but the driver or the data source does not support th

SQLSTATE	Error	Description
HYC00	Optional feature not implemented	e catalog. The schema is specified, but the driver or the data source does not support th e schema. The combination of current setting of SQL_ATTR_CONCURRENCY and SQL_A TTR_CURSOR_TYPE statement attributes is not supported by the driver or dat a source. SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABL E, and SQL_ATTR_CURSOR_TYPE statement attribute is set to the cursor type for the bookmark that is not supported by the driver.
HYT00	Timeout expired	The query timeout is expired before getting the result set from the data sourc e. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAtt r.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. Th e timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtA ttr.
IM001	Driver does not supp ort this function	The driver which is related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notific ation mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync h as not been called to complete the previou s asynchronous oper ation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING an d if the notification mode is activated, then SQLCompleteAsync should be call ed for the handle to do post processing and complete the operation.

Description

SQLProcedures lists all procedures in the requested range. A user may or may not have privileges to execu te these procedures. Refer SQL_ACCESSIBLE_PROCEDURES of SQLGetInfo to check accessibility. If a user selects the procedure which can not be executed, the application should be able to handle the situation. SQLProcedures returns the standard result set, and it is sorted in an order of PROCEDURE_CAT, PROCED URE_SCHEMA, PROCEDURE_NAME

The following column names are changed in ODBC 3.x. The column name change does not affect the co mpatibility with the previous version because the application binds by the column number.

ODBC 2.0 column	ODBC 3.x column

ODBC 2.0 column	ODBC 3.x column
PROCEDURE_QUALIFIER	PROCEDURE_CAT
PROCEDURE_OWNER	PROCEDURE_SCHEM

SQLGetInfo is called together with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME, SQL_MAX_PROCEDURE_NAME_LEN options in an application to determine the actual column length of PROCEDURE_CAT, PROCEDURE_SCHEM, PROCEDURE_NAME, COLUMN_NAME

The following table lists the columns in the result set. The additional row after column 8 (PROCEDURE_TYPE) is defined by the driver. The applications should get access to a specific driver column by performing the countdown from the end of the result set instead of specifying an explicit ordinal position.

Column name	Column number	Data type	Comments
PROCEDURE_CAT (ODBC 2.0)	1	Varchar	It is the procedure catalog name. If it can not be used in the data source, it is NULL. If the driver supports the catalog only for some tables, such as when the drive retrieves the data from another DBMS, it returns an empty string ("") for the table which does not have a catalog.
PROCEDURE_SCHEM (ODBC 2.0)	2	Varchar	It is the procedure schema identifier. If it can not be used in the data source, it is NULL. If the driver supports the schema only for some table, such as when the drive retrieves the data from another DBMS, it returns an empty string ("") for the table which does not have a schema.
PROCEDURE_NAME (ODBC 2.0)	3	Varchar not null	It is the procedure identifier.
REMARK (ODBC 2.0)	4	Varchar	It is the description on the procedure.
PROCEDURE_TYPE (ODBC 2.0)	5	Smallint	It defines a procedure type. • SQL_PT_UNKNOWN: Where the procedure returns the value or not is unknown. • SQL_PT_PROCEDURE: The returned object is a procedure. In other words, a return value does not exist. • SQL_PT_FUNCTION: The returned object is a function. In other words, a return value exists.

SQLPutData

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLPutData allows the application to transfer a parameter to the driver or transfer the data to a column at statement execution time.
The function can be used to transfer a character or binary data value in parts to a column with a character, binary, or data source specific data type (For example, the parameter of SQL_LONGVARBINARY or SQL_LONGVARCHAR types).
Even if the default driver does not support unicode, SQLPutData supports the binding to Unicode C data types.

Syntax

```
SQLRETURN SQLPutData(
    SQLHSTMT     StatementHandle,
    SQLPOINTER   DataPtr,
    SQLLEN       StrLen_or_Ind);
```

Arguments

StatementHandle

[Input] It is the statement handle.

DataPtr

[Input] It is the buffer pointer which includess the actual data for the parameter or column. The data should be the C data types specified by ValueType argument of SQLBindParameter (parameter data) or TargetType argument of SQLBindCol (column data).

StrLen_or_Ind

[Input] It is the length of *DataPtr. It specifies the amount of data transferred to SQLPutData call. The amount of data can be varied depending on each call to the given parameter or the column. StrLen_or_Ind is ignored if one of the following conditions is not satisfied.

- StrLen_or_Ind is SQL_NTS, SQL_NULL_DATA, or SQL_DEFAULT_PARAM.

• The C data type that is specified in SQLBindParameter or SQLBindCol is SQL_C_CHAR or SQL_C_BINARY.

• The C data type is SQL_C_DEFAULT, and the default C data type for the specified SQL data type is SQL_C_CHAR or SQL_C_BINARY.

For all other types of C data, if StrLen_or_Ind is not SQL_NULL_DATA or SQL_DEFAULT_PARAM, the driver determines that the size of *DataPtr is the size of C data type specified in ValueType or TargetType, and transfers the entire data value.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The string or binary data returned to the input/output or output parameters are truncated. If a string is truncated, the right part of the string is truncated. (The function returns SQL_SUCCESS_WITH_INFO.)
07006	Restricted data type attribute violation	The data value identified by the ValueType argument in SQLBindParameter for the bound parameter can not be converted to the data type identified by the ParameterType argument in SQLBindParameter.
07S01	Invalid use of default parameter	The parameter value set in SQLBindParameter is SQL_DEFAULT_PARAM, and the corresponded parameter does not have the default value.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
22001	String data, right truncation	The string or binary data is truncated. SQL_NEED_LONG_DATA_LEN information type is "Y" in SQLGetInfo, and more data is transferred for a long parameter than is specified with StrLen_or_IndPtr argument in SQLBindParameter. SQL_NEED_LONG_DATA_LEN information type is "Y" in SQLGetInfo, and more data is transferred for a long column than is specified in the buffer length corresponding to the data rows which are added or updated with SQLBulkOperation or updated with SQLSetPos.
22003	Numeric value out of range	The bound numeric parameter or the data which is transferred to the column causes the truncation for the numeric value when the related table column is allocated. The numeric value which is returned for the input/output parameter or output parameter is truncated.

SQLSTATE	Error	Description
22007	Invalid datetime format	The data sent for a parameter or column which is bound to a date, time, or timestamp structure is invalid for each type. An input/output or output parameter is bound to a date, time, or timestamp C structure, and a value in the returned parameter is invalid for each type. (The function returns SQL_SUCCESS_WITH_INFO.)
22008	Datetime field overflow	DATETIME expression is not valid for the bound DATE, TIME or TIMESTAMP C structure.
22012	Division by zero	An arithmetic expression calculated for an input/output or output parameter is in divided by zero.
22015	Interval field overflow	The significant digits are lost due to the data transfer for an exact numeric or interval column or parameter to an interval SQL data type. The data transferred to one or more INTERVAL columns or parameters is converted into a numeric data type, but it can not be expressed as a numeric data type. The data transferred for the column or parameter data is assigned to INTERVAL SQL type, but it can not be expressed as the value of C type in INTERVAL SQL type. The significant digits of the data transferred for the exact number or the INTERVAL C column or parameter are lost. The data transferred for the column or parameter data is assigned to INTERVAL C type, but it can not be expressed as INTERVAL data structure.
22018	Invalid character value for cast specification	The character not represented as the character set of C buffer is included in the character column of the result set. The C type is the exact or approximate numeric, datetime, interval data type, and if the SQL type is the character data type, then the value of the column bound to the C type is invalid.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then, this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before this function is called and completed.
HY009	Invalid use of null	DataPtr argument is a null pointer, and StrLen_or_Ind argument is neither S

SQLSTATE	Error	Description
	pointer	QL_DEFAULT_PARAM nor SQL_NULL_DATA.
HY010	Function sequence error	The previous function is not a call to SQLPutData or SQLParamData. The asynchronously executing function is called for the connection handle related to StatementHandle, but it is still being asynchronously executed when SQLPrimaryKeys is called. The asynchronously executing function is called for StatementHandle, but it is still being asynchronously executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos is called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The internal memory can not be accessed or the available memory size is small.
HY019	Non-character and non-binary data sent in pieces	SQLPutData is called for the parameter or column one or more times, and it is not used to transfer the character C data to a column with the character, the binary or the data source-specific data type, or to transfer the binary C data to a column with the character, the binary or the data source-specific data type.
HY020	Attempt to concatenate a null value	SQLPutData is called once or more after SQL_NEED_DATA is returned, and StrLen_or_Ind argument includes SQL_NULL_DATA or SQL_DEFAULT_PARAM in one of these calls.
HY090	Invalid string or buffer length	DataPtr argument is not a null pointer, and StrLen_or_Ind is not equal to SQL_NTS or SQL_NULL_DATA, or is smaller than than 0.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
	SQLCompleteAsy	

SQLSTATE	Error	Description
IM018	nc has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SQLPutData can be called to provide data-at-execution data for two uses. One is to use it as parameter data when calling SQLExecute or SQLExecDirect. The other is to use it as column data when updating or adding a row by calling SQLBulkOperations, or when updating a row by calling SQLSetPos.

When the application calls SQLParamData to determine which data should be transferred, the driver returns an indicator that the application can use to determine which parameter data to send or where column data can be found. The function also returns SQL_NEED_DATA which is an indicator to the application that it should call SQLPutData to transfer the data. In the DataPtr argument to SQLPutData, the application passes a pointer to the buffer including the actual data for the parameter or column.

When the driver returns SQL_SUCCESS for SQLPutData, the application calls SQLParamData again. For transferring more data, SQLParamData returns SQL_NEED_DATA, and the application calls SQLPutData again. If all data-at-execution data are transferred, SQL_SUCCESS is returned. And then the application calls SQLParamData again. If the driver returns SQL_NEED_DATA and another marker in *ValuePtrPtr, then it requests the data for other parameter or column and calls SQLPutData again. If the driver returns SQL_SUCCESS, then all data-at-execution data are transferred, and the SQL statement can be executed or SQLBulkOperations or SQLSetPos can be processed.

The application is allowed to use SQLPutData only when the character C data or binary C data is transferred to the character, binary or data source specific data type. If SQLPutData is called once or more under different conditions, SQL_ERROR and SQLSTATE HY019 are returned. (Non-character and non-binary data sent in pieces)

SQLRowCount

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLRowCount returns the number of rows whih are affected by UPDATE, INSERT, or DELETE statement. (SQL_ADD, SQL_UPDATE_BY_BOOKMARK or SQL_DELETE_BY_BOOKMARK operation in SQLBulkOperations. Or SQL_UPDATE or SQL_DELETE operation in SQLSetPos)

Syntax

```
SQLRETURN SQLRowCount(
    SQLHSTMT    StatementHandle,
    SQLLEN *    RowCountPtr);
```

Arguments

StatementHandle

[Input] It is the statement handle.

RowCountPtr

[Output] It is the buffer pointer to which the number of rows is to be returned. For UPDATE, INSERT, DELETE statements, for the SQL_ADD, SQL_UPDATE_BY_BOOKMARK, SQL_DELETE_BY_BOOKMARK operations in SQLBulkOperations, and for the SQL_UPDATE or SQL_DELETE operations in SQLSetPos, the value returned to *RowCountPtr is the number of rows affected by the request. Or, it is -1 if the number of affected rows is not available.

When SQLExecute, SQLExecDirect, SQLBulkOperations, SQLSetPos or SQLMoreResults is called, SQL_DIAG_ROW_COUNT field of the diagnostic data structure is set to the number of rows, and the number of rows are cached in a way that depends on the implementation. SQLRowCount returns the number of cashed rows. The number of cashed rows are valid until when the statement handle is set again in the prepared or assigned state, or when the statement is executed again or when SQLCloseCursor is called. If SQL_DIAG_ROW_COUNT field is set and the function is called, then SQL_DIAG_ROW_COUNT field is set to 0 by calling any function, and the return value by SQLRowCount can be different from the value in SQL_DIAG_ROW_COUNT field.

For other statements and functions, the driver can define the value returned in *RowCountPtr. For

example, some data source can return the number of rows returned by SELECT statement before r ows are patched.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_S UCCESS_WITH_INFO.)
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLRowCount is called. SQLExecute, SQLExecDirect, SQLMoreResults is called for StatementHandl e, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called before data is retrieved for all streamed parameters. The function is called for StatementHandle, before SQLExecute, SQLExecD irect, SQLBulkOperations, or SQLSetPos is called. The asynchronously executing function is called for StatementHandle, and this function is still being executed when this function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called fo r StatementHandle, and SQL_NEED_DATA is returned. This function is call ed before data is sent for all data-at-execution parameters or columns.
HY013	Memory management er ror	The internal memory can not be accessed or the available memory size is s mall.
HY117	Connection is suspended due to unknown transac tion state. Only disconne ct and read-only functio ns are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT00	Timeout expired	The query timeout is expired before getting the entire result set from the data source. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of S QLSetStmtAttr.
HYT01	Connection timeout expi	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSet

SQLSTATE	Error	Description
	red	StmtAttr.
IM001	Driver does not support t his function	The driver which is related to StatementHandle does not support the func tion.

Description

If the last SQL statement executed for the statement handle is not UPDATE, INSERT, DELETE, or if an oper ation argument of the previous SQLBulkOperations call is not SQL_ADD, SQL_UPDATE_BY_BOOKMARK, SQL_DELETE_BY_BOOKMARK or if an operation argument of the previous SQLSetPos call is not SQL_UP DATE, SQL_DELETE, then the value of *RowCountPtr is defined by the driver.

SQLSetConnectAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLSetConnectAttr sets the attribute which controls the connection.

Syntax

```
SQLRETURN SQLSetConnectAttr(
    SQLHDBC       ConnectionHandle,
    SQLINTEGER    Attribute,
    SQLPOINTER    ValuePtr,
    SQLINTEGER    StringLength);
```

Arguments

ConnectionHandle

[Input] It is the connection handle.

Attribute

[Input] It is the attribute for setting.

ValuePtr

[Input] It is the pointer of the value related to attribute. According to the value of attribute, ValueP tr can be an unsigned integer or it points to a null-termination string. The integer type of attribute argument may not be the fixed length data type. For more information, refer to the Description sec tion.

StringLength

[Input] If attribute is the ODBC-defined attribute and ValuePtr points to the string or binary buffer, then the argument should be the length of *ValuePtr. For string data, the argument should includ e the number of bytes of the string.

If attribute is the ODBC-defined attribute and ValuePtr is an integer, then StringLength is ignored.

If attribute is the driver-defined attribute, then the application indicates the attribute characteristics set by StringLength argument to the driver manager. StringLength may have one of the following v

alues:

• If ValuePtr is a string pointer, StringLength is the string length or SQL_NTS.

• If ValuePtr is a binary buffer pointer, the application stores the result of SQL_LEN_BINARY_ATTR (length) macro which is a negative value in StringLength.

• If ValuePtr is neither string pointer nor binary buffer pointer, StringLength must have SQL_IS_POINTER.

• If ValuePtr contains the fixed length value, StringLength is SQL_IS_INTEGER or SQL_IS_UINTEGER.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE, SQL_STILL_EXECUTING

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value changed	The value specified in ValuePtr is not supported by the driver and it is replaced with a similar value. (The function returns SQL_SUCCESS_WITH_INFO.)
08002	Connection name in use	Attribute argument is SQL_ATTR_ODBC_CURSORS, and the driver is already connected to the data source.
08003	Connection not open	Attribute value is assigned to request an open connection, but ConnectionHandle is not in a connected state.
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	Attribute argument is SQL_ATTR_CURRENT_CATALOG, and the result set is deferred.
25000	Illegal operation while in a local transaction	The local transaction is connected while attempting to connect the distributed transaction by setting of the connection attribute SQL_ATTR_ENLIST_IN_DTC. The connection to the distributed transaction is already enlisted. The connection to the distributed transaction is already enlisted, the local transaction is started by setting SQL_ATTR_AUTOCOMMIT to SQL_AUTOCOMMIT_OFF.
3D000	Invalid catalog name	Attribute argument is SQL_ATTR_CURRENT_CATALOG and the specified catalog name is not valid.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocatio	It is a memory allocation error.

SQLSTATE	Error	Description
	n error	
HY008	Operation cancel ed	The asynchronous processing is activated for ConnectionHandle. The SQLSe tConnectAttr function is called, and before it completes execution, the SQL CancelHandle function is called on the ConnectionHandle, and then the SQ LSetConnectAttr function is called again on the ConnectionHandle. Or, SQLSetConnectAttr function is called, and before it completes execution, SQLCancelHandle is called on the ConnectionHandle from a different thread in a multithread application.
HY009	Invalid use of null pointer	Attribute argument identifies the connection attribute which requires the st ring value, and ValuePtr argument is a null pointer.
HY010	Function sequenc e error	The asynchronously executing function is called for the statementHandle rel ated to ConnectionHandle, and this function is still being executed when SQ LSetConnectAttr is called. The asynchronously executing function is called for the ConnectionHandle, and this function is still being executed when this function is called. SQLExecute, SQLExecDirect, SQLMoreResults is called for one of Statement Handle related to ConnectionHandle, and SQL_PARAM_DATA_AVAILABLE i s returned. The function is called before data is retrieved for all streamed pa rameters. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle related to ConnectionHandle, and SQL_NEED_DATA is ret urned. This function is called before data is sent for all data-at-execution par ameters or columns. SQLBrowseConnect is called for ConnectionHandle, and SQL_NEED_DATA i s returned. The function is called before SQLBrowseConnect returns SQL_SU CCESS_WITH_INFO or SQL_SUCCESS.
HY011	Attribute cannot be set now	Attribute argument is SQL_ATTR_TXN_ISOLATION, and the transaction is op en.
HY013	Memory manage ment error	The internal memory can not be accessed or the available memory size is sm all.
HY024	Invalid attribute v alue	The specified Attribute value is assigned, and the invalid value is specified to ValuePtr. Attribute argument is SQL_ATTR_TRACEFILE or SQL_ATTR_TRANSLATE_LIB, and ValuePtr is an empty string.
HY090	Invalid string or b uffer length	ValuePtr is a string and StringLength argument is smaller than 0 but it is not SQL_NTS.
	Driver does not s upport connectio	The application tries to activate asynchronous execution with SQL_ATTR_AS

SQLSTATE	Error	Description
HY114	n-level asynchron ous function exe cution	YNC_DBC_FUNCTIONS_ENABLE when the driver does not support asynchro nous connection.
HY117	Connection is sus pended due to u nknown transacti on state. Only dis connect and read -only functions ar e allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HY121	Cursor Library an d Driver-Aware P ooling cannot be enabled at the sa me time	It is not supported by the driver.
HYC00	Optional feature not implemented	The value specified for Attribute argument is valid for the ODBC connection or the statement attribute for the version supported by the driver, but it is n ot supported by the driver.
HYT01	Connection time out expired	The connection is expired before the data source responds to the request. T he timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStm tAttr.
IM001	Driver does not s upport this functi on	The driver which is related to ConnectionHandle does not support the functi on.
IM009	Unable to load tr anslation DLL	The driver can not load the transaction DDL specified for the connection. Th e error can be returned only when attribute is SQL_ATTR_TRANSLATE_LIB.
IM017	Polling is disable d in asynchronou s notification mo de	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsy nc has not been called to complet e the previous as ynchronous oper ation on this han dle.	If the previous function call for the handle returns SQL_STILL_EXECUTING a nd if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.
S1118	Driver does not s upport asynchron ous notification	SQL_ATTR_ASYNC_DBC_EVENT is set but the asynchronous notification is n ot supported by the driver.

Description

The application can call SQLSetConnectAttr at any time between the connection is assigned and released. All connections and the statement attributes set by the application for connection are maintained until SQLFreeHandle is called. For example, if an application calls SQLSetConnectAttr before connecting to a data source, the attribute is maintained even when SQLSetConnectAttr fails in the driver when the application connects to the data source. If the application sets the driver-specific attribute then the attribute is maintained even when the application connects to a different driver.

The feature to set the statement attribute at the connection level by SQLSetConnectAttr call is not used in ODBC 3.x. ODBC 3.x application should not set the statement attribute at the connection level. ODBC 3.x application can not set the statement attributes except for SQL_ATTR_METADATA_ID and SQL_ATTR_ASYNC_ENABLE attributes at the connection level. The two attributes are both the connection attribute and statement attribute and they can be set at the connection level or statement level. If ODBC 3.x driver operates with ODBC 2.x application which sets the ODBC 2.x statement option at the connection level, the ODBC 3.x driver is required to support it.

Some connection attributes can be set only before the connection is made, and some other attributes can be set only after the connection is made. The following table describes these connection attributes.

Attribute	Whether it is set before or after connection
SQL_ATTR_ACCESS_MODE	Either[1]
SQL_ATTR_ASYNC_DBC_EVENT	Either
SQL_ATTR_ASYNC_DBC_FUNCTIONS_ENABLE	Either[4]
SQL_ATTR_ASYNC_DBC_PCALLBACK	Either
SQL_ATTR_ASYNC_DBC_PCONTEXT	Either
SQL_ATTR_ASYNC_ENABLE	Either[2]
SQL_ATTR_AUTO_IPD	Either
SQL_ATTR_AUTOCOMMIT	Either[5]
SQL_ATTR_CONNECTION_DEAD	After
SQL_ATTR_CONNECTION_TIMEOUT	Either
SQL_ATTR_CURRENT_CATALOG	Either[1]
SQL_ATTR_DBC_INFO_TOKEN	After
SQL_ATTR_ENLIST_IN_DTC	After
SQL_ATTR_LOGIN_TIMEOUT	Before
SQL_ATTR_METADATA_ID	Either
SQL_ATTR_OLDPWD	Before
SQL_ATTR_ODBC_CURSORS	Before
SQL_ATTR_PACKET_SIZE	Before

Attribute	Whether it is set before or after connection
SQL_ATTR_QUIET_MODE	Either
SQL_ATTR_TRACE	Either
SQL_ATTR_TRACEFILE	Either
SQL_ATTR_TRANSLATE_LIB	After
SQL_ATTR_TRANSLATE_OPTION	After
SQL_ATTR_TXN_ISOLATION	Either[3]

[1]SQL_ATTR_ACCESS_MODE and SQL_ATTR_CURRENT_CATALOG can be set before and after the connection according to the driver. But the application which uses multiple drivers should be set before the connection because these changes are not supported after the connection depending on the driver.

[2]SQL_ATTR_ASYNC_ENABLE should be set before the statement is activated.

[3]SQL_ATTR_TXN_ISOLATION can be set only when there is not any open transaction on the connection. Some connection attributes is supported by replacing with the similar value if the data source does not support the value specified by *ValuePtr. In this case, the driver returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value changed). For example, if Attribute is SQL_ATTR_PACKET_SIZE and *ValuePtr exceeds the maximum packet size, the driver replaces it with the maximum packet size, the application calls SQLSetConnectAttr to check the replaced value.

[4] If SQL_ATTR_ASYNC_DBC_FUNCTIONS_ENABLE is set before the connection is open, the driver manager sets the driver attribute when the driver is loaded while SQLBrowseConnect, SQLConnect, or SQLDriverConnect is called. Before SQLBrowseConnect, SQLConnect, or SQLDriverConnect is called, the driver manager does not know which driver is connected and does not know whether the driver supports the asynchronous operation for connection. Therefore, the driver manager returns SQL_SUCCESS. However if the driver does not support the asynchronous operation for connection, then calling SQLBrowseConnect, SQLConnect, or SQLDriverConnect will fail.

[5] If SQL_ATTR_AUTOCOMMIT is set to FALSE and API returns SQL_ERROR, the application should call SQLEndTran (SQL_ROLLBACK) to guarantee the transaction consistency.

Information type in *ValuePtr buffer depends on the specified attribute. SQLSetConnectAttr accepts one of the null-termination character or integer value as attribute information. The character string indicated to by the ValuePtr argument of SQLSetConnectAttr has StringLength bytes length.

If the length is defined in the attribute, StringLength argument is ignored as is the case of all attributes introduced in ODBC 2.x or the previous version.

Attribute	ValuePtr contents
	It is an SQLUINTEGER value. SQL_MODE_READ_WRITE is the default value. SQL_MODE_READ_ONLY is used in the driver or data source as an indicator of which the conn

Attribute	ValuePtr contents
SQL_ATTR_ACCESS_MODE (ODBC 1.0)	ection is not requested to support SQL statement which causes update to occur. The mode can be used to optimize the proper lock strategy, transaction management or other area for the driver or the data source. The driver is not required to prevent such information which is sent to the data source. The behavior of the driver and data source when asked to process SQL statements which are not read-only during a read-only connection is implementation-defined.
SQL_ATTR_ASYNC_DBC_EVENT (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_DBC_FUNCTIONS_ENABLE (ODBC 3.8)	It is an SQLUINTERGER value which activates or deactivates asynchronous execution of selected functions on the connection handle. • SQL_ASYNC_DBC_ENABLE_ON: It activates an asynchronous operation for the function related to the specified connection. • SQL_ASYNC_DBC_ENABLE_OFF: It deactivates an asynchronous operation for the function related to the specified connection. SQL_ATTR_ASYNC_DBC_FUNCTIONS_ENABLE setting is always synchronous. (SQL_STILL_EXECUTING is not returned.) Asynchronous execution of the statement is activated by SQL_ATTR_ASYNC_ENABLE.
SQL_ATTR_ASYNC_DBC_PCALLBACK (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_DBC_PCONTEXT (ODBC 3.8)	It is not supported by the driver..
SQL_ATTR_ASYNC_ENABLE (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_AUTO_IPD (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_AUTOCOMMIT (ODBC 1.0)	It is an SQLUINTEGER value which specifies whether to use the auto-commit or manual commit mode. • SQL_AUTOCOMMIT_OFF: The driver uses the manual commit mode, and the application should explicitly commit or roll back the transaction with SQLEndTran. • SQL_AUTOCOMMIT_ON: The driver uses the auto-commit mode. Each statement is immediately executed and committed. All open transactions in the connection are committed when SQL_ATTR_AUTOCOMMIT is set to SQL_AUTOCOMMIT_ON. Some data sources remove the access plan at the time of when the statement is committed to the connection and close the cursor. It may occur in auto commit mode after each non-query statements are executed or after the cursor is closed for the query. For more information, refer to SQL_CURSOR_COMMIT_BEHAVIOR and SQL_CURSOR_ROLLBACK_BEHAVIOR information type of **SQLGetInfo**.

Attribute	ValuePtr contents
	The batch can be executed in auto commit mode in two ways. The entire batch can be treated as the automatic processing unit, or each statement in a batch can be treated as the automatic processing unit. A particular data source may support both of these ways or it may select one and support it. The driver defines the entire batch or each statement in the batch processing can be treated as the automatic processing unit.
SQL_ATTR_CONNECTION_DEAD(ODBC 3.5)	It is not supported by the driver.
SQL_ATTR_CONNECTION_TIMEOUT (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_CURRENT_CATALOG (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_DBC_INFO_TOKEN (ODBC 3.8	It is not supported by the driver.
SQL_ATTR_ENLIST_IN_DTC (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_LOGIN_TIMEOUT (ODBC 1.0)	It is SQLUINTERGER value corresponding to a wait time, in seconds, until the login request is completed before returning to the application. The default value depends on the driver. If ValuePtr is 0, the time limit is deactivated and the connection attempt will indefinitely wait. If the specified login request timeout exceeds the maximum login time limit, then the driver replaces the value and returns SQLSTATE 01S02 (Option value changed).
SQL_ATTR_METADATA_ID (ODBC 3.0)	It is SQLUINTEGER value which determines how to handle the string argument of the catalog function. The default value is SQL_FALSE. If it is SQL_TRUE, string argument of the catalog function is regarded as an identifier and it is not case-sensitive. For a non-delimited string, the driver removes all trailing spaces and changes the string to uppercase. For a delimited string, the driver removes leading or trailing spaces and still has the character between delimiters. If one of these arguments is a null pointer, the function returns SQL_ERROR and SQLSTATE HY009 (Invalid use of null pointer). If it is SQL_FALSE, string argument of the catalog function is not regarded as an identifier and it is case-sensitive. So it may be processed as a string pattern according to the argument, or not. TableType argument of SQLTables which has the value list is not affected by the attribute. SQL_ATTR_METADATA_ID can be set in the statement step. (It is the unique connection attribute in the statement attribute.)

Attribute	ValuePtr contents
	For more information, refer to **Arguments of Catalog Function**.
SQL_ATTR_OLDPWD	It is SQLPOINTER for the previous encrypted string. The value is write only, and it should be set prior to connecting to the server.
SQL_ATTR_ODBC_CURSORS (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_PACKET_SIZE (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_QUIET_MODE (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_TRACE (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_TRACEFILE (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_TRANSLATE_LIB (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_TRANSLATE_OPTION (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_TXN_ISOLATION (ODBC 1.0)	It is 32-bit bit mask for setting the transaction isolation level for the current connection. The application should call SQLEndTran by using this option before calling SQLSetConnectAttr to commit or roll back all open transactions on connection. The valid value for ValuePtr can be determined by calling SQLGetInfo with InfoType which is equal to SQL_TXN_ISOLATION_OPTIONS. For more information about the transaction isolation level, refer to SQL_DEFAULT_TXN_ISOLATION information type of **SQLGetInfo**.

[1] The function can be asynchronously called only when the descriptor is the implementation descriptor, but not the application descriptor.

SQLSetConnectOption

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

ODBC 2.0 function SQLSetConnectOption is replaced with SQLSetConnectAttr In ODBC 3.x. For more inf ormation, refer to **SQLSetConnectAttr**.

SQLSetCursorName

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLSetCursorName connects the cursor name to the activated statement. If the application does not call SQLSetCursorName, then the driver generates the cursor name which is necessary to the SQL statement p rocessing.

Syntax

```
SQLRETURN SQLSetCursorName(
    SQLHSTMT      StatementHandle,
    SQLCHAR *     CursorName,
    SQLSMALLINT   NameLength);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CursorName

[Input] It is the cursor name. A cursor name should not contain leading or trailing spaces for efficie nt processing, and if the cursor name includes a limited identifier, then the delimiter should be posi tioned on the first letter of the cursor name.

NameLength

[Input] It is the string length of *CursorName.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncated	The cursor name length exceeds the maximum, and only the string of the maximum allowable number is used.
24000	Invalid cursor state	The statement corresponding to StatementHandle is already running or it is in use as the to a positioning cursor.
34000	Invalid cursor name	The cursor name specified in *CursorName exceeds the maximum value of the driver, or it is not valid because it is started with SQLCUR or SQL_CUR.
3C000	Duplicate cursor name	The name specified in *CursorName already exists.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY009	Invalid use of null pointer	CursorName argument is a NULL pointer.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLSetCursorName is called. SQLSetCursorName function is called and the asynchronously executing function is called for StatementHandle. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The internal memory can not be accessed or the available memory size is small.
HY090	Invalid string or buffer length	NameLength argument is smaller than 0. (It is not SQL_NTS.)
HY117	Connection is suspended due to unknown tracsaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source responds to the request. The timeout can be set through SQL_ATTR_CONNECTION_TIMEOUT of SQLSetConnectAttr.
IM001	Driver does not support this function	The driver does not support the function.

Description

The cursor name is used for positioning update statements and positioning delete statements. (e.g. UPD ATE table-name ... WHERE CURRENT OF cursor-name). If the application does not define the cursor nam e by calling SQLSetCursorName in the execution of query statement, then the driver generates the name which starts with SQL_CUR and does not exceed a length of 18 characters.

All cursor names should be unique within a connection. The maximum length of the cursor name is defin ed in the driver. For maximum interoperability, it is recommended that the application limit the cursor na me of more than 18 characters. In ODBC 3.x, if the cursor name is enclosed in double quotes ("), it is con sidered to be case sensitive and it is not allowed by SQL syntax or it can include the specially treated chara cters like space or reserved word. The case-sensitive cursor name should be enclosed with double quotes (") identifier.

The cursor name remains until the related statement is deleted by using SQLFreeHandle. SQLSetCursorNa me can be called to rename a cursor on a statement when the cursor is in an allocated or prepared state.

SQLSetDescField

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLSetDescField sets the value of a single field of the descriptor record.

Syntax

```
SQLRETURN SQLSetDescField(
    SQLHDESC      DescriptorHandle,
    SQLSMALLINT   RecNumber,
    SQLSMALLINT   FieldIdentifier,
    SQLPOINTER    ValuePtr,
    SQLINTEGER    BufferLength);
```

Arguments

DescriptorHandle

[Input] It is the descriptor handle.

RecNumber

[Input] It points to the descriptor record including a field which the application seeks to set. The de scriptor records are numbered from 0 and the record number 0 is the bookmark record. RecNumb er argument is ignored for the header field.

FieldIdentifier

[Input] It indicates the descriptor field to be set.

ValuePtr

[Input] It describes a buffer which contains the descriptor information or integer value. The data ty pe depends on the value of FieldIdentifier. If ValuePtr is an integer value, it can be considered to be 8 bytes (SQLLEN), 4 bytes (SQLINTEGER), 2 bytes (SQLSMALLINT) according to the value of FieldIde ntifier argument.

BufferLength

[Input] If FieldIdentifier is the ODBC defined field and ValuePtr points to the string or binary buffer, the argument should be the length of *ValuePTr. The argument should contain the number of byt es of the string for the string data.

If FieldIdentifier is the ODBC defined field and ValuePtr is an integer, BufferLength is ignored.

If FieldIdentifier is the driver defined field, the application describes the attribute features to the dri ver manager by setting BufferLength argument. BufferLength can have the following values.

- If ValuePtr is a string buffer pointer, BufferLength is the string length or SQL_NTS.
- If ValuePtr is a binary buffer pointer, the application stores the result of SQL_LEN_BINARY_ATTR (length) macro in BufferLengfth. BufferLength stores the negative value.
- If ValuePtr includes the fixed length value, BufferLength is one of SQL_IS_INTEGER, SQL_IS_UIN TEGER, SQL_IS_SMALLINT or SQL_IS_USMALLINT.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	Genaral warning	It is the driver-specific informational message. (The function returns S QL_SUCCESS_WITH_INFO.)
01S02	Option value changed	The driver does not support the value specified in *ValuePtr (if the val ue of ValuPtr is an integer.), or *ValuPtr is not valid on the implemen tation conditions, so the driver replaces it with a similar value. (The fu nction returns SQL_SUCCESS_WITH_INFO.)
07009	Invalid descriptor index	When FieldIdentifier argument is a record field, and RecNumber argu ment is 0, then DescriptorHandle argument refers to IPD handle. RecNumber argument is smaller than 0, and DescriptorHandle argum ent refers to ARD or APD. RecNumber argument is bigger than the maximum of the column or parameter supported by the data source, and DescriptorHandle argu ment refers to APD or ARD. FieldIdentifier argument is SQL_DESC_COUNT, and *ValuePtr argum ent is smaller than 0. RecNumber argument is equal to 0, and DescriptorHandle argument refers to APD which is implicitly assigned. (This error does not occur f

SQLSTATE	Error	Description
		or the explicitly assigned application descriptor because it is unknown the application descriptor is APD or ARD until the execution time.)
08S01	Communication link failure	Before completing the function processing, the connection between the driver and the data source is failed.
22001	String data, right truncated	FieldIdentifier argument is SQL_DESC_NAME, and BufferLength argument has the value which is bigger than SQL_MAX_IDENTIFIER_LEN.
HY000	General error	It is an error without any specific SQLSTATE.
HY001	Memory allocation error	It is a memory allocation error.
HY010	Function sequence error	The asynchronously executing function is called for DescriptorHandle related to StatementHandle, and this function is still being executed when SQLSetDescField is called. SQLExecute, SQLExecDirect, SQLBulkOperations or SQLSetPos is called on StatementHandle related to DescriptorHandle, and SQL_NEED_DATA is returned. The function is called before all data of the column or parameter are sent at the execution time. The asynchronously executing function is called for connection handle related to DescriptorHandle, and this function is still being executed when SQLSetDescField is called. SQLExecute, SQLExecDirect or SQLMoreResults is called for one of the statement handles related to DescriptorHandle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called before retrieving data for all streamed parameters.
HY013	Memory management error	The internal memory can not be accessed or the available memory size is small.
HY016	Cannot modify an implementation row descriptor	DescriptorHandle argument is related to IRD, and FieldIdentifier argument is not SQL_DESC_ARRAY_STATUS_PTR nor SQL_DESC_ROWS_PROCESSED_PTR.
HY021	Inconsistent descriptor information	SQL_DESC_TYPE and SQL_DESC_DATETIME_INTERVAL_CODE fields are not a valid ODBC SQL type, valid driver-specific SQL type or a valid ODBC C type. Descriptor information is not consistent when checking the integrity.
HY090	Invalid string or buffer length	*ValuePtr is a string and BufferLength is smaller than 0. (It is not SQL_NTS.) When the driver is the ODBC 2.x driver and the descriptor is ARD and ColumnNumber argument is set to 0, then the value specified in BufferLength is not 4.
		The value specified in FieldIdentifier argument is not the value of OD

SQLSTATE	Error	Description
HY091	Invalid descriptor field identifier	BC defined field or the implementation defined value. FieldIdentifier argument is invalid for DescriptorHandle argument. FieldIdentifier argument is the ODBC defined field and it is read-only.
HY092	Invalid attribute/option identifier	The *ValuePtr value is invalid for FieldIdentifier argument. FieldIdentifier argument is SQL_DESC_UNNAMED,and ValuePtr is SQL_NAMED.
HY105	Invalid parameter type	The value specified in SQL_DESC_PARAMETER_TYPE field is invalid. (Refer to **InputOutputType Argument** in SQLBindParameter.)
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection timeout period expired before the response to the data request. The connection timeout period be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetConnectAttr.
IM001	Driver does not support this function	The driver does not support the function.

Description

The application can call SQLSetDescField to set any descriptor field one at a time. One call sets a single field in a single descriptor. The function can be called for setting any field in any descriptor type if the field can be set.

If calling SQLSetDescField fails, the descriptor record contents identified by RecNumber argument is undefined.

Other functions can be called to set multiple descriptor fields with a single call. SQLSetDescRec function can set various fields which affect the data type and the binding column or the parameter buffer. (SQL_DESC_TYPE, SQL_DESC_DATETIME_INTERVAL_CODE, SQL_DESC_OCTET_LENGTH, SQL_DESC_PRECISION, SQL_DESC_SCALE, SQL_DESC_DATA_PTR, SQL_DESC_OCTET_LENGTH_PTR, SQL_DESC_INDICATOR_PTR)

SQLBindCol or SQLBindParameter can be used to completely set the columns and parameters. These functions can set a group of descriptor field with a single function call.

SQLSetDescField can be called to change the binding buffer by adding the offset to the binding points. (SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR) It allows the application change the binding buffers without calling SQLBindCol or SQLBindParameter like as SQL_DESC_DATA_TYPE changes SQL_DESC_DATA_PTR without changing other fields.

If the application calls SQLSetDescField to set any field other than SQL_DESC_COUNT or deferred fields (SQL_DESC_DATA_PTR, SQL_DESC_OCTET_LENGTH_PTR, SQL_DESC_INDICAITOR_PTR), then the record binding can be released.

The descriptor header fields is set by calling SQLSetDescField with appropriate FieldIdentifier. Many header fields are the statement attributes, so they can be set by calling SQLSetStmtAttr. It allows the application to set the descriptor field first without obtaining the descriptor handle. When the header field is set by calling SQLSetDescField, RecNumber argument is ignored.

RecNumber which is 0 is used to set the bookmark field.

The statement attribute SQL_ATTR_USE_BOOKMARKS should be set before calling SQLSetDescField to set the bookmark fields. It is not necessary but is strongly recommended.

Order of Setting Descriptor Fields

When setting the descriptor fields by calling SQLSetDescField, the application should follow the specified order.

1. The application should preferentially set SQL_DESC_TYPE, SQL_DESC_CONCISE_TYPE or SQL_DESC_DATETIME_INTERVAL_CODE field.

2. After one of these fields is set, the application can set the attributes of the data types and the driver can set the data type setting fields to appropriate default values for the data types. Automatic default setting of the type attribute fields ensures that the descriptor is always ready to use after the application specifies the data types. When the application explicitly sets the data type attribute, the default attribute will be overwritten.

3. After setting one of the fields in step 1 and setting the data type attribute, the application can set SQL_DESC_DATA_PTR. It prompts the consistency check of the descriptor fields. If the application sets SQL_DESC_DATA_PTR field after changing the data type or attribute, the driver sets SQL_DESC_DATA_PTR to a NULL pointer and releases the record binding. It forces the application to sequentially complete the appropriate procedures before the descriptor record is able to be used.

Initializing Descriptor Field

When a descriptor is allocated, the descriptor fields can be initialized to the default value or it can be initialized to the value which does not have default or is not defined in the descriptor type. The following table describes the initialization of each field of each descriptor type. D refers to the initialization field with th

e default value. ND refers to the initialization field without default. The number refers that the default val ue of field is a number. The table also indicates whether the field is read/write or read-only.

The field of IRD can have the default value after the statement is prepared or executed and IRD is generat ed, and it is not when the statement handle or descriptor is allocated. Any access attempt to the IRD field returns an error until IRD is generated.

Some descriptor fields are defined for one or more, but not for all descriptor types (ARD, IRD, APD, IPD). I f a field is not defined in the descriptor type, it is not required for the function which uses the descriptor.

The accessible fields by SQLGetDescField are not necessarily possible to be set with SQLSetDescField. The fields which can be set by SQLSetDescField are listed in the following table.

The following table describes the initialization of the header fields.

Header field name	Format	R/W	Default value
SQL_DESC_ALLOC_TYPE	SQLSMALLINT	ARD: R APD: R IRD: R IPD: R	ARD: SQL_DESC_ALLOC_AUTO for implicit or SQL_DESC_ALLOC_USER for explicit APD: SQL_DESC_ALLOC_AUTO for implicit or SQL_DESC_ALLOC_USER for explicit IRD: SQL_DESC_ALLOC_AUTO IPD: SQL_DESC_ALLOC_AUTO
SQL_DESC_ARRAY_SIZE	SQLULEN	ARD: R/W APD: R/W IRD: Unused IPD: Unused	ARD:[1] APD:[1] IRD: Unused IPD: Unused
SQL_DESC_ARRAY_STATUS_PTR	SQLUSMALLINT*	ARD: R/W APD: R/W IRD: R/W IPD: R/W	ARD: Null ptr APD: Null ptr IRD: Null ptr IPD: Null ptr

[1]Fields are defined only when IPD is automatically generated by the driver. Otherwise, they are not defin ed. When the application tries to set the fields, SQLSTATE HY091 (Invalid descriptor field identifier) will b e returned.

[2]SQL_DESC_DATA_PTR field of IPD is set to force check the consistency. In the subsequent SQLGetDesc Field or SQLGetDescRec call, the driver does not need to return the value which SQL_DESC_DATA_PTR is set to.

FieldIdentifier Argument

FieldIdentifier argument indicates the descriptor field to be set. Descriptor consists of a descriptor header and a header field described in the following header field. Descriptor records consists of the record fields described in the following header field.

Header Field

Each descriptor consists of the following fields.

SQL_DESC_ALLOC_TYPE[All] (read-only)

This read-only SQLSMALLINT header field specifies whether the descriptor is automatically allocate d by the driver or explicitly allocated by the application. The application can obtain this field but ca n not update it. The field is set to SQL_DESC_ALLOC_AUTO by the driver when the descriptor is au tomatically allocated by the driver.

SQL_DESC_ARRAY_SIZE[Application descriptors]

This SQLLEN header field in ARD specifies the number of rows in a row set. This is the number of r ows to be returned by calling SQLFetch, SQLFetchScroll, or to be operated by calling SQLBulkOpera tions or SQLSetPos.

The header field in APD, SQLULEN, specifies the number of parameters.

The default value of the field is 1. If SQL_DESC_ARRAY_SIZE is bigger than 1, SQL_DESC_DATA_PT R, SQL_DESC_INDICATOR_PTR and SQL_DESC_OCTET_LENGTH_PTR of APD or ARD points to an a rray. The constant of each array is equal to the field value.

The field in ARD can be set by calling SQLSetStmtAttr with SQL_ATTR_ROW_ARRAY_SIZE attribute. The field in APD can be set by calling SQLSetStmtAttr with SQL_ATTR_PARAMSET_SIZE attribute.

SQL_DESC_ARRAY_STATUS_PTR[All]

SQLSMALLINT* header field for each descriptor type points to an array of SQLUSMALLINT value. Th e arrays are named such as row status array (IRD), parameter status array (IPD), row operation arra y (ARD), parameter operation array (APD).

The header field in IRD points to the row status array which includes the status value after calling S QLBulkOperations, SQLFetch, SQLFetchScroll, or SQLSetPos. The application allocates the SQLUSM ALLINT array and makes the field to point to the array. The field is a NULL pointer by default. The dr iver will create an array if SQL_DESC_ARRAY_STATUS_PTR field is not set to a NULL pointer.

If the application sets the elements of the row status array pointed by SQL_DESC_ARRAY_STAT US_PTR of IRD, the driver operation is not defined.

The array is initially populated by calling SQLBulkOperations, SQLFetch, SQLFetchScroll or SQLSetPos. If th e call does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the content of array pointed by the fi eld is undefined. Elements of the array may contain the following values.

- SQL_ROW_SUCCESS: The row is successfully fetched, and it is not changed since the last fetch.
- SQL_ROW_SUCCESS_WITH_INFO: The row is successfully fetched, and it is not changed since the last fetch, but the warning for the row is returned.
- SQL_ROW_ERROR: An error occurs while the row is fetched.
- SQL_ROW_UPDATED: The row is successfully fetched, and it is updated since the last fetch. If the ro w is fetched again, the state is SQL_ROW_SUCCESS.
- SQL_ROW_DELETED: The row is deleted since the last fetch.
- SQL_ROW_ADDED: The row is inserted by SQLBulkOperations. If the row is fetched again, the state is

SQL_ROW_SUCCESS.
- SQL_ROW_NOROW: The row set is overlapped with the end of the result set. And any row is not retu rned corresponding to elements of the row status array.

This field of IRD can be set by calling SQLSetStmtAttr with SQL_ATTR_ROW_STATUS_PTR attribute.

SQL_DESC_ARRAY_STATUS_PTR field of IRD is valid after SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is returned. If the return code is not one of these, anything pointed by SQL_DESC_ROWS_PROCESSED_PTR is not defined.

This header field in IPD indicates the parameter status array which includes status information of each par ameter after calling SQLExecute or SQLExecDirect. If SQLExecute or SQLExecDirect is called and SQL_SUC CESS or SQL_SUCCESS_WITH_INFO is not returned, then the content of the array which is pointed by the field is not defined. The application allocates SQLUSMALLINT array, the field should point to the array. Th e driver will create an array if SQL_DESC_ARRAY_STATUS_PTR field is not set to a NULL pointer. Elements in the array contain the following values.

- SQL_PARAM_SUCCESS: The SQL statement is successfully executed for the parameter set.
- SQL_PARAM_SUCCESS_WITH_INFO: The SQL statement is successfully executed for the parameter se t, but there is a warning information available to the diagnostic data structure.
- SQL_PARAM_ERROR: An error occurs to process the parameter set. The additional error information i s in the diagnostic data structure.
- SQL_PARAM_UNUSED: This parameter is not used because some previous parameter set causes an e rror which aborts further processing, or SQL_PARAM_IGNORE is set to the parameter set in the array specified by SQL_DESC_ARRAY_STATUS_PTR field of APD.
- SQL_PARAM_DIAG_UNAVAILABLE: The diagnostic information can not be used. For example, the dri ver does not generate the level of error information by treating the array of the parameter as single o ne.

This field in IPD can be set by calling SQLSetStmtAttr with SQL_ATTR_PARAM_STATUS_PTR attribute.

In ARD, this field points to the row operation array for the value set by the application to determine whet her the row is ignored in SQLSetPos operation. Elements of the array may contain the following values.

- SQL_ROW_PROCEED: The row is included in bulk operation using SQLSetPos. (This setting does not guarantee that the operation occurs on the row. If the row has SQL_ROW_ERROR state of IRD row st atus array, the driver will not be able to perform the operation for the row.)
- SQL_ROW_IGNORE: The row is excluded from the bulk operation using SQLSetPos.

If an element in the array is not set, all rows are included in the bulk operation. If the value of SQL_DESC_ ARRAY_STATUS_PTR field of ARD is a NULL pointer, all rows are included in the bulk operation. It means that the pointer points to a valid array and all elements of the array are SQL_ROW_PROCEED. If all eleme nts in an array are set to SQL_ROW_IGNORE, the values in the row status array are not updated for the ig nored row.

This field in ARD also can be set by calling SQLSetStmtAttr with SQL_ATTR_ROW_OPERATION_PTR attrib ute.

This header field in ARD indicates the parameter operation array of the values which can be set by the ap plication to determine whether the parameter set is ignored when SQLExecute or SQLExecDirect is called. Elements of the array may contain the following values.

- SQL_PARAM_PROCEED: The parameter set is included in SQLExecute or SQLExecDirect call.
- SQL_PARAM_IGNORE: The parameter set is not included in SQLExecute or SQLExecDirect call.

If an element in the array is not set, all parameter sets of the array are used to call SQLExecute or SQLExec Direct. If the value of SQL_DESC_ARRAY_STATUS_PTR field of APD is a NULL pointer, all parameter sets a re used. It is interpreted as if the pointer points to the valid array and all elements of the array are SQL_PA RAM_PROCEED.

This field in APD can be set by calling SQLSetStmtAttr with SQL_ATTR_PARAM_OPERATION_PTR attribut e.

SQL_DESC_BIND_OFFSET_PTR[Application descriptors]

This SQLLEN* header field indicates the offset of the binding. It is set as a NULL pointer by default. If the field is not a NULL pointer, the driver dereferences the pointer and adds the dereferenced val ue to each of the deferred fields which has a non-null value in the descriptor record(SQL_DESC_DA TA_PTR_, SQL_DESC_INDICATOR_PTR and SQL_DESC_OCTET_LENGTH_PTR), and uses a new poin ter value when binding.

The binding offset is always directly added to SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR and SQL_DESC_OCTET_LENGTH_PTR fields. If the offset is changed to the other value, the new val ue is continuously and directly added as each descriptor field value.

The field is a deferred field. The field is not used at the time to be set and it is used later by the driv er when the addresses of the data buffers are needed to be checked.

This field in ARD can be set by calling SQLsetStmtAttr with SQL_ATTR_ROW_BIND_OFFSET_PTR att ribute. This field in ARD can be set by calling SQLsetStmtAttr with SQL_ATTR_PARAM_BIND_OFFS ET_PTR attribute.

For more information, refer to **SQLFetchScroll** or **SQLBindParameter**.

SQL_DESC_BIND_TYPE[Application descriptors]

This SQLUINTEGER header field is used to set the binding direction.

This field in ARD specifies the binding direction when SQLFetchScroll or SQLFetch is called in the rel ated statement handle.

This field is set to SQL_BIND_BY_COLUMN(default) to select the column-wise binding for the colu mn.

This field in ARD can be set by calling SQLSetStmtAttr with SQL_ATTR_ROW_BIND_TYPE attribute.

This field specifies the binding direction to be used in the Dynamic parameters.

This field is set to SQL_BIND_BY_COLUMN(default) to select the column-wise binding for the para meter.

This field can be set by calling SQLSetStmtAttr with SQL_ATTR_PARAM_BIND_TYPE attribute.

SQL_DESC_COUNT[All]

This header field of SQLSMALLINT specifies a 1-based index of the best record including the data. When the driver sets the data structure to the descriptor, SQL_DESC_COUNT should be set to displ ay how many of the important records. The application does not need to specify the amount of sp ace reserved for the records when allocating instances of the data structure. As like the application specifies the contents of the records, the driver performs the requested operation to ensure that th e descriptor handle indicates the data structure of sufficient size.

SQL_DESC_COUNT is not the number of all bound data columns or the number of parameters but is the number of highest-numbered records. If the binding of the highest-numbered column or par ameter is released, SQL_DESC_COUNT is changed to the number of the next highest-numbered co lumns or parameters. If the binding of column or parameter which is smaller than the number of hi ghest-numbered columns or parameters is released(when TargetValuePtr argument is set to a NUL L pointer and SQLBindCol is called, or when ParameterValuePtr argument is set to a NULL pointer a nd SQLBindParameter is called.) SQL_DESC_COUNT is not changed. If columns or parameters to be added are bound with the number which is bigger than the highest-numbered record including th e data, the driver automatically increases the value of SQL_DESC_COUNT field. If the binding for all columns are released by calling SQLFreeStmt with SQL_UNBIND option, SQL_DESC_COUNT field in ARD or IRD is set to 0. If SQLFreeStmt is called as SQL_RESET_PARAMS option, SQL_DESC_COUNT fields in APD and IPD are set to 0.

SQL_DESC_COUNT value can be explicitly set by calling SQLSetDescField in the application. If SQL_ DESC_COUNT value is clearly reduced, all records having a bigger value than the new SQL_DESC_C OUNT value are effectively deleted. If the value of SQL_DESC_COUNT field of ARD is clearly set to 0, all buffers are released except for the bound bookmark column. The number of records in the field of ARD do not include the bound bookmark column. The only way to release the bound bookmark column is set SQL_DESC_DATA_PTR to a NULL pointer.

SQL_DESC_ROWS_PROCESSED_PTR[Implementation descriptors]

This SQLULEN* header field in IRD points to the buffers which include the number of rows fetched after SQLFetch or SQLFetchScroll is called, or the number of rows and errors affected in the bulk o peration performed by calling SQLBulkOperations or SQLSetPos.

This SQLUINTEGER* header field of IPD points to the buffers which include the number of paramet er set and errors processed. If it is a NULL pointer, it will not return the number.

SQL_DESC_ROWS_PROCESSED_PTR is valid only after SQL_SUCCESS or SQL_SUCCESS_WITH_INF O has been returned after calling SQLFetch or SQLFetchScroll (for an IRD field) or SQLExecute, SQL ExecDirect, or SQLParamData (for an IPD field). If the functions does not return SQL_SUCCESS or S

QL_SUCCESS_WITH_INFO, the buffer content is not defined and the buffer value is set to 0 until S QL_NO_DATA is returned.

This field in ARD can be set by calling SQLSetStmtAttr with SQL_ATTR_ROWS_FETCHED_PTR attrib ute. This field in APD can be set by calling SQLSetStmtAttr with SQL_ATTR_PARAMS_PROCESSED_ PTR attribute.

The buffer which is pointed by this field is allocated by the application. It is the deferred output buf fer set by the driver. A NULL pointer is set by default.

Record Field

Each descriptor includes at least one record consisting of the fields which defines one of the columns of d ata or dynamic parameters depending on the descriptor type. Each record is a complete specification of a single column or parameter.

SQL_DESC_AUTO_UNIQUE_VALUE[IRDs] (read-only)

This read-only SQLINTEGER record field has SQL_TRUE if it is auto-increment column. Otherwise, it has the SQL_FALSE. The field is read-only but it does not necessarily need to be read-only, if it is au to-increment column.

SQL_DESC_BASE_COLUMN_NAME[IRDs] (read-only)

This read-only SQLCHAR* record field includes the base column name of the result set column. If t he base column name does not exist, the field includes an empty string.

SQL_DESC_TABLE_NAME[IRDs] (read-only)

This read-only SQLCHAR* record field includes the base table name of the result set column. If the base table name can not be defined or not available, the field includes an empty string.

SQL_DESC_CASE_SENSITIVE[Implementation descriptors] (read-only)

This read-only SQLINTEGER record field is SQL_TRUE if columns or parameters is case-sensitive whe n sorting and comparing. It is SQL_FALSE if it is case-insensitive or the column with non-character.

SQL_DESC_CATALOG_NAME[IRDs] (read-only)

This read-only SQLCHAR* record field includes the catalog of the base table including the column. If the column is a part of a expression or view, the return value depends on the driver. If the data s ource does not support or the catalog can not be determined, the field includes an empty string.

SQL_DESC_CHAR_LENGTH_UNITS[IPD]

This SQLSMALLINT record field describes the unit of SQL_DESC_LENGTH. (SQL_CLU_NONE/ SQL_C LU_CHARACTERS/ SQL_CLU_OCTETS)

SQL_DESC_CONCISE_TYPE[All]

This SQLSMALLINT header field specifies a simplified form for all data types including datetime and interval data types.

The values of SQL_DESC_CONCISE_TYPE, SQL_DESC_TYPE and SQL_DESC_DATETIME_INTERVAL_ CODE fields are interdependent. If time is set in a field, it should be set in others fields as well. SQL

_DESC_CONCISE_TYPE can be set by calling SQLBindCol, SQLBindParameter or SQLSetDescField. SQL_DESC_TYPE can be set by calling SQLSetDescField or SQLSetDescRec.

If SQL_DESC_CONCISE_TYPE is set to a concise data type except for the interval or datetime data type, SQL_DESC_TYPE field is set to the same value and SQL_DESC_DATETIME_INTERVAL_CODE field is set to 0.

If SQL_DESC_CONCISE_TYPE is set to a concise interval or datetime data type, SQL_DESC_TYPE field is set to a detailed data type(SQL_DATETIME or SQL_INTERVAL), and SQL_DESC_DATETIME_INTERVAL_CODE field is set to the appropriate sub code.

SQL_DESC_DATETIME_INTERVAL_CODE[All]

This SQLSMALLINT record field includes the sub code for specifying datetime or interval data type if SQL_DESC_TYPE field is SQL_DATETIME or SQL_INTERVAL. It is same for both SQL and C. The code includes the data type name with CODE which is replaced with TYPE or C_TYPE of datetime types, INTERVAL or C_INTERVAL of interval types.

If SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE of the application descriptor are set to SQL_C_DEFAULT and the descriptor is not related to the statement handle, the content of SQL_DESC_DATETIME_INTERVAL_CODE is not defined.

This field can set the datetime data types which is listed in the following table.

Datetime type	DATETIME_INTERVAL_CODE
SQL_TYPE_DATE/ SQL_C_TYPE_DATE	SQL_CODE_DATE
SQL_TYPE_TIME/ SQL_C_TYPE_TIME	SQL_CODE_TIME
SQL_TYPE_TIME_WITH_TIMEZONE/ SQL_C_TYPE_TIME_WITH_TIMEZONE	SQL_CODE_TIME_WITH_TIMEZONE
SQL_TYPE_TIMESTAMP/ SQL_C_TYPE_TIMESTAMP	SQL_CODE_TIMESTAMP
SQL_TYPE_TIMESTAMP_WITH_TIMEZONE/ SQL_C_TYPE_TIMESTAMP_WITH_TIMEZONE	SQL_CODE_TIMESTAMP_WITH_TIMEZONE

This field can set the interval data types which is listed in the following table.

Interval type	DATETIME_INTERVAL_CODE
SQL_INTERVAL_DAY/ SQL_C_INTERVAL_DAY	SQL_CODE_DAY
SQL_INTERVAL_DAY_TO_HOUR/ SQL_C_INTERVAL_DAY_TO_HOUR	SQL_CODE_DAY_TO_HOUR
SQL_INTERVAL_DAY_TO_MINUTE/ SQL_C_INTERVAL_DAY_TO_MINUTE	SQL_CODE_DAY_TO_MINUTE
SQL_INTERVAL_DAY_TO_SECOND/ SQL_C_INTERVAL_DAY_TO_SECOND	SQL_CODE_DAY_TO_SECOND

Interval type	DATETIME_INTERVAL_CODE
SQL_INTERVAL_HOUR/ SQL_C_INTERVAL_HOUR	SQL_CODE_HOUR
SQL_INTERVAL_HOUR_TO_MINUTE/ SQL_C_INTERVAL_HOUR_TO_MINUTE	SQL_CODE_HOUR_TO_MINUTE
SQL_INTERVAL_HOUR_TO_SECOND/ SQL_C_INTERVAL_HOUR_TO_SECOND	SQL_CODE_HOUR_TO_SECOND
SQL_INTERVAL_MINUTE/ SQL_C_INTERVAL_MINUTE	SQL_CODE_MINUTE
SQL_INTERVAL_MINUTE_TO_SECOND/ SQL_C_INTERVAL_MINUTE_TO_SECOND	SQL_CODE_MONUTE_TO_SECOND
SQL_INTERVAL_MONTH/ SQL_C_INTERVAL_MONTH	SQL_CODE_MONTH
SQL_INTERVAL_SECOND/ SQL_C_INTERVAL_SECOND	SQL_CODE_SECOND
SQL_INTERVAL_YEAR/ SQL_C_INTERVAL_YEAR	SQL_CODE_YEAR
SQL_INTERVAL_YEAR_TO_MONTH/ SQL_C_INTERVAL_YEAR_TO_MONTH	SQL_CODE_YEAR_TO_MONTH

SQL_DESC_DATETIME_INTERVAL_PRECISION[All]

This SQLINTEGER record field includes interval leading precision if SQL_DESC_TYPE field is SQL_INTERVAL. When SQL_DESC_DATETIME_INTERVAL_CODE field is set to interval data type, the field is set to the default interval leading precision.

SQL_DESC_DISPLAY_SIZE[IRDs] (read-only)

This read-only SQLINTEGER record field includes the maximum number of characters required to display the data from the column.

SQL_DESC_FIXED_PREC_SCALE[Implementation descriptors] (read-only)

This read-only SQLSMALLINT record field is set to SQL_TRUE if the column is a exact numeric column and it has the non-zero scale and the fixed precision. Otherwise, it is set to SQL_FALSE.

SQL_DESC_INDICATOR_PTR[Application descriptors]

This SQLLEN* record field in ARD indicates the indicator variable. The variable contains SQL_NULL_DATE if the column value is NULL. In APD, the indicator variable is set to SQL_NULL_DATA to specify a dynamic argument to NULL. Otherwise, the variable is 0.

If SQL_DESC_INDICATOR_PTR field of ARD is a NULL pointer, the driver is prevened from returning the information about whether the column is NULL. If the column is NULL and SQL_DESC_INDICATOR_PTR is a NULL pointer, SQLSTATE 22002(Indicator variable required but not supplied) is returned when the driver tries to create a buffer after calling SQLFetch or SQLFetchScroll. If SQLFetch or SQLFetchScroll call does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is not defined.

SQL_DESC_INDICATOR_PTR field defines whether to set the field indicated by SQL_DESC_OCTET_LENGTH_PTR. If the column data value is NULL, the driver sets the indicator variable to SQL_NULL_DATA. The field indicated by SQL_DESC_OCTET_LENGTH_PTR is not set at that time. If the NULL value is not encountered during the fetch, the buffer indicated by SQL_DESC_INDICATOR_PTR is set to 0, and the buffer indicated by SQL_DESC_OCTET_LENGTH_PTR is set to the data length.

If SQL_DESC_INDICATOR_PTR field of APD is a NULL pointer, the application can not use the descriptor record to specify the arguments as NULL.

It is a deferred field. The field is not used when it is set but it is used when the driver describes the possibility of NULL (for ARD) or determines the possibility of NULL (for APD).

SQL_DESC_LABEL[IRDs] (read-only)

This read-only SQLCHAR* record field includes the column label or cover. If the column does not have its label, the variable includes the column name. If the column is not named or can not use its label, the variable includes an empty string.

SQL_DESC_LENGTH[All]

This SQLULEN record field is a maximum length or actual length of the string, or binary data type in bytes. It is the actual length of fixed length data types or the maximum length of variable-length data types. The value always excludes NULL termination character at the end of the string. If the data type of the value is SQL_TYPE_DATE, SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP or SQL interval data type, the field has the length of characters when the datetime or interval value is represented by string again.

This field value may be different from the value of the length defined in ODBC 2.x.

SQL_DESC_LITERAL_PREFIX[IRDs] (read-only)

This read-only SQLCHAR* record field includes the characters or character which the driver recognizes as a suffix. The variable includes an empty string for the data type to which the character suffix is not applicable.

SQL_DESC_LOCAL_TYPE_NAME[Implementation descriptors] (read-only)

This read-only SQLCHAR* record field includes a localized name for the data type which may be different from the regular name of the data type. If the localized name does not exist, then an empty string is returned. The field is only for the display purpose.

SQL_DESC_NAME[Implementation descriptor]

This SQLCHAR* record field includes the alias of the field in the row descriptor. If the alias of a column is not applied, the column name is returned. In either case, the driver sets SQL_DESC_UNNAMED field to SQL_NAMED when setting SQL_DESC_NAME. If column name or its alias does not exist, then the driver returns an empty string of SQL_DESC_NAME field and sets SQL_DESC_UNNAMED field to SQL_UNNAMED.

The application can set SQL_DESC_NAME field of IPD to a parameter name or alias to specify stored procedure parameters by name. SQL_DESC_NAME field of IRD is a read-only field. If the application tries to set the field, SQLSTATE HY091 (Invalid descriptor field identifier) is returned.

For IPD, if the driver does not support the named parameters, the field is not defined. If the driver s upports the named parameters and it can explain the parameters, the parameter name is returned in this field.

SQL_DESC_NULLABLE[Implementation descriptors] (read-only)

For IRD, if the column of this read-only SQLSMALLINT record field is allowed to be NULL, it is SQL_ NULLABLE. If NULL is not allowed, it is SQL_NO_NULLS. If the column is unknown whether or not t o allow NULL, it is SQL_NULLABLE_UNKNOWN. The field exists particularly for a column in the resu lt set.

For IPD, this field is always set to SQL_NULLABLE because the dynamic parameters are always allow ed to have NULL and can not be set by the application.

SQL_DESC_NUM_PREC_RADIX[All]

This SQLINTEGER record field has the value of 2 when SQL_DESC_TYPE field is the approximate nu meric data type. Because SQL_DESC_PRECISION field includes the number of the bits. The field has the value of 10 when SQL_DESC_TYPE field has the exact numeric data type because SQL_DESC_P RECISION field includes the number of decimal places. The field sets 0 for a non-numeric data type.

SQL_DESC_OCTET_LENGTH[All]

This SQLLEN record field includes the length in bytes of a string or binary data type. For the fixed le ngth character or binary data type, it is the actual length (in bytes). For the variable length characte r or binary data type, it is the maximum length (in bytes). The value does not include a space of nul l-termination character for the implementation descriptor but it includes a space of null-terminatio n character for the application descriptor. For the application data, the field contains the buffer siz e. For APD, the field is defined only for the output or input/output parameters.

SQL_DESC_OCTET_LENGTH_PTR[Application descriptors]

This SQLLEN* record field points to a variable which includes the total length in bytes of the dynam ic argument (for parameter descriptor) or the bound column value (for row descriptors).

For APD, the value is ignored for all argument except for the string and binary. If the field is SQL_N TS, the dynamic argument should be null-terminated. The application sets the variable which inclu des the result of SQL_DATA_AT_EXEC or SQL_LEN_DATA_AT_EXEC macro at execution time in th e record field of APD to indicate that it is a bound parameter to be data-at-execution parameter. If one or more of such fields exist, SQL_DESC_DATA_PTR can be set to a value identifying the param eter to help the application determine which parameter is being requested.

If OCTET_LENGTH_PTR field of ARD is a NULL pointer, the driver does not return the column lengt h information. If SQL_DESC_OCTET_LENGTH_PTR of APD is a NULL pointer, the driver assumes tha t the string and binary values are null-terminated. (Binary values should not be null-terminated, but a length should be given to avoid data interruption.)

If SQLFetch or SQLFetchScroll which fills the buffer pointed by the field does not return SQL_SUCC ESS or SQL_SUCCESS_WITH_INFO, the buffer content is not defined. It is the deferred field. The fie ld is not immediately used, but it is used later when the driver indicates or determines the octet len gth of the data.

SQL_DESC_PARAMETER_TYPE[IRDs]

This SQLSMALLINT record field is set to SQL_PARAM_INPUT for the input parameters, to SQL_PARAM_INPUT_OUTPUT for the input/output parameters, to SQL_PARAM_OUTPUT for the output parameters, to SQL_PARAM_INPUT_OUTPUT_STREAM for the stream input/output parameters or to SQL_PARAM_OUTPUT_STREAM for the stream output parameters. The default is SQL_PARAM_INPUT.

SQL_DESC_PRECISION[All]

This SQLSMALLINT record field includes the number of effective integer for the exact numeric type, and the number of bits of mantissa (binary precision) for the approximate numeric type. Or, it includes the number of digits in fractional seconds part of SQL_TYPE_TIME, SQL_TYPE_TIMESTAMP, or SQL_INTERVAL_SECOND data type. The field is undefined for all other data types.

The field value may be different from the value of the precision defined in ODBC 2.x.

SQL_DESC_ROWVER[Implementation descriptors] (read-only)

This SQLSMALLINT record field indicates whether the column is automatically updated by DBMS when the row is updated (e.g. timestamp of SQL server). The value of record field is set to SQL_TRUE if the column is the versioning column. Otherwise, it is set to SQL_FALSE. The column attribute is similar to calling SQLSpecialColumns with IdentifierType of SQL_ROWVER to determine whether to automatically update the column.

SQL_DESC_SCALE[All]

This SQLSMALLINT record field includes the number of decimal places defined in the decimal and numeric data types. The field is not defined for all other data types.

The field value may be different from the value of the scale defined in ODBC 2.x.

SQL_DESC_SCHEMA_NAME[IRDs] (read-only)

This read-only SQLCHAR* record field includes the schema name of the base table including the column. The return value is driver-dependent if the column is a part of a expression or view. If the data source does not support the schema or can not identify the schema name, then this variable contains an empty string.

SQL_DESC_SEARCHABLE[IRDs] (read-only)

This read-only SQLSMAINT record field sets one of the following values.

• It is set to SQL_PRED_NONE if the column can not be used in WHERE clause. (It is as same as SQL_UNSEARCHABLE of ODBC 2.X.)

• It is set to SQL_PRED_CHAR if the column can be used in a WHERE clause but only with the LIKE predicate.

• It is set to SQL_PRED_BASIC if the column can be used with all comparison operators except for LIKE in WHERE clause. (It is as same as SQL_EXCEPT_LIKE of ODBC 2.x .)

• It is set to SQL_PRED_SEARCHABLE if the column can be used with all comparison operators in WHERE clause.

SQL_DESC_TABLE_NAME[IRDs] (read-only)

This read-only SQLCHAR* record field includes the base table name containing this column. The return value is driver-dependent if the column is an expression or a part of view.

SQL_DESC_TYPE[All]

This SQLSMALLINT record field includes an abbreviated SQL or C data types for all data types except for the datetime or interval data type. The field specifies SQL_DATETIME or SQL_INTERVAL for datetime or interval data type.

Whenever the field includes SQL_DATETIME or SQL_INTERVAL, SQL_DESC_DATETIME_INTERVAL_CODE field should include the appropriate server code of the concise form. SQL_DESC_TYPE includes SQL_DATETIME for the datetime data type, and SQL_DESC_DATETIME_INTERVAL_CODE field includes the sub code specifying the datetime data type. SQL_DESC_TYPE includes SQL_INTERVAL for the interval data type and SQL_DESC_DATETIME_INTERVAL_CODE field includes the sub code specifying the interval data type.

The values of SQL_DESC_TYPE and SQL_DESC_CONCISE_TYPE fields are interdependent. The other field should be set when one of the fields is set. SQL_DESC_TYPE can be set by calling SQLSetDescField or SQLSetDescRec. SQL_DESC_CONCISE_TYPE can be set by calling SQLBindCol, SQLBindParameter or SQLSetDescField.

If SQL_DESC_TYPE is set to the concise data type which is not interval nor datetime data type, SQL_DESC_CONCISE_TYPE field is set to the same value and SQL_DESC_DATETIME_INTERVAL_CODE field is set to 0.

If SQL_DESC_TYPE is set to the verbose data type of the datetime or interval data type(SQL_DATETIME or SQL_INTERVAL) and SQL_DESC_DATETIME_INTERVAL_CODE field is set to the appropriate sub code, SQL_DESC_CONCISE_TYPE field is set to the value corresponding to the concise data type. When trying to set SQL_DESC_TYPE to one of the concise datetime or interval data types, SQL STATE HY021(Inconsistent descriptor information) will be returned.

If SQL_DESC_TYPE field is set by calling SQLBindCol, SQLBindParameter or SQLSetDescField, the following fields are set to the default values described in the following table. The remaining field values of the same record are undefined.

SQL_DESC_TYPE value	Other fields implicitly set
SQL_CHAR, SQL_VARCHAR, SQL_C_CHAR, SQL_C_VARCHAR	SQL_DESC_LENGTH is set to 1. SQL_DESC_PRECISION is set to 0.
SQL_DATETIME	When SQL_DESC_DATETIME_INTERVAL_CODE is set to SQL_CODE_DATE or SQL_CODE_TIME, SQL_DESC_PRECISION is set to 0. When it is set to SQL_DESC_TIMESTAMP, SQL_DESC_PRECISION is set to 6.
SQL_DECIMAL, SQL_NUMERIC,	SQL_DESC_SCALE is set to 0. SQL_DESC_PRECISION is set to the implementation-defined precision for each data type.

SQL_DESC_TYPE value	Other fields implicitly set
SQL_C_NUMERIC	
SQL_FLOAT, SQL_C_FLOAT	SQL_DESC_PRECISION is set to the implementation-defined precision for SQL_FLOAT.
SQL_INTERVAL	If SQL_DESC_DATETIME_INTERVAL_CODE is set to interval data type, SQL_DESC_DATETIME_INTERVAL_PRECISION is set to 2 (default interval leading precision). When interval has the part of seconds, SQL_DESC_PRECISION is set to 6 (default interval seconds precision).

When the application sets the field of the descriptor by calling SQLSetDescField not SQLSetDescRec, the application should firstly define the data type. When doing like this, the other fields described in the table above are implicitly set. If any value is not allowed to set implicitly, the application can call SQLSetDescField or SQLSetDescRec to set the value explicitly.

SQL_DESC_TYPE_NAME[Implementation descriptors] (read-only)

This read-only SQLCHAR* record field includes the data source dependent type name (CHAR, VARCHAR etc.). If the data type name is unknown, the variable contains an empty string.

SQL_DESC_UNNAMED[Implementation descriptors]

If SQL_DESC_NAME field is set, the SQLSMALLINT record field in the row descriptor is set to one of SQL_NAME or SQL_UNNAMED by the driver. If SQL_DESC_NAME field includes the column alias or the column alias is not used, the driver sets SQL_DESC_UNNAMED field to SQL_NAMED. If the application sets SQL_DESC_NAME field of IPD to the parameter name or alias, the driver sets SQL_DESC_UNNAMED of IPD to SQL_NAMED. If column name or alias does not exist, the driver sets SQL_DESC_UNNAMED field to SQL_UNNAMED.

The application sets SQL_DESC_UNNAMED field of IPD to SQL_UNNAMED. If the application tries to set SQL_DESC_UNANMED field of IPD to SQL_NAMED, the driver returns SQLSTATE HY091 (Invalid descriptor field identifier). If the application tries to set SQL_DESC_UNNAMED field of IRD (read-only), SQLSTATE HY091 (Invalid descriptor field identifier) will be returned.

SQL_DESC_UNSIGNED[Implementation descriptors] (read-only)

The read-only SQLSMALLINT record field is set to SQL_TRUE if the column type is the unsigned or non-numeric, or it is set to SQL_FALSE if the column type is signed.

SQL_DESC_UPDATABLE[IRDs] (read-only)

This read-only SQLSMALLINT record field is set to one of the following values.

- It is set to SQL_ATTR_READ_ONLY if the result set column is read-only.
- It is set to SQL_ATTR_WRITE if the result set column is read and write.
- It is set to SQL_ATTR_READWRITE_UNKNOWN if the updatability of the result set column is unknown.

SQL_DESC_UPDATABLE describes the updatability of the column (It is not the column in the base t

able.) in the result set. The updatability of the column in the base table whose result set columns ar e based on can be different from the value in the field. The updatability of the column is based on t he definition of the data type, user privilege and result set itself. If the updatability of the column is unsure, SQL_ATTR_READWITE_UNKNOWN should be returned.

SQL_DESC_CHAR_LENGTH_UNITS[Alls] (read-only)

This SQLSMALLINT record field indicates the length unit of the column whose SQL type is SQL_CH AR, SQL_VARCHAR and SQL_LONGVARCHAR.

• SQL_CLU_CHARACTERS: The length unit is CHARACTER. For example, data of "문자열" refers to the length of 3, if the encoding type is UHC(Unified Hangul Code).

• SQL_CLU_OCTETS: The length unit is OCTETS. For example, data of "문자열" refers to the length of 6, if the encoding type is UHC(Unified Hangul Code).

• SQL_CLU_NONE: The length unit is undefined. It is the value returned for SQL type except for th e SQL types listed above.

Consistency Check

Concurrency check is automatically implemented by the driver each time the application passes the value to SQL_DESC_DATA_PTR of ARD, APD, or IPD. If anything of the fields is inconsistent with other fields, S QLSetDescField will return SQLSTATE HY021(Inconsistent descriptor information). For more information, refer to **Consistency Check** of **SQLSetDescRec**.

SQLSetDescRec

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLSetDescRec function sets the multiple descriptor fields affecting the buffer bound to a data type or co lumn or parameter data.

Syntax

```
SQLRETURN SQLSetDescRec(
    SQLHDESC      DescriptorHandle,
    SQLSMALLINT   RecNumber,
    SQLSMALLINT   Type,
    SQLSMALLINT   SubType,
    SQLLEN        Length,
    SQLSMALLINT   Precision,
    SQLSMALLINT   Scale,
    SQLPOINTER    DataPtr,
    SQLLEN *      StringLengthPtr,
    SQLLEN *      IndicatorPtr);
```

Arguments

DescriptorHandle

[Input] It is the descriptor handle. IRD handle can not be set.

RecNumber

[Input] It indicates the descriptor record including the fields to be set. The descriptor record starts f rom 0, and the 0 record is a bookmark record. The argument should be equal to or bigger than 0. I f RecNumber is bigger than SQL_DESC_COUNT, then SQL_DESC_COUNT is changed to RecNumbe r value.

Type

[Input] It is the value which sets SQL_DESC_TYPE field for the descriptor record.

SubType

[Input] It is the value which sets SQL_DESC_DATETIME_INTERVAL_CODE field for a record type of SQL_DATETIME or SQL_INTERVAL.

Length

[Input] It is the value which sets SQL_DESC_OCTET_LENGTH field for the descriptor record.

Precision

[Input] It is the value which sets SQL_DESC_PRECISION field for the descriptor record.

Scale

[Input] It is the value which sets SQL_DESC_SCALE field for the descriptor record.

DataPtr

[Deferred Input or Output] It is the value which sets SQL_DESC_DATA_PTR field for the descriptor record. DataPtr can be set to a NULL pointer.

DataPtr argument can be set to a NULL pointer to set SQL_DESC_DATA_PTR field to a NULL pointer. If the handle in DescriptorHandle argument is related to ARD, it unbinds the column.

StringLengthPtr

[Deferred Input or Output] It is the value which sets SQL_DESC_OCTET_LENGTH_PTR field for the descriptor record. StringLengthPtr can be set to a NULL pointer to set SQL_DESC_OCTET_LENGTH_PTR field to a NULL pointer.

IndicatorPtr

[Deferred Input or Output] It is the value which sets SQL_DESC_INDICATOR_PTR field of the descriptor record. IndicatorPtr can be set to a NULL pointer to set SQL_DESC_INDICATOR_PTR to a NULL pointer.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
07009	Invalid descriptor index	RecNumber argument is set to 0, and DescriptorHandle refers to the IPD handle. RecNumber argument is bigger than the maximum number of columns or parameters supported by the data source, and DescriptorHandle argument is APD, IPD or ARD.

SQLSTATE	Error	Description
		RecNumber argument is 0, and DescriptorHandle argument refers to the implicitly allocated APD. (The error does not occur for the explicitly assigned application descriptor. This is because it is unknown whether the explicitly allocated application descriptor is APD or ARD until the execution time.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY010	Function sequence error	The asynchronously executing function is called for StatementHandle related to DescriptorHandle, and this function is still being executed when SQLSetDescRec is called.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY016	Cannot modify an implementation row descriptor	DescriptorHandle argument is related to IRD.
HY021	Inconsistent descriptor information	The Type field, or other field related to SQL_DESC_TYPE field of the descriptor is not valid or consistent.
HY090	Invalid string or buffer length	The driver is set to ODBC 2.x driver, and the descriptor is set to ARD, and ColumnNumber argument is set to 0 and the value specified in BufferLength argument is not 4.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed	For more information about the suspended state, refer to **SQLEndTran**.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source response to the request. The connection timeout interval can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetConnectAttr.
IM001	Driver does not support this function	The driver does not support the function.

Description

The application can call SQLSetDescRec to set the following fields for a column or parameter.

- SQL_DESC_TYPE
- SQL_DESC_DATETIME_INTERVAL_CODE (For the record of SQL_DATETIME or SQL_INTERVAL type)
- SQL_DESC_OCTET_LENGTH
- SQL_DESC_PRECISION
- SQL_DESC_SCALE
- SQL_DESC_DATA_PTR
- SQL_DESC_OCTET_LENGTH_PTR
- SQL_DESC_INDICATOR_PTR

If calling SQLSetDescRec fails, the content of the descriptor record identified by RecNumber argument is not defined.

When binding a column or parameter, SQLSetDescRec allows to change the multiple fields which affect the binding without calling SQLBindCol, SQLBindParameter or calling SQLSetDescField multiple times. SQLSetDescRec can set the descriptor fields which are not related to the current statement. SQLBindParameter can set more fields than SQLSetDescRec, and it can set the fields of APD and IPD with a single call and it does not require a descriptor handle.

The SQL_ATTR_USE_BOOKMARKS statement attribute should be set before calling SQLSetDescRec with RecNumber argument of 0 to set bookmark fields. It is not necessary but is strongly recommended.

Consistency Check

The consistency check is automatically implemented by the driver whenever the application sets SQL_DESC_DATA_PTR field of APD, ARD, or IPD. If any of the fields is not consistent with other fields, SQLSetDescRec will return SQLSTATE HY021. (Inconsistent descriptor information)

Whenever the application sets SQL_DESC_DATA_PTR field of APD, ARD or IPD, the driver checks the value of SQL_DESC_TYPE field, and checks if the values applicable to that SQL_DESC_TYPE field is valid and consistent. The check is implemented when SQLBindParameter or SQLBindCol is called or whenever SQLSetDescRec is called to APD, ARD or IPD. The consistency check includes the following descriptor fields.

- SQL_DESC_TYPE field should be one of the valid ODBC C, SQL type or the driver-specific SQL type. SQL_DESC_CONCISE_TYPE field should be one of the valid ODBC C, SQL Type or the driver-specific SQL type, and it includes the simplified datetime and interval types.
- If SQL_DESC_TYPE record field is SQL_DATETIME or SQL_INTERVAL, SQL_DESC_DATETIME_INTERVA

L_CODE field should be one of the valid datetime or interval codes. (For more information refer to th e description of SQL_DESC_DATETIME_INTERVAL_CODE field in **SQLSetDescField**.)

- If SQL_DESC_TYPE field is a NUMERIC type, SQL_DESC_PRECISION and SQL_DESC_SCALE fields are c hecked whether they are valid.
- If SQL_DESC_CONCISE_TYPE field is the time or timestamp data type an interval type with a seconds component, or one of the interval data types with a time component, SQL_DESC_PRECISION field is c hecked whether it is a valid second precision.
- If SQL_DESC_CONCISE_TYPE is an interval data type, SQL_DESC_DATETIME_INTERVAL_PRECISION fi eld is checked to be a valid interval leading precision value.

SQL_DESC_DATA_PTR field of IPD is not generally set. The application can do so to force the consistency check for the IPD fields. Consistency check can not be executed in IRD. The value of SQL_DESC_DATA_PT R field of IPD is not actually stored and it can not be retrieved via SQLGetDescField or SQLGetDescRec. Th e setting is made only to force the consistency check.

SQLSetEnvAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLSetEnvAttr sets the environment management attributes.

Syntax

```
SQLRETURN SQLSetEnvAttr(
    SQLHENV      EnvironmentHandle,
    SQLINTEGER   Attribute,
    SQLPOINTER   ValuePtr,
    SQLINTEGER   StringLength);
```

Arguments

EnvironmentHandle

[Input] It is the environment handle.

Attribute

[Input] They are listed in **Description**.

ValuePtr

[Input] It is a pointer to the value which is related to an attribute. Depending on the value of Attribute, ValuePtr points to a 32 bit integer value or null-terminated character.

StringLength

[Input] If ValuePtr points to the string or binary buffer, the argument should be the length of *ValuePtr. The argument should include the number of bytes in string for the character string data.

If ValuePtr is an integer, StringLength is ignored.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value changed	The driver does not support the value specified in ValuePtr and replaces it with a similar value. (The function returns SQL_SUCCESS_WITH_INFO.)
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY009	Invalid use of null pointer	The attribute argument identifies an environment attribute which requires a string value, and ValuePtr argument is a NULL pointer.
HY010	Function sequence error	The connection handle is allocated to EnvironmentHandle. SQL_ATTR_ODBC_VERSION is not set to SQLSetEnvAttr, Attribute is different from SQL_ATTR_ODBC_VERSION. If SQLAllocHandleStd is used, SQL_ATTR_ODBC_VERSION does not need to be explicitly specified.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY024	Invalid attribute value	Considering the specified attribute value, the value of ValuePtr is not valid.
HY090	Invalid string or buffer length	StringLength argument is smaller than 0. (It is not SQL_NTS.)
HY092	Invalid attribute/option identifier	The specified value of attribute argument is not valid in ODBC version supported by the driver.
HY117	Connection is suspended due to unknown trasaction state. Only disconnect and read-only functions ard allowed	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The specified value of attribute argument is valid fot the ODBC environment attribute supported by the driver but it is not supported by the driver. An attribute argument is SQL_ATTR_OUTPUT_NTS, and ValuePtr is SQL_FALSE.

Description

The application can call SQLSetEnvAttr only when connection handle allocated to the environment handl e does not exist. The environment attributes which is set by the application persist until SQLFreeHandle is called to the environment handle. It is recommended to allocate and use only one environment handle.

The information format set through ValuePtr is dependent on the specified attribute. SQLSetEnvAttr acce pts one attribute information of two different formats which are the null-termination string or 32 bits int eger value. Each attribute format is described in the description of the attribute.

The driver-specific environment attributes does not exist.

The connection attribute can not be set with SQLSetEnvAttr. If it is tried, SQLSTATE HY092 (Invalid attrib ute/option identifier) will be returned.

Attribute	ValuPtr contents
SQL_ATTR_CONNECTION_POOLING (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_CP_MATCH (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_ODBC_VERSION (ODBC 3.0)	32-bit integer which indicates whether a particular feature is operated as ODBC 2.x or ODBC 3.x. The following values are used to set the attribute. • SQL_OV_ODBC3_80: The driver manager and driver exhibit the following ODBC 3.8 behaviors. ◦ The driver expects and returns ODBC 3.x code value for DATE, TIME, TIMESTAMP. ◦ The driver returns ODBC 3.x SQLSTATE codes when SQLError, SQLGetDiagField or SQLGetDiagRec is called. ◦ CatalogName argument of SQLTables allows the pattern search. • SQL_OV_ODBC3: The driver manager and driver exhibit the following ODBC 3.x behaviors. ◦ The driver expects and returns ODBC 3.x code value for DATE, TIME, TIMESTAMP. ◦ The driver returns ODBC 3.x SQLSTATE codes when SQLError, SQLGetDiagField or SQLGetDiagRec is called. ◦ CatalogName argument of SQLTables allows the pattern search. ◦ The driver manager does not support the extensibility of C data types. • SQL_OV_ODBC2: The driver manager and driver exhibit the following ODBC 2.x behaviors. It is very useful when the ODBC 2.x application operates in ODBC 3.x. ◦ The driver expects and returns ODBC 2.x code value for DATE, TIME, TIMESTAMP. ◦ The driver returns ODBC 2.x SQLSTATE codes when SQLError, SQLGetDiagFi

Attribute	ValuPtr contents
	eld or SQLGetDiagRec is called. ◦ CatalogName argument of SQLTables does not allow the pattern search. ◦ The driver manager does not support the extensibility of C data types. The application should set the environment attribute value before calling any function which has SQLHENV argument, or it returns SQLSTATE HY010 (Function sequence err or). It is driver-specific whether additional behavior exists for these environmental flag s.
SQL_ATTR_OUTPUT_NTS (ODBC 3.0)	It is not supported by the driver.

SQLSetParam

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

ODBC 1.0 function SQLSetParam is replaced with ODBC 2.0 function SQLBindParameter. For more information, refer to **SQLBindParameter**.

SQLSetPos

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLSetPos sets the cursor position in the row set and allows the application to update the data in the ro w set or to update or delete the data in the result set.

Syntax

```
SQLRETURN SQLSetPos(
    SQLHSTMT        StatementHandle,
    SQLSETPOSIROW   RowNumber,
    SQLUSMALLINT    Operation,
    SQLUSMALLINT    LockType);
```

Arguments

StatementHandle

[Input] It is the statement handle.

RowNumber

[Input] It is the row position in the row set which is specified with Operation argument to impleme nt the operation. If RowNumgber is 0, the operation is applied to all rows in the row set.

For more information, refer to **Description** section.

Operation

[Input] The operations to perform are SQL_POSITION, SQL_REFRESH, SQL_UPDATE, SQL_DELETE.

SQL_ADD value of Operation argument is not used in ODBC 3.x any more. The ODBC 2.x driver wil l be required to support SQL_ADD for the backward compatibility. This feature is replaced by callin g SQLBulkOperaions with operation of SQL_ADD. When ODBC 3.x application is performed with O DBC 2.x driver, the driver manager maps a call of SQLBulkOperations with an operation of SQL_AD D to a call of SQLSetPos with an operation of SQL_ADD.

For more information, refer to **Description** section.

LockType

[Input] The way to lock the row is specified after implementing the operation specified in Operation argument.

SQL_LOCK_NO_CHANGE, SQL_LOCK_EXCLUSIVE, SQL_LOCK_UNLOCK

For more information, refer to **Description** section.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_NEED_DATA, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01001	Cursor operation conflict	Operation argument is SQL_DELETE or SQL_UPDATE. One or more rows are deleted/ updated, or any row is not deleted/ updated. Operation argument is SQL_DELETE or SQL_UPDATE, and optimistic concurrency causes the operation failure. (The function returns SQL_SUCCESS_WITH_INFO.)
01004	String data, right truncation	Operation argument is SQL_REFRESH, and string or binary data returned for a column(s) with a data type of SQL_C_CHAR or SQL_C_BINARY truncates non white space character or non-NULL binary data.
01S01	Error in row	RowNumber argument is 0, and an error occurred in one or more rows while the operation which is specified in operation argument is executed. (If an error occurs on one or more, but not all, rows of a multirow operation, SQL_SUCCESS_WITH_INFO is returned. If an error occurs on a single row operation, SQL_ERROR is returned) (If the driver is ODBC 2.x and the cursor library is not used, then this SQLSTATE occurs only when SQLSetPos is called after SQLExtendedFetch.)
01S07	Fractional truncation	If an operation argument is SQL_REFRESH and the buffer type of the application is not SQL_C_CHAR or SQL_C_BINARY, and the data returned to the application buffer for one or more columns are truncated. For the numeric data types, the fractional parts of the number are truncated. For time, timestamp, and interval data types including a time component, the fractional parts of the time are truncated.
07006	Restricted data type attribute viola	The column data value of the result set can not be converted to the data type specified in TargetType when SQLBindCol is called.

SQLSTATE	Error	Description
	tion	
07009	Invalid descriptor index	Operation argument is SQL_REFRESH or SQL_UPDATE, and the column value which is bigger than the number of columns in the result set is bound.
21S02	Degree of derived table does not match column list	Operation argument is SQL_UPDATE, and updatable column does not exist because all bound column are released, read-only or the value in bound length/indicator buffer is SQL_COLUMN_IGNORE.
22001	String data, right truncation	Operation argument is SQL_UPDATE, and the assignment of a character or binary value to a column causes the truncation of a non empty string (for character), or non-null string (for binary) or bytes.
22003	Numeric value out of range	Operation argument is SQL_UPDATE, and the assignment of a numeric value to a column in the result set causes the truncation of whole part of the number. Operation argument is SQL_REFRESH, and returning the numeric value for one or more bound column causes the loss of significant digits.
22007	Invalid datetime format	Operation argument is SQL_UPDATE, and the assignment of date or timestamp value to a column in the result set causes the year, month, day field to be out of range. Operation argument is SQL_REFRESH, and returning date or timestamp value for one or more bound column causes the year, month, day field to be out of range.
22008	Date/time field overflow	Operation argument is SQL_UPDATE, and the performance of datetime arithmetic on data being sent to a column in the result set causes a datetime field (the year, month, day, hour, minute, or second field) of the result being outside the permissible range of values for the field, or being invalid based on the Gregorian calendar's natural rules for datetimes. Operation argument is SQL_REFRESH, and the performance of datetime arithmetic on data being retrieved from the result set causes a datetime field (the year, month, day, hour, minute, or second field) of the result being outside the permissible range of values for the field, or being invalid based on the Gregorian calendar's natural rules for datetimes.
22015	Interval field overflow	The Operation argument is SQL_UPDATE, and assigning an exact numeric or interval C type to an interval SQL data type causes a loss of significant digits. The Operation argument is SQL_UPDATE, and when assigning to an interval SQL type, representation of the value of the C type does not exist in the interval SQL type. The Operation argument is SQL_REFRESH, and assigning from an exact nu

SQLSTATE	Error	Description
		meric or interval SQL type to an interval C type causes a loss of significant di gits in the leading field. The Operation argument is SQL_ REFRESH, and when assigning to an interv al C type, representation of the value of the SQL type does not exist in the in terval C type.
22018	Invalid character value for cast spe cification	Operation argument is SQL_REFRESH, and C type is the exact or approximat e numeric, datetime or interval data types. The SQL type of the column is a c haracter data type. And the column value is not a valid character for the bo und C type. Operation argument is SQL_UPDATE, and the SQL type is the exact or appro ximate numeric, datetime or interval data type. The C type of the column is SQL_C_CHAR. And the column value is not a valid character for the bound SQL type.
23000	Intergrity constrai nt violation	Operation argument is SQL_DELETE or SQL_UPDATE, and it violates the inte grity constraints.
24000	Invalid cursor stat e	StatementHandle is in the executed state but the result is not related to Stat ementHandle. The cursor is open to StatementHandle, but SQLFetch or SQLFetchScroll is n ot called. The cursor is open to StatementHandle and SQLFetch or SQLFetchScroll is ca lled. But the cursor is positioned before the starting point of the result set or after the end of the result set. Operation argument is SQL_DELETE, SQL_REFRESH or SQL_UPDATE.
40001	Serialization failu re	The transaction is rolled back due to a resource deadlock with another trans actions.
40003	Statement compl etion unknown	The connection is failed during the function execution, and the status of tra nsaction can not be determined.
42000	Syntax error or ac cess violation	The driver can not lock the rows as needed to implement the operation req uested in the operation argument. The driver can not lock the rows as requested in the LockType argument.
44000	WITH CHECK OP TION violation	Operation argument is SQL_UPDATE, and update on a viewed table or the t able derived from the viewed table which was created by specifying WITH_C HECK OPTION is performed to prevent the existence of one or more rows af fected by the update in the viewed table.
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cau se.

SQLSTATE	Error	Description
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY008	Operation canceled	The asynchronous processing is activated for StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed, and the function is called again on StatementHandle. The function is called, and before it completed execution, SQLCancel or SQLCancelHandle is called on the StatementHandle from a different thread in a multithread application.
HY010	Function sequence error	The asynchronously executing function is called for the StatementHandle when SQLSetPos was executed, and this function is still being executed when SQLSetPos is called. SQLExecute, SQLExecDirect or SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned, and the function is called before the data was retrieved from the streamed parameters. The asynchronously executing function is called for the StatementHandle, and this function is still being executed when this function is called. SQLExecute, SQLExecDirect or SQLMoreResults is executed in StatementHandle, and SQL_NEED_DATA is returned, and the function is executed before all data is sent. The driver is ODBC 2.x, and SQLSetPos is called in StatementHandle after SQFetch is called.
HY011	Attribute cannot be set now	The driver version is ODBC 2.x, SQL_ATTR_ROW_STATUS_PTR statement attribute is set, and SQLSetPos is called before SQLFetch, SQLFetchScroll or SQLExtendedFetch is called at the time.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY090	Invalid string or buffer length	Operation argument is SQL_UPDATE.
HY092	Invalid attribute identifier	The value which is specified in Operation argument is not valid. The value which is specified in LockType argument is not valid. Operation argument is SQL_UPDATE or SQL_DELETE, and SQL_ATTR_CONCURRENCY statement attribute is SQL_ATTR_CONCUR_READ_ONLY.
HY107	Row value out of range	The value which is specified in RowNumber argument is bigger than the number of rows in the row set.
		The cursor can not be positioned in the row set because the cursor which is

SQLSTATE	Error	Description
HY109	Invalid cursor position	related to StatementHandle is set to forward-only. For more information, refer to the description of SQL_ATTR_CURSOR_TYPE attribute of SQLSetStmtAttr. Operation argument is SQL_UPDATE, SQL_DELETE or SQL_REFRESH, and the row which is identified by RowNumber argument is deleted or returned. RowNumber argument is 0, and operation argument is SQL_POSITION. SQLSetPos is called after SQLBulkOperations is called and before SQLFetchScroll or SQLFetch is called.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The driver or data source does not support the operation requested in operation argument or LockType argument.
HYT00	Timeout expired	The query timeout period is expired before returning the entire result set from the data source. The timeout can be set via SQL_ATTR_QUERY_TIMEOUT of SQLSetStmtAttr.
HYT01	Connection timeout expired	The connection is expired before the data source responds to the request. The timeout can be set via SQL_ATTR_CONNECTION_TIMEOUT of SQLSetStmtAttr.
IM001	Driver does not support this function	The driver which is related to StatementHandle does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

RowNumber Argument

RowNumber argument specifies the number of rows in the row set affected by the operation implementation specified in Operation argument. If RowNumber is 0, it is applied to all rows in the row set. RowNumber should be from 0 up to the number of rows in the row set.

The array is 0-based 0 in C language but the RowNumber is 1-based. For example, when updating the fifth row in the row set, the application updates the row set buffer of the array index 4, but RowNumber specifies to 5.

All operations position the cursor on the row specified by RowNumber. The following operation requires the cursor position.

- Positioned update or delete statements
- Calling SQLGetData
- Calling SQLSetPos with the SQL_DELETE, SQL_REFRESH or SQL_UPDATE option

Operation Argument

Operation argument supports the following operations. The application calls SQLGetInfo with the information type of SQL_DYNAMIC_CURSOR_ATTRIBUTES1, SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES1, SQL_KEYSET_CURSOR_ATTRIBUTES1 or SQL_STATIC_CURSOR_ATTRIBUTES1 (depending on the cursor type.) to verify the options supported by the data source.

Operation argument	Operation
SQL_POSITION	The driver positions the cursor at the row specified in RowNumber. The content of row status array which is pointed by SQL_ATTR_ROW_OPERATION_PTR statement attribute is ignored by SQL_POSITION.
SQL_REFRESH	It is not supported by the driver.
SQL_UPDATE	It is not supported by the driver.
SQL_DELETE	It is not supported by the driver.

LockType Argument

LockType argument provides the method for the application to control the concurrency. In most case, the data source which provides the concurrency level and transaction supports SQL_BLOCK_NO_CHANGE value to LockType argument.

LockType argument specifies the lock state of rows after executing SQLSetPos. If the driver can not lock the row either to perform the requested operation or to satisfy the LockType argument, it returns SQL_ERROR and SQLSTATE 42000(Syntax error or access violation).

Although LockType argument is specified in a statement, it is applied to all statements of the same privile ges on the connection. The special lock which is acquired by a statements on the connection can be unlo cked by another statement on the same connection.

A row locked through SQLSetPos remains locked until the application calls SQLSetPos for the row with Lo ckType set to SQL_LOCK_UNLOCK, or until the application calls SQLFreeHandle for the statement or SQLF reeStmt with the SQL_CLOSE option. When the driver supports the transaction, the row lock through SQ LSetPos is unlocked when the application commits or rolls back the transaction on the connection by calli ng SQLEndTran. (If the cursor is closed when a transaction is committed or rolled back as indicated by the of SQL_CURSOR_COMMIT_BEHAVIOR and SQL_CURSOR_ROLLBACK_BEHAVIOR information types retur ned by SQLGetInfo.)

LockType argument supports the following lock types. The application calls SQLGetInfo with the SQL_DY NAMIC_CURSOR_ATTRIBUTES1, SQL_FORWARD_ONLY_CURSOR_ATTRIBUTES1, SQL_KEYSET_CURSOR _ATTRIBUTES1 or SQL_STATIC_CURSOR_ATTRIBUTES1 information type to verify the lock supported by t he data source.

LockType argument	Lock type
SQL_LOCK_NO_CHANGE	The driver or data source ensures the locking or unlocking of the same row as it was b efore SQLSetPos is called. The value of LockType does not allow explicit row-level locki ng so that any lock required by the current concurrency and transaction isolation level s can be used.
SQL_LOCK_EXCLUSIVE	The driver or data source performs the exclusive lock on a row. The statement on oth er connection or in other application can not be used to acquire any locks on the row.
SQL_LOCK_UNLOCK	The driver or data source releases the lock.

When the update and delete operations are performed in SQLSetPos, the application uses the following L ockType argument.

- An application calls SQLSetPos with operation set to SQL_REFRESH, and LockType set to SQL_LOCK_ EXCLUSIVE to guarantee that the row is not updated after it is retrieved.
- If the application sets LockType to SQL_LOCK_NO_CHANGE, the driver guarantees the update or del ete operation only when the application specifies SQL_CONCUR_LOCK for SQL_ATTR_CONCURRENC Y statement attribute.
- If the application specifies SQL_CONCUR_ROWVER or SQL_CONCUR_VALUES for SQL_ATTR_CONCU RRENCY statement attribute, the driver compares the version or value of the row and denies the oper ation when the row is changes since the application fetched the row.
- If the application specifies SQL_CONCUR_READ_ONLY for SQL_ATTR_CONCURRENCY statement attr ibute, the driver denies any update or delete operation.

For more information about SQL_ATTR_CONCURRENCY statement attribute, refer to **SQLSetStmtAttr**.

Status and Operation Array

The following status and operation arrays are used when SQLSetPos is called.

- The row status array includes the status value of each row data in the row set. The driver sets the stat us value in the array after calling SQLFetch, SQLFetchScroll, SQLBulkOperations or SQLSetPos. The arr ay is pointed to by SQL_ATTR_ROW_STATUS_PTR statement attribute.
- The row operation array includes each row value in the row set which indicates whether SQLSetPos c all for the bulk operation is ignored or performed. Each element in the array sets one of SQL_ROW_P ROCEED or SQL_ROW_IGNORE. The array is pointed to by SQL_ATTR_ROW_OPERATION_PTR statem ent attribute.

The number of elements in the status and operation array should be equal to the number of rows in the r ow set (as defined by the SQL_ATTR_ROW_ARRAY_SIZE statement attribute).

For more information about the row status array, refer to **SQLFetch**.
For more information about the row operation array, refer to **Ignoring Rows in the Bulk Operation**.

Using SQLSetPos

The application should perform the following steps before using SQLSetPos.

1. If the application calls SQLSetPos with operation set to SQL_UPDATE, call SQLBindCol (or SQLSetDes cRec) for each column to specify its data type and bind buffers for the column's data and length.
2. If the application calls SQLSetPos with operation set to SQL_DELETE or SQL_UPDATE, call SQLColAttr ibute to make sure that the columns to be deleted or updated are updatable.
3. The result set is generated by calling SQLExecDirect, SQLExecute or the catalog function.
4. The data is retrieved by calling SQLFetch or SQLFetchScroll.

Deleing Data Using SQLSetPos

An application calls SQLSetPos with RowNumber set to the number of the row to delete and calls operati on set to SQL_DELETE, to delete data by using SQLSetPos.

After the data is deleted, the driver changes the value in the implementation row status array for the app ropriate row to SQL_ROW_DELETED (or SQL_ROW_ERROR).

Updating Data Using SQLSetPos

The application can pass the data to the column through one of the bound buffer or once or more SQLPu tData calls. Columns whose data is passed with SQLPutData are known as data-at-execution columns. Us ually it may be used to transfer data to SQL_LONGVARBINARY and SQL_LONGVARCHAR and it can be m ixed with other columns.

Updating Data Using SQLSetPos in Application

1. Place value in the data and length/indicator buffer bound with SQLBindCol.

- For general columns, the application positions the new column value in *TargetValuPtr buffer and th e value length in *StrLen_or_IndPtr buffer. If the row should not be updated, the application position s SQL_ROW_IGNORE in the row element in the row operation array.
- For data-at-execution columns, the application positions an application-defined value, such as the col umn number, in the *TargetValuePtr buffer. The value can be used later to identify the column.
  The application positions the macro result of SQL_LEN_DATA_AT_EXEC(length) in *StrLen_or IndPtr buffer. If the SQL data type of the column is SQL_LONGVARBINARY, SQL_LONGVAR_CHAR or the so urce-defined long data type and the driver returns Y to SQL_NEED_LONG_DATA information type of SQLGetInfo, length is the number of bytes to be sent to the parameter. Otherwise, it is not a negative and it should be ignored.

2. Call SQLSetPos with the operation argument set to SQL_UPDATE to update the row of data.

- If data-at-execution columns do not exist, the processing is completed.
- If data-at-execution columns exist, the function returns SQL_NEED_DATA and proceeds the step 3.

3. Call SQLParamData to retrieve the address of *TargetValuePtr buffer for the first data-at-execution c olumn to be processed. SQLParamData returns SQL_NEED_DATA. The application retrieves the appli cation-defined value in *TargetValuPtr buffer.

- Though data-at-execution parameter is similar to the data-at-execution column, but each v alue which is returned by SQLParamData is different.

- Data-at-execution parameters are parameters in an SQL statement for which data will be se nt with SQLPutData when the statement is executed with SQLExecDirect or SQLExecute. Th ey are bound to SQLBindParameter or SQLSetDescRec by setting the descriptors. The value which is returned by SQLParamData is the 32 bits value and it is sent to SQLBindParameter of ParameterValuePtr argument.

- Data-at-execution columns are columns in a row set for which data will be sent with SQLPu tData when a row is updated with SQLSetPos. They are bound with SQLBindCol. The value r eturned by SQLParamData is the address of the row in the *TargetValuePtr buffer which is being processed.

4. Call SQLPutData once or more times to transfer data to the column. If all data values can not be retu rned in *TargetValuePtr buffer specified in SQLPutData, multiple calls are needed. Only when the ch aracter data of C language is sent to the column with a character, binary or a data source data type, or when the binary data of C language is sent to to the column with a character, binary or a data so

urce data type, then multiple calls of SQLPutData are allowed for the same column.

5. Call SQLParamData again to indicate all data are sent to the column.

- If more data-at-execution columns exist, then SQLParamData returns SQL_NEED_DATA and the addr ess of the TargetValuePtr buffer for the next data-at-execution column to be processed. The applicati on repeats the steps 4 and 5.
- If data-at-execution columns do not exist any more, then the processing is completed. If the stateme nt is successfully executed, SQLParamData returns SQL_SUCCESS or SQL_SUCCESS_WITH_INFO. If ex ecution is failed, SQL_ERROR is returned. At this point, SQLParamData returns any SQLSTATE which c an be returned by SQLSetPos.

If the data is updated, the driver changes the value in the implementation row status array for the approp riate row to SQL_ROW_UPDATED.

If the operation is canceled or an error occurs in SQLParamData or SQLPutData, after SQLSetPos returns S QL_NEED_DATA and before data is transferred for all data-at-execution columns, the application can call only SQLCancel, SQLGetDiagField, SQLGetDiagRec, SQLGetFunctions, SQLParamData, or SQLPutData for the statement or the connection related to the statement. At this point, if another function is called, SQL _ERROR and SQLSATATE HY010 (Function sequence error) are returned.

If the application calls SQLCancel while the driver still needs the data of data-at-execution columns, the d river cancels the operation. The application can call SQLSetPos again later. Cancellation does not affect th e cursor state or the current cursor position.

When SELECT-list of the query specification related to the cursor includes one or more references in the s ame column, the driver defines whether an error occurs or the driver ignores the duplicated reference an d implements the requested operation.

Executing the Bulk Operation

If the RowNumber argument is 0, the driver performs the operation specified in the operation argument f or every row in the rowset which has a value of SQL_ROW_PROCEED in its field in the row operation arra y pointed to by SQL_ATTR_ROW_OPERATION_PTR statement attribute. This is a valid value of the RowNu mber argument for an operation argument of SQL_DELETE, SQL_REFRESH, or SQL_UPDATE, but not SQL _POSITION. SQLSetPos with an operation of SQL_POSITION and a RowNumber equal to 0 will return SQL STATE HY109 (Invalid cursor position).

If an error occurs in the entire row set, such as SQLSTATE HYT00 (Timeout expired), the driver returns SQ L_ERROR and the appropriate SQLSTATE. The contents of the row set buffers are undefined, and the curs or position is unchanged.

If an error occurs in a single row, the driver performs the followings.

- It sets the row element in the row status array pointed by SQL_ATTR_ROW_STATUS_PTR statement a

ttribute to SQL_ROW_ERROR.
- It adds one or more SQLSTATE to an error in the error queue, and sets SQL_DIAG_ROW_NUMBER fie ld of the diagnostic data structure.

If the driver completes the remaining row operation in the row set after an error or warning is processed, SQL_SUCCESS_WITH_INFO is returned. Therefore, the error queue includes zero or more SQLSTATE for t he rows which return the errors. The driver stops the operation after processing an error or warning and r eturns SQL_ERROR.

If the driver returns a warning such as SQLSTATE 01004 (Data truncated), then the driver returns a warni ng applied to the entire row set or unknown rows in the row set before returning the error information w hich is applied to a specific row. It returns warnings for specific rows together with other error informatio n about those rows.

If RowNumber is 0 and operation is SQL_UPDATE, SQL_REFRESH or SQL_DELETE, then the number of ro ws on which SQLSetPos operates is set by SQL_ATTR_ROWS_FETCHED_PTR statement attribute.

If RowNumber is 0 and the operation is SQL_DELETE, SQL_REFRESH or SQL_UPDATE, then the current ro w after the operation is as same as the row before the operation.

Ignoring Rows in the Bulk Operation

The row operation array can be used to specify the row which should be ignored in the current row set d uring the bulk operation with SQLSetPos. The application should perform the following steps to make the driver ignore one or more rows in the driver during the bulk operation.

1. It calls SQLSetStmtAttr to set the SQL_ATTR_ROW_OPERATION_PTR statement attribute to point to an array of SQLUSMALLINTs. This field can also be set by calling SQLSetDescField to set the SQL_DES C_ARRAY_STATUS_PTR header field of the ARD, which requires that an application obtains the desc riptor handle.

2. It sets each element in the row operation array to one of the following values.

- Setting to SQL_ROW_IGNORE it indicates that the row is excluded in the bulk operation.
- Setting to SQL_ROW_PROCEED it indicates that the row is included in the bulk operation.

3. It performs the bulk operation by calling SQLSetPos.

The following rules are applied to the row operation array.

- SQL_ROW_IGNORE and SQL_ROW_PROCEED affect only bulk operations using SQLSetPos with an o peration of SQL_DELETE or SQL_UPDATE. They do not affect calling SQLSetPos with an operation of SQL_REFRESH or SQL_POSITION.
- The pointer is set to NULL by default.
- If the pointer is NULL, then all rows are updated like as all elements are set to SQL_ROW_PROCEED.
- Setting the element to SQL_ROW_PROCEED does not guarantee occurrance of the operation in a par

ticular row. If a certain row in the row set has the SQL_ROW_ERROR status, the driver can not updat e that row regardless of whether the application specified SQL_ROW_PROCEED. The application sho uld always check the row status array to see whether the operation was successful.

- SQL_ROW_PROCEED is defined as 0 in the header file. The application can initialize the row operatio n array to 0 to process all rows.
- If the n-th element of the row status array is set to SQL_ROW_IGNORE and the bulk update or delete operation is executed by calling SQLSetPos, the n-th row in the row set remains unchanged after calli ng SQLSetPos.
- The application should automatically set a read-only column to SQL_ROW_IGNORE.

Ignoring Columns in the Bulk Operation

The application can set the value in the bound length/indicator buffer to SQL_COLUMN_IGNORE so that i t can avoid unnecessary processing diagnostics caused by attempting to update one or more read-only co lumns. For more information, refer to **SQLBindCol**.

SQLSetScrollOptions

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLSetScrollOptions function in ODBC 2.0 is replaced with calling SQLGetInfo and SQLSetStmtAttr in ODBC 3.x.

When the driver manager maps SQLSetScrollOptions for the application which operates with ODBC 3.x driver which does not support SqlSetScrollOptions, the driver manager sets SQL_ROW_SET_SIZE statement option, not the SQL_ATTR_ROW_ARRAY_SIZE statement attribute in RowsetSize argument of SQLSetScrollOptins. As a result, SQLSetScrollOptions can not be used by an application when fetching multiple rows by calling SQLFetch or SQLFetchScroll, and it can be used only when fetching multiple rows by calling SQLExtendedFetch.

SQLSetStmtAttr

Conformance

Introduced version: ODBC 3.0
Standards compliance: ISO 92

Overview

SQLSetStmtAttr sets the attributes related to the statements.

Syntax

```
SQLRETURN SQLSetStmtAttr(
    SQLHSTMT      StatementHandle,
    SQLINTEGER    Attribute,
    SQLPOINTER    ValuePtr,
    SQLINTEGER    StringLength);
```

Arguments

StatementHandle

[Input] It is the statement handle.

Attribute

[Input] It is the option to be set. For more information, refer to the **Description** section.

ValuePtr

[Input] It is the value which is related to the attribute. ValutPtr can be one of the followings accordi ng to the attribute value.

- ODBC descriptor handle
- SQLUINTEGER value
- SQLULEN value
- One of the following pointers

° Null-termination character string

° Binary buffer

° SQLLEN, SQLULEN, SQLUSMALLINT values or the array of values

° Driver-defined value

If Attribute argument is the driver-specific value, ValuePtr may be an integer.

StringLength

[Input] If an attribute is an ODBC-defined attribute and ValuePtr points to a string or binary buffer, the argument is the length of *ValuePtr. If Attribute is a ODBC-defined attribute and ValuePtr is an integer, the argument is ignored. StringLength may have one of the following values.

If Attribute is a driver-defined attribute, the application indicates the nature of the attribute to the driver manager by setting StringLength argument.

- If ValuePtr is a string pointer, Stringlength is the string length or SQL_NTS.
- If ValuePtr is a binary buffer, the application stores SQL_LEN_BINARY_ATTR (length) macro result in StringLength. StringLength has a negative value.
- If ValuePtr is a pointer of a different value other than a string or a binary buffer, StringLength must have SQL_IS_POINTER value.
- If ValuePtr includes a fixed length value, StringLength is SQL_IS_INTEGER or SQL_IS_UINTEGER.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
01S02	Option value changed	It is temporarily replaced with a similar value because the driver does not support the value specified in ValuePtr or the value specified in ValuePtr is invalid due to the implementation working conditions. (SQLGetStmtAttr can be called to see which value is temporarily replaced.) The replaced value is valid for the StatementHandle until the cursor is closed, and it is changed to the previous value when the cursor is closed. The statement attributes which can be changed are as follows. SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ATTR_KEYSET_SIZE, SQL_ATTR_MAX_LENGTH, SQL_ATTR_MAX_ROWS, SQL_ATTR_QUERY_TIMEOUT, SQL_ATTR_ROW_ARRAY_SIZE, SQL_ATTR_SIMULATE_CURSOR. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	Attribute is SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ATTR_SIMULATE_CURSOR or SQL_ATTR_USE_BOOKMARKS, and the cursor is open.

SQLSTATE	Error	Description
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY009	Invalid use of null pointer	The statement attribute which is identified by Attribute argument requires the string attribute, and ValuePtr argument is a NULL pointer.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLSetStmtAttr is called. SQLExecute, SQLExecDirect or SQLMoreResults are called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. This function is called before the data is returned for the streamed parameters. The asynchronously executing function is called for StatementHandle, and is still being executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY011	Attribute cannot be set now	Attribute is SQL_ATTR_CONCURRENCY, SQL_ATTR_CURSOR_TYPE, SQL_ATTR_SIMULATE_CURSOR or SQL_ATTR_USE_BOOKMARKS, and the statement is prepared.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY017	Invalid use of an automatically allocated descriptor handle	Attribute argument is SQL_ATTR_IMP_ROW_DESC or SQL_ATTR_IMP_PARAM_DESC. Attribute argument is SQL_ATTR_APP_ROW_DESC or SQL_ATTR_APP_PARAM_DESC, and the value in ValuePtr is an implicitly allocated descriptor handle other than the handle originally allocated for the ARD or APD.
HY024	Invalid attribute value	Considering the specified Attribute value, the value in ValuePtr is invalid. (The driver manager returns this SQLSTATE only for the statement attribute and connection which allows the separate set such as SQL_ATTR_ACCESS_MODE or SQL_ATTR_ASYNC_ENABLE. The driver should verify the value in ValuePtr for other connection and statement attribute.) Attribute argument is SQL_ATTR_APP_ROW_DESC or SQL_ATTR_APP_PARAM_DESC, and ValuePtr is an explicitly allocated descriptor handle which is not on the same connection as the StatementHandle argument.
HY090	Invalid string or buffer length	*ValuePtr is a string and StringLength is smaller than 0. (It is not SQL_NTS.)

SQLSTATE	Error	Description
HY092	Invalid attribute/ option identifier	The value specified for the Attribute argument is invalid for the version of ODBC supported by the driver. The value which is specified in Attribute is the read-only attribute.
HY117	Connection is suspended due to unknown tracsaction state. Only disconnect and read-only functions are allowed	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	The value which is specified in Attribute argument is valid in ODBC version supported by the driver but it is not supported by the driver. Attribute argument is SQL_ATTR_ASYNC_ENABLE. When SQLGetInfo is called in InforType with SQL_ASYNC_MODE, then SQL_AM_CONNECTION is returned. Attribute argument is SQL_ATTR_ENABLE_AUTO_IPD, and the value of SQL_ATTR_AUTO_IPD connection attribute is SQL_FALSE.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source response to the request. The connection timeout period can be set via SQLSetConnectAttr of SQL_ATTR_CONNECTION_TIMEOUT.
IM001	Driver does not support this function	The driver does not support the function.
S1118	Driver does not support asynchronous notification	When calling SQLSetStmtAttr to set SQL_ATTR_ASYNC_STMT_EVENT the driver does not support the asynchronous notification.

Description

The statement attribute is updated by calling SQLSetStmtAttr or it remains effective until the statement is deleted by SQLFreeHandle. Calling SQLFreeStmt with SQL_CLOSE, SQL_UNBIND or SQL_RESET_PARAMS option does not reset the statement attribute.

Some statements attributes is replaces with a similar value if the driver does not support the value specified in ValuePtr. The driver returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value changed) for these cases. For example, if attribute is SQL_ATTR_CONCURRENCY and ValuePtr is SQL_CONCUR_ROWVER and the data source does not support it, the driver replace it with SQL_CONCUR_VALUES and returns SQL_SUCCESS_WITH_INFO. The application calls SQLGetStmtAttr to obtain the replaced value.

The format of information set with ValuePtr depends on the value specified in Attribute. SQLSetStmtAttr

accepts one of attribute information types such as a different character string or integer. Each type is described in the description of the attribute. The type is applied to the information returned for each attribute in SQLGetStmtAttr. The length of the character string pointed to by the ValuePtr argument of SQLSetStmtAttr is StringLength.

- The feature whose statement attribute is set at the connection level by calling SQLSetConnectAttr may disappear in ODBC 3.x. The ODBC 3.x application should not set the statement attribute at the connection level. The ODBC 3.x statement attribute can not be set at the connection level except for SQL_ATTR_METADATA_ID, and SQL_ATTR_ASYNC_ENABLE attribute is both the connection attribute and the statement attribute, and it can be set at the connection level and the statement level.

- ODBC 3.x driver requires the option feature which sets the driver version to ODBC 2.x at the connection level if the driver should operate with the ODBC 2.x application.

Statement Attribute to Set the Descriptor Field

Many statement attributes correspond to the header fields of the descriptor. Setting these attributes is the same result with setting the descriptor fields. Setting fields by calling SQLSetStmtAttr rather than calling SQLSetDescField has the advantage that a descriptor handle does not have to be obtained for the function call.

Calling SQLSetStmtAttr in a single statement may affect other statements. It happens when APD or ARD is explicitly assigned to the statement and it is related to other statements. SQLSetStmtAttr is applied to all statements related to this descriptor because it modifies APD or ARD. If it is not required operation, the application should separate this descriptor with other statements (by calling SQLSetStmtAttr to set the SQL_ATTR_APP_ROW_DESC or SQL_ATTR_APP_PARAM_DESC field to a different descriptor handle) before calling SQLSetStmtAttr again.

When the descriptor field is set as a result of the corresponding statement attribute being set, the field is set only for the applicable descriptors which are currently related to the statement identified by the StatementHandle argument, and the attribute setting does not affect any descriptor of the related statement in the future. When the descriptor field which is related to the statement handle is set to SQLSetDescField, the corresponding statement attribute is also set. If an explicitly allocated descriptor is dissociated from a statement, a statement attribute which corresponds to a header field will revert to the value of the field in the implicitly allocated descriptor.

When the statement is allocated, four descriptor handles are automatically allocated and is related to the statement. Explicitly allocated descriptor handles can be associated with the statement by calling SQLAllocHandle with an HandleType of SQL_HANDLE_DESC to allocate a descriptor handle and then calling SQLS

etStmtAttr to associate the descriptor handle with the statement.

The following is the statement attributes corresponding to the descriptor header field.

Statement attribute	Header field	Description
SQL_ATTR_PARAM_BIND_OFFSET_PTR	SQL_DESC_BIND_OFFSET_PTR	APD
SQL_ATTR_PARAM_BIND_TYPE	SQL_DESC_BIND_TYPE	APD
SQL_ATTR_PARAM_OPERATION_PTR	SQL_DESC_ARRAY_STATUS_PTR	APD
SQL_ATTR_PARAM_STATUS_PTR	SQL_DESC_ARRAY_STATUS_PTR	IPD
SQL_ATTR_PARAMS_PROCESSED_PTR	SQL_DESC_ROWS_PROCESSED_PTR	IPD
SQL_ATTR_PARAMSET_SIZE	SQL_DESC_ARRAY_SIZE	APD
SQL_ATTR_ROW_ARRAY_SIZE	SQL_DESC_ARRAY_SIZE	ARD
SQL_ATTR_ROW_BIND_OFFSET_PTR	SQL_DESC_BIND_OFFSET_PTR	ARD
SQL_ATTR_ROW_BIND_TYPE	SQL_DESC_BIND_TYPE	ARD
SQL_ATTR_ROW_OPERATION_PTR	SQL_DESC_ARRAY_STATUS_PTR	ARD
SQL_ATTR_ROW_STATUS_PTR	SQL_DESC_ARRAY_STATUS_PTR	IRD
SQL_ATTR_ROWS_FETCHED_PTR	SQL_DESC_ROWS_PROCESSED_PTR	IRD

Statement Attributes

The following table describes currently defined attributes and the version of ODBC in which they were int roduced.

Attribute	ValuePtr contents
SQL_ATTR_APP_PARAM_DESC (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_APP_ROW_DESC (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_ASYNC_ENABLE (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_EVENT (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_PCALLBACK (ODBC3.8)	It is not supported by the driver.
SQL_ATTR_ASYNC_STMT_PCONTEXT (ODBC 3.8)	It is not supported by the driver.
SQL_ATTR_ATOMIC_EXEC	SQLUSMALLINT: It is whether an atomic insert operation is operable.

Attribute	ValuePtr contents
UTION	• SQL_ATOMIC_EXECUTION_OFF • SQL_ATOMIC_EXECUTION_ON
SQL_ATTR_CONCURRENCY (ODBC 2.0)	The default value of SQL_ATTR_CONCURRENCY is SQL_CONCUR_READ_ONLY. • SQLULEN: It is the value which specifies the cursor concurrency. ◦ SQL_CONCUR_READ_ONLY: The cursor is read-only and the update is not allowed. ◦ SQL_CONCUR_LOCK: The cursor uses the minimum level locking enough to completely update the row. ◦ SQL_CONCUR_POWVER: The cursor uses the concurrency to control and compare the row version, such as SQLBase ROWID or Sybase TIMESTAMP. ◦ SQL_CONCUR_VALUES: The cursor uses the concurrency to control and compare the values. If SQL_ATTR_CURSOR_TYPE attribute is changed to the value which is not supported in SQL_ATTR_CONCURRENCY, the value of SQL_ATTR_CONCURRENCY may be changed at the execution time and a warning may occur when SQLExecDirect or SQLPrepare is called. While the driver supports SELECT FOR UPDATE statement and the statement is executed, an error occurs if SQL_ATTR_CONCURRENCY is changed to SQL_CONCUR_READ_ONLY. If SQL_ATTR_CONCURRENCY value is changed to SQL_ATTR_CURSOR_TYPE value which is supported by the driver, or to the value not supported by the driver, SQL_ATTR_CURSOR_TYPE value is changed at the execution time, and SQLSTATE 01S02 (Option value changed) may be returned when SQLExecDirect or SQLPrepare is executed. If the specified concurrency is not supported by the data source, the driver replaces it with other concurrency and returns SQLSTATE 01S02 (Option value changed). The driver replaces SQL_CONCUR_VALUES with SQL_CONCUR_ROWVER, or reverse. Also, SQL_CONCUR_LOCK is replaced with SQL_CONCUR_ROWVER, SQL_CONCUR_VALUES order. The validity of the replaced value is not confirmed until the execution time.
SQL_ATTTR_CURSOR_SCROLLABLE (ODBC 3.0)	• SQLULEN: It is the value specifying the required support level of the application. Setting the attribute affects the next SQLExecDirect and SQLExecute. ◦ SQL_NONSCROLLABLE: It is the default value. The scroll cursor is not required to the statement handle. If the application calls SQLFetchScroll to the handle, the only valid value of FetchOrientation is SQL_FETCH_NEXT. ◦ SQL_SCROLLABLE: The scroll cursor is required to the statement handle. When SQLFetchScroll is called, the application positions the cursor on the mode except the sequential mode and the valid value of FetchOrientation may be specified.
	• SQLULEN: The value which determines whether the cursor of the statement handle can view the change in the result set generated by the other cursor. Setting t

Attribute	ValuePtr contents
SQL_ATTR_CURSOR_SENSITIVITY (ODBC 3.0)	he field affects the next calls of SQLExecDirect and SQLExecute. The application can read again the attribute value to obtain the initial state or its latest state set by the application. ◦ SQL_UNSPECIFIED: It is the default value. It is unspecified what the cursor type is and whether cursors on the statement handle make visible the changes made to a result set by another cursor. The cursor of the statement handle can probably view none, some, or all such changes. ◦ SQL_INSENSITIVE: All cursors of the statement handle can view only the result but they can not view any changes made by the other cursor. The insensitive cursor is read-only. It corresponds to a static cursor with a read-only concurrency. ◦ SQL_SENSITIVE: It allows all cursors of the statement handle can view all of the changes in the result set generated by the other cursor.
SQL_ATTR_CURSOR_TYPE (ODBC 2.0)	• SQLULEN: It is the value which specifies the cursor type. ◦ SQL_CURSOR_FORWARD_ONLY: The cursor can only move forward. ◦ SQL_CURSOR_KEYSET_DRIVEN: The driver stores and uses the keys as many as the number of rows specified in SQL_ATTR_KEYSET_SIZE statement attribute. ◦ SQL_CURSOR_DYNAMIC: The driver stores and uses the key for only the row in the row set. The default value is SQL_CURSOR_FORWARD_ONLY. The attribute can not be specified in the prepared SQL statement. If the specified cursor type is not supported by the data source, the driver replaces it with the other type and returns SQLSTATE 01S02 (Option value changed. The driver replaces the mixed or dynamic cursor with the keyset-driven or static cursor. The driver replaces a keyset-driven cursor with a static cursor.
SQL_ATTR_ENABLE_AUTO_IPD (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_EXPLAIN_PLAN_OPTION	SQLUSMALLINT: Whether to create the plan information. • SQL_EXPLAIN_PLAN_OFF: Plan information is not generated. • SQL_EXPLAIN_PLAN_ON: The SQL statement is performed and plan information is generated. • SQL_EXPLAIN_PLAN_ONLY: The SQL statement is not performed and plan information is generated.
SQL_ATTR_EXPLAIN_PLAN_TEXT	It is the generated plan string. (read-only)
SQL_ATTR_FETCH_BOOKMARK_PTR (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_FETCH_FAILOV	SQLUSMALLINT: It is whether to use fetch failover.

Attribute	ValuePtr contents
ER	• SQL_FETCH_FAILOVER_OFF: It does not use fetch failover. • SQL_FETCH_FAILOVER_ON: It uses fetch failover.
SQL_ATTR_IMP_PARAM_DESC (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_IMP_ROW_DESC (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_KEYSET_SIZE (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_MAX_LENGTH (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_MAX_ROWS (ODBC 1.0)	• SQLULEN: It is the value corresponding to the maximum number of rows returned by SELECT statement. If *ValuePtr is equal to 0, the driver returns all rows. The purpose of this attribute is to reduce the network traffic. Notionally, it is applied when the result set is generated, and it limits the result set of the first ValuePtr rows. If the number of rows in the result set are bigger than ValuePtr, the result set is reduced. SQL_ATTR_MAX_ROWS is applied to all result set of the statement including those which are returned by the catalog functions. SQL_ATTR_MAX_ROWS sets the maximum number of cursor rows. If it is not sure if the SQL_ATTR_MAX_ROWS is to be properly implemented (If the limit of the result set size can not be implemented in the data source), the driver should not emulate the SQL_ATTR_MAX_ROWS operation for SQLFetch or SQLFetchScroll. The driver defines whether SQL_ATTR_MAX_ROWS is applied to the statements except for SELECT statement (such as the catalog functions). The attribute value is set on the cursor which is open. But it would not be immediately effective. In this case, the driver returns SQLSTATE 01S02 (Option value changed) and sets the attribute to its original value.
SQL_ATTR_METADATA_ID	• SQLULEN: It is the value which specifies the way to process the string arguments of the catalog functions. If it is SQL_TRUE, catalog functions treates a string argument as an identifier. It is not case-sensitive. The driver removes the trailing spaces of the string whose range is not determined and converts them to uppercase. The driver removes the leading and trailing spaces of the strings whose range is determined and takes the string literally between delimiters. If one of the argument is set to a NULL pointer, the function returns SQL_ERROR and SQLSTATE HY009. (Invalid use of null pointer).

Attribute	ValuePtr contents
(ODBC 3.0)	If it is SQL_FALSE, catalog functions does not treat a string argument as an identifier. I t is case-sensitive. They can either include a string search pattern or not, depending o n the argument. The default value is SQL_FALSE. It is the TableType argument of SQLTables which takes a list of values, is not affected by this attribute. SQL_ATTR_METADATA_ID can be set in the connection level. (SQL_ATTR_METADAT A_ID and SQL_ATTR_ASYNC_ENABLE are unique, and they are the statement attribut es and at the same time they are the connection attributes.) For more information, refer to **Arguments of Catalog Function**.
SQL_ATTR_NOSCAN (ODBC 1.0)	It is not supported by the driver.
SQL_ATTR_PARAM_BIND_ OFFSET_PTR (ODBC 3.0)	• SQLULEN*: It is the value which indicates the offset added to a pointer to chang e the binding of the dynamic parameters. If the field is not NULL, the driver dere ferences the pointer and adds the dereferenced value to each of the deferred fie lds in the descriptor record (SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, and SQL_DESC_OCTET_LENGTH_PTR), and it uses a new pointer value when bin ding. The default value is set to NULL. The bind offset is always directly added to SQL_DESC_DATA_PTR, SQL_DESC_INDICA TOR_PTR, SQL_DESC_OCTET_LENGTH_PTR fields. If the offset is changed to a differe nt value, the new value is still directly added to the descriptor field value. A new offset is not added to the field value plus previous offsets. Setting this statement attribute sets the SQL_DESC_BIND_OFFSET_PTR field in the AP D header.
SQL_ATTR_PARAM_BIND_ TYPE (ODBC 3.0)	• SQLULEN: It represents the binding direction used for the dynamic parameter. The field is set to SQL_PARAM_BIND_BY_COLUMN which is for the column-wise bind ing. (The default value) To select the row-wise binding, the field is set to the structure length or the buffer ins tance which is bound to the dynamic parameter set . If the length includes the space f or the padding of all the bound parameter and structure or the address of the bound parameter is increased to the specified length, the result should be buffered to point t o the beginning of the next parameter. Using sizeof operator of ANSI C guarantees th is operation. Setting this statement attribute sets the SQL_DESC_BIND_TYPE field in the APD head

Attribute	ValuePtr contents
	er.
SQL_ATTR_PARAM_OPERATION_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value which points to an array of SQLUSMALLINT values used to ignore the parameter while executing the SQL statement. Each value is SQL_PARAM_PROCEED (to execute the parameter) or SQL_PARAM_IGNORE (to ignore the parameter). The parameter set can be ignored during the process if it sets the status value of the array pointed by SQL_DESC_ARRAY_STATUS_PTR in APD. The parameter set is processed only if the status value is SQL_PARAM_PROCEED or the the array element is not set. The statement attribute can be set to a NULL pointer. In this case, the driver does not return the parameter status value. The attribute can be set at any time, but a new value is not used until the next SQLExecDirect or SQLExecute is called. If the bound parameter does not exist, the attribute is ignored. Setting this statement attribute sets the SQL_DESC_ARRAY_STATUS_PTR field in the APD header.
SQL_ATTR_PARAM_STATUS_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value which points to SQLUSMALLINT array value including the status information value of each of the rows of the parameter value after calling SQLExecute or SQLExecDirect. The field is required only when PARAMSET_SIZE is bigger than 1. The status value may include the following values. ◦ SQL_PARAM_SUCCESS: The SQL statement is successfully executed for the parameter set. ◦ SQL_PARAM_SUCCESS_WITH_INFO: The SQL statement is successfully executed for the parameter set, but warning information is in the diagnostic data structure. ◦ SQL_PARAM_ERROR: An error occurs when processing the parameter set. Additional error information is in the diagnostic data structure. ◦ SQL_PARAM_UNUSED: The parameter set is not used because some previous parameter set caused an error which aborted further processing, or because SQL_PARAM_IGNORE is set for the parameter set in the array specified by the SQL_ATTR_PARAM_OPERATION_PTR. ◦ SQL_PARAM_DIAG_UNAVAILABLE: The driver treats the parameter arrays in a monolithic unit because it does not generate the error information level. The statement attribute can be set to a NULL pointer, and the driver does not return the status value of the parameter. The attribute can be set at any time. But a new value is not used until the next SQLExecDirect or SQLExecute is called. Setting the attribute can affect the operation that outputs the parameter to the driver. Setting this statement attribute sets the SQL_DESC_ARRAY_STATUS_PTR field in the IPD header.

Attribute	ValuePtr contents
SQL_ATTR_PARAMS_PROCESSED PTR (ODBC 3.0)	• SQLULEN*: It is the record field which points to the buffer returning the number of parameter sets processed and it includes the error set. If it is a NULL pointer, it is not returned. Setting this statement attribute sets SQL_DESC_ROWS_PROCESSED_PTR field of IPD header. If SQLExecDirect or SQLExecute that fills the buffer specified in the attribute does not return SQL_SUCCESS or SQL_SUCCESS_WITH_INFO, the buffer content is not defined.
SQL_ATTR_PARAMSET_SIZE (ODBC 3.0)	• SQLULEN: It is the value which specifies the number of each of the parameter values. If SQL_ATTR_PARAMSET_SIZE is bigger than 1, SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR of APD point to the array. Each array constant is equal to the value of the field. If the bound parameter does not exist, the attribute is ignored. Setting this statement attribute sets SQL_DESC_ARRAY_SIZE field of APD header.
SQL_ATTR_QUERY_TIMEOUT (ODBC 1.0)	• SQLULEN: The value of seconds that waits before the SQL statement is executed and returned to the application. If ValuePtr is 0 (the default value), timeout does not occur. If the specified time out value exceeds the maximum value of the data source or smaller than the minimum value of the data source, SQLSetStmtAttr replaces the value and returns SQLSTATE 01S02 (Option value changed). Even if SELECT statement is timeout the application does not need to call SQLCloseCursor to reuse the statement. Setting the query timeout of the statement attribute is valid for both synchronous and asynchronous modes.
SQL_ATTR_RETRIEVE_DATA (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_ROW_ARRAY_SIZE (ODBC 3.0)	• SQLULEN: It is the value which specifies the number of rows returned by calling SQLFetch or SQLFetchScroll. It is also the number of rows of the bookmark array which is used in the bulk bookmark operation of SQLBulkOperations. The default value is 1. If the specified row set size exceeds the maximum row set size supported by the data source, the driver replaces the value and returns SQLSTATE 01S02 (Option value changed). Setting this statement attribute sets SQL_DESC_ARRAY_SIZE field of ARD header.

Attribute	ValuePtr contents
SQL_ATTR_ROW_BIND_OFFSET_PTR (ODBC 3.0)	• SQLULEN: It is the value which points the added offset value to indicate the change of the column data binding. If the field is not NULL, the driver dereferences the pointer and adds the dereference value to each field in the descriptor record (SQL_DESC_DATA_PTR, SQL_DESC_INDICATOR_PTR, SQL_DESC_OCTET_LENGTH_PTR) and uses a new pointer value when it is bound. The default value is NULL. Setting this statement attribute sets SQL_DESC_BIND_OFFSET_PTR field of ARD header.
SQL_ATTR_ROW_BIND_TYPE (ODBC 1.0)	• SQLULEN: It is the value which sets the binding direction when SQLFetch or SQLFetchScroll is called in the related statement. If SQL_BIND_BY_COLUMN value is set, the column-wise binding is selected. If the value to length of a structure or an instance of a buffer into which result columns will be bound is set, the row-wise binding is selected. If a length is specified, they should include space for all bound columns and any padding of the structure or buffer to ensure that when the address of a bound column is increased as the specified length, the result will point to the beginning of the same column in the next row. Using sizeof operator with the structure or union of ANSI C guarantees this operation. The column-wise binding is the default binding direction of SQLFetch and SQLFetchScroll. Setting this statement attribute sets SQL_DESC_BIND_TYPE field of ARD header.
SQL_ATTR_ROW_NUMBER (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_ROW_OPERATION_PTR (ODBC 3.0)	It is not supported by the driver.
SQL_ATTR_ROW_STATUS_PTR (ODBC 3.0)	• SQLUSMALLINT*: It is the value which points to the SQLUSMALLINT array including the row status values after calling SQLFetch or SQLFetchScroll. The array has the elements as many as the number of rows included in the row set. The statement attribute can be set to a NULL pointer, and the driver does not return the row status values in this case. The attribute can be set at any time, but a new value is not used until the next call of SQLBulkOperations, SQLFetch, SQLFetchScroll or SQLSetPos. Setting this statement attribute sets SQL_DESC_ARRAY_STATUS_PTR of IRD header. The attribute is mapped to rgbRowStatus array of SQLExtendedFetch in ODBC 2.x driver.

Attribute	ValuePtr contents
SQL_ATTR_ROWS_FETCHED_PTR (ODBC 3.0)	• SQLULEN*: It points to the buffer which returns the number of rows fetched after calling SQLFetch or SQLFetchScroll. It is the number of rows affected by a bulk operation performed by a call to SQLSetPos with an operation argument of SQL_REFRESH, or it is the number of rows affected by a bulk operation performed by SQLBulkOperations. The number of rows includes the error rows. Setting this statement attribute sets SQL_DESC_ROWS_PROCESSED_PTR field of the IRD header. When SQLFetch or SQLFetchScroll is called to fill the buffer pointed by the attribute, the contents of the buffer are not defined if SQL_SUCCESS or SQL_SUCCESS_WITH_INFO is not returned.
SQL_ATTR_SIMULATE_CURSOR (ODBC 2.0)	It is not supported by the driver.
SQL_ATTR_USE_BOOKMARKS (ODBC 2.0)	It is not supported by the driver.

SQLSetStmtOption

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLSetStmtOption function in ODBC 2.0 is replaced with SQLSetStmtAttr in ODBC 3.x.
For more information, refer to **SQLSetStmtAttr**.

SQLSpecialColumns

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is open group.

Overview

SQLSpecialColumns function retrieves the following information for a column in the specified table.

- The optimal column set that uniquely identifies a row in the table
- The columns which are automatically updated when a row value is updated by the transaction

Syntax

```
SQLRETURN SQLSpecialColumns(
    SQLHSTMT      StatementHandle,
    SQLSMALLINT   IdentifierType,
    SQLCHAR *     CatalogName,
    SQLSMALLINT   NameLength1,
    SQLCHAR *     SchemaName,
    SQLSMALLINT   NameLength2,
    SQLCHAR *     TableName,
    SQLSMALLINT   NameLength3,
    SQLSMALLINT   Scope,
    SQLSMALLINT   Nullable);
```

Arguments

StatementHandle

[Input] It is the statement handle.

IdentifierType

[Input] It is the column type to return. It should be one of the following values.

• SQL_BEST_ROWID: It returns the optimal column or set of columns that, by retrieving values fro m the column(s), allows any row in the specified table to be uniquely identified. The column may b e a pseudo column for the special purpose (ROWID of ORACLE, TID of INGRES), a general column or a column of a unique index on the table.

• SQL_ROWVER: It returns the column or columns in the specified table, if any, which are automatically updated by the data source when any value in the row is updated by any transaction.(such as in SQLBase ROWID or Sybase TIMESTAMP).

CatalogName

[Input] It is the table catalog. If the driver does not support the catalog, an empty string ("") is returned and the tables do not have a catalog. The catalog name can not include a string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, CatalogName is generally treated as an string argument and it is case-sensitive. For more information, refer to **Arguments of Catalog Function**.

NameLength1

[Input] It is the length of *CatalogName string.

SchemaName

[Input] It is name of the table schema. It is the string search pattern for the schema name. If the driver does not support the schema, it returns an empty string ("") and the tables do not have a schema. SchemaName can not include a string search pattern .

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, SchemaName is an ordinary argument, it is treated literally and it is case-sensitive.

NameLength2

[Input] It is the length of *SchemaName string.

TableName

[Input] It is name of the table. The argument can not be a NULL pointer. The table name can not include a string search pattern.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, TableName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, TableName is an ordinary argument, it is treated literally, and it is case-sensitive.

NameLength3

[Input] It is the length of *TableName string.

Scope

[Input] It is minimum required scope of the rowid. The returned ROWID scope may be of a bigger scope. The value should be one of the followings.

• SQL_SCOPE_CURROW: The rowid is guaranteed to be valid only while it is positioned on that row. If it is updated or deleted by another transaction, the used ROWID is not retrieved.

• SQL_SCOPE_TRANSACTION: The rowid is guaranteed to be valid while the current transaction is maintained.

• SQL_SCOPE_SESSION: The rowid is guaranteed to be valid while the session is maintained. (It across the transaction boundaries.)

Nullable

[Input] It checks that the particular column can have NULL value. It should be one of the followings.

• SQL_NO_NULLS: A particular column can not have NULL value. Some drivers do not support SQL_NO_NULLS and they will return an empty result set if SQL_NO_NULLS is specified. The application should be prepared this case and request SQL_NO_NULLS only if it is required.

• SQL_NULLABLE: A particular column can have NULL value.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	A cursor is open on the StatementHandle, and SQLFetch or SQLFetchScroll had been called. This error is returned by the Driver Manager if SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, and is returned by the driver if SQLFetch or SQLFetchScroll returns SQL_NO_DATA. A cursor is open on the StatementHandle, but SQLFetch or SQLFetchScroll is not called.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other transactions.
40003	Statement completion unknown	The related connection is failed while executing this function, and the state of the transaction cannot be determined.
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the required memory for execution or completion of the function.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from oth

SQLSTATE	Error	Description
		er thread in the multithreaded application before the function is called and completed.
HY009	Invalid use of null poin ter	The TableName argument is a null pointer. The SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, the CatalogName argument is a null pointer, and the SQL_CATALOG_ NAME InfoType returns that catalog names are supported. The SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and the SchemaName argument is a null pointer.
HY010	Function sequence err or	The asynchronously executing function is called for the connection han dle related to StatementHandle, and this function is still being execute d when SQLSpecialColumns is called. SQLExecute, SQLExecDirect, SQLMoreResults is called for StatementHa ndle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called, before the data is retrieved for all streamed parameters. The asynchronously executing function is called for StatementHandle, a nd is still being executed when this function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function i s called before data is sent for all data-at-execution parameters or colu mns.
HY013	Memory management error	The function is not executed because the underlying memory object ca n not be accessed because of the low memory condition.
HY090	Invalid string or buffer length	The value of a length arguments is smaller than 0 but it is not SQL_NTS. The value of a length arguments exceeds the maximum length value f or the corresponding name.
HY097	Column type out of ra nge	An invalid IdentifierType value is specified.
HY098	Scope type out of ran ge	An invalid scope value is specified.
HY099	Nullable type out of ra nge	An invalid nullable value is specified.
HY117	Connection is suspend ed due to unknown tr ansaction state. Only disconnect and read-o nly functions are allow ed.	For more information about the suspended state, refer to **SQLEndTran**.

SQLSTATE	Error	Description
HYC00	Optional feature not implemented	A catalog is specified, and the driver or data source does not support catalogs. A schema is specified, and the driver or data source does not support schemas. A string search pattern is specified, and all or one of the catalog name, table schema, table name, data source does not support it. The combination of the current settings of the SQL_ATTR_CONCURRENCY and SQL_ATTR_CURSOR_TYPE statement attributes is not supported by the driver or data source. The SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABLE, and the SQL_ATTR_CURSOR_TYPE statement attribute is set to a cursor type for which the driver does not support bookmarks.
HYT00	Timeout expired	The query timeout period is expired before the data source returns the requested result. The time limit can be set via SQLSetStmtAttr of SQL_ATTR_CONNECTION_TIMEOUT.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source responds to the request. The connection time limit can be set via SQLSetConnectAttr of SQL_ATTR_CONNECTION_TIMEOUT.
IM001	Driver does not support this function	The driver does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync had not been called to complete the previous asynchronous on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

If IdentifierType argument is SQL_BEST_ROWID, SQLSpecialColumns returns a column or the column which uniquely identifies each row of the table. The column can be used in select-list or WHERE clause. SQLColumns returns various information of the table column, but it is not necessary to return the column which uniquely identifies each row nor does return a column automatically updated when any value in a row is updated by the transaction. For example, SQLColumns does not return ROWID which is the pseudo column of Oracle. It is the reason that SQLSpecialColumns is used to return information of particular column. For more information, refer to **Using Catalog Data**.

For more information about the general use, arguments, and returned data of ODBC catalog fu nctions, refer to **Catalog Function**.

If column to uniquely identify each row in the table does not exist, SQLSpecialColumns does not return a ny column. Then, SQL_NO_DATA is returned when SQLFetch or SQLFetchScroll is called in the statement.

The characteristics which are specified in IdentifierType, scope, nullable arguments are not supported by t he data source, SQLSpecialColumn returns an empty result set.

If SQL_ATTR_METADATA_ID attribute is set to SQL_TRUE, then CatalogName, SchemaName, TableName arguments are treated as identifiers and they can not use a NULL pointer. (For more information, refer to **Arguments of Catalog Function**.)

SQLSpecialColumns function returns a standard result set which is sorted by SCOPE.

The following columns are renamed in ODBC 3.x. Changing column name does not affect the backward compatibility because applications bind by column number.

ODBC 2.0 column	ODBC 3.x column
PRECISION	COLUMN_SIZE
LENGTH	BUFFER_LENGTH
SCALE	DECIMAL_DIGITS

SQLGetInfo function can be called with SQL_MAX_COLUMN_NAME_LEN option in the application to det ermine the actual length of COLUMN_NAME column.

The following table lists the columns in the result set. The additional columns beyond the column 8(PSEU DO_COLUMN) can be defined by the driver. The application should count from the end of the result set r ather than specifying an explicit position to access the columns defined by the driver. For more informatio n, refer to **Data Returning of Catalog Function**.

Column name	Column number	Data type	Description
SCOPE (ODBC 1.0)	1	Smallint	It is the actual scope of ROWID. It includes one of SQL_SCOPE_CURRO W, SQL_SCOPE_TRANSACTION, or SQL_SCOPE_SESSION. If IdentifierType is SQL_ROWVER, NULL is returned. For more information about each value, refer to scope in **Syntax**.
COLUMN_N AME (ODBC 1.0)	2	Varchar not NULL	It is the column name. If the column does not have a name, the driver r eturns an empty string.
DATA_TYPE (ODBC 1.0)	3	Smallint not NULL	It is SQL data type. It may be the ODBC SQL data type or the SQL data t ype specified in the driver. All ODBC SQL data types are valid. For more information about SQL data types specified in the driver, refer to the d ocumentation of the driver.

Column name	Column number	Data type	Description
TYPE_NAME (ODBC 1.0)	4	Varchar not NULL	It is name of the data source-dependent data type. e.g. CHAR, VARCHAR, MONEY, LONG VARBINARY, CHAR() FOR BIT DATA, etc.
COLUMN_SIZE (ODBC 1.0)	5	Integer	It is the column size in the data source.
BUFFER_LENGTH (ODBC 1.0)	6	Integer	It is the length in bytes of data transferred on an SQLGetData or SQLFetch operation if SQL_C_DEFAULT is specified. The numeric data may be different from the size of the data stored in the data source. The value is as same as COLUMN_SIZE for a string or binary data.
DECIMAL_DIGITS (ODBC 1.0)	7	Smallint	It is the number of decimal places of the column in the data source. NULL is returned if the number of decimal places can not be applied.
PSEUDO_COLUMN (ODBC 2.0)	8	Smallint	It displays whether the column is the pseudo-column such as Oracle ROWID. • SQL_PC_UNKNOWN • SQL_PC_NOT_PSEUDO • SQL_PC_PSEUDO The pseudo-column is not allowed to quote an identifier in quotation marks returned in SQLFetInfo for maximum interoperability.

After the application retrieves the SQL_BEST_ROWID value. The application can use the retrieved values to reselect the row within the defined scope. It guarantees that SELECT statement returns either *no rows* or *one row*.

If the application does not find the row when the row is re-queried based on ROWID or the column, it is assumed that the row is deleted or the ROWID column is changed. Although ROWID is not changed, the other column of the row may be updated.

The columns which are returned for the column type SQL_BEST_ROWID are very useful when the application need to move forward or backward within a result set to retrieve the most recent data among the row set. The column(s) of ROWID are not updated while it is positioned on that row.

The ROWID columns remain valid even when the cursor is not positioned on the row. The application can determine it by checking the SCOPE column in the result set.

SQLStatistics

Conformance

Introduced version: ODBC 1.0
Standards compliance: ISO 92

Overview

SQLStatistics retrieves a list of statistics about a single table and the indexes related to the table. The drive r returns the information as a result set.

Syntax

```
SQLRETURN SQLStatistics(
    SQLHSTMT        StatementHandle,
    SQLCHAR *       CatalogName,
    SQLSMALLINT     NameLength1,
    SQLCHAR *       SchemaName,
    SQLSMALLINT     NameLength2,
    SQLCHAR *       TableName,
    SQLSMALLINT     NameLength3,
    SQLUSMALLINT    Unique,
    SQLUSMALLINT    Reserved);
```

Arguments

StatementHandle

[Input] It is the statement handle.

CatalogName

[Input] It is the catalog name. If the driver does not support the catalog, an empty string ("") is retu rned and the tables do not have a catalog. The catalog name can not include a string search patter n .

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier and it is n ot case-sensitive. If it is set to SQL_FALSE, CatalogName is treated as an ordinary argument, it is tre ated literally, and it is case-sensitive. For more information, refer to **Arguments of Catalog Function**.

NameLength1

[Input] It is the length of *CatalogName string.

SchemaName

[Input] It is the schema name. If the driver does not support the schema, an empty string ("") is ret urned and the tables do not have a schema.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier and it is n ot case-sensitive. If it is set to SQL_FALSE, SchemaNameis treated as an ordinary argument, it is tre ated literally, and it is case-sensitive.

NameLength2

[Input] It is the length of *SchemaName string.

TableName

[Input] It is the table name. The argument can not be a NULL pointer. TableName does not include a string search pattern .

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier and it is n ot case-sensitive. If it is set to SQL_FALSE, SchemaName is treated as an ordinary argument, it is tre ated literally, and it is case-sensitive.

NameLength3

[Input] It is the length of *TableName string.

Unique

[Input] It is the index type. It can be SQL_INDEX_UNIQUE or SQL_INDEX_ALL.

Reserved

[Input] The importance of CARDINALITY and PAGES columns is displayed in the result set. The foll owing options affect only the results of CARDINALITY and PAGES columns. The index information is returned even when CARDINALITY and PAGES are not returned.

• SQL_ENSURE: It requests the driver to unconditionally search for statistics. (The driver which co mplies with Open Group standards, but does not support the ODBC extension can not support SQ L_ENSURE.)

• SQL_QUICK: If it is readily available from the server, it requests the driver to unconditionally sear ch for CARDINALITY and PAGES. The driver does not guarantee that the retrieved value is the curr ent value. (The application which is registered in Open Group will always get SQL_QUICK from OD BC 3.x-compliant drivers.)

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	Genera warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	The cursor is open in StatementHandle, and SQLFetch or SQLFetchScroll is called. If SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, the driver manager returns this error. If SQLFetch or SQLFetchScroll returns SQL_NO_DATA, the driver returns this error. The cursor is open in StatementHandle, but SQLFetch or SQLFetchScroll is not called.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other transactions.
40003	Statement completion unknown	The related connection fails during the function execution and the status of the transaction is not able to be checked.
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before the function is called and completed.
HY009	Invalid use of null pointer	TableName argument is the null pointer. The SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, the CatalogName argument is a null pointer, and the SQL_CATALOG_NAME InfoType returns that catalog names are supported. The SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and the SchemaName argument is a null pointer.
		The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLStatistics is called.

SQLSTATE	Error	Description
HY010	Function sequence error	SQLExecute, SQLExecDirect, SQLMoreResults is called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called, before the data retrieves all streamed parameters. The asynchronously executing function is called for StatementHandle, and is still being executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY090	Invalid string or buffer length	A name length argument value is smaller than 0, but it is not SQL_NTS. A single value of the name length arguments exceeds the maximum length.
HY100	Uniqueness option type out of range	The invalid unique value is specified.
HY101	Accuracy option type out of range	The invalid reserved value is specified.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed.	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	A catalog is specified, and the driver or data source does not support catalogs. A schema is specified, and the driver or data source does not support schemas. A string search pattern is specified, and the catalog name, table schema, table name, data source does not support it. The combination of the current settings of the SQL_ATTR_CONCURRENCY and SQL_ATTR_CURSOR_TYPE statement attributes is not supported by the driver or data source. The SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABLE, and the SQL_ATTR_CURSOR_TYPE statement attribute is

SQLSTATE	Error	Description
		set to a cursor type for which the driver does not support bookmarks.
HYT00	Timeout expired	The query timeout period is expired before the data source returns the requested result. The time limit can be set via SQLSetStmtAttr of SQL_ATTR_CONNECTION_TIMEOUT.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source responds to the request. The connection time limit can be set via SQLSetConnectAttr of SQL_ATTR_CONNECTION_TIMEOUT.
IM001	Driver does not support this function	The driver does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SQLStatistics returns information of a table as a standard result set sorted by NON_UNIQUE, TYPE, INDEX_QUALIFIER, INDEX_NAME, ORDINAL_POSITION. The result set combines the table statistics information (CARDINALITY and PAGES row of the result set) along with information for each index. For more information, refer to **Using Catalog Data**.

SQLGetInfo is called with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME_LEN, SQL_MAX_TABLE_NAME_LEN, SQL_MAX_COLUMN_NAME_LEN to determine the actual length of TABLE_CAT, TABLE_SCHEM, TABLE_NAME, COLUMN_NAME rows in the application.

For more information about the general use, arguments, and returned data of ODBC catalog functions, refer to **Catalog Function**.

The following columns are renamed in ODBC 3.x. Changing column name does not affect the backward compatibility because applications bind by column number.

ODBC 2.0 column	ODBC 3.x column
TABLE_QUALIFIER	TABLE_CAT
TABLE_OWNER	TABLE_SCHEM
SEQ_IN_INDEX	ORDINAL_POSITION
COLLATION	ASC_OR_DESC

The following table lists the columns in the result set. The additional columns beyond the column 13 (FILTER_CONDITION) can be defined by the driver. The application should count from the end of the result set rather than specifying an explicit position to access the columns defined by the driver. For more information, refer to **Data Returning of Catalog Function**.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	Varchar	It is the catalog name. If the data source can not be converted, it is NULL. If the driver does not support the catalog, an empty string ("") is returned and the tables do not have the catalog.
TABLE_SCHEM (ODBC 1.0)	2	Varchar	It is the schema name. If it is not applicable to the data source, it is NULL. If the driver does not support the schema, an empty string ("") is returned and the tables do not have the schema.
TABLE_NAME (ODBC 1.0)	3	Varchar not NULL	It is the table name to which the statistics or index is applied.
NON_UNIQUE (ODBC 1.0)	4	Smallint	It indicates whether the duplication of the index value is allowed. • SQL_TRUE: The index values may not be unique. • SQL_FALSE: The index values should be unique. If TYPE is SQL_TABLE_STAT, NULL is returned.
INDEX_QUALIFIER (ODBC 1.0)	5	Varchar	It is an identifier which executes DROP INDEX and specifies the index name. If it is the data source which does not support the index rules or TYPE is SQL_TABLE_STAT, then NULL is returned. If a non-NULL value is returned in the row, the value is used to define the index identified in DROP INDEX. Otherwise, the TABLE_SCHEM should be used to qualify the index name.
INDEX_NAME (ODBC 1.0)	6	Varchar	It is the index name. If TYPE is SQL_TABLE_STAT, NULL is returned.
TYPE (ODBC 1.0)	7	Smallint not NULL	It is the information type to be returned. • SQL_TABLE_STAT: It indicates statistics for the table. (in CARDINALITY or PAGES row) • SQL_INDEX_BTREE: It indicates B-Tree index. • SQL_INDEX_CLUSTERED: It indicates the cluster index. • SQL_INDEX_CONTENT: It indicates the content of the index. • SQL_INDEX_HASHED: It indicates the hash index. • SQL_INDEX_OTHER: It indicates other types of index.
ORDINAL_POSITION (ODBC 1.0)	8	Smallint	It is the row order on the index (starting from 1). If TYPE is SQL_TABLE_STAT, NULL is returned.
COLUMN_N			It is the column name. If the row is an expression such as SALARY + BE

Column name	Column number	Data type	Description
AME (ODBC 1.0)	9	Varchar	NEFITS, the expression is returned. If the expression is unknown, an empty string is returned. If TYPE is SQL_TABLE_STAT, NULL is returned.
ASC_OR_DESC (ODBC 1.0)	10	Char(1)	It is the column sorting sequence. A is ascending, and D is descending. If the row sorting sequence is not supported in the data source or TYPE is SQL_TABLE_STAT, then NULL is returned.
CARDINALITY (ODBC 1.0)	11	Integer	The cardinality of the table or index. If TYPE is SQL_TABLE_STAT, it is the number of rows of the table. If TYPE is not SQL_TABLE_STAT, it is the number of unique values of the index. If the value can not be used from the data source, NULL is returned.
PAGES (ODBC 1.0)	12	Integer	It is the number of pages stored in the index or table. If TYPE is SQL_TABLE_STAT, it is the number of pages of the table. If TYPE is not SQL_TABLE_STAT, it is the number of pages of the index. If the value of the data source can not be used or converted, then NULL is returned.
FILTER_CONDITION (ODBC 2.0)	13	Varchar	If the index is the filtered index such as SALARY> 30000, it is the filter condition. If the filter condition can not be determined, it is an empty string. If it is not an index, the filtered index can not be determined or TYPE is SQL_TABLE_STAT.

If the row in the result set corresponds to the table, the driver sets TYPE to SQL_TABLE_STAT, and sets NON_UNIQUE, INDEX_QUALIFIER, INDEX_NAME, ORDINAL_POSITION, COLUMN and ASC_OR_DESC to NULL. If CARDINALITY or PAGES can not be used in the data source, the driver sets them to NULL.

SQLTablePrivileges

Conformance

Introduced version: ODBC 1.0
Standards compliance: ODBC

Overview

SQLTablePrivileges returns the table list and the privileges related to each table. The driver returns the inf ormation in the form of the result set in the specified statement.

Syntax

```
SQLRETURN SQLTablePrivileges(
    SQLHSTMT      StatementHandle,
    SQLCHAR *     CatalogName,
    SQLSMALLINT   NameLength1,
    SQLCHAR *     SchemaName,
    SQLSMALLINT   NameLength2,
    SQLCHAR *     TableName,
    SQLSMALLINT   NameLength3);
```

Arguments

StatementHandle

[Input] It is the statement handle for the search results.

CatalogName

[Input] It is the table catalog. If the driver does not support the catalog, an empty string ("") is retur ned and the tables do not have a catalog. The catalog name can not include a string search patter n .

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, CatalogName is treated as an identifier and it is n ot case-sensitive. If it is set to SQL_FALSE, CatalogNameis treated as an ordinary argument, it is tre ated literally, and it is case-sensitive. For more information, refer to **Arguments of Catalog Function**.

NameLength1

[Input] It is the string length of *CatalogName.

SchemaName

[Input] It is a string search pattern for the schema name. If the driver does not support the schema, an empty string ("") is returned and the tables do not have a schema.

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, SchemaName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, SchemaName is treated as a pattern value string argument and it is case-sensitive.

NameLength2

[Input] It is the string length of *SchemaName.

TableName

[Input] It is table name string search pattern .

If SQL_ATTR_METADATA_ID is set to SQL_TRUE, TableName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, TableName is treated as a pattern value string argument and it is case-sensitive.

NameLength3

[Input] It is the string length of *TableName.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General warning	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid curosr state	A cursor is open on the StatementHandle, and SQLFetch or SQLFetchScroll had been called. This error is returned by the driver manager if SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, and is returned by the driver if SQLFetch or SQLFetchScroll returns SQL_NO_DATA. A cursor is open on the StatementHandle, but SQLFetch or SQLFetchScroll is not called.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other transactions.
40003	Statement completion unknown	The related connection fails during the function execution and the status of the transaction is not able to be checked.

SQLSTATE	Error	Description
HY000	General error	It is an error without specific SQLSTATE, and the error message returned by SQLGetDiagRec in *MessageText buffer describes error message and its cause.
HY001	Memory allocation error	The driver can not allocate the memory required for execution or completion of the function.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCancel or SQLCancelHandle is called on StatementHandle before the function is called and completed. Then this function is called again on StatementHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from other thread in the multithreaded application before the function is called and completed.
HY009	Invalid use of null pointer	SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and CatalogName argument is a null pointer. SQL_CATALOG_NAME InfoType returns that catalog names are supported. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and SchemaName or TableName argument is a null pointer.
HY010	Function sequence error	The asynchronously executing function is called for the connection handle related to StatementHandle, and this function is still being executed when SQLTablePrevileges is called. SQLExecute, SQLExecDirect or SQLMoreResults are called for StatementHandle, and SQL_PARAM_DATA_AVAILABLE is returned. This function is called before data is retrieved for all streamed parameters. The asynchronously executing function is called for StatementHandle, and is still being executed when the function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function is called before data is sent for all data-at-execution parameters or columns.
HY013	Memory management error	The function is not executed because the underlying memory object can not be accessed because of the low memory condition.
HY090	Invalid string or buffer length	The value of a length arguments is smaller than 0 but it is not SQL_NTS. The value of a length arguments exceeds the maximum length value for the corresponding name.
HY117	Connection is suspended due to unknown transaction state. Only	For more information about the suspended state, refer to **SQLEndTran**.

SQLSTATE	Error	Description
	disconnect and read-only functions are allowed.	
HYC00	Optional feature not implemented	A catalog is specified, and the driver or data source does not support catalogs. A schema is specified, and the driver or data source does not support schemas. A string search pattern is specified, and the catalog name, table schema, table name, data source does not support it. The combination of the current settings of the SQL_ATTR_CONCURRENCY and SQL_ATTR_CURSOR_TYPE statement attributes is not supported by the driver or data source. The SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABLE, and the SQL_ATTR_CURSOR_TYPE statement attribute is set to a cursor type for which the driver does not support bookmarks.
HYT00	Timeout expired	The query timeout period is expired before the data source returns the requested result. The time limit can be set via SQLSetStmtAttr of SQL_ATTR_CONNECTION_TIMEOUT.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source responds to the request. The connection time limit can be set via SQLSetConnectAttr of SQL_ATTR_CONNECTION_TIMEOUT.
IM001	Driver does not support this function	The driver does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteAsync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SchemaName and TableName arguments accept search patterns. For more information about valid search patterns, refer to **Pattern Value Argument**.

SQLTablePrivileges returns the result as a standard result set sorted by TABLE_CAT, TABLE_SCHEM, TABLE_NAME, PRIVILEGE, GRANTEE.

SQLGetInfo function is called with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME_LEN, SQL_MAX_TABLE_NANE_LEN to determine the actual length of TABLE_CAT, TABLE_SCHEM, TABLE_NAME columns in the application.

For more information about the general use, arguments, and returned data of ODBC catalog functions, refer to **Catalog Function**.

The following columns are renamed in ODBC 3.x. Changing column name does not affect the backward compatibility because applications bind by column number.

ODBC 2.0 column	ODBC 3.x column
TABLE_QUALIFIER	TABLE_CAT
TABLE_OWNER	TABLE_SCHEM

The following table lists the columns in the result set. The additional columns beyond the column 7 (IS_GRANTABLE) can be defined by the driver. The application should count from the end of the result set rather than specifying an explicit position to access the columns defined by the driver. For more information, refer to **Data Returning of Catalog Function**.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	Varchar	It is the catalog name. If the data source can not be converted, it is NULL. If the driver does not support the catalog, an empty string ("") is returned and the tables do not have the catalog.
TABLE_SCHE (ODBC 1.0)	2	Varchar	It is the schema name. If it is not applicable to the data source, it is NULL. If the driver does not support the schema, an empty string ("") is returned and the tables do not have the schema.
TABLE_NAME (ODBC 1.0)	3	Varchar not NULL	It is the table name.
GRANTOR (ODBC 1.0)	4	Varchar	It is the user name who grants the privilege. If it is not applicable to the data source, it is NULL. For all rows in which the value in the GRANTEE column is the owner of the object, the GRANTOR column is _SYSTEM.
GRANTEE (ODBC 1.0)	5	Varchar not NULL	It is the user name to whom the privilege is granted.
			The table privilege. It is one of the followings or the a data source-specific privilege. • SELECT: Grantee is allowed to retrieve one or more columns in a table.

Column name	Column number	Data type	Description
PRIVILEGE (ODBC 1.0)	6	Varchar not NULL	• INSERT: Grantee is allowed to insert new rows containing data for one or more columns into a table. • UPDATE: Grantee is allowed to update one or more columns in a table. • DELETE: Grantee is allowed to delete the data of a table. • REFERENCES: Grantee is allowed to refer to one or more columns in a table within constraints. (e.g. unique, referential, Table constraints check) The scope of action allowed to grantee who is given the table privilege depends on the data source. For example, the UPDATE privilege permits the grantee to update all columns in a table on one data source and only the columns for which the grantor has the UPDATE privilege on another data source.
IS_GRANTABLE (ODBC 1.0)	7	Varchar	It indicates whether GRANTEE can give other user the privilege and it is YES or NO. If it is not applicable to the data source or unknown, it is NULL. The privilege is grantable or not grantable, and it can not be both of them. The result set that SQLColumnPrivileges returns does not include the two rows which all columns except for IS_GRANTABLE have the same value.

SQLTables

Conformance

Introduced version: ODBC 1.0
Standards compliance: Open group

Overview

SQLTables returns the table list, catalog, or schema name, table type stored in the specified data source. The driver returns the information as a result set.

Syntax

```
SQLRETURN SQLTables(
    SQLHSTMT       StatementHandle,
    SQLCHAR *      CatalogName,
    SQLSMALLINT    NameLength1,
    SQLCHAR *      SchemaName,
    SQLSMALLINT    NameLength2,
    SQLCHAR *      TableName,
    SQLSMALLINT    NameLength3,
    SQLCHAR *      TableType,
    SQLSMALLINT    NameLength4);
```

Arguments

StatementHandle

[Input] It is the statement handle for the search results.

CatalogName

[Input] It is the catalog name. If SQL_ODBC_VERSION environment attribute is SQL_OV_ODBC3, CatalogName argument accepts a search pattern. If the driver supports catalogs only for a few tables, for example, the driver retrieves the data from another DBMS, an empty string ("") indicates that the table does not have a catalog.

If SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, CatalogName is treated as an identifier and it is not case-sensitive. If it is set to SQL_FALSE, CatalogName is a pattern value argument, it is treated literally and it is case-sensitive. For more information, refer to **Arguments of Catalog Function** .

NameLength1

[Input] It is the string length of *CatalogName.

SchemaName

[Input] It is the string search pattern for the schema name. An empty string ("") such as CatalogName indicates that the table does not have schema. The argument processing depends on SQL_ATTR_METADATA_ID statement attribute such as CatalogName.

NameLength2

[Input] It is the character length of *SchemaName.

TableName

[Input] It is the string search pattern for the table name. Also, the argument processing depends on SQL_ATTR_METADATA_ID statement attribute such as CatalogName.

NameLength3

[Input] It is the character length of *TableName.

TableType

[Input] It is the matched table type list.

SQL_ATTR_METADATA_ID statement attribute does not affect TableType argument. TableType is the value list argument, regardless of setting of SQL_ATTR_METADATA_ID.

NameLength4

[Input] It is the character length of *TableType.

Returns

SQL_SUCCESS, SQL_SUCCESS_WITH_INFO, SQL_STILL_EXECUTING, SQL_ERROR, SQL_INVALID_HANDLE

Diagnosis

SQLSTATE	Error	Description
01000	General waring	It is the driver-specific informational message. (The function returns SQL_SUCCESS_WITH_INFO.)
08S01	Communication link failure	Before the function processing is completed, the connection between the driver and the data source is failed.
24000	Invalid cursor state	A cursor is open on the StatementHandle, and SQLFetch or SQLFetchScroll had been called. This error is returned by the Driver Manager if SQLFetch or SQLFetchScroll does not return SQL_NO_DATA, and is returned by the driver if SQLFetch or SQLFetchScroll returns SQL_NO_DATA. A cursor is open on the StatementHandle, but SQLFetch or SQLFetchSc

SQLSTATE	Error	Description
		roll is not called.
40001	Serialization failure	The transaction is rolled back due to a resource deadlock of other trans actions.
40003	Statement completion unknown	The related connection is failed while executing this function, and the s tate of the transaction cannot be determined.
HY000	General error	It is an error without specific SQLSTATE, and the error message returne d by SQLGetDiagRec in *MessageText buffer describes error message a nd its cause.
HY001	Memory allocation err or	The driver can not allocate the required memory for execution or compl etion of the function.
HY008	Operation canceled	Asynchronous processing for StatementHandle is available and SQLCan cel or SQLCancelHandle is called on StatementHandle before the functi on is called and completed. Then this function is called again on State mentHandle. SQLCancel or SQLCancelHandle is called on StatementHandle from oth er thread in the multithreaded application before the function is called and completed.
HY009	Invalid use of null poi nter	SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and CatalogName argument is a null pointer. SQL_CATALOG_NAME InfoTy pe returns that catalog names are supported. SQL_ATTR_METADATA_ID statement attribute is set to SQL_TRUE, and SchemaName or TableName argument is a null pointer.
HY010	Function sequence err or	The asynchronously executing function is called for the connection han dle related to StatementHandle, and this function is still being executed when SQLTables is called. SQLExecute, SQLExecDirect, SQLMoreResults is called for StatementHa ndle, and SQL_PARAM_DATA_AVAILABLE is returned. The function is called, before the data for all streamed parameters is retrieved. The asynchronously executing function is called for StatementHandle, a nd is still being executed when SQLTables function is called. SQLExecute, SQLExecDirect, SQLBulkOperation or SQLSetPos are called for StatementHandle, and SQL_NEED_DATA is returned. This function i s called before data is sent for all data-at-execution parameters or colu mns.
HY013	Memory management error	The function is not executed because the underlying memory object ca n not be accessed because of the low memory condition.
HY090	Invalid string or buffer length	The value of a length arguments is smaller than 0 but it is not SQL_NTS.

SQLSTATE	Error	Description
		The value of a length arguments exceeds the maximum length value for the corresponding name.
HY117	Connection is suspended due to unknown transaction state. Only disconnect and read-only functions are allowed	For more information about the suspended state, refer to **SQLEndTran**.
HYC00	Optional feature not implemented	A catalog is specified, and the driver or data source does not support catalogs. A schema is specified, and the driver or data source does not support schemas. A string search pattern is specified, and the catalog name, table schema, table name, data source does not support it. The combination of the current settings of the SQL_ATTR_CONCURRENCY and SQL_ATTR_CURSOR_TYPE statement attributes is not supported by the driver or data source. The SQL_ATTR_USE_BOOKMARKS statement attribute is set to SQL_UB_VARIABLE, and the SQL_ATTR_CURSOR_TYPE statement attribute is set to a cursor type for which the driver does not support bookmarks.
HYT00	Timeout expired	The query timeout period is expired before the data source returns the requested result. The time limit can be set via SQLSetStmtAttr of SQL_ATTR_CONNECTION_TIMEOUT.
HYT01	Connection timeout expired	The connection timeout period is expired before the data source responds to the request. The connection time limit can be set via SQLSetConnectAttr of SQL_ATTR_CONNECTION_TIMEOUT.
IM001	Driver does not support this function	The driver does not support the function.
IM017	Polling is disabled in asynchronous notification mode	Whenever using the notification model, polling can not be used.
IM018	SQLCompleteASync has not been called to complete the previous asynchronous operation on this handle.	If the previous function call for the handle returns SQL_STILL_EXECUTING and if the notification mode is activated, then SQLCompleteAsync should be called for the handle to do post processing and complete the operation.

Description

SQLTables lists all tables in the requested scope. The user may have the SELECT privilege on the tables, or not. The application checks the accessibility as follows.

- SQL_ACCESSIBLE_TABLES information type is checked by calling SQLGetInfo.
- The privilege on each table is checked by calling SQLTablePrivileges.

Otherwise, the application should deal with the situation that the user performs a select statement without SELECT privilege.

SchemaName and TableName arguments can use the search pattern. If SQL_ODBC_VERSION is SQL_OV_ODBC3, then CatalogName argument can also use the search pattern. For more information about valid search pattern, refer to **Pattern Value Argument**.

For more information about the general use, arguments, and returned data of ODBC catalog functions, refer to **Catalog Function**.

The particular meaning of CatalogName, SchemaName, TableName, TableType arguments of SQLTables is defined as follows to support the enumeration of catalog, schema, and table types.

- If CatalogName is SQL_ALL_CATALOGS and SchaemaName and TableName are the empty string, the result set includes a valid catalog for the data source. (All columns except for TABLE_CAT column include NULL.)
- If SchemaName is SQL_ALL_SCHEMAS and CatalogName and TableName are the empty string, the result set includes a valid schema for the data source. (All columns except for TABLE_SCHE column include NULL.)
- If TableType is SQL_ALL_TABLE_TYPES and CatalogName, SchemaName, and TableName are the empty string, the result set includes a valid table type for the data source. (All columns except for TABLE_TYPE column include NULL.)

If TableType is not an empty string, it should include a list of comma-separated values for the types of interest. Each value can be enclosed in single quote (') or unquoted such as 'TABLE', 'VIEW' or TABLE, VIEW. An application should always specify the table type in uppercase. The driver should convert the table type to whatever case is needed by the data source. If the data source does not support the specified table type, SQLTables does not return any data result for that type.

SQLTables returns the result as a standard result set ordered by TABLE_TYPE, TABLE_CAT, TABLE_SCHE, TABLE_NAME. For more information, refer to **Using Catalog Data**.

SQLGetInfo is called with SQL_MAX_CATALOG_NAME_LEN, SQL_MAX_SCHEMA_NAME_LEN, SQL_MAX_TABLE_NAME_LEN to determine the actual length of TABLE_CAT, TABLE_SCHEM, TABLE_NAME column in the application.

The following columns are renamed in ODBC 3.x. Changing column name does not affect the backward compatibility because applications bind by column number.

ODBC 2.0 column	ODBC 3.x column
TABLE_QUALIFIER	TABLE_CAT
TABLE_OWNER	TABLE_SCHEM

The following table lists the columns in the result set. The additional columns beyond the column 5 (REMARKS) can be defined by the driver. The application should count from the end of the result set rather than specifying an explicit position to access the columns defined by the driver.
For more information, refer to **Data Returning of Catalog Function**.

Column name	Column number	Data type	Description
TABLE_CAT (ODBC 1.0)	1	Varchar	It is the catalog name. If it is not applicable to the data source, it is NULL. If the driver does not support the catalog, an empty string ("") is returned and the tables do not have the catalog.
TABLE_SCHEM (ODBC 1.0)	2	Varchar	It is the schema name. If it is not applicable to the data source, it is NULL. If the driver does not support the schema, an empty string ("") is returned and the tables do not have the schema.
TABLE_NAME (ODBC 1.0)	3	Varchar	It is the table name.
TABLE_TYPE (ODBC 1.0)	4	Varchar	It is the table type name. It is one of "TABLE", "VIEW", "SYSTEM TABLE", "GLOBAL TEMPORARY", "LOCAL TEMPORARY", "ALIAS", "SYNONYM" or the name specified in the data source. The meaning of "ALIAS" and "SYNONYM" is driver-specific.
REMARKS (ODBC 1.0)	5	Varchar	It is the description for the table.

SQLTransact

Conformance

Introduced version: ODBC 1.0
Standards compliance: It is not available.

Overview

SQLTransact function in ODBC 2.x is replaced with SQLEndTran in ODBC 3.x.
For more information, refer to **SQLEndTran**.

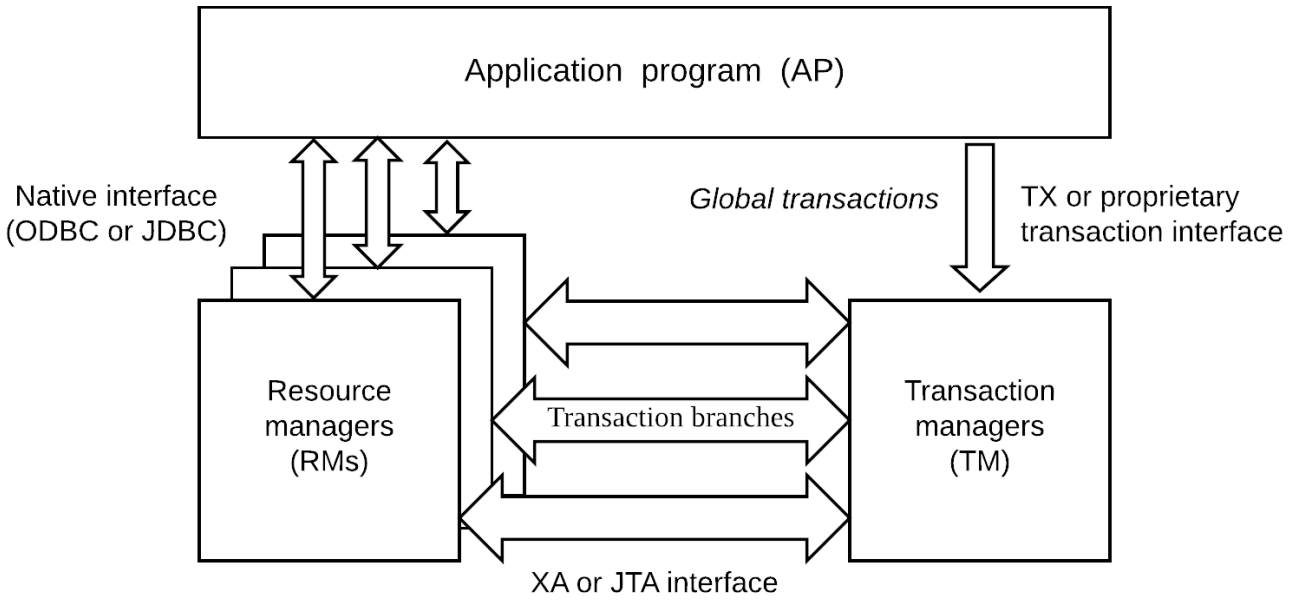
31.7 XA API References

Overview

X/Open XA is the standards for distributed transaction processing defined in X/Open. Typically, it prescribes the interface between a multi-transaction manager and a local resource manager. XA describes what is needed for the resource manager to process the transaction.

GOLDILOCKS XA is implemented based on X/Open CAE document, Distributed Transaction Processing: The XA Specification (**http://www.opengroup.org/public/catalog/c193.htm**).

X/Open DTP (Distributed Transaction Processing) model defines the transaction management between different heterogeneous computer databases.



- Application Program (AP): It defines the work consisting of transactions.
- Resource Managers (RM): It manages the shared resources accessed by a distributed transaction. It means a database management system, such as GOLDILOCKS.
- Transaction Manager (TM): It assigns ID(XID) of a distributed transaction, and manages the progress of a distributed transaction, and has the responsibility for the termination and recovery of a distributed transaction.

AP is a program developed by using the precompiler or ODBC. AP does not directly use the XA interface, and it uses the native interface of RM, or it controls the transaction by using TX interface provided by TM.

XA Interface

XA interface is the interface specification between RM and TM. GOLDILOCKS does not provide a separate library for XA interface, and it is included in the ODBC libraries provided by GOLDILOCKS.

switch_t Structure

It is a structure which includes information about the entry point for XA interface and information about RM.
xa_switch_t provided by GOLDILOCKS is goldilocks_xa_switch.

Variable name	Description
char name[RMNAMESZ]	It is RM name.
long flags	It is the option provided in RM. • MIGRATE option is not supported. (It is set to TMNOMIGRATE.)
long version	It is RM version.
int (*xa_open_entry)(char *, int, long);	It is xa_open function pointer.
int (*xa_close_entry)(char *, int, long);	It is xa_close function pointer.
int (*xa_start_entry)(XID *, int, long);	It is xa_start function pointer.
int (*xa_end_entry)(XID *, int, long);	It is xa_end function pointer.
int (*xa_rollback_entry)(XID *, int, long);	It is xa_rollback function pointer.
int (*xa_prepare_entry)(XID *, int, long);	It is xa_prepare function pointer.
int (*xa_commit_entry)(XID *, int, long);	It is xa_commit function pointer.
xint (*xa_recover_entry)(XID *, long, int, long);	It is xa_recover function pointer.
int (*xa_forget_entry)(XID *, int, long);	It is xa_forget function pointer.
int (*xa_complete_entry)(int *, int *, int, long);	It is xa_complete function pointer. • It is not provided in GOLDILOCKS.

ODBC Functions Related to XA

It describes the functions which are added to use the XA interface besides the standard ODBC.

SQLGetXaSwitch

It gets xa_switch_t provided by ODBC function.

```
xa_switch_t * SQLGetXaSwitch( void );
```

Return

It returns a pointer to sw_switch_t structure provided by ODBC. NULL can not be returned.

SQLGetXaConnectionHandle

It gets the connection handle related to the current XA session.

```
SQLHANDLE SQLGetXaConnectionHandle( void );
```

Return

If the connected XA session exist at the corresponding thread, it returns the related connection handle. O therwise, it returns NULL.

XA Functions

It describes the details for XA related functions of xa_switch_t structure.

xa_open

It connects to RM.

It is ignored if it is already connected in the thread which called xa_open.

```
int xa_open(
    char * xa_info,
    int    rmid,
    long   flags );
```

Arguments

xa_info

[Input] It is a string which includes the access information, and the maximum length is 256 bytes. For more information, refer to InConnectionString of **SQLDriverConnect**.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is connection flag. It should be set to TMNOFLAGS.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when RM can not be used.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XAER_INVAL	It occurs when passing the abnormal argument.

xa_close

It terminates the connection of RM, and releases the connection handle.

```
int xa_close(
    char * xa_info,
    int    rmid,
    long   flags );
```

Arguments

xa_info

[Input] It is a string which includes the access information, and the argument is ignored.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the termination flag. The argument is ignored.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when RM can not be used.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XAER_INVAL	It occurs when passing the abnormal argument.

xa_start

It creates a new transaction branch or starts the existing transaction branch.

```
int xa_start(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be started.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the start flag.

flags can use the following values.

- TMASYNC: It starts a transaction branch in asynchronous mode. (It is not supported.)
- TMNOFLAGS: FLAG is not used and the appropriate flag should be specified if flag is not used.
- TMNOWAIT: If the specified transaction branch is used by another session, XA_RETRY error is returne d without waiting.
- TMRESUME: The previously suspended transaction branch is continued. It can not be used with TMJ OIN.
- TMJOIN: It is connected to an existing transaction branch. It can not be used with TMRESUME.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XAER_PROTO	It occurs when the execution order does not fit into XA protocol.
XAER_INVAL	It occurs when passing the abnormal argument.
XAER_DUPID	The transaction branch with the same XID already exists.
XAER_NOTA	The transaction branch specified as XID does not exist. It may occur when TMRESUME or TMJOIN is used.
XA_RETRY	It occurs when the specified transaction branch is already used by another session. It may occur when using TMNOWAIT.
XAER_OUTSIDE	The local transaction is already in progress in the session.

Return value	Description
XA_RBROLLBACK	The transaction branch is set to rollback-only.

xa_end

It terminates the transaction branch operation.

```
int xa_end(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be terminated.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the job termination flag.

flags can use the following values.

- TMFAIL: It indicates that the operation failed. It can not be used with TMSUSPEND or TMSUCCESS, a nd it changes the status of the transaction branch to rollback-only.
- TMMIGRATE: It is restarted in connection with another branch. (It is not supported.)
- TMSUCCESS: It indicates that the operation is successfully terminated. It can not be used with TPSUS PEND or TMFAIL.
- TMSUSPEND: The transaction branch is suspended and terminated.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XA_NOMIGRATE	MIGRATE flag is not supported.
XAER_PROTO	It occurs when the execution order does not fit into XA protocol.
XAER_INVAL	It occurs when passing the abnormal argument.
XAER_NOTA	The transaction branch specified as XID does not exist.

xa_prepare

It prepares to commit the transactions corresponding to XID. It is the first phase of Two-phase Commit Pr otocol (2PC).

```
int xa_prepare(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be prepared.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the prepare flag. TMNOFLAGS should be set.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XA_PROTO	It occurs when the execution order does not fit into XA protocol.
XA_RDONLY	The transaction branch is the read-only transaction.
XAER_NOTA	The transaction branch specified as XID does not exist.
XA_RBROLLBACK	The transaction branch is set to rollback-only.

xa_commit

It commits the transactions corresponding to XID. It is the second phase of Two-phase Commit Protocol (2PC).

```
int xa_commit(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be committed.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the commit flag.

flags can use the following values.

- TMNOFLAGS: It means that FLAG is not used, and if any flag is not used, the appropriate flag should be specified.
- TMONEPHASE: It performs One Phase Commit (1PC).

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XA_PROTO	It occurs when the execution order does not fit into XA protocol.
XA_RDONLY	The transaction branch is the read-only transaction.
XAER_NOTA	The transaction branch specified as XID does not exist.
XA_RBROLLBACK	The transaction branch is set to rollback-only.

xa_rollback

It rolls back the transaction corresponding to XID.

```
int xa_rollback(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be rolled back.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is rollback flag. TMNOFLAGS should be set.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XA_HEURRB	The transaction branch is already rolled back heuristically. (heuristic rollback)
XA_HEURCOM	The transaction branch is already committed heuristically. (heuristic commit)
XAER_NOTA	The transaction branch specified as XID does not exist.

xa_recover

It gets a list of transactions which are heuristically committed or rolled back.

```
int xa_recover(
    XID *  xids,
    long   count,
    int    rmid,
    long   flags );
```

Arguments

xids

[Output] It is the list of transactions which are heuristically committed or rolled back.

count

[Input] It refers to the array size of xids.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the recover flag.

flags can use the following values.

- TMSTARTSCAN: It starts to scan, or it starts again from the beginning.
- TMENDSCAN: It terminates the scan.
- TMNOFLAGS: If it is used after TMSTARTSCAN, the following list is obtained. XA_PROTO error occurs if TMNOFLAGS is used from the beginning.

Diagnosis

Return value	Description
>= 0	It is the number of returned XIDs. (The array size that is valid in xids.)
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XA_PROTO	It occurs when the execution order does not fit into XA protocol.

xa_forget

It deletes the information about transactions which are heuristically committed or rolled back.

```
int xa_forget(
    XID *  xid,
    int    rmid,
    long   flags );
```

Arguments

xid

[Input] It is the transaction ID to be deleted.

rmid

[Input] It is the unique ID of RM to be connected. The argument is ignored.

flags

[Input] It is the delete flag. TMNOFLAGS should be set.

Diagnosis

Return value	Description
XA_OK	The operation is normally performed.
XAER_RMFAIL	It occurs when the session in use is abnormally terminated.
XAER_RMERR	RM can not perform the operation in a transaction branch due to lack of resources.
XAER_PROTO	It occurs when the execution order does not fit into XA protocol.
XAER_INVAL	It occurs when passing the abnormal argument.
XAER_NOTA	The transaction branch specified by XID does not exist.

Example

The following is a simple example of connecting to GOLDILOCKS and performing Two-phase Commit aft er inserting/ retrieving/ updating/ deleting the record. The complete code for the following example is in $GOLDILOCKS_HOME/sample/ODBC/SAMPLE_XA.c.

1. SQLGetXaSwitch()
   Obtain xa switch_t structure for using XA interface.

2. SQLAllocHandle()
   Obtain ODBC environment handle.

3. xa_open()
   Connect to the server with the given connection string.
   Use the existing connection if it is already connected to the server. Otherwise, try a new connection.

4. SQLGetXaConnectionHandle()
   Obtain XA connection handle related to the corresponding thread.

5. xa_start()
   Start the transaction branch.

6. Perform the transaction by using standard ODBC functions.

7. xa_end()
   Terminate the transaction.

8. xa_prepare()
   Prepare to commit the transaction, and which is the first phase of 2PC.

9. xa_commit()
   Commit the transaction, and which is the second phase of 2PC.

10. xa_close()
    Terminate the connection and release the connection handle.
    SQLDisconnect() and SQLFreeHandle() which are the ODBC standard functions, may be used.

11. SQLFreeHandle()
    Release ODBC environment handle.

```
int main( int aArgc, char** aArgv )
{
    SQLHENV       sEnv    = NULL;
    SQLHDBC       sDbc    = NULL;
    SQLINTEGER    sState  = 0;
    xa_switch_t * sXaSwitch;
    XID           sXid;
    sXaSwitch = SQLGetXaSwitch();
```

- If a user calls SQLAllocEnv() which is included in GOLDILOCKS ODBC

```
GOLDILOCKS_SQL_TRY( SQLAllocHandle( SQL_HANDLE_ENV,
                                    NULL,
                                    &sEnv ) );
    sState = 1;
```

- SQLSetEnvAttr sets attributes which govern aspects of environments.

```
GOLDILOCKS_SQL_TRY( SQLSetEnvAttr( sEnv,
                                   SQL_ATTR_ODBC_VERSION,
                                   (SQLPOINTER)SQL_OV_ODBC3,
                                   0 ) );
    if( (sXaSwitch->xa_open_entry)(
                "DSN=GOLDILOCKS;UID=test;PWD=test",
                0,
                TMNOFLAGS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }
    sState = 2;
    sDbc = SQLGetXaConnectionHandle();
    sXid.formatID = 0;
    sXid.gtrid_length = 2;
    sXid.bqual_length = 1;
    memcpy( sXid.data,
            "100",
            sXid.gtrid_length + sXid.bqual_length );

    if( (sXaSwitch->xa_start_entry)( &sXid, 0, TMNOFLAGS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }
```

- If SQL_SUCCESS which is an insert function succeeds

```
GOLDILOCKS_SQL_TRY( testInsert( sDbc ) );
```

- If SQL_SUCCESS which is a select function succeeds

```
GOLDILOCKS_SQL_TRY( testSelect( sDbc ) );
```

- If SQL_SUCCESS which is an update function succeeds

```
GOLDILOCKS_SQL_TRY( testUpdate( sDbc ) );
```

- If SQL_SUCCESS which is a delete function succeeds

```
GOLDILOCKS_SQL_TRY( testDelete( sDbc ) );

    if( (sXaSwitch->xa_end_entry)( &sXid, 0, TMSUCCESS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }

    if( (sXaSwitch->xa_prepare_entry)( &sXid, 0, TMNOFLAGS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }

    if( (sXaSwitch->xa_commit_entry)( &sXid, 0, TMNOFLAGS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }

    sState = 1;
    if( (sXaSwitch->xa_close_entry)( "", 0, TMNOFLAGS ) != XA_OK )
    {
        GOLDILOCKS_SQL_THROW( GOLDILOCKS_FINISH_LABEL );
    }
    sDbc = NULL;
```

- SQLFreeHandleEnv releases resources which are related to an environment.

```
sState = 0;
    GOLDILOCKS_SQL_TRY( SQLFreeHandle( SQL_HANDLE_ENV,
                                  sEnv ) );
    sEnv = NULL;
    return EXIT_SUCCESS;
    GOLDILOCKS_FINISH;
    if( sDbc != NULL)
    {
        PrintDiagnosticRecord( SQL_HANDLE_DBC, sDbc );
    }
    if( sEnv != NULL)
    {
        PrintDiagnosticRecord( SQL_HANDLE_ENV, sEnv );
    }
    switch( sState )
```

```
    {
```

- Case 2: SQLDisconnect closes the connection which is related to a specific connection handle.

```
(void)(sXaSwitch->xa_close_entry)( "", 0, TMNOFLAGS );
```

- Case 1: SQLFreeHandleEnv releases resources which are related to an environment.

```
(void)SQLFreeHandle( SQL_HANDLE_ENV, sEnv );
            sEnv = NULL;
        default:
            break;
    }
    return EXIT_FAILURE;
}
```

32.

JDBC

32.1 Overview of GOLDILOCKS JDBC Driver

Concepts of GOLDILOCKS JDBC Driver

GOLDILOCKS provides GOLDILOCKS JDBC driver (excluding some features) which complies with standard JDBC 4.0 based on TCP/IP connection. The user can use various transaction features and data query features by using GOLDILOCKS JDBC driver and connecting to GOLDILOCKS in Java program. GOLDILOCKS JDBC driver is written and built based on JDK 1.6. Therefore, it supports JDBC 4.0 features. The driver can be used by adding $GOLDILOCKS_HOME/lib/goldilocks6.jar file to the class path.

The number after goldilocks refers to the JDK version. For more information, refer to **Supporting Versions**.

GOLDILOCKS JDBC complies with most of JDBC standard specifications, and it also supports non-standard API methods and classes to provide some unique features. For more information about non-standard methods, refer to each class API of **JDBC API References** or **Using Other Data Types**.

Characteristics

- **Type-4 JDBC Driver**

GOLDILOCKS JDBC is a JDBC Type-4 type which is implemented only with pure Java. A user can use a JDBC driver only with jar file without any additional libraries. Also, it is faster and reliable than JDBC-ODBC Bridge type, and it has better portability than Type-2 using Native API.

- **JDBC Standard Compliance**

GOLDILOCKS JDBC can recycle most of other existing JDBC programs without changing because it complies with the JDBC standard. The connection, various statements and ResultSet features can be used without modifying. However, the connection URL and property name, the name of driver class to be loaded should be changed to suit GOLDILOCKS. And the non-standard features and types are usable with the separate classes and methods API.

- **Supporting Various Java Versions**

GOLDILOCKS JDBC driver supports three files such as goldilocks8.jar, goldilocks7.jar, goldilocks6.jar, so that a user can select and use the file appropriate for user's Java run-time environment. Because each jar file was built based on JDK 1.8, JDK 1.7, JDK 1.6, it complies with each JDBC 4.2, JDBC 4.1, JDBC 4.0 specifications.

- **Flexible Version Compatibility with the Server**

Refer to the protocol version for the compatibility with the server and the JDBC driver. If the protocol vers ion of server is higher than that of the JDBC driver, it can be connected.

- **API Support for Connection Pooling**

JDBC connection object is a resource which is expensive to generate. Therefore, the JDBC standard define a pooling system for it, and ConnectionPoolDataSource and PooledConnection are its interfaces. GOLDIL OCKS JDBC implements these interfaces and provides the pooling facility in third party middleware produ cts.

- **Supporting XA API**

A user can perform the global transaction work by implementing XA interface which is the global transac tion standard. And a user can perform the various XA features complying with a standard by using XARes ource which is JDBC interface.

- **GOLDILOCKS-specific Data Type**

GOLDILOCKS uses the data types which are not provided by the JDBC standard. For example, they are Int erval related type, the type with time zone information such as Timestamp with time zone, etc. The driver provides a way to obtain or insert these types to DB.

- **Server-based Powerful Cursor Scroll Feature**

Other JDBC drivers cache the row set in the driver for ResultSet scroll, so uses excessively memory of a clie nt application program. For example, if the cursor is open by scroll insensitive and the rows are patched u p to the last, all rows are cached in the driver, and the entire table resides in the client memory. It causes t he out of memory error and the excessive use of client memory resource.

However, GOLDILOCKS supports the cursor scroll feature within the server, and clients may have lightwei ght, fast and reliable performance.

- **Efficient Use of Resources**

Because GOLDILOCKS minimizes the memory which maintains the row information compared to other JD BC drivers and it does not use Java objects as possible. It can avoid the excessive garbage collection, and perform fast and reliable table scanning with less memory.

- **Accurate and Extensive Metadata**

Because DatabaseMetaData interface of JDBC standard is faithfully and accurately implemented, it is easy to be linked with various DB tools. In addition, the usability is increased by retrieving DB meta information through various system views.

- **Powerful Logging**

Various logging features are provided to monitor the usual JDBC API calls and network usage as well as t he problem. If the logging-related features are specified in the connection URL, a user can leave a the con tent log to the console or files. Four types of logging exist, which are logging for JDBC method call record ing, logging for protocol sending and receiving, logging for the SQL statement used, logging for global c onnection usage.

- **Connection Failover**

Connection failover is supported on JDBC driver level to continuously use an existing connection by auto matically reconnecting to the previously registered alternate server when the connection with the executi on GOLDILOCKS server fails or is disconnected. A user can use connection failover feature as an existing J DBC program without any exception handling in preparation for the broken connection.

- **Connectivity between server and direct attach**

Other than TCP/IP based connection, it can be connected with direct attach method interworking with a process as same as the server. Like as ODBC connection supports direct attach method and Client/ Server method, GOLDILOCKS JDBC driver also provides both methods. JDBC program connected with direct atta ch does not communicate with TCP/IP, but it can use the server features in jvm by directly interworking w ith the server process. The perfomance is doubled or more than the JDBC program connected with TCP/ I P.

Supporting Versions

GOLDILOCKS JDBC versions

GOLDILOCKS JDBC version information can be viewed when executing goldilocks6.jar file as follows.

```
shell>java -jar goldilocks6.jar
 GOLDILOCKS JDBC Driver 1.1 Procotol-2.5.2, JDBC4.0 compiled with JDK1.6
```

The examples above describe that current GOLDILOCKS JDBC driver version is 1.1, and the protocol versio n is 2.5.2, and JDBC standard version is 4.0 and it is built in JDK 1.6. The driver version is displayed apart f rom GOLDILOCKS product version, and it goes up whenever the function is strengthened. For more infor mation about JDBC driver version, refer to **getDriverMajorVersion**, **getDriverMinorVersion**, **getDriverVersi on** of DatabaseMetaData.

Protocol version determines compatibility with the server, and the driver can interwork with the server if t he version is equal to or lower than the server protocol version. The server supports all clients API of the l ower protocol version.

goldilocks6.jar complies with JDBC 4.0 standard and it was built in JDK 1.6. goldilocks7.jar complies with JDBC 4.1 standard and it was built in JDK 1.7. goldilocks8.jar complies with JDBC 4.2 standard and it was built in JDK 1.8. Therefore, if the user's java environment is higher than JDK 1.8, use goldilocks8.jar. However, when using Java JDK 1.9 or higher, goldilocks8.jar can be used but API or classes of JDBC 4.3 can not be used.

Examples

Setting Class Path

CLASSPATH should be set to use GOLDILOCKS JDBC driver.

```
export CLASSPATH=.:$GOLDILOCKS_HOME/lib/goldilocks6.jar
```

Or, add a suitable jar file for the user's Java execution environment to the path.

Loading Driver Class

The driver class can be loaded as follows.

```
Class.forName("sunje.goldilocks.jdbc.GoldilocksDriver");
```

The example above is the conventional method of using JDBC, and it is the method of dynamically loading the driver class and registering in DriverManager and getting the connection. Nowadays, the way to get the connection through DataSource is used more. For more information, refer to the corresponding class in **JDBC API References**.

Getting Connection

The following code is used to get the connection.

```
Connection con = DriverManager.getConnection(
    "jdbc:goldilocks://127.0.0.1:22581/test", "TEST", "test");
```

The connection URL should be started with "jdbc:goldilocks:" to use GOLDILOCKS JDBC. The next is the IP address and port number of the server and "/test" which is the final part of URL is the DB name. The current GOLDILOCKS does not specifically check the DB name because it does not support multi DB. A user connected URL may be obtained again through DatabaseMetaData.getURL().

It connects in Direct Attach (D/A) mode when setting IP to 0.0.0.0, and a port to 0. Or, the connecting protocol, *da*, can be used instead of ip:port. In other words, both of the following two URL enables connect

ing in DA mode.

```
"jdbc:goldilocks://0.0.0.0:0/test"
"jdbc:goldilocks:da/test"
```

Username and password should respectively use the account and password for DB.

Using Statement and ResultSet

Statement and ResultSet are used in the same way as other JDBC programs.

```
Statement stmt = con.createStatement();
ResultSet rs = stmt.executeQuery("SELECT NAME, ADDRESS FROM EMP");
while (rs.next())
{
    System.out.println("name = " + rs.getString(1));
    System.out.println("address = " + rs.getString(2));
}
rs.close();
stmt.close();
```

32.2 Feature Specification

Connection

Connection Using DriverManager

The traditional way to get a connection is to use DriverManager.

```
Connection con = DriverManager.getConnection(url_string, user_name, password);
```

url_string has the following three types.

```
jdbc:goldilocks://[ip address]:[port_no]/[db_name]
```

```
jdbc:goldilocks:da/[db_name]
```

```
jdbc:goldilocks:locator//[ip address]:[port_no][, [ip address]:[port_no] ]*/[db_name]
```

The host name, IPv4 and IPv6 are available for IP address, and port_no refers to the port number set. db_name is not used for the current connection so it can have any name. However, it can not be omitted. The following is an example of URL.

```
String url_string = "jdbc:goldilocks://localhost:22581/test";
```

```
String url_string = "jdbc:goldilocks://127.0.0.1:22581/test";
```

```
String url_string = "jdbc:goldilocks://[::1]:22581/test";
```

IP "0.0.0.0" and port 0 are used as a special address for D/A connection. For more information about D/A mode, refer to **Connecting in Direct Attach Mode**.

user_name and password refer to GOLDILOCKS account.

The following method is used for various property settings except for the getConnection() method above.

```
Properties prop = new Properties();
prop.setProperty("user", user_name);
prop.setProperty("password", password);
Connection con = DriverManager.getConnection(url_string, prop);
```

A locator keyword can be added to url_string to obtain the server connection information from glocator instead of using the connection property. In this case, ip address and port_no is considered as the connec tion information of glocator.
The following is an example of using the locator keyword to the connection statement.

```
String url_string =
"jdbc:goldilocks:locator//127.0.0.1:42581,127.0.0.1:42582/test?locator_service=S1";
```

The first connection information (127.0.0.1:42581) is the connection information of glocator, and the lat ter connection information is processed as ALTERNATE_LOCATORS property such as 127.0.0.1:42582.

The following is the property setting which has the meaning as same as the url_string above.

```
String url_strng = "jdbc:goldilocks://0.0.0.0:0/test";
Properties prop = new Properties();
prop.setProperty("locator_host", "127.0.0.1");
prop.setProperty("locator_port", "42581");
prop.setProperty("alternate_locators", "127.0.0.1:42582");
prop.setProperty("locator_service", "S1");
Connection con = DriverManager.getConnection(url_string, prop);
```

The property list which can be used for the connection is known through getPropertyInfo() method of Go ldilocksDriver. For more information, refer to **Table 32-1 Connection property**.

The login timeout of the connection object which is created by DriverManager and the logger uses the va lue registered in DriverManager. The logger is used by all JDBC interfaces generated from the connection object. Each connection object is not allowed to have an individual logger.

Connection Using DataSource

The JDBC standard recommends to use DataSource rather than the previous DriverManager. It is because DataSource is a single interface to access any data source, and it can individually set the values related to the various data sources, and may remotely send a DataSource object literally.

A connection object can be obtained through DataSource as follows.

```
import sunje.goldilocks.jdbc.GoldilocksDataSource;
GoldilocksDataSource ds = new GoldilocksDataSource();
ds.setServerName("127.0.0.1");
ds.setPortNumber(22581);
ds.setDatabaseName("test");
ds.setUser("TEST");
ds.setPassword("test");
```

```
Connection con = ds.getConnection();
```

GoldilocksDataSource classes should be used to create a DataSource object.
Then, various connection information should use setter method which is not DataSource standard API.For more information, refer to **DataSource**.

When using DriverManager, the login timeout and the logger should be globally set. However, when using DataSource, the login timeout and the logger can be individually set.

```
ds.setLoginTimeout(10);
ds.setLogWriter(out);
```

Interworking with Middleware

It is necessary to know the name of the class which implements XADataSource, ConnectionPoolDataSource interface to interwork with middleware such as Weblogic, JBoss, etc. GOLDILOCKS provides Goldilocks XADataSource, GoldilocksConnectionPoolDataSource for sunje.goldilocks.jdbc package. Both classes offer the various setter methods such as GoldilocksDataSource.

```
import sunje.goldilocks.jdbc.GoldilocksXADataSource;
GoldilocksXADataSource ds = new GoldilocksXADataSource();
ds.setServerName("127.0.0.1");
ds.setPortNumber(22581);
ds.setDatabaseName("test");
ds.setUser("TEST");
ds.setPassword("test");
XAConnection con = ds.getXAConnection();
```

Connection Property

Table 32-1 Connection property

Name	Mandatory/ optional	Valid value	Description
alternate_servers	Optional	IP:PORT[,IP:PORT]+	It is the list of alternate servers for failover. It is delimited by comma (,).
alternate_locators	Optional	IP:PORT[,IP:PORT]+	It is the list of alternate of glocator.
batch_count	Optional	Any integer	It is the number of the batch jobs which can be processed in a single protocol transmission and reception. The default value is 1,000. If the value is too small, too much frequent network communication causes poor performance of the batch processi

Name	Mandatory/ optional	Valid value	Description
			ng. If the value is too large, the server memory is increased be cause the session stacks the execution results.
connection_retry_count	Optional	Any integer	It stores the number of retrials to connect. The default value is 0, then it does not retry to connect.
connection_retry_delay	Optional	Any integer	It stores the delay before the connection retrial in seconds wh en trying to connect again. The default value is 3.
date_format	Optional	Any string	It is the character format which is used to interconvert betwee n date and string inside the driver.
da_buffer_size	Optional	Any integer	It sets the size of a buffer which sends and receives data when fetching and binding while connected in direct attach mode. T he default value is 100000.
decoding_replacement	Optional	Any string	It is the character replacing a byte value which can not be dec oded when decoding a byte array into a string. The default val ue is ?.
failover_granularity	Optional	{"0", "1", "2"}	It determines whether failover is successful. non-atomic(0), at omic(1), 2 are not yet supported. When an error occurs for th e existing prepared statements in the prepare process during f ailover, if it is 0, then it proceeds the failover, and if it is 1, it d etermines that the failover fails. The default value is 0.
failover_type	Optional	{"connection", "session"}	It determines the failover types. • Connection: Failover is used only when connecting to ser ver. • Session: Failover is used when connecting to server as we ll as communicating with the server like execution. The default value is session.
format_grammar	Optional	{"db", "java"}	It determines whether the property string such as date_format is the GOLDILOCKS syntax or the syntax used in SimpleDateFo rmat of java. The default value is db.
global_connection_log	Optional	boolean	It determines whether to perform the global connection loggi ng. The default value is false.
global_logger	Optional	{"console"}	It specifies the logging target. Currently only console is available. Only the first specified one i s valid.
home_dir	Optional	Any string	It specifies a home directory of a cluster server. The default val ue is null.
include_synonyms	Optional	boolean	It sets whether to include the synonym object in DatabaseMet aData.getColumns(). The default value is false.
keep_alive	Optional	boolean	It determines whether to set the keep_alive as the socket prop erty of the connection. Using the property, the connection re mains by periodically sending and receiving ack inside TCP soc ket. LAN cable error detection can forcibly cut off the connecti

Name	Mandatory/ optional	Valid value	Description
			on. The default value is false.
locality_aware_transaction	Optional	boolean	It determines whether to use GLOBAL CONNECTION. If it is set to true, then it uses GLOBAL CONNECTION. The default value is false.
locality_group_policy	Optional	{"0", "1", "2"}	It determines how to select a group if neither of groups are available, or two or more groups are available when using GLOBAL CONNECTION. • 0: It randomly selects the group. • 1: It sequentially selects groups which exist in LOCALITY_GROUP_PATH setting. If neither of groups in LOCALITY_GROUP_PATH are not available, it randomly selects the group. • 2: It sequentially selects groups. It always selects groups in an order of they are connected to the driver.
locality_group_path	Optional	Group name list	It defines the list of selected groups when the available group is not a single one when using GLOBAL CONNECTION. Each group is distinguished with comma (,). e.g. G1,G2,G3
locality_member_policy	Optional	{"0","1","2","3","4"}	It determines how to select a member in the selected group when using GLOBAL CONNECTION. • 0: DML : MASTER / SELECT : MASTER • 1: DML : ANY / SELECT : ANY • 2: DML : MASTER / SELECT : ANY • 3: DML : MASTER / SELECT : SLAVE • 4: It sequentially selects members which exist in LOCALITY_MEMBER_PATH setting. If neither of members in LOCALITY_MEMBER_PATH are not available, it uses the MASTER in the selected group.
locality_member_path	Optional	Member name list	It defines the list of members to be used in the selected group when using GLOBAL CONNECTION. Each member is distinguished with comma (,). e.g. G1N1,G2N1,G3N1,G1N2,G2N2,G3N2
locality_on_demand	Optional	boolean	It accesses to a specific member in need when using GLOBAL CONNECTION. The default value is false. • false: It accesses to all members from the beginning. • true: It accesses to a specific member when it is required.
locator_connection_timeout	Optional	Any integer	It is the time of waiting for receiving a packet from glocator.
locator_file	Optional	Any string	It is a location file.
locator_host	Optional	IP address	It is host address of glocator.
locator_port	Optional	Port no	It is port of glocator.

Name	Mandatory/ optional	Valid value	Description
locator_service	Optional	Any string	It is the service name to obtain the server connection informati on.
login_timeout	Optional	Any integer	It sets the timeout duration (second) of the socket when conn ecting to the server. The default value is 0, and it indefinitely waits.
lzeros	Optional	Any integer	When a numeric is expressed as a string and the number of ze ros following the decimal point exceeds this value, it is express ed in exponent notation. The default value is 15.
new_password	Optional	Any string	It can change the account password by using old_password pr operty together.
old_password	Optional	Any string	It can change the account password by using new_password property together.
packet_compre ssion_threshold	Optional	Any integer	It compresses the communication data to be sent to the server when the data size is bigger than packet_compression_thresh old. The property range is 32 ~ 2113929216.
password	Mandatory	Any string	It is user account password.
prefer_ipv6	Optional	boolean	It sets whether IPv6 takes precedence over other IP addresses on the host name. The default value is false.
program	Optional	Any string	It is program description.
protocol_log	Optional	boolean	It determines whether to log sending and receiving a protocol. The default value is false.
query_log	Optional	boolean	It determines whether to log a query. The default value is false.
role	Optional	{"", "SYSDBA", "ADMIN"}	It specifies the account role. The default value is "".
session_type	Optional	{"1", "2", "3"} or {"dedicate", "sh ared", "default" }	It is one of dedicated/ shared/ default. (It is selected by DB when it is set to default.)
statement_poo l_on	Optional	boolean	It enables the statement pool. The default value is false.
statement_poo l_size	Optional	Any integer	It sets the size of the statement pool.
time_format	Optional	Any string	It is the character format which is used to interconvert betwee n time and string inside the driver.
tcp_nodelay	Optional	boolean	It sets TCP_NODELAY(Nagle's Algorithm) property on the sock et of the connection. The default value is true.
timestamp_for mat	Optional	Any string	It is the character format which is used to interconvert betwee n timestamp and string inside the driver.
time_with_tim	Optional	Any string	It is the character format which is used to interconvert betwee

Name	Mandatory/ optional	Valid value	Description
e_zone_format			n time with timezone and string inside the driver.
timestamp_with_time_zone_format	Optional	Any string	It is the character format which is used to interconvert between timestamp with timezone and string inside the driver.
trace_log	Optional	boolean	It determines whether to log the trace. The default value is "" (not). The default value is false.
tzeros	Optional	Any integer	When a numeric is expressed as a string and the number of zeros in digit goes beyond this value, it is expressed in exponent notation. The default value is 15.
user	Mandatory	Any string	It is user account name.
use_global_session	Optional	boolean	It is whether to use GLOBAL SESSION. The default value is false.
use_targettype	Optional	{"0", "1", "2"}	It is the information which is to be received together when receiving a column type through communication. • 0: none • 1: name • 2: all

- locator_file is applied prior to locator_host and locator_port. For more information about locator_file, refer to **Location File**.
- locator_service property enables the access to the server belonging to locator_service. For more information, refer to **glocator** and **gloctl**.

Data Manipulation

Data Manipulation Using Statement

Various SQL statements can be executed by using statement objects. Statement object can be obtained from the connection object as follows.

```
Connection con = DriverManager.getConnection(...);
Statement stmt = con.createStatement();
```

Various DML or DDL statements can be executed by using the execute method of the created statement object, and the executeUpdate method.

```
stmt.executeUpdate("create table emp ( id varchar(20), name varchar(30), age integer )");
stmt.executeUpdate("insert into emp values ('1234560000', 'Yuna', 24)");
int updated = stmt.executeUpdate("delete from emp where age > " + age);
```

The difference between execute and executeUpdate methods is only the return values. The execute meth od indicates whether the executed SQL statement returns ResultSet. The executeUpdate method returns the number of updated rows. The execute method can be used for both of DML and SELECT statements, but it throws SQLException if the executeUpdate method is used for SELECT statement.

Direct-execution refers to execution of SQL statement by using statement. It is the method of p erforming the prepare operation(parsing, validation, optimization) and execution for the SQL st atement at a time. On the other hand, prepare-execution refers to the method of preparing the operation, then repeating the execution. Direct-execution repeatedly performs prepare and exe cution operation every time it is performed, so prepare-execution is more efficient when repeat edly performing the SQL statement.

Data Manipulation Using PreparedStatement

The JDBC standard provides PreparedStatement interface which can use a parameter for data manipulati on, and it enables a user to run it more efficiently. In addition, PreparedStatement quickly perform the re peated operation of the SQL statement because performs the prepare operation for the SQL statement o nly once.

```
Connection con = DriverManager.getConnection(...);
PreparedStatement pstmt = con.prepareStatement(
  "insert into emp values (?, ?, ?)");
pstmt.setString(1, "55544123000");
pstmt.setString(2, "Gildong");
pstmt.setInt(3, 32);
pstmt.executeUpdate();
pstmt.setString(1, "1357924680");
pstmt.setString(2, "Dooli");
pstmt.setInt(3, 41);
pstmt.executeUpdate();
```

After preparing the SQL statement as shown in the lines 2-3, the data is bound and performed. Prepared Statement which is prepared once, can bind and execute repeatedly.

If the binding is omitted and execute() is performed, the previously bound values are used.

```
pstmt.setString(1, "333555777000");
pstmt.setString(2, "Kang");
pstmt.setInt(3, 55);
pstmt.executeUpdate();
pstmt.setString(1, "245778884440");
pstmt.executeUpdate();
```

When the value is not bound to the second, third parameters as shown in line 6 but immediately execute d, the value, "Kang" and 55, which was previously bound, is used. If the previously bound value does not exist, it throws SQLException.

All bound values are deleted by using clearParameters().

```
pstmt.setString(1, "333555777000");
pstmt.setString(2, "Kang");
pstmt.setInt(3, 55);
pstmt.executeUpdate();
pstmt.clearParameters();
pstmt.setString(1, "245778884440");
pstmt.executeUpdate();
```

After deleting parameters in line 5, if the value is bound only to the first parameter and executed (line 7), then it throws SQLException.

The main reason to use PreparedStatement is because it can bind the data of various types. It is inconveni ent to handle the data of the type such as binary or timestamp because the value can be expressed only i n the character string when using Statement. Therefore, it is more convenient to bind all types by using P reparedStatement.

```
pstmt.setTimestamp(1,
  new Timestamp(Calendar.getInstance().getTimeInMillis()));
pstmt.setCharacterStream(2, new StringReader(BIG_STRING));
pstmt.setObject(3, someObj, Types.LONGVARCHAR);
pstmt.setObject(4, otherObj);
```

In the sample above, lines 1 ~ 2 binds java.sql.Timestamp object. The binding type (It is GOLDILOCKS typ e of the data when the data is sent to the server) is TIMESTAMP. For more information about the binding type which is determined by the various setter methods, refer to the corresponding API of **PreparedState ment**.

Line 3 binds a reader object, and it is bound as LONG VARCHAR type internally.

Line 4 binds the object of Java object type, and explicitly notifies that the type is LONG VARCHAR. For mo re information about GOLDILOCKS type which is mapped to the type of Types, refer to **SQL types → GOL**

DILOCKS types.

Line 5 literally binds the Java object type, and it is bound to the corresponding GOLDILOCKS data type ac cording to the class type. For more information about mapping between class types and GOLDILOCKS da ta types, refer to **Table 32-2 Java objects → GOLDILOCKS types**.

Batch Execution Using Statement

The different SQL statements can be executed as the batch job by using addBatch() and executeBatch() o f Statement.

```
stmt.addBatch("insert into emp values ("12345", "Jake", 22)");
stmt.addBatch("insert into salary values ("12345", 5000)");
stmt.addBatch("update members set total_count=total_count+1 where age=22");
stmt.executeBatch();
```

Likewise, different SQL statements may be performed through a single executeBatch () method. However, this does not mean that the method call executes three statements in the server, gathers the results, send s the results to the JDBC driver with a single protocol. Internally, three times of protocol transmission, exe cution in the server and result transmission are performed. In other words, it does not have a big perform ance advantage.

After performing executeBatch, all registered jobs are deleted.

Even if an error occurs during execution, all registered jobs are performed until it is completed. Whether an error occurs or not can be known by the value of the returned int [] type. In other words, if int [] has E XECUTE_FAILED value, it means that the job is failed.

Batch Execution Using PreparedStatement

More powerful batch operation can be performed by using addBatch() and executeBatch() methods of Pr eparedStatement.

```
PreparedStatement pstmt = con.prepareStatement("insert into emp values (?, ?, ?)");
pstmt.setString(1, "12345000");
pstmt.setString(2, "John");
pstmt.setInt(3, 33);
pstmt.addBatch();
pstmt.setString(1, "222333555");
pstmt.setString(2, "Henry");
pstmt.setInt(3, 24);
pstmt.addBatch();
int[] inserted = pstmt.executeBatch();
```

The example above is a process of inserting two rows. The values configuring the two rows are bound thr ough addBatch (), and then if executeBatch () is called, the bound value and the protocol for execution a re sent to the server and executed. It is more efficient than the batch execution of Statement and the perf ormance is faster because communication occurs only when executeBatch() is called.

The new value should be bound to execute executeBatch() again because the bound values are deleted a fter executing executeBatch(). clearBatch() does not be to be explicitly called to delete the registered job after execution.

Even if an error occurs during execution, all registered jobs are performed until it is completed. Whether an error occurs or not can be known by the value of the returned int [] type. In other words, if int [] has E XECUTE_FAILED value, it means that the job is failed.

GOLDILOCKS JDBC provides a separate method which is executeBatchAtomic() in addition to executeBat ch(). executeBatch () performs the execution as many as the number of the registered jobs in the server, but the response time is fast because executeBatchAtomic() performs the execution at once with the regi stered job (the bound values). However, if any one fails, everything fails as it can be seen from the name which is atomic. Therefore, the return type is not int[], but int.

```
...
int inserted = ((GoldilocksPreparedStatement)pstmt).executeBatchAtomic();
```

Data Retrieval

Getting Column Values

The data can be retrieved through ResultSet object which is obtained by executeQuery () of the Statemen t or PreparedStatement.

```
...
ResultSet rs = pstmt.executeQuery();
while(rs.next())
{
    String id = rs.getString(1);
    String name = rs.getString(2);
    int age = rs.getInt(3);
    ...
}
```

The contents of the column can be obtained through various getter methods in the ResultSet after retriev ing the data in the table. The data in the table is sent to JDBC drivers in the original form of GOLDILOCKS data type, and it is converted to an appropriate Java data type according to the types of getter methods c

alled by a user and it is transmitted to the user. For more information about type conversion mapping of GOLDILOCKS data type and getter method, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .

If GOLDILOCKS data type can not be converted to the type of getter, it throws SQLException.

Closing ResultSet

The ResultSet which is used up can release the resources through close(). Even if a user does not explicitly call close(), the followings bring the result as same as when calling close() of ResultSet.

- When superordinate statement is closed
- When superordinate connection is closed
- When executeQuery() of Statement is called again
- When an error occurs during fetching

The two ResultSets which are created from a single statement can not be remained simultaneously in the third case above. Only the ResultSet object which is created by the last executeQuery() is valid.

Fetch Size

JDBC can specify the number of rows fetched at once from the server through setFetchSize(int rows) of S tatement. The default value of the ResultSet property of GOLDILOCKS is 0. 0 automatically determines th e number of rows fetched by the server. For forward only, it is the maximum number of rows fetched in a communication packet. For scrollable, it is fixed to 100. If the value is too large, the amount of memory u sed by JDBC ResultSet becomes large. If the value is too small, the communication is frequently executed.

The value is mainly used in a scrollable ResultSet because it is not sensitive even when it is scroll sensitive while moving within the row cache of ResultSet. If the value is set too large, the latest information about the changes of rows can not be known.

Field Size Limit

JDBC may limit the maximum length of the column through setMaxFieldSize(int size) of statement. The maximum length can be limited for the types of CHAR, VARCHAR, LONG VARCHAR, BINARY, VARBINAR Y, and LONG VARBINARY. The data bigger than the length is truncated. The default value is 0, and the m aximum length is not limited in this case.

This property is ignored for other types such as INTEGER, DATE, etc..

ResultSet Scroll

Getting Scrollable ResultSet

There are two kinds of scrollable ResultSet, which are scroll sensitive and scroll insensitive. Scroll sensitive is the cursor type which can view the values changed by the transaction itself or other transaction while tr aversing the ResultSet, but scroll insensitive is not. GOLDILOCKS server supports both of the scroll types, a nd those facilities can be used by JDBC.

```
Statement stmt = con.createStatement(ResultSet.TYPE_SCROLL_SENSITIVE,
                                     ResultSet.CONCUR_READ_ONLY);
ResultSet rs = stmt.executeQuery("select id, name, age from emp");
```

If the ResultSet type is TYPE_SCROLL_INSENSITIVE when creating statement as line 1, ResultSet which is c reated from the statement object is scroll sensitive cursor. However, the current GOLDILOCKS does not su pport the updatable ResultSet.

The type should be set to TYPE_SCROLL_INSENSITIVE to obtain scroll insensitive ResultSet. The default val ue is TYPE_FORWARD_ONLY.

However, even it is a scroll sensitive ResultSet, a user can not know the latest value or whether it is chang ed, when moving within the row cache of ResultSet. The row should be fetched again from the server to find out the latest value or whether it is changed.

Scrolling

JDBC API provides the following methods to scroll the cursor.

```
public boolean next() throws SQLException;
public boolean previous() throws SQLException;
public boolean first() throws SQLException;
public boolean last() throws SQLException;
public boolean absolute(int rows) throws SQLException;
public boolean relative(int rows) throws SQLException;
public void beforeFirst() throws SQLException;
public void afterLast() throws SQLException;
```

next() is the method which can be used for forward only or scrollable ResultSet, and it sets the cursor pos ition to the next row. If the row can be read at the moved position, it is true. Otherwise, it is false. Other methods can be used only for scrollable ResultSet.

previous() moves the cursor to the previous row, first() moves the cursor to the first row, last() moves the

cursor to the last row, absolute() moves the cursor to the absolute position and relative() moves the curso r to the relative position from the current position. beforeFirst() moves the cursor to before the first row. afterLast()moves the cursor to after the last row.

```
rs.afterLast();
while (rs.previous())
{
    String id = rs.getString(1);
    String name = rs.getString(2);
    int age = rs.getInt(3);
    ...
}
```

The code above will query backwards from the last row to the first row.

The current cursor position can be known by the following method.

```
public int getRow() throws SQLException;
```

Scrolling Principle

The ResultSet scroll is easy to use, but it may cause poor performance without knowing internal operatin g principles. Scrolling is performed in result cache within ResultSet of JDBC driver, but it is performed on t he server in case when the range exceeds the cache, so the communication may occur. Therefore, it shou ld be used carefully to prevent the poor performance.

The internal default value of the fetch size of scrollable ResultSet is 100 (the external default value is 0 an d it can be changed through setFetchSize() method). It means that the number of rows that are fetched t o JDBC driver at once are 100. The row cache of ResultSet consists of 100 rows, and the cursor position o f ResultSet should be changed if the row position to be moved is in the cache. However, if it is not in the cache, the row at the position where to be moved should be got from the server. At this time, it is necess ary to know how to get the row set including the row to be moved.

For example, if the ResultSet has rows from 1 to 100 and the current cursor position is at 100, calling nex t () will fetch rows 101 through 200 from the server because the next row does not exist in the cache. On the other hand, the rows from 101 to 200 are in ResultSet cache, and it is not appropriate to fetch rows f rom 100 to 199 from the server by calling previous() if the current cursor position is 101 row. When this approach is used, row should be fetched from the server whenever previous() is called. However, GOLDIL OCKS fetches the rowset which includes the corresponding last row from the server when it is required to fetch the row from the server due to calling previous () to prevent this inefficiency. For example, when it i s necessary to fetch row of the number 100 by calling previous(), GOLDILOCKS fetches the rows from 1 t o 100. Then it is fetched in favor of previous ().

The rule is generalized as follows.

- If the position to be moved is after the current position, 100 rows (the fetch size) after that position a re fetched.
- If the position to be moved is before the current position, 100 rows before that position are fetched.
- When moved with first(), the first 100 rows are fetched.
- When moved with last(), the last 100 rows are fetched.

When moved backward, the fetch is performed in favor of next(). When moved forward, the fetch is perf ormed in favor of previous(). This is also applied to absolute () and relative ().

Using Other Data Types

Interval Type

GOLDILOCKS supports the following 13 types related to interval.

- interval year
- interval month
- interval year to month
- interval day
- interval hour
- interval minute
- interval second
- interval minute to second
- interval hour to minute
- interval hour to second
- interval day to hour
- interval day to minute
- interval day to second

sunje.goldilocks.jdbc.GoldilocksInterval object is created and the insert operation is executed by setObjec t() of PreparedStatement to insert the interval data into a table using JDBC.

GoldilocksInterval object can be created by using createIntervalXXX which is the static method of Goldilo cksInterval.

```
import sunje.goldilocks.jdbc.GoldilocksInterval;
...
GoldilocksInterval interval = GoldilocksInterval.createIntervalDayToSecond(2, 6, "2
08:23:54.560843");
```

```
PreparedStatement pstmt = con.prepareStatement("insert into interval_table values (?,?)");
pstmt.setString(1, someId);
pstmt.setObject(2, interval);
pstmt.executeUpdate();
```

For more information about createIntervalXXX method, refer to **GoldilocksInterval**. Likewise, GoldilocksInterval is created and it is bound via setObject. Or, a type is explicitly specified as follows.

```
import sunje.goldilocks.jdbc.GoldilocksTypes;
...
pstmt.setObject(2, interval, GoldilocksTypes.INTERVAL_DAY_TO_SECOND);
```

The data may be inserted by using a character string without GoldilocksInterval object.

```
pstmt.setObject(2, "2 08:23:54.560843", GoldilocksTypes.INTERVAL_DAY_TO_SECOND);
```

In this case, a GoldilocksInterval object is created within JDBC driver and bound to a host variable. Or it may be bound as a string by using setString() method.

```
pstmt.setString(2, "2 08:23:54.560843");
```

The string is literally sent to the server when using this method, and the string is converted to Interval day to second type and inserted in the server.

getObject() or getString() of ResultSet queries the Interval type from the DB.

```
import sunje.goldilocks.jdbc.GoldilocksInterval;
ResultSet rs = stmt.executeQuery("select interval_value from some_table");
while (rs.next())
{
    GoldilocksInterval interval = (GoldilocksInterval)rs.getObject(1);
    System.out.println("type = " + interval.getTypeName() +
                       ", value = " + interval.toString());
}
```

The data of GoldilocksInterval type can be retrieved via getObject() of ResultSet. GoldilocksInterval class provides getter like getYear(), getHour(), etc. that return various time data. For more information about getter API, refer to **GoldilocksInterval**.

Time with Time Zone and Timestamp with Time Zone Types

Concerning time, GOLDILOCKS provides not only SQL standard types such as Date, Time, Timestamp but also Time with time zone and Timestamp with time zone types.

```
CREATE TABLE SAMPLE_TABLE ( C1 TIME WITH TIME ZONE,
                            C2 TIMESTAMP WITH TIME ZONE );
```

GOLDILOCKS JDBC provides setTimeTimeZone(int colIndex, Time time, Calendar timezone) method and setTimestampTimeZone(int colIndex, Timestamp time, Calendar timezone) method in GoldilocksPreparedStatement class to insert the data of Time with time zone and Timestamp with time zone types. For more information about specifications refer to **setTimeTimeZone** and **setTimestampTimeZone**.

The data can be inserted via existing setTime() and setTimestamp() methods, but the time zone value of the column is unconditionally set to the local time zone of Java execution environment. Therefore, setTimeTimeZone() or setTimestampTimeZone should be used to insert various time zone information.

Time, Timestamp data can be inserted with the given time zone value via setTimeTimeZone and setTimestampTimeZone.

```
import sunje.goldilocks.jdbc.GoldilocksPreparedStatement;
PreparedStatement pstmt = con.prepareStatement(
    "INSERT INTO SAMPLE_TABLE VALUES (?,?,?,?)");
Calendar now = Calendar.getInstance();
Calendar usNow = Calendar.getInstance(TimeZone.getTimeZone("GMT-8"));
Time t = new Time(now.getTimeInMillis());
Timestamp ts = new Timestamp(now.getTimeInMillis());
pstmt.setTime(1, t);
pstmt.setTimestamp(2, ts);
pstmt.executeUpdate();
((GoldilocksPreparedStatement)pstmt).setTimeTimeZone(1, t, now);
((GoldilocksPreparedStatement)pstmt).setTimestampTimeZone(2, ts, now);
pstmt.executeUpdate();
((GoldilocksPreparedStatement)pstmt).setTimeTimeZone(1, t, usNow);
((GoldilocksPreparedStatement)pstmt).setTimestampTimeZone(2, ts, usNow);
pstmt.executeUpdate();
```

Line 11, 12 binds the column to time type and timestamp type. Each value of t and ts is sent to the server and the default time zone value is inserted to DB column in the server.

On the other hand, line 15, 16 binds the column to time with time zone type and timestamp with time zone type, and is sent to the server together with time zone information. As a result, if the time zone settings of a server and a client are same, the rows which are inserted by lines 11~13 and 15~17 are same.

Line 19, 20 inserts time zone information of GMT-8 time zone.

There are two ways to query data, which are time with time zone and timestamp with time zone. One is t he way to get data as char from the server, and the other is the way to get data of the corresponding typ e by JDBC and to obtain as time or as timestamp object.

```
ResultSet rs = stmt.executeQuery("select c1, cast(c1 as char(33)), c2, cast(c2 as char(33))
from sample_table");
while (rs.next())
{
    System.out.println("c1 = " + rs.getTime(1).toString());
    System.out.println("c1 as char = " + rs.getString(2));
    System.out.println("c2 = " + rs.getTimestamp(3).toString());
    System.out.println("c2 as char = " + rs.getString(4));
}
```

When executing the code above, the results are as follows.

```
c1 = 12:35:26
c1 as char = 12:35:26.052000 +09:00
c2 = 2014-03-27 12:35:26.052
c2 as char = 2014-03-27 12:35:26.052000 +09:00
c1 = 12:35:26
c1 as char = 12:35:26.052000 +09:00
c2 = 2014-03-27 12:35:26.052
c2 as char = 2014-03-27 12:35:26.052000 +09:00
c1 = 12:35:26
c1 as char = 19:35:26.052000 -08:00
c2 = 2014-03-27 12:35:26.052
c2 as char = 2014-03-26 19:35:26.052000 -08:00
```

REF CURSOR Type

REF CURSOR which was used as PARAMETER in PSM is available in JDBC as well.

```
CREATE OR REPLACE PROCEDURE proc_cursor1( p1 OUT SYS_REFCURSOR )
AS
  var1 INTEGER;
BEGIN
  OPEN p1 FOR SELECT r_c1 FROM r;
  FETCH p1 INTO var1;
  DBMS_OUTPUT.PUT_LINE(var1);
```

```
END;
/
```

```
CREATE OR REPLACE PROCEDURE proc_cursor2( p1 IN SYS_REFCURSOR )
AS
  var1 INTEGER;
BEGIN
  LOOP
    FETCH p1 INTO var1;
    EXIT WHEN p1%NOTFOUND;
    DBMS_OUTPUT.PUT_LINE(var1);
  END LOOP;
  CLOSE p1;
END;
/
```

Set sqlType typr to Types.REF_CURSOR (JDK 1.8 or higher) or GoldilocksTypes.REF_CURSOR (lower than JDK 1.8) to use REF CURSOR as OUTPUT PARAMETER in JDBC.

```
import import java.sql.Types;
CallableStatement cstmt1 = con.prepareCall("{CALL proc_cursor1(?)}");
cstmt1.registerOutParameter(1, Types.REF_CURSOR);
cstmt1.execute();
```

```
import sunje.goldilocks.jdbc.GoldilocksTypes;
CallableStatement cstmt1 = con.prepareCall("{CALL proc_cursor1(?)}");
cstmt1.registerOutParameter(1, GoldilocksTypes.REF_CURSOR);
cstmt1.execute();
```

ResultSet object is received through CallableStatement.getObject() after executing CallableStatement.

```
ResultSet rs = (ResultSet)cstmt1.getObject(1);
if (!rs)
{
    if (rs.next())
    {
        System.out.println(rs.getInt(1));
    }
}
```

Set ResultSet object which was received through CallableStatement.getObject() to PreparedStatement.setObject() to use REF CURSOR received as OUTPUT PARAMETER as INPUT PARAMETER in the new statem

ent.

```
CallableStatement cstmt2 = con.prepareCall("{CALL proc_cursor2(?)}");
cstmt2.setObject(1, rs);
cstmt2.execute();
```

It is fetched as may times as the value set with Statement.setFetchSize() when executing ResultSet.next(). When using REF CURSOR received as OUTPUT PARAMETER as INPUT PARAMETER in the new statement, then set the fetch size of CallableStatement which uses OUTPUT PARAMETER.

Logging

Logging Types

When developing a project by using JDBC, it is helpful in many ways for JDBC driver to leave various logs. GOLDILOCKS provides the facility to log the useful information even during operation, as well as the project development.
There are three types of log, which are trace log, protocol log and query log.

Trace log leaves information every time when JDBC API is called. It can be known which JDBC API is called. Protocol log shows the situation to send and receive communication packets between JDBC driver and GOLDILOCKS server. Query log records the SQL statement to be executed, when PreparedStatement or Statement is executed.

Logging by Using DriverManager

First, the logging is left by using DriverManager. The logging media can be determined by using setLogWriter() method in DriverManager, and the type of logging to be left can be specified in connection url.

```
DriverManager.setLogWriter(new PrintWriter(System.out));
String url = "jdbc:goldilocks://localhost:22581/test?trace_log=on&query_log=on";
Connection con = DriverManager.getConnection(url, "TEST", "test");
```

Line 1 defines the logging media. All logging is output to the console. Line 2 defines the connection url, and the property can be defined after ? character. It means to using trace_log, query_log.

Likewise, these properties can be specified in URL, or they can be defined with properties object.

```
Properties prop = new Properties();
prop.put("trace_log", "on");
prop.put("query_log", "on");
prop.put("protocol_log", "on");
prop.put("user", "TEST");
prop.put("password", test");
Connection con = DriverManager.getConnection(url, prop);
```

The connection properties which can be used in GOLDILOCKS are defined in **Table 32-1 Connection property**.

Sometimes it is difficult to call setLogWriter() of DriverManager. When using the middleware, the code like that can not be added. For such a case, GOLDILOCKS JDBC provides a global property called global_logger. Other general properties are limited to a single connection, but this property is global. In other words, if the property is set, it does not have to call DriverManager.setLogWriter ().

```
String url = "jdbc:goldilocks://localhost:22581/test?" +
             "global_logger=console&trace_log=on&query_log=on";
Connection con = DriverManager.getConnection(url, "TEST", "test");
```

global_logger property is applied only once initially, and it is ignored if log writer is already set in DriverManager. Only the current console is applicable as the property value. Other value does not cause any operation.

Logging by Using DataSource

Unlike DriverManager, DataSource can set the log writer by each object. If the log writer is set for a DataSource object, all connections which are generated from the DataSource are logged by the log writer. The following describes how to set the logging in the DataSource.

```
import sunje.goldilocks.jdbc.GoldilocksDataSource;
...
GoldilocksDataSource ds = new sunje.goldilocks.jdbc.GoldilocksDataSource();
ds.setServerName("localhost");
ds.setDatabaseName("test");
ds.setUser("TEST");
ds.setPassword("test");
ds.setPortNumber(22581);
ds.setLogTarget("console");
ds.setTraceLog("on");
ds.setQueryLog("on");
ds.setProtocolLog("on");
```

```
Connection con = ds.getConnection();
```

Likewise, the logging feature is set by using setLogTarget(), setTraceLog(), setQueryLog() and setProtocol Log() methods. setLogWriter() of DataSource can be called instead of setLogTarget(). When using the mi ddleware, the method such as setLogWriter() can not be directly called, so it should be controlled with th e property. In this case, if logTarget, traceLog, queryLog and protocolLog properties are defined, the mid dleware automatically calls the methods.

Viewing Plan Text

Usage

The plan text can be obtained by using GOLDILOCKS JDBC like as the plan text of the executed statement is obtained by using GOLDILOCKS ODBC. It can be configured to generate a plan text by using non-stand ard API method in GoldilocksStatement class, or obtain the plan text which is already generated.

```
Connection con = ...
GoldilocksStatement stmt = (GoldilocksStatement)con.createStatement();
stmt.setExplainPlanOption(GoldilocksStatement.EXPLAIN_PLAN_OPTION_ON);
ResultSet rs = stmt.executeQuery("select * from t1");
System.out.println(stmt.getExplainPlan());
```

For example, when querying a simple table, the plan text is output as follows.

```
< Execution Plan >
================================================================================
|  IDX  |  NODE DESCRIPTION                                |       ROWS |
--------------------------------------------------------------------------------
|    0  |  SELECT STATEMENT                                |            |
|    1  |    TABLE ACCESS ("T1")                           |          0 |
================================================================================
     1  -  READ COLUMNS : A
```

Option Types

GOLDILOCKS provides the following four properties about the plan text generation.

- EXPLAIN_PLAN_OPTION_OFF: It does not generate the plan text as the default value of the property r elated to the plan text of statement.
- EXPLAIN_PLAN_OPTION_ON: It generates the plan text when executing or fetching.

- EXPLAIN_PLAN_OPTION_ON_VERBOSE: It generates more detailed plan text such as execution time when executing or fetching.
- EXPLAIN_PLAN_OPTION_ONLY: It generates the plan text like as EXPLAIN_PLAN_OPTION_ON when executing or fetching but it is not actually executed.

These properties are set by using GoldilocksStatement.setExplainPlanOption(int) method, and the property which is set once is continuously maintained. A constant value of the property is defined in GoldilocksStatement.

The plan text for non-SELECT DML statements or other SQL statements is generated at run-time, but the plan text for the SELECT statements is generated when the SELECT statement is fetched and the cursor is positioned at the end in the server. The plan text should be obtained after all rows are traversed with ResultSet for the SELECT statement. The plan text can be obtained when there are few rows in a table because the cursor can traverse until the end in the server without fetching all rows.

Connection Failover

GOLDILOCKS supports the connection failover of the client level (JDBC, ODBC). The application which accesses with client/ server mode by using the JDBC or ODBC to GOLDILOCKS, may perform connection to the alternative server automatically when the connection fails or disconnected. This allows a user to use high availability applications which utilize multiple servers. In particular, when a user registers the main server URL and the alternative server URL through the connection property under interworking web server environment, it can safely use the connection object obtained from the connection pool without worrying about the interruption. Failover is performed entirely automatically inside the driver and the user does not need to worry about the reconnection logics.

alternate_servers property should be given to use failover. IP and port of the alternative server are given for this property, and it may indicate the multiple alternative servers by using the comma (,).

```
Class.forName("sunje.goldilocks.jdbc.GoldilocksDriver");
String url = "jdbc:goldilocks://192.168.0.101:22581/test";
Property prop = new Properties();
prop.setProperty("user", "TEST");
prop.setProperty("password", "test");
prop.setProperty("alternate_servers", "192.168.0.201:22581");
Connection con = DriverManager.getConnection(url, prop);  ❶
Statement stmt = con.createStatement();
stmt.executeUpdate("insert into time_tab values (sysdate)");  ❷
...
```

For example, if ❶ fails to connect to the main server (192.168.0.101), it will automatically connect to an alternative server (192.168.0.201) and returns a connection object. Any error is not returned to the user. If it can not communicate with the server because the connection is broken at ❷ during executeUpdate () or before then, it automatically connects to the alternative server inside the driver and continues to use the existing connection object and returns SQLException. Users can continue to use the existing connecti on object after processing SQLException.

Whether failover or not can be viewed through getWarnings() of connection object.

A failover feature of GOLDILOCKS JDBC is that a user can continue to use statement object or PreparedSt atement object created from connection object. (ResultSet can not continue to be used.)

In particular, a user can continue to use the object because PreparedStatements perform the prepare ope rations internally again in the alternative server if a failover occurs.

```
Connection con = DriverManager.getConnection(url, prop);
PreparedStatement pstmt =
    con.prepareStatement("insert into t1 values (?,?)");
...
try
{
    pstmt.setInt(1, 100);
    pstmt.setString(2, "John");
    pstmt.executeUpdate();
}
catch (SQLException sException)
{
    if (sException.getErrorCode() == 21012)
    {
```

- Failover occurs due to the communication link failure error.
- A user can continue to use the pstmt object.

```
pstmt.executeUpdate();
    }
    else
    {
        ...
    }
}
```

GOLDILOCKS JDBC driver provides some properties related to failover. These can help a user to decide th e failover type, connection order and simple policy used for failover.

failover_type

The property is used to select the failover type. In the example above, the failover at ❶ is the connection failover and the failover at ❷ is the session failover. If the property value is *connection*, only the connecti on failover is used, and if it is *session*, both of the connection failover and session failover can be used. Th e default value is *session*.

failover_granularity

When failover occurs, the prepare operation is performed after the PreparedStatement objects which are generated from the current connection object are connected to the alternative server. If the prepare oper ation fails in the alternative server (An error may occur due to the different server environment.), the pro perty is used to determine whether to consider the failover failed or to ignore the prepare error. The prop erty value is either 0 or 1. If the property value is 0, the prepare error is ignored and the failover continuo usly proceeds. If the property value is 1, the failover is failed. The default value is 0. If the value is 0 and th e prepare operation is failed, PreparedStatement object can not continue to be used and the user should directly create the PreparedStatement object again.

Connecting in Direct Attach Mode

Since JDBC 1.1, Goldilocks provides the connection in direct attach mode (D/A mode) besides the existin g connection in Client/ Server mode (C/S mode) based on TCP/ IP. Like as ODBC D/A connection mode, t his is operated directly interworking with the server process. so the server module interworks within a sin gle process (in a process same as jvm). Therefore, the remote host can not connect in D/A mode.

D/A mode is designed to utilize the merit of GOLDILOCKS, which is a fast processing. TCP/ IP based conn ection offsets the fast processing of GOLDILOCKS by expensive cost, so an alternative method is required when a fast processing is required. Though it is restricted to be operated within the host which is same as the host of GOLDILOCKS server, this D/A mode connection is a good solution.

JDBC program connecting in D/A mode can directly call the server feature by loading GOLDILOCKS jni libr ary when DB connection is created first within jvm. A server module can be directly called through native interface in jvm without network cost, it enables faster processing than the existing C/S mode.

Connecting Method

Use *0.0.0.0:0* instead of existing ip:port in the connection URL to connect in D/A mode. The existing URL can be literaly used and using a special ip:port address (0.0.0.0:0) can minimize changing exisiting applic ations. Or, use a special protocol (*da*) to connect in D/A mode.

```
Connection con =
 DriverManager.getConnection("jdbc:goldilocks://0.0.0.0:0/test","TEST","test");
```

or,

```
Connection con =
 DriverManager.getConnection("jdbc:goldilocks:da/test", "TEST", "test");
```

Features of D/A Connection

GOLDILOCKS server module can be directly called in jvm when connecting in D/A mode. It is called throu gh JNI (Java Native Interface) between JDBC program and GOLDILOCKS server module. It uses the server module with minimum call cost considering that it is expensive to call JNI, so it is faster double than the J DBC based on existing TCP/ IP.

When using the connection based on the existing TCP/ IP, it uses only goldilocks6.jar file. However, when using the connection based on D/A mode, it uses libgoldilocksjni.so file and libgoldilocksas.so file in $GO LDILOCKS_HOME/lib by dynamically loading them. Therefore, an error occurs when connecting if those t wo library files do not exist. However, the location of the library files need not to be separately specified when operating java program. Because it searches for those two library files and loads them as long as it i s in the directory as same as the directory of goldilocks6.jar file.

Global Connection

It support the global connection feature. When using the global connection, an application selects a nod e appropriate for a query process and performs it in the cluster environment.

Settings

locator_file or locator_host, locator_port should be set together with locality_aware_transaction property value to use the global connection. use_global_session property value should be set to 1 to use the global connection.

```
Properties prop = new Properties();
prop.put("locality_aware_transaction", "1");
prop.put("locator_file", "/home/goldilocks/.location.ini");
prop.put("user", "TEST");
prop.put("password", test");
Connection con = DriverManager.getConnection(url, prop);
```

```
String url = "jdbc:goldilocks://192.168.0.1:22581/test?" +
             "locality_aware_transaction=1&locator_host=192.168.0.2&locator_port=42581";
Connection con = DriverManager.getConnection(url, "TEST", "test");
```

Procedure

1. Connect to the database.

After connecting to the server input by a user and receiving the information of the cluster system, the cluster system information is built through the locator file or glocator, then it connects to all nodes in the cluster system.

2. Execute the statement.

If the cluster system information is not built, then the cluster system information is built through the locator file or glocator, then it connects to all nodes in the cluster system.

When connecting to a new server by adding a node to the cluster, then it creates all statements of another node on the node, and is ready to execute SQL.

The statement class does not have the information about the sharding key, so the node is selected according to locality_group_policy or locality_member_policy property and the statement is executed.

If PreparedStatement or CallableStatement class does not have the information about the sharding key, then it builds the information about the sharding key of the SQL from an arbitrary server. If the information about the sharding key is built, then an appropriate node is selected by using the information about the sharding key or locality_group_policy, locality_member_policy, and the query is executed.

If an error occurs on the selected node, then it selects an appropriate node again except for that node, and executes the query.

If the sharding information is updated after executing the statement, then the built sharding key information is dropped.

If the cluster system information is updated by adding/ dropping the cluster node after executing the statement, then the built cluster system information is dropped.

3. Receive ResultSet data.

It receives the data from the node where SQL was executed.

4. Close ResultSet.

It closes a cursor on the node where SQL was executed.

5. Close the statement.

It releases the statement from all connected node.

6. Close the database.

It releases connection to all nodes.

Exception Handling for High Availability

When using GLOBAL CONNECTION, if an error occurs on the selected node during the operation, then it is operated as follows according to the transaction occurrence and SELECT progress.

- When a transaction did not occur

If an error occurs on the selected node when a transaction did not occur, then it selects another node wit hin JDBC and executes the query. Though an error occurred on the selected node, the query was normall y executed on another node, so it does not transfer an error to a user.

- When a transaction occurred or SELECT is in progress

If an error occurs on the selected node when a transaction occurred or ResultSet.next() is in progress, the n JDBC can not proceeds the current operation any more so it transfers 21047(Retry the transactional op erations again). If 21047 error occurs, then a user should perform the transaction or SELECT again.

```
PreparedStatement pstmt = con.prepareStatement("INSERT INTO T1 VALUES (?)");
boolean retry;
do
{
    retry = false;
    try
    {
        pstmt.setInt(1, 1);
        pstmt.executeUpdate();
    }
    catch (SQLException e)
    {
        if (e.getErrorCode() == 21047)
        {
            retry = true;
        }
        else
        {
            throw e;
        }
```

```
    }
} while (retry == true);
```

```
PreparedStatement pstmt = con.prepareStatement("SELECT * FROM T1 WHERE C1 = ?");
boolean retry;
do
{
    retry = false;
    try
    {
        pstmt.setInt(1, 1);
        ResultSet rs = pstmt.executeQuery();
        while (rs.next())
        {
            ...
        }
        rs.close();
    }
    catch (SQLException e)
    {
        if (e.getErrorCode() == 21047)
        {
            retry = true;
        }
        else
        {
            throw e;
        }
    }
} while (retry == true);
```

- When committing or rolling back a transaction

If an error occurs on the selected node when committing a transaction, then JDBC checks whether the tra nsaction has been committed before the error occurred through another node. Though an error occurred on the selected node, if the transaction was normally committed, then it does not transfer an error. Also, if an error occurred on the selected node when a transaction has not been committed, then it transfers 2 1047(Retry the transactional operations again) error. If 21047error occurs, then a user should perform th e transaction again.

If an error occurs on the selected node when rolling back a transaction, then JDBC does not transfer an er ror. It is because the transaction already has been rolled back due to the node error.

```
con.setAutoCommit(false);
PreparedStatement pstmt = con.prepareStatement("INSERT INTO T1 VALUES (?)");
boolean retry;
do
{
    retry = false;
    try
    {
        pstmt.setInt(1, 1);
        pstmt.executeUpdate();
        con.commit();
    }
    catch (SQLException e)
    {
        if (e.getErrorCode() == 21047)
        {
            retry = true;
        }
        else
        {
            throw e;
        }
    }
} while (retry == true);
```

Constraints

- Use only PreparedStatement and CallableStatement class to select a node appropriate for SQL.

The statement class does not have the information required to select the node appropriate for the query, so the node is selected according to locality_group_policy or locality_member_policy property.

- Use Connection.commit(). Connection.rollback() to commit or rollback a transaction.

If committing or rolling back with SQL statement when using GLOBAL CONNECTION, then the status cha nge of the transaction is not detected. It is mandatory to use Connection.commit(). Connection.rollback() to commit or rollback the transaction.

- Global session feature does not support Data Definition Language (DDL) among SQL statements.

Statement Pooling

GOLDILOCKS supports the statement pooling feature. Statement pooling improves the performance by p ooling statements which are repeatedly used such as a repetitive statement and a repeatedly called meth od. The interface for the statement pooling is defined in JDBC 3.0.

An application pools the statement related to a specific connection by using the statement pool. Each co nnection object has its own pool. GoldilocksConnection includes a method which enables the statement pool. If the statement pool is used, then the statement object is pooled when the close method is called.

Description

If the statement pool is enabled and the close method of the statement object is called, then GOLDILOCK S JDBC driver automatically pools the statement, PreparedStatement and CallableStatement. PreparedSta tement and CallableStatement objects perform pooling by using SQL string as a key value. JDBC driver au tomatically compares/ retrieves PreparedStatement or CallableStatement when creating them.

It is compared based on the following basis.

- SQL strings should be same.
- The statement types should be same.
- The result set properties should be same.

SQL string of the statement object is subject to change, so SQL string is not used for the pooling, but JDB C driver automatically processes it.

If the matching statement is retrieved while searching in the pool, then it is returned, and if it is not foun d, then a new statement is created. The statement, the cursor and the status are pooled in both cases if t he close method of the object is called. However, the statement becomes closed. Create the statement w hose SQL string, the statement type and the result set property are same to use the closed statement agai n.

If pooled PreparedStatement and CallableStatement objects are retrieved, then the status and the data in formation are automatically initialized again, and reset to the default value. When the statement pool is f ull, then it is dropped from the pool by LRU algorithm. Statements stored in the statement pool can be cl eared when the close method of the connection object is called.

Usage

Enabling Statement Pool

STATEMENT_POOL_ON and STATEMENT_POOL_SIZE properties should be set to use the statement pool of the connection object. Even when STATEMENT_POOL_ON property is enabled, the default value of ST ATEMENT_POOL_SIZE is 0, so use the figure bigger than 0.

The statement pool feature is enabled by adding STATEMENT_POOL_ON and STATEMENT_POOL_SIZE pr operties to the properties object. The statement pool feature is also enabled through GoldilocksDataSour ce API and GoldilocksConnection API.

Enabling through GoldilocksDataSource

If GoldilocksDataSource class is used, then all connection objects gets statement pools with the identical STATEMENT_POOL_SIZE.

- Call setStatementPoolOn(true) method.
- Call setStatementPoolsize method.

```
GoldilocksDataSource sDataSource = new GoldilocksDataSource();
sDataSource.setStatementPoolOn( true );
sDataSource.setStatementPoolSize( 10 );
```

The property setting values can be viewed as follows.

```
System.out.println("Statement Pool on:" + sDataSource.getStatementPoolOn());
System.out.println("Statement Pool size:" + sDataSource.getStatementPoolSize());
```

Enabling through GoldilocksConnection

If GoldilocksConnection class is used, then the statement pool is enabled aside from other objects.

- Call setStatementPoolOn(true) method.
- Call setStatementpoolSize method.

```
GoldilocksConnection sCon = sDataSource.getConnection();
sCon.setStatementPoolOn( true );
sCon.setStatementPoolSize( 10 );
```

The property setting values can be viewed as follows.

```
System.out.println("Statement Pool on:" + sCon.getStatementPoolOn());
System.out.println("Statement Pool size:" + sCon.getStatementPoolSize());
```

Disabling Statement Pool

Enabled statement pool can be disabled. If switching the enabled status to the disabled status, then state ments stored in the statement pool are dropped and closed.

Disabling by using setStatementPoolOn method

```
sCon.setStatementPoolOn(false);
```

Disabling by using setStatementPoolSize method

```
sCon.setStatementPoolSize(0);
```

Creating Statement

The method to created the statement, PreparedStatement, and CallableStatement while the statement p ool is enabled is as same as the general creating method.

The following is a code to create the new statement object.

```
PreparedStatement sPstmt = sCon.prepareStatement( "INSERT INTO EMP VALUES ( ?, ? )" );
```

Disabling Specific Statement

If the statement pool is enabled, then GOLDILOCKS JDBC driver automatically pools all statements. Using setPoolable method excludes a specific statement from the pooling.

The following is an example of checking whether it is pooled by using isPoolable method and setPoolable method.

```
PreparedStatement sPstmt = sCon.prepareStatement( "SELECT 1 FROM DUAL" );
System.out.println( "Is poolable: " + sPstmt.isPoolable() );
sPstmt.setPoolable( false );
System.out.println( "Is poolable: " + sPstmt.isPoolable() );
```

32.3 JDBC API References

Array

The class is not implemented.

free

```
void free() throws SQLException
```

getArray

```
Object getArray() throws SQLException
```

```
Object getArray(Map<String,Class<?>> map) throws SQLException
```

```
Object getArray(long index, int count) throws SQLException
```

```
Object getArray(long index, int count, Map<String,Class<?>> map) throws SQLException
```

getBaseType

```
int getBaseType() throws SQLException
```

getBaseTypeName

```
String getBaseTypeName() throws SQLException
```

getResultSet

```
ResultSet getResultSet() throws SQLException
```

```
ResultSet getResultSet(Map<String,Class<?>> map) throws SQLException
```

```
ResultSet getResultSet(long index, int count) throws SQLException
```

```
ResultSet getResultSet(long index, int count, Map<String,Class<?>> map) throws SQLException
```

Blob

free

```
void free() throws SQLException
```

- Operation: It frees the sources owned by this object.
- Exception: It does not occur.

getBinaryStream

```
InputStream getBinaryStream() throws SQLException
```

- Operation: It returns the blob object value in InputStream type.
- Exception: If the blob is freed, it throws SQLException.

```
InputStream getBinaryStream(long pos, long length) throws SQLException
```

- Operation: It returns InputStream type which includes the blob object value as big as the length from the byte defined as pos.
- Exception: When the blob is freed, if pos is smaller than 1 or bigger than the byte length of the blob object, or if pos + length is bigger than the byte length of blob object, then it throws SQLException.

getBytes

```
byte[] getBytes(long pos, int length) throws SQLException
```

- Operation: It returns byte array which includes the blob object value as big as the length from the byt e defined as pos.
- Exception: When the blob is freed, if pos is smaller than 1 or if the length is smaller than 0, then it thr ows SQLException.

length

```
long length() throws SQLException
```

- Operation: It returns the byte length of the blob object.
- Exception: If the blob is freed, it throws SQLException.

position

```
long position(byte[] pattern, long start) throws SQLException
```

- Operation: It returns the location of the byte from which the byte array pattern starts defined in the b lob object value. pattern search starts from the location of start. If the pattern is not found in the blo b object then -1 is returned.
- Exception: When the blob is freed, if start is smaller than 1, then it throws SQLException.

```
long position(Blob pattern, long start) throws SQLException
```

- Operation: It returns the location of the byte from which the blob object pattern starts defined in the blob object value. pattern search starts from the location of start. If the pattern is not found in the bl ob object then -1 is returned.
- Exception: When the blob is freed, if start is smaller than 1, then it throws SQLException.

setBinaryStream

```
OutputStream setBinaryStream(long pos) throws SQLException
```

- Operation: It is not implemented.
- Exception: It always throws SQLFeatureNotSupportedException.

setBytes

```
int setBytes(long pos, byte[] bytes) throws SQLException
```

- Operation: It records the byte array bytes from the given pos location in the blob object value, and ret urns the length of the recorded bytes. If the value exists in pos location, then the byte array is overwri tten. If it reaches to the end of the blob value while recording byte array, then the length of the blob value is extended so that it can include the additional bytes.
- Exception: When the blob is freed, if pos is smaller than 1, then it throws SQLException.

```
int setBytes(long pos, byte[] bytes, int offset, int len) throws SQLException
```

- Operation: It records the blob object value from pos location as long as the len length from offset loc ation of the given byte array bytes, and returns the length of the recorded bytes. If the value exists in pos location, then the byte array is overwritten. If it reaches to the end of the blob value while recordi ng byte array, then the length of the blob value is extended so that it can include the additional bytes.
- Exception: When the blob is freed, if pos is smaller than 1 or offset is smaller than 0 or offset + len is bigger than bytes length, then it throws SQLException.

truncate

```
void truncate(long len) throws SQLException
```

- Operation: It truncates the length of the blob object into the given len length.
- Exception: When the blob is freed, if len is smaller than 0, then it throws SQLException.

CallableStatement

getArray

```
Array getArray(int parameterIndex) throws SQLException
```

- Operation: It does not support an array type.
- Exception: It always returns SQLFeatureNotSupportedException.

```
Array getArray(String parameterName) throws SQLException
```

- Operation: It does not support an array type.
- Exception: It always returns SQLFeatureNotSupportedException.

getBigDecimal

```
BigDecimal getBigDecimal(int parameterIndex) throws SQLException
```

- Operation: It obtains column data at parameterIndex-th position in BigDecimal type. For more information about whether it supports GOLDILOCKS types, refer to **Whether supporting getter method for GOLDILOCKS type - 1** .
- Exception: If the parameterIndex is invalid, database is not accessible, or CallableStatement is already closed, then it throws SQLException.

```
BigDecimal getBigDecimal(int parameterIndex, int scale) throws SQLException
```

- Operation: It is not implemented. (It is a deprecated method.)
- Exception: It always throws SQLFeatureNotSupportedException.

```
BigDecimal getBigDecimal(String parameterName) throws SQLException
```

- Operation: It is not implemented.
